Component – A component -is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. Title: **Protection System Maintenance**

2. Number: PRC-005-2

3. Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. Applicability:

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

5. Effective Date: See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

The PSMP shall:

1.1. Address all Protection System **component types.**

1.2. Identify which maintenance method (time-based,

> ***Component Type** - Any one of the five specific elements of the Protection System definition.*

performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5 ~~and~~ , Table 2, and Table 3.

1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, ~~and~~ Table 2, and Table 3.

***~~Maintenance Correctable~~Unresolved Maintenance* Issue** - *~~Failure of a component to operate within design parameters such that the~~ A deficiency that cannot be corrected during the performance of the maintenance activity~~. Therefore this issue~~ and requires follow-up corrective action.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any ~~identified~~ **~~maintenance correctable~~unresolved maintenance issues**.
[Violation Risk Factor: High] [Time Horizon: Operations Planning]

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence that its current performance-based maintenance program is in accordance with Requirement R2, which may include but is not limited to equipment lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of ~~identified Maintenance Correctable Issues~~unresolved maintenance issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For Requirement R2 and Requirement R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System **components**, or all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date, whichever is longer.

Component – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one component type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address one component type included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to specify whether two component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address two component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to include station batteries in a time-based program (Part 1.2) OR The responsible entity failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5, ~~and~~ Table 2, and Table 3. (Part 1.3 and 1.4)	The responsible entity has not established a PSMP. OR The responsible entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to reduce countable events to less than 4% within three years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but has failed to reduce countable events to less than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to establish the entire technical justification described within R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce countable events to less than 4% within five years OR 3) Failed to annually document program activities, results, maintenance dates, or countable

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				events for over 5% of components in any individual segment OR 4) Maintained a segment with less than 60 components OR 5) Failed to: • Annually update the list of components, OR • Perform maintenance on the greater of 5% of the segment population or 3 components, OR • Annually analyze the program activities and results for each segment.
R3	The responsible entity has failed to implement and follow scheduled program on 5% or less of total Protection System components. OR The responsible entity has failed to initiate resolution on 5% or less of ~~identified maintenance correctable~~unresolved maintenance issues.	The responsible entity has failed to implement and follow scheduled program on greater than 5%, but no more than 10% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of ~~identified~~ unresolved maintenance~~maintenance correctable~~ issues.	The responsible entity has failed to implement and follow scheduled program on greater than 10%, but no more than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of ~~identified~~unresolved maintenance issues.	The responsible entity has failed to implement and follow scheduled program on greater than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 15% of ~~identified~~ unresolved maintenance~~maintenance correctable~~ issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program..

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — July~~February~~ 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1
Component Type - Protective Relay
Excluding distributed UFLS and UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval[1]	Maintenance Activities
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2
Component Type - Communications Systems
Excluding distributed UFLS and UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	~~3~~ 4 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (~~e.g~~e.g. -signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.

Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (~~e.g~~e.g. signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for ~~distribution breakers~~non-BES interrupting devices for ~~UFLS or UVLS~~SPS or non-distributed UVLS systems are excluded (see Table 1-4(e)).	~~3~~ 4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for non-BES interrupting devices ~~distribution breakers~~ for ~~UFLS or UVLS~~SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	~~3~~ 4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries Excluding UFLS and non-distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for non-BES interrupting devices ~~distribution breakers~~ for ~~UFLS or UVLS~~SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	~~3~~ 4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for non-BES interrupting devices ~~distribution breakers~~ for ~~UFLS, UVLS and~~ SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	~~3~~ 4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Device for SPS and non-distributed UVLS and UFLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply for tripping only non-BES interrupting devices as part of a ~~UFLS, UVLS or~~ SPS or non-distributed UVLS and UFLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify~~:~~ ~~•~~ Station dc supply voltage

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2)		No periodic verification of float voltage of battery charger is required
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with internal ohmic value monitoring, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2)		.No periodic measurement and evaluation relative to baseline of battery cell/unit internal ohmic values is required to verify the station battery can perform as designed .
Any Valve Regulated Lead-Acid (VRLA) station battery with monitoring and alarming of each cell/unit internal Ohmic value. (See Table 2)		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA battery is required.

Table 1-5 **Component Type - Control Circuitry Associated With Protective Functions** **Excluding distributed UFLS and UVLS (see Table 3)** **Note:** Table requirements apply to all Control Circuitry components of Protection Systems, ~~UVLS and UFLS Systems,~~ and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices ~~(excluding UFLS or UVLS systems).~~	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
~~Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.~~Unmonitored control circuitry associated with SPS	~~No periodic maintenance specified~~12 calendar years	~~None.~~Verify all paths of the control circuits essential for proper operation of the SPS.
Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip ~~coil .~~coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored control circuitry associated with protective functions.	12 calendar years	Verify all paths of the ~~control and~~ trip circuits through the trip coil(s) of the circuit breakers or other interrupting devices~~circuits~~.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of DETECTION to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	~~No periodic maintenance specified~~None.

Table 3

Maintenance Activities and Intervals for distributed UFLS and UVLS Systems

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping only non-BES interrupting devices as part of a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices.	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems.	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices.	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

> **Segment** – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

> **Countable Event** – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.
5. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

Implementation Plan for PRC-005-02

Standards Involved

- Approval:
  - PRC-005-2 – Protection System Maintenance and Testing

- Retirements (phased to coincide with each entity's implementation of PRC-005-2 as specified in the Implementation Plan for Requirements R1 through R3 later in this document):
  - PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing
  - PRC-005-1a – Transmission and Generation Protection System Maintenance and Testing
  - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
  - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
  - PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of "Protection System"

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.
4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within 12 months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.
5. The Implementation Schedule set forth in this document further requires implementation of the revised Protection System Maintenance Program in roughly equally-distributed steps over the maintenance intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 (for the Protection System components identified in PRC-005-2 Tables 1-1 through 1-5, Table 2, and Table 3) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same Protection System component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is being addressed according to PRC-005-2 or under PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, or PRC-017-0.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:

The existing Standards PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following the latter of 156 months following applicable regulatory approval in all jurisdictions or 168 months following Board of Trustees adoption of PRC-005-2.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 and R3 which use this defined term.

Implementation Plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-one (21) months following Board of Trustees adoption.

Implementation Plan for Requirements R2 and R3:

1. For Protection System components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 15 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 24 months following Board of Trustees adoption.

2. For Protection System components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:

   a. The entity shall be 100% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.

3. For Protection System components with maximum allowable intervals of 3 years, as established in Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 24 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 36 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 48 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 60 months following Board of Trustees adoption.

4. For Protection System components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5 and Table 3:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.

5. For Protection System components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5 Table 2, and Table 3:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 108 months following applicable regulatory approval, or in those jurisdictions

where no regulatory approval is required, on the first day of the first calendar quarter 120 months following Board of Trustees adoption.

c. The entity shall be 100% compliant on the first day of the first calendar quarter 156 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 168 months following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Implementation Plan for PRC-005-02

Standards Involved:

- Approval:
  - PRC-005-2 – Protection System Maintenance and Testing

- Retirements (phased to coincide with each entity's implementation of PRC-005-2 as specified in the Implementation Plan for Requirements R1 through R3 later in this document):
  - PRC-005-1 —Transmission and Generation Protection System Maintenance and Testing
  - PRC-005-1a –Transmission and Generation Protection System Maintenance and Testing
  - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
  - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
  - PRC-017-0 —Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of "Protection System"

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.
4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within 12 months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.
5. The Implementation Schedule set forth in this document further requires implementation of the revised Protection System Maintenance Program in roughly equally-distributed steps over the maintenance intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:
Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 (for the Protection System components identified in PRC-005-2 Tables 1-1 through 1-5, Table 2, and Table 3) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same Protection System component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is being addressed according to PRC-005-2 or under PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, or PRC-017-0.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:
The existing Standards PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following the latter of 156 months following applicable regulatory approval in all jurisdictions or 168 months following Board of Trustees adoption ~~.upon regulatory approval~~ of PRC-005-2.

Implementation Plan for Definition:
Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 and R3 which use this defined term.

Implementation Plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-one (21) months following Board of Trustees adoption.

Implementation Plan for Requirements R2 and R3:

1. For Protection System components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 15 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 24 months following Board of Trustees adoption.

2. For Protection System components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:

   a. The entity shall be 100% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.

3. For Protection System components with maximum allowable intervals of 3 years, as established in Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 24 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 36 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 48 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 60 months following Board of Trustees adoption.

4. For Protection System components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5 and Table 3:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.

5. For Protection System components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5, ~~and~~ Table 2, and Table 3:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 108 months following applicable regulatory approval, or in those jurisdictions

where no regulatory approval is required, on the first day of the first calendar quarter 120 months following Board of Trustees adoption.

c. The entity shall be 100% compliant on the first day of the first calendar quarter 156 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 168 months following Board of Trustees adoption.

Applicability:

This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Standard Authorization Request Form

Title of Proposed Standard:	Transmission and Generation Protection System Maintenance and Testing
Request Date:	August 4, 2011

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: System Protection and Controls Task Force (Attachment A)	☐	New Standard
Primary Contact Charles Rogers	X	Revision to existing Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs PRC-011-0 — UVLS System Maintenance and Testing PRC-017-0 — Special Protection System Maintenance and Testing
Telephone (517) 788-0027 Fax (517) 788-0917	X	Withdrawal of existing Standard
E-mail cwrogers@cmsenergy.com	☐	Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of standard PRC-005 should remain "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

In Order 693, the Federal Energy Regulatory Commission directed that changes be made to these standards.

These standards should be consolidated into a single standard to reduce the costs of compliance and a number of technical short comings in these standards should be corrected to provide reliable performance when responding to abnormal system conditions.

Brief Description (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

Revise PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, to consolidate PRC-005-1, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs; PRC-011-0 — UVLS System Maintenance and Testing; and PRC-017-0 — Special Protection System Maintenance and Testing into a single maintenance and testing standard. Standards PRC-008-0, PRC-011-0, and PRC-017-0 would then be withdrawn.

The revised PRC-005 standard should address the issues raised in the FERC Order 693, the issues raised by stakeholders during the development of Version 0 and Phase III & IV standards (Attachment D), and the issues addressed in the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" (Attachment B) The revised standard should also address the comments submitted by stakeholders during the development of Version 0, and Phase III & IV and should reflect improvements identified in the Reliability Standards Review Guidelines. (Attachment C)

Detailed Description:

The PRC-005, 008, 011, and 017 reliability standards are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

- Applicable to PRC-017 — Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between various protection system technologies.
- Applicable to all four standards — The terms "maintenance programs" and "testing programs" should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.
- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor.

The revised standard should also include the general improvements identified in the attached Reliability Standard Review Guidelines (Attachment C) and should address the comments submitted by stakeholders (Attachment D).

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☒	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☒	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

NERC SPCTF Assessment of Standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

DRAFT 1.0
March 8, 2007

A Technical Review of Standards

Prepared by the
System Protection and Controls Task Force
of the
NERC Planning Committee

Table of Contents

This report and its attendant Standards Authorization Request were approved by the Planning Committee on March 21, 2007, for forwarding to the Standards Committee.

Introduction

When the original scope for the System Protection and Control Task Force was developed, one of the assigned items was to review all of the existing PRC-series Reliability Standards, to advise the Planning Committee of our assessment, and to develop Standards Authorization Requests, as appropriate, to address any perceived deficiencies.

This report presents the SPCTF's assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing. The report includes the SPCTF's understanding of the intent of this standard and contains specific observations relative to the existing standard.

The SPCTF sees the parallel intent for each of the PRC-005, PRC-008, PRC-011, and PRC-017 as being maintenance and testing standards for different protective systems. In fact, PRC-005 & PRC-008, and PRC-011 & PRC-017 have very similar format respectively. Since all protective relay systems require some means of maintenance and testing, it would seem that all protective system maintenance and testing could be included in one standard regardless of scheme type. The SPCTF recommends that these four standards be reduced to one standard covering the issues detailed for PRC-005 on maintenance and testing.

These four standards were developed primarily by translating the requirements of an earlier Phase I Planning Standard; thus they have not been previously subjected to a critical review of the Requirements.

Executive Summary

Reliability standards PRC-005, 008, 011, and 017 are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Only PRC-005 will be commented on in detail although the other three standards have the same concerns.

SPCTF concluded that:

- Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."
- Applicable to PRC-017 — Part of the stated purpose in PRC-017 states: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is, the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between different technologies of protection systems.
- Applicable to all four standards — The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.

- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor.

Assessment of PRC-005-1

Purpose

To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

A review of PRC-005 indicates that this standard is intended to assure that all affected entities have adequate maintenance and testing programs for their Protection Systems to ensure reliability. SPCTF agrees with the Purpose statement of PRC-005-1.

General Comments

The SPCTF offers the following general comments:

- None of the requirements within PRC-005-1 specifically indicate what minimum attributes should be included in protective system maintenance and testing procedures.
- For interval-based procedures, no allowable maximum interval is prescribed.
- None of the requirements in the existing PRC-005-1 reflect condition-based or performance-based maintenance and testing criteria.

Standard PRC-005 should clarify that two goals are being covered:

- The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers' design specification throughout the service life.
- The testing portion should have requirements that verify that the functional performance of the protection systems is consistent with the design intent throughout the service life.

Applicability

Applicability 4.3 suggests that the definition of a Protection System in the Glossary of Terms should

> **4.1.** Transmission Owners
>
> **4.2.** Generation Owners
>
> **4.3.** Distribution Providers that owns a transmission Protection System

clarify how a Distribution Provider may be the owner of a transmission Protection System.

Requirements

R1

> **R1.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:
>
> **R1.1.** Maintenance and testing intervals and their basis.
>
> **R1.2.** Summary of maintenance and testing procedures.

The following clarifications should be made to Requirement R1:

1. How is the phrase "that affect the reliability of the BES" to be interpreted? The standard should clearly specify which Protection Systems are subject to the requirements.
2. The standard should clearly specify which components of the Generation Protection System are subject to the requirements.

The following clarifications should be made to Subparts R1.1 & R1.2:

1. Interval-based, condition-based, or performance-based maintenance and testing minimum criteria should be established within R1.1, including, but not limited to the following:
   a. For time-based maintenance and testing programs, maximum maintenance intervals should be specified.
   b. For condition-based or performance-based maintenance and testing programs, the program should have sufficient justification and documentation.
2. Definitions should be established for the terms "maintenance programs" and "testing programs."
3. A minimum set of attributes to be included in maintenance and testing programs should be established within R1.2.

R2

> **R2.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:
>
> **R2.1.** Evidence Protection System devices were maintained and tested within the defined intervals.
>
> **R2.2.** Date each Protection System device was last tested/maintained

The following clarification should be made to requirement R2:

- The appropriate entity should have their Protection System maintenance program and testing program and associated documentation, including maintenance records and testing records, available to its Regional Reliability Organization and NERC during audits or upon request within 30 days.

FERC Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

In the October 20, 2006 Notice of Proposed Rulemaking for adoption of NERC Standards (Docket Number RM06-16-000), the Federal Energy Regulatory Commission commented on these four standards and proposed changes. The observations and proposals are excerpted from the NOPR and included below.

PRC-005-1

> The Commission proposes to approve PRC-005-1 as mandatory and enforceable. In addition, we propose to direct that NERC develop modifications to the Reliability Standard as discussed below.
>
> Proposed Reliability Standard PRC-005-1 does not specify the criteria to determine the appropriate maintenance intervals, nor do it specify maximum allowable maintenance intervals for the protections systems. The Commission therefore proposes that NERC include a requirement that maintenance and testing of these protection systems must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-005-1 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.

PRC-008-0

The Commission notes that the commenters generally share staff's concern that the proposed Reliability Standard does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protection systems. The Commission agrees and proposes to require NERC to modify the proposed Reliability Standard to include a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of relay used and the impact on the reliability of the Bulk-Power System.

Accordingly, the Commission proposes to approve Reliability Standard PRC-008-0 as mandatory and enforceable. In addition, the Commission proposes to direct that NERC submit a modification to PRC-008-0 that includes a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval appropriate to the relay type and the potential impact on the Bulk-Power System.

PRC-011-0

PRC-011-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes that NERC include a Requirement that maintenance and testing of these UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of the relay used and the impact of these UFLS on the reliability of the Bulk-Power System.

The Commission believes that Reliability Standard PRC-011-0 serves an important purpose in requiring transmission owners and distribution providers to implement their UVLS equipment maintenance and testing programs. Further, the proposed Requirements are sufficiently clear and objective to provide guidance for compliance.

Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-011-0 that includes a requirement that maintenance and testing of UVLS programs must be carried out within a maximum allowable interval appropriate to the applicable relay and the impact on the reliability of the Bulk-Power System.

PRC-017-0

> PRC-017-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes to require NERC to include a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used and the impact of these special protection system programs on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-017-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-017-0 that: (1) includes a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used; and (2) identifies the impact of these special protection system programs on the reliability of the Bulk-Power System.

Other Activities Related to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

These four Standards are contained in several projects and draft SARs as part of the "Draft Reliability Standards Development Plan: 2007–2009", which was approved by the NERC Board of Trustees.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the Standards Development Plan, and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

Conclusions and Recommendations

PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 require additions, clarifications, and definitions to insure that the Protection Systems are properly maintained and tested.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the "Draft Reliability Standards Development Plan: 2007–2009," and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

SPCTF submits the attached SAR for that purpose of consolidating PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 into a single standard to the Planning Committee for endorsement.

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. (‘Violation severity levels’ replace existing ‘levels of non-compliance.’) The violation severity levels must be applied for each requirement and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: more than 95% but less than 100% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: more than 85% but less than or equal to 95% compliant.
- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: more than 70% but less than or equal to 85% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: 70% or less compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan. The effective date should be linked to the NERC BOT adoption date.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

PRC-005-0 — Transmission Protection System Maintenance and Testing

Version 0 Comments:

- This section should not move forward in Version 0. More procedure/data oriented, not really stand alone "standard" material but more tools or reference material for executing a standard
- R3-1.a – should breakers and switches be included in the list?
- M3-2 – what kind of evidence?
- M3-2 The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

Phase III & IV Comments:

- PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term.
- Need to add language to ensure the Regional Requirements focus on the most impactive scenarios
- Modify applicability to clarfify that the requirements are applicable to the following:
- All protection systems on the bulk electric system.
- All generation protection systems whose misoperations impact the bulk electric system
- There is no performance requirement or measure of effectiveness of a maintenance program required by the standard

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

Version 0 Comments:

- The language for protection system maintenance and testing programs should be consistant from standard to standard. The requirement in this standard should match Standard 063, Requirement R3-1. This will provide a consistent reporting requirement for all protection system.
- From standard 063.3: The Transmission Owner, Generator Owner and Distribution Provider that owns a transmission protection system shall have a transmission protection system maintenance and testing program in place. The program(s) shall include:
- From Standard 067.3: The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

PRC-011-0 — UVLS System Maintenance and Testing

Version 0 Comments:

- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.
- UVLS : Under voltage load shedding should not be a requirement for all parties. Those who have shunt reactors can meet the objective by not shedding load but by shedding shunt reactors. Flexibility in achieving the desired goal is appropriate.

PRC-017-0 — Special Protection System Maintenance and Testing

Version 0 Comments:

- In f, it needs to be changed to require that the last two dates of testing and maintenance are kept. This is necessary to verify an action that is required bi-annually or bi-monthly.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

The new proposed definition of Protection System reads as follows:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

PRC-005-2
Protection System Maintenance

Supplementary Reference & FAQ

Draft

to ensure the reliability of the bulk power system

July 29, 2011

Prepared by the
Protection System Maintenance and Testing Standard Drafting Team

116-390 Village Blvd., Princeton, NJ 08540
609.452.8060 | 609.452.9550 fax

Table of Contents

This supplementary reference to PRC-005-2 is neither mandatory nor enforceable.

1. Introduction and Summary

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to relays for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO’s and TO’s have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?
BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse. This Standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. As stated in Requirement R1, this Standard covers protective relays that use measurements of electrical quantities to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This Standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.

- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R3 of the Standard does require that the entity "initiate resolution of any identified unresolved maintenance issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term “Condition-Based-Maintenance” (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the “monitored-basis-time-intervals” existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

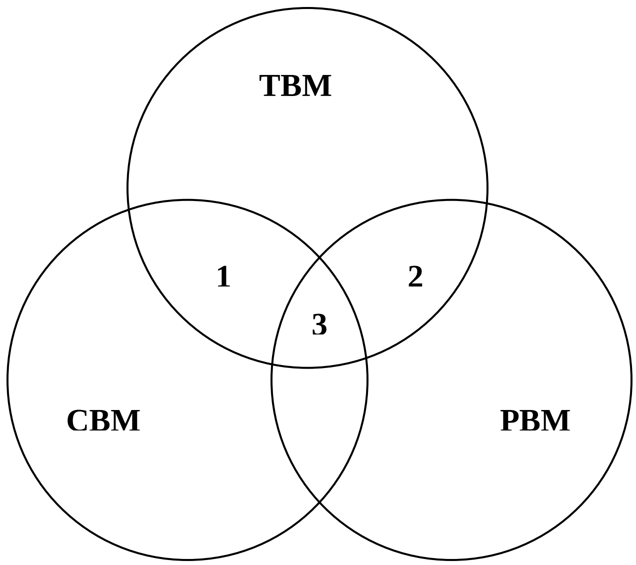
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



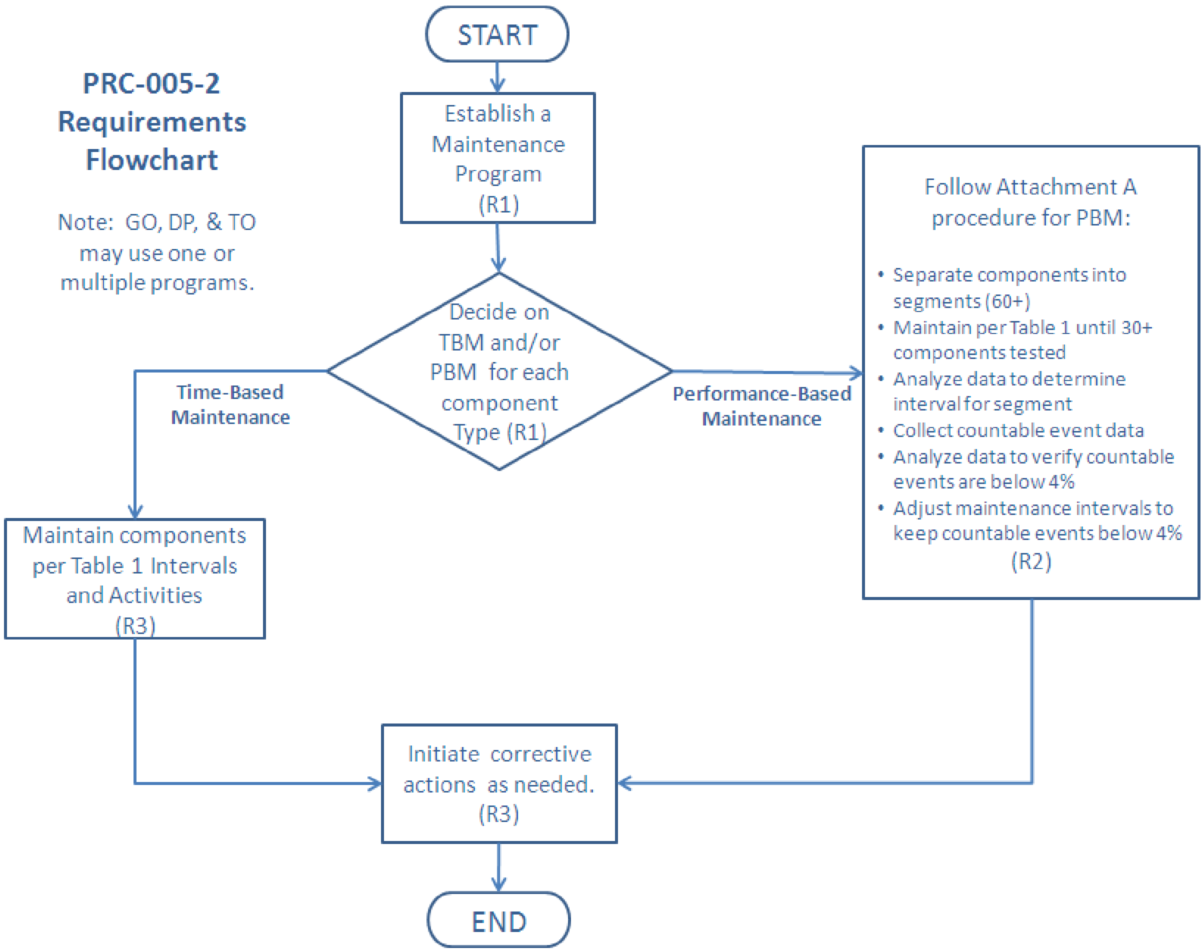
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or

manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP …" if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1.4 of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval", the next event would have to occur on or before December 31, 2010.

Please provide an example of "3 Calendar Months".

If a maintenance activity is described as being needed every 3 Calendar Months then it is performed in a (given) month and due again 3 months later. For example a battery bank is inspected in month number 1 then it is due again in month number 4. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of April. Another example could be that a 3-month inspection was performed in January is due in April, but if performed in March (instead of April) would still be due three

months later therefore the activity is due again June. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?
An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2 , the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance

- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices
- Battery performance test (if ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Verify that current and voltage signal values are provided to the protective relays
- Verify that Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices **Example #3:** A combination of monitored and unmonitored components within a given Protection System might be:
  - A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
  - Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
  - Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
  - Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”) and Table 2 (“Alarming Paths and Monitoring”), the particular components shall have maximum activity intervals of:

Every 3 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Cell condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years or when a unresolved maintenance issue arises. The control circuitry can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the Standard, specifies maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a Generation station layout. The various subsystems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

Distributed UFLS and UVLS systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits. There is an additional table,
    - Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
    - Table 3 presents the maintenance activities and intervals for protective relays, current and voltage sensing devices, station dc supply, and control circuitry for distributed UFLS and UVLS systems.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.

- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.
4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station

battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. “End-to-end test” as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed mostly towards microprocessor based relays.
For relay maintenance departments that choose to test microprocessor based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?
Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0. These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?
Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting

device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?
No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?
As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?
Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?
Since components of the SPS, UFLS, and UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.
For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?
No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

We believe that the 4-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 4-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays

- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) and auxiliary tripping relays (94) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or 94 that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.
The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electromechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?
This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.
However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the “Calendar Year” language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3.

How do I achieve a “grace period” without being out of compliance?

For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007. the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods". To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?
Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?
Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?
No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.

- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures “Control Circuitry” as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of “Component”:

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity’s specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity’s population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant

microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures “voltage and current inputs to the protective relays” as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a “Relay Scheme”. Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT’s or specific PT’s. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of “Component”:

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 “Relay Schemes”, all of which have three current signals supplied from bushing CT’s and three voltage signals supplied from substation bus PT’s. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT’s and voltage signals from PT’s built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity’s relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their “Voltage and Current Sensing” population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.
The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).
(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?
Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may

indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?
For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays “that are designed to provide protection for the BES,” this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific

requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?
The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?
If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?
Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would

dictate that an “out-of-service” device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?
Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R3 states (the entity must):

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified unresolved maintenance issues.

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.
The maintenance and testing requirements (R3) (in essence) state “…shall implement and follow its PSMP and initiate resolution of any identified unresolved maintenance issues...” The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.
Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a unresolved maintenance issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?
Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.

- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …"   Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?
No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?
Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are electromechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?
Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?
Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?
Table 1-5 specifies that each breaker trip coil, auxiliary relay that carries trip current to a trip coil, and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?
Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3)
An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.

- The unmonitored trip circuit between the lock-out or auxiliary relay does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit does not have to be proven with an electrical trip.
- The trip coil of the circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?
The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by “continuity” of the dc supply?
The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term “continuity” was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the

various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?
The answer to this question depends on the type of battery (Valve-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.
For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?
Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon

installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment).

Although many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great

detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?
The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulphuric acid, is consumed and the concentration of the sulphuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?
High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum

maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?

Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.
The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the

entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manfacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit

internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, "depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity" they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the

station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.

Why check for the electrolyte level?
In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?
There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is “verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.” This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to “Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.”

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the “capacity 6 month test” at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the “thermal runaway test” at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be performed on any communications-assisted trip scheme regardless of the vintage of technology.The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?
For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 3-month inspection of communications-assisted trip scheme equipment?

The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and

set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?
An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?
There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Question:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?
There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to

revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?
If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and UVLS Systems (Table 3)

Distributed UFLS and UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current sensing devices have the same maintenance activity and interval as Table 1-2. DC systems need only have their voltage read at the relay every twelve years. Control circuits have the following maintenance activities every twelve years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out and/or auxiliary tripping device(s).
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS/UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however the part of the trip path control circuitry between the load shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

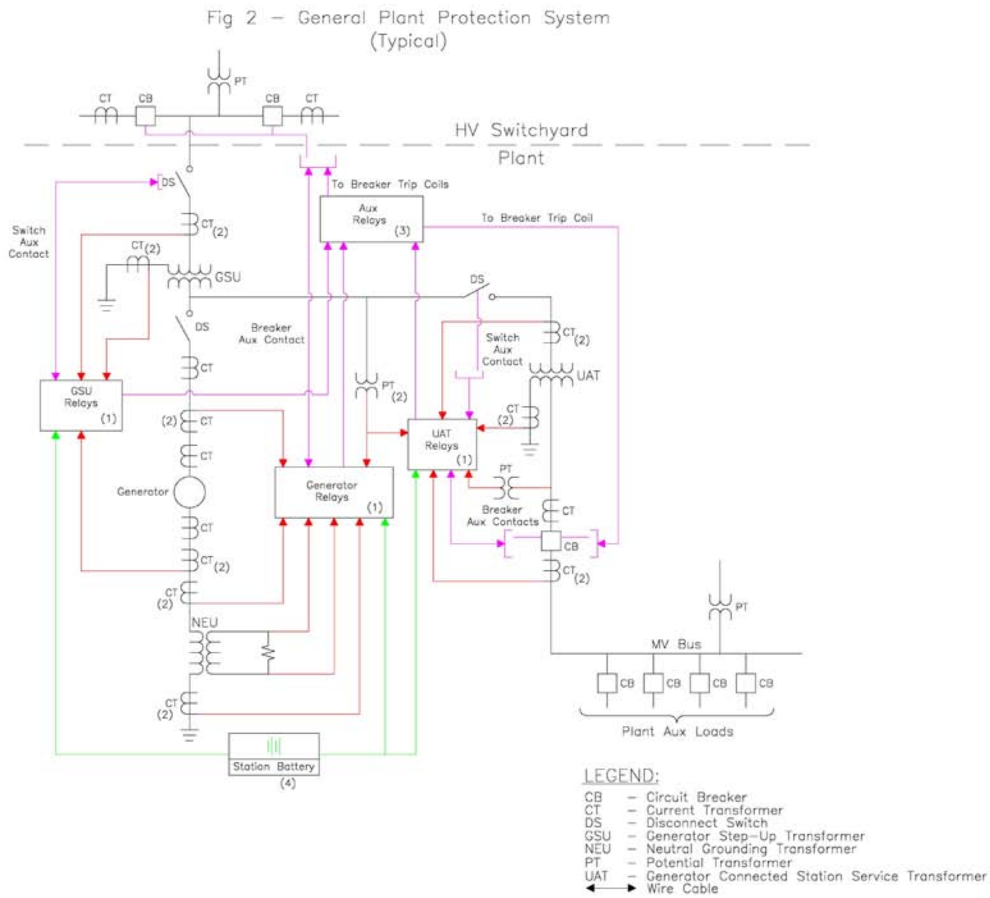
Figure 2: Typical Generation System



For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

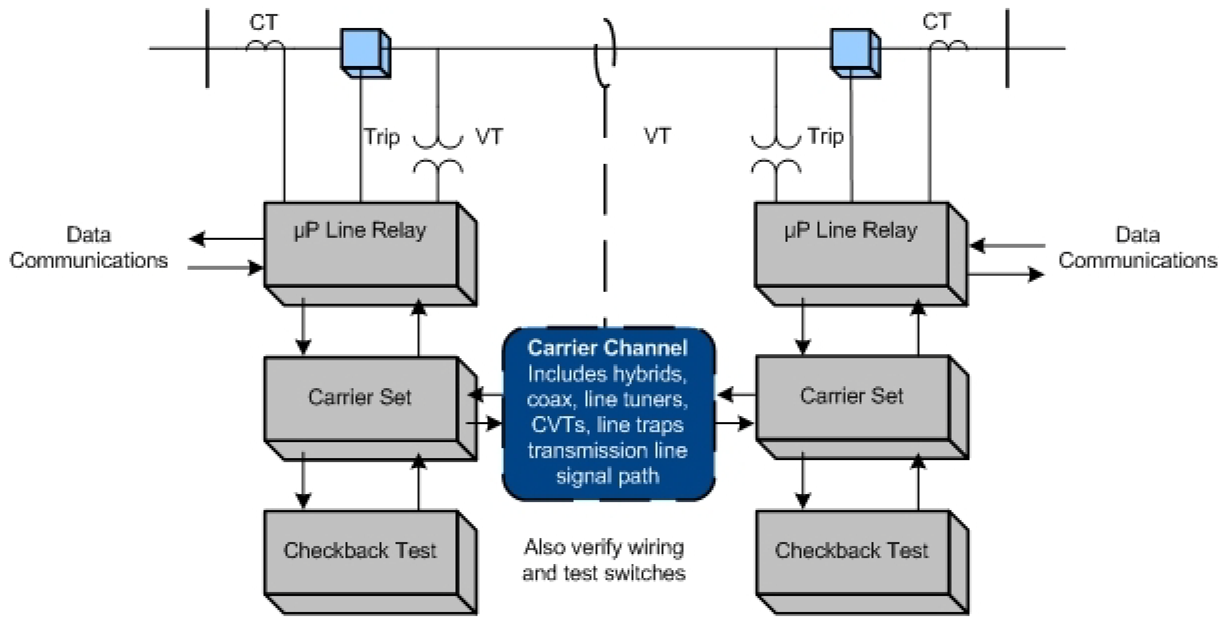
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

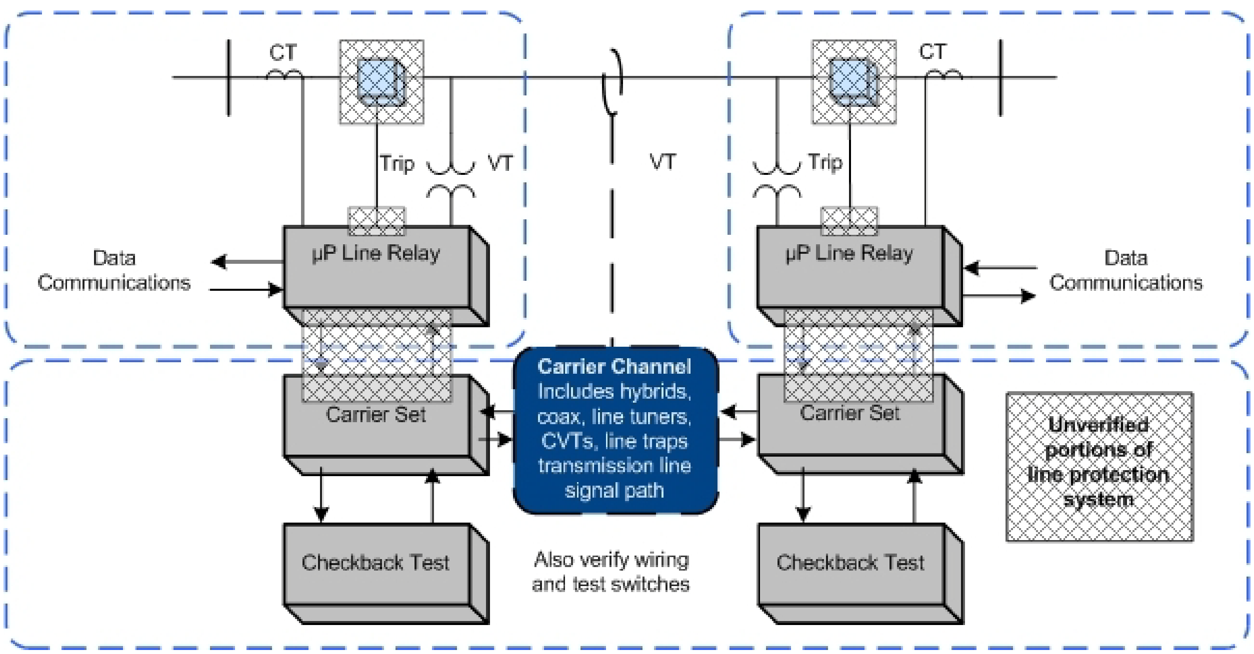
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the

relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Table of Contents

This supplementary reference to PRC-005-2 is ~~not~~neither mandatory ~~and~~nor enforceable.

1. Introduction and Summary

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to relays for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?
BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse.
This Standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. As stated in Requirement R1, this Standard covers protective relays that use measurements of electrical quantities to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This Standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.

- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R3 of the Standard does require that the entity "initiate resolution of any identified unresolved maintenance~~-correctable~~ issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

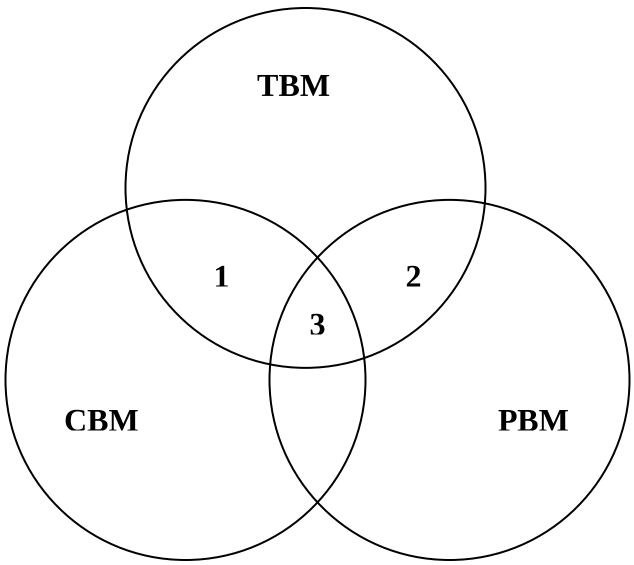
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



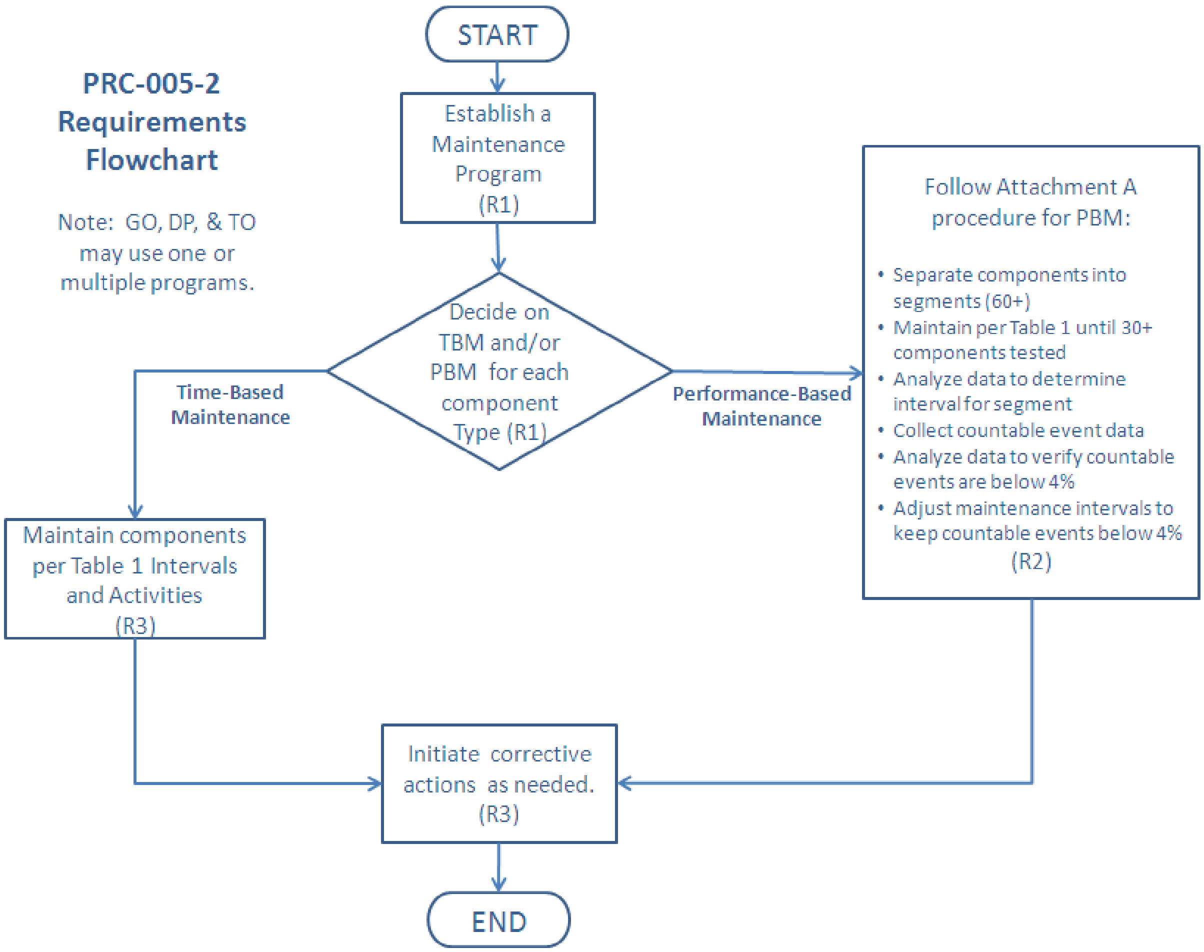
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?
This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or

manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP …" if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1.4 of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?
Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval", the next event would have to occur on or before December 31, 2010.

Please provide an example of "3 Calendar Months".
If a maintenance activity is described as being needed every 3 Calendar Months then it is performed in a (given) month and due again 3 months later. For example a battery bank is inspected in month number 1 then it is due again in month number 4. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of April. Another example could be that a 3-month inspection was performed in January is due in April, but if performed in March (instead of April) would still be due three

months later therefore the activity is due again June. Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?
An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2 , the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance

- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices
- Battery performance test (if ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Verify that current and voltage signal values are provided to the protective relays
- Verify that Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices **Example #3:** A combination of monitored and unmonitored components within a given Protection System might be:
  - A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
  - Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
  - Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
  - Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components shall have maximum activity intervals of:

Every 3 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Cell condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years or when a unresolved maintenance ~~correctable~~ issue arises. The control circuitry can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the Standard, specifies maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a Generation station layout. The various subsystems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

Distributed UFLS and UVLS systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits. There is an additional table,
    - Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
    - Table 3 presents the maintenance activities and intervals for protective relays, current and voltage sensing devices, station dc supply, and control circuitry for distributed UFLS and UVLS systems.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.

- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.
4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station

battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed mostly towards microprocessor based relays.
For relay maintenance departments that choose to test microprocessor based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?
Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0. These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?
Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting

device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?
No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?
As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?
Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for ~~Centralized~~non-distributed UFLS or UVLS Systems?
Since components of the SPS, UFLS, ~~or~~and UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.
For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?
No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

We believe that the ~~3~~4-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the ~~3~~4-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays

- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) and auxiliary tripping relays (94) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or 94 that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

~~Other devices in the control circuitry that are used for other protective functions besides tripping (including, but not limited to, electromechanical breaker fail initiation relays) need only be verified with the control circuitry every twelve years.~~

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.
The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electromechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?
This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3.

How do I achieve a "grace period" without being out of compliance?
For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007. the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years –

the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for “time-interval extensions” or “grace periods” to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. “Maximum time intervals” by their very term negates any “time-interval extension” or “grace periods”. To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was “…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…” The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity’s use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program
One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program
The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation
Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?
Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?
Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.

- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant

microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme". Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes", all of which have three current signals supplied from bushing CT's and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT's and voltage signals from PT's built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.
The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).
(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?
Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may

indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?
For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific

requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?
The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?
If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?
Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would

dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R3 states (the entity must):

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified unresolved maintenance ~~correctable~~ issues.

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP and initiate resolution of any identified unresolved maintenance ~~correctable~~ issues..." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.
Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a unresolved maintenance ~~correctable~~ issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?
Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.

- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?
No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?
Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

~~Circuit breakers that participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements; however the circuitry must be tested at least once every 12 years. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers~~

~~are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.~~ The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are electromechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?
Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?
Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?
Table 1-5 specifies that each breaker trip coil, auxiliary relay that carries trip current to a trip coil, and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?
Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3)

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out or auxiliary relay does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit does not have to be proven with an electrical trip.
- The trip coil of the circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?
The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

<u>Battery Charger</u> - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

<u>Station Battery</u> - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

<u>Emerging Technologies</u> - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (Valve-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.

For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment).

Although many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulphuric acid, is consumed and the concentration of the sulphuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?
Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.
The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a

station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?
Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?
With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manfacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for “cell/unit internal ohmic measurements (impedance, conductance and resistance)” and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, “depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell’s capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs “an accurate measure of the overall battery capacity” they should “perform a battery capacity test.”

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station’s battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.

Why check for the electrolyte level?

In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is “verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.” This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to “Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.”

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the “capacity 6 month test” at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the “thermal runaway test” at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.
Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be performed on any communications-assisted trip scheme regardless of the vintage of technology.The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?
For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.

- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 3-month inspection of communications-assisted trip scheme equipment?
The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?
An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?
There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Question:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?
There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?
If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

~~15.7~~15.7 Distributed UFLS and UVLS Systems (Table 3)

Distributed UFLS and UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current sensing devices have the same maintenance activity and interval as Table 1-2. DC systems need only have their voltage read at the relay every twelve years. Control circuits have the following maintenance activities every twelve years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out and/or auxiliary tripping device(s).
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS/UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however the part of the trip path control circuitry between the load shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.~~7~~8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?
Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?
These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?
Yes.

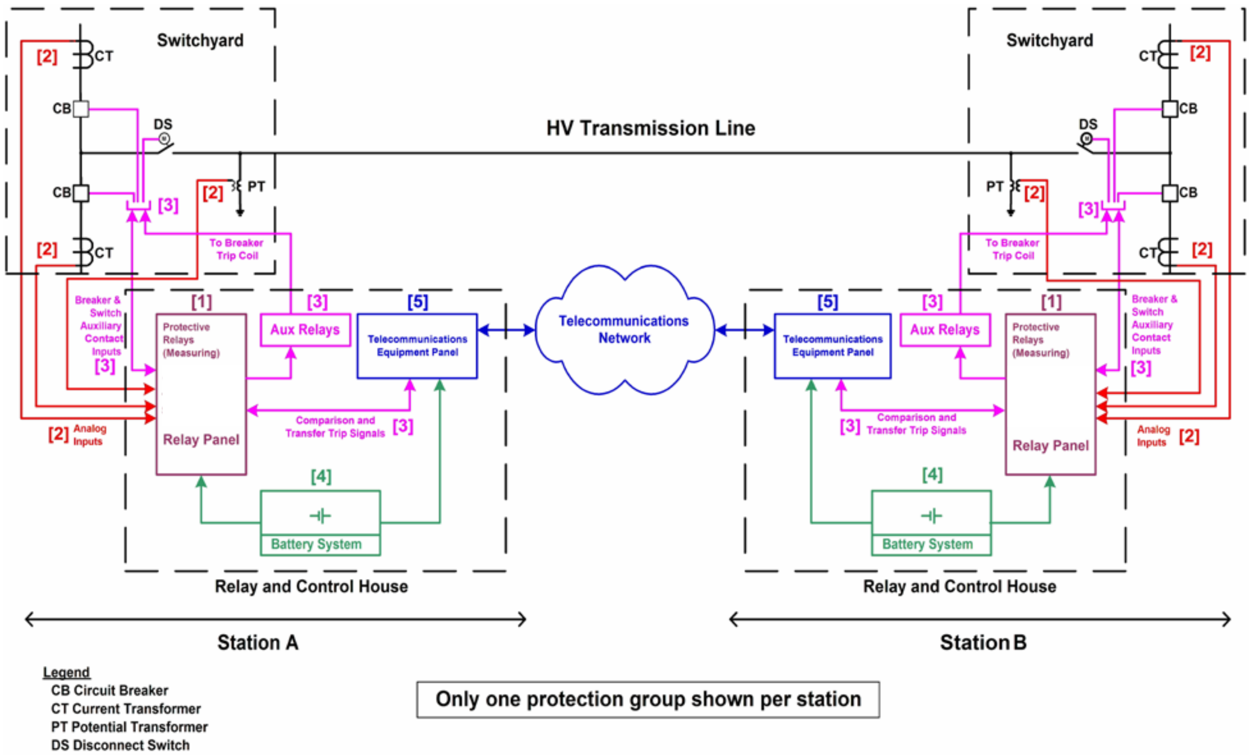
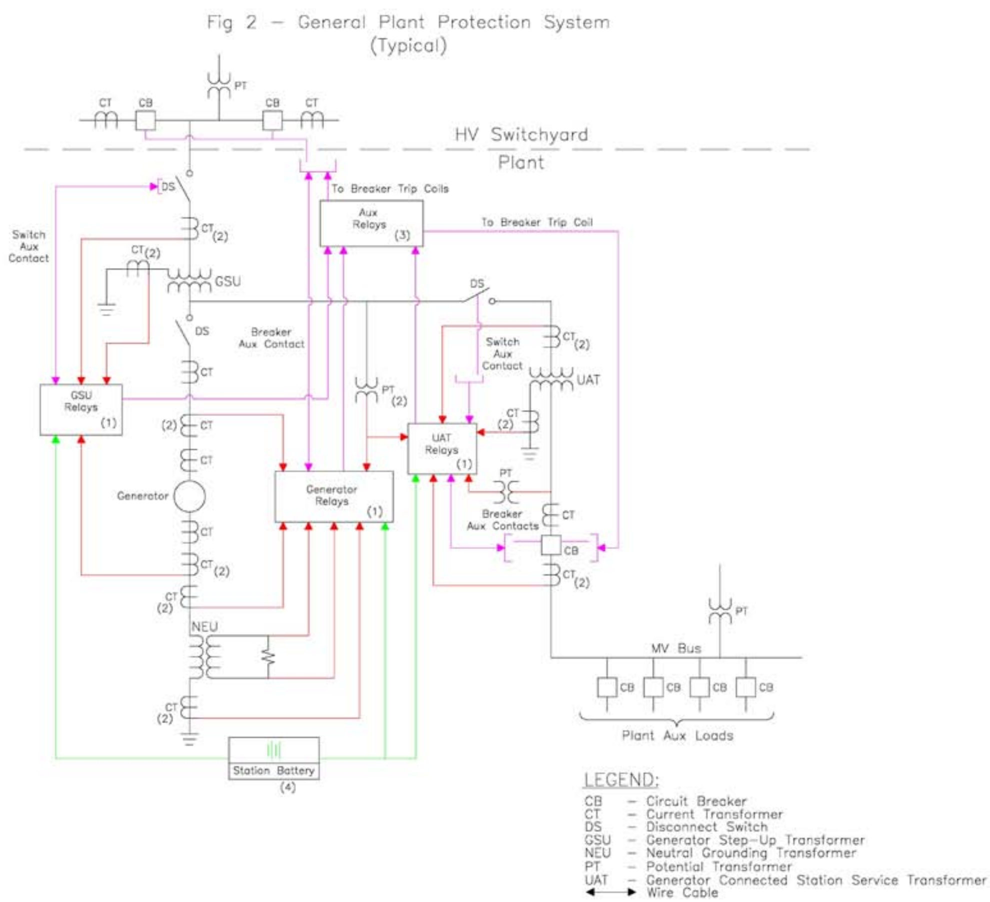
Figures

Figure 1: Typical Transmission System



For information on components, see ***[Figure 1 & 2 Legend – Components of Protection Systems]()***

Figure 2: Typical Generation System



For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

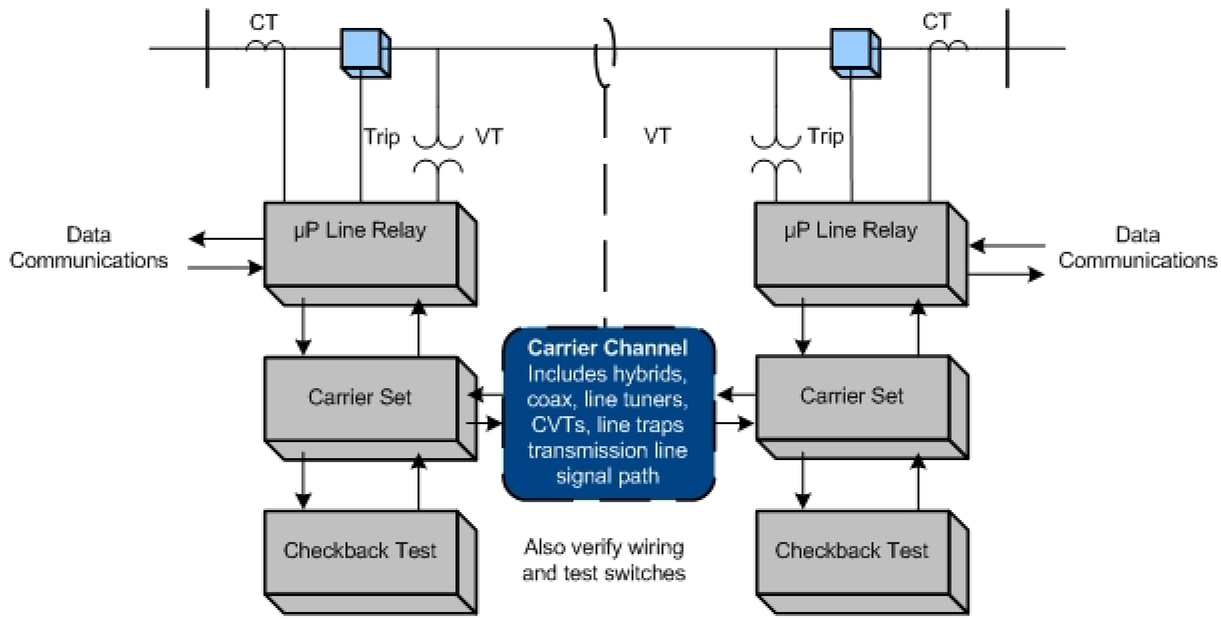
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

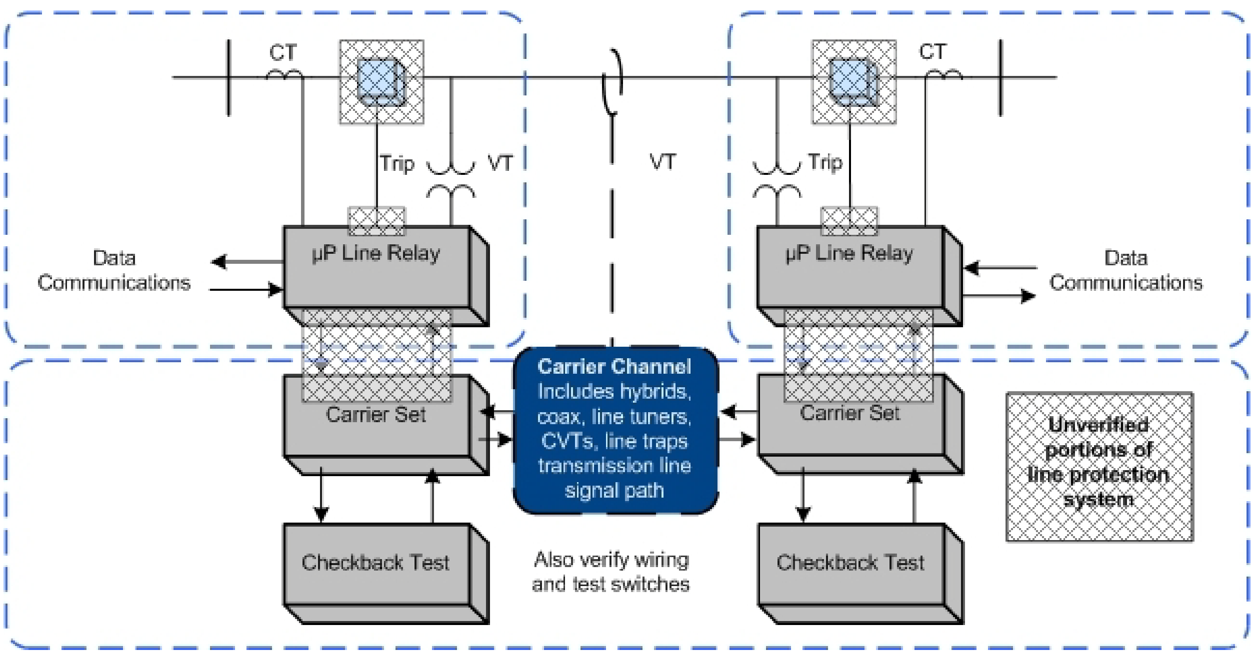
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the

relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Mapping Document Showing Translation of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing, PRC-008-0- Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 - Undervoltage Load Shedding System Maintenance and Testing, and PRC-017-0 - Special Protection System Maintenance and Testing into PRC-005-2 – Protection System Maintenance

Standard: PRC-005-1 - Transmission and Generation Protection System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in PRC-005-2 – Protection System Maintenance Or Comment**
R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:	PRC-005-2, R1	**R1.** Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). The PSMP shall: *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]* **1.1.** Address all Protection System component types. **1.2.** Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3. **1.3.** Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5, Table 2, and Table 3. **1.4.** Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table3.

Standard: PRC-005-1 - Transmission and Generation Protection System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in PRC-005-2 – Protection System Maintenance Or Comment**
R1.1. Maintenance and testing intervals and their basis. R1.2. Summary of maintenance and testing procedures.	PRC-005-2, Tables 1-1 through 1-5 and Table 2.	See Tables 1-1 through 1-5 and Table 2. The Tables establish prescribed maximum intervals and minimum maintenance activities.
R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:	PRC-005-2, R3	**R3**. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues.
R2.1. Evidence Protection System devices were maintained and tested within the defined intervals. R2.2. Date each Protection System device was last tested/maintained.	PRC-005-2, M3	**M3**. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of unresolved maintenance issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

Standard: PRC-008-0 - Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Comments**
R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.	PRC-005-2, R1, R2, R3, and Applicability 4.2.2 Tables 1-1 – 1-5 and Table 3	See PRC-005-2. Each Transmission Owner and Distribution Provider that owns an underfrequency load-shedding system, (UFLS) as established by Regional underfrequency load-shedding requirements, shall establish and document a Protection System maintenance program for that underfrequency load-shedding system. The program may be time-based, performance-based, or a combination thereof, and must address all Protection System components that are used within the underfrequency load shedding system. Batteries must be maintained via a time-based program.
R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).	PRC-005-2, R3	**R3**. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. Each Transmission Owner and Distribution Provider that owns an underfrequency load-shedding system, (UFLS) as established by Regional underfrequency load-shedding requirements, shall establish and document a Protection System maintenance program for that underfrequency load-shedding system. The program may be time-based, performance-based, or a combination thereof, and must address all Protection System components that are used within the underfrequency load shedding system. Batteries must be maintained via a time-based program.

Standard: PRC-011-0 - Undervoltage Load Shedding System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Comments**
R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include: **R1.1.** The UVLS system identification which shall include but is not limited to: **R1.1.1.** Relays. **R1.1.2.** Instrument transformers. **R1.1.3.** Communications systems, where appropriate. **R1.1.4.** Batteries. **R1.2.** Documentation of maintenance and testing intervals and their basis. **R1.3.** Summary of testing procedure. **R1.4.** Schedule for system testing. **R1.5.** Schedule for system maintenance. **R1.6.** Date last tested/maintained.	PRC-005-2, R1, R2, R3, and Applicability 4.2.3 Tables 1-1 through 1-5, Table 2, and Table 3.	See PRC-005-2. Each Transmission Owner and Distribution Provider that owns an undervoltage load-shedding system, (UVLS) installed to prevent system voltage collapse or voltage instability for Bulk Electric System reliability, shall establish and document a Protection System Maintenance program for that undervoltage load-shedding system. The program may be time-based, performance-based, or a combination thereof, and must address all components that are used within the undervoltage load shedding system. Batteries must be maintained via a time-based program.
R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).	PRC-005-2, M3	**M3**. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of unresolved maintenance issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

Standard: PRC-017-0 - Special Protection System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Comments**
R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include: **R1.1.** SPS identification shall include but is not limited to: **R1.1.1.** Relays. **R1.1.2.** Instrument transformers. **R1.1.3.** Communications systems, where appropriate. **R1.1.4.** Batteries. **R1.2.** Documentation of maintenance and testing intervals and their basis. **R1.3.** Summary of testing procedure. **R1.4.** Schedule for system testing. **R1.5.** Schedule for system maintenance. **R1.6.** Date last tested/maintained.	PRC-005-2, R1, R2, R3, and Applicability 4.2.4 Tables 1-1 through 1-5 and Table 2.	See PRC-005-2. Each Transmission Owner, Generator Owner, and Distribution Provider that owns a Special Protection System, or portion thereof, for Bulk Electric System reliability shall establish and document a Protection System Maintenance program for their portion of that Special Protection System. The program may be time-based, performance-based, or a combination thereof, and must address all components that are used within the Special Protection System. Batteries must be maintained according to the time-based program.
R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).	PRC-005-2, M3	**M3**. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of unresolved maintenance issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

Unofficial Comment Form for 1st Draft of the Standard for Protection System Maintenance and Testing Project 2007-17

Please **DO NOT** use this form. Please use the electronic comment form to submit comments on the 1st draft of the PRC-005-2 standard for Protection System Maintenance and Testing. Comments must be submitted by **September 28, 2011.** If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:
This project recently failed to receive two-thirds weighted stakeholder approval on recirculation ballot. The Standards Committee directed that the Standard Drafting Team post the SAR and standard for a 45-day comment period with an initial ballot conducted during the last 10 days. During the posting period, the Standard Drafting Team plans to conduct a Webinar to discuss recently-presented industry comments and how they are addressed in the draft standard.

The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) has made several changes to the fifth posting of PRC-005-2 based on comments received from industry. The changes include:

- Revising the term, “Maintenance Correctable Issue” to “Unresolved Maintenance Issue”.
- Revising the “3 calendar months” interval for various station dc supply and communications system maintenance activities to “4 calendar months”.
- The maintenance activities and intervals for distributed UFLS and UVLS systems were extracted from Table 1-1 through 1-5 and placed into a new Table 3 to more clearly illustrate the requirements related to these systems, which are often implemented on the distribution system.
- Modifying the VSLs and VRFs to reflect the changes listed above.
- Revising the Supplemental Reference and FAQ document to reflect changes made to the draft standard and to address additional issues raised within comments.
- Revising the Implementation Plan.

The PSMT SDT would like to receive industry comments on this standard.

For questions 1-5, please provide specific comments related to the individual question. Please reserve question 6 for general comments not related to questions 1-5.

1. Do you have any comments regarding the existing SAR for this project?

☐ Yes
☐ No

Comments:

2. In response to comments, the term “Maintenance Correctable Issue” was revised to “Unresolved Maintenance Issue”. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

3. In response to comments, the SDT revised the previous “3 calendar months” interval to “4 calendar months” for communications systems and station dc supply. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

4. The SDT extracted the maintenance activities and intervals for distributed UFLS and UVLS systems from Table 1-1 through 1-5 and placed them into a new Table 3 to more clearly illustrate the requirements related to these systems. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

5. The SDT has revised the “Supplementary Reference” document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change.

☐ Yes

☐ No

Comments:

6. If you have any other comments on this Standard that you **have not already provided in response to the prior questions**, please provide them here.

Comments:

A. Introduction

1. **Title:** **Transmission and Generation Protection System Maintenance and Testing**

2. **Number:** PRC-005-1

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

4. **Applicability**

    4.1. Transmission Owner.

    4.2. Generator Owner.

    4.3. Distribution Provider that owns a transmission Protection System.

5. **Effective Date:** May 1, 2006

B. Requirements

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained.

C. Measures

M1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have an associated Protection System maintenance and testing program as defined in Requirement 1.

M2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have evidence it provided documentation of its associated Protection System maintenance and testing program and the implementation of its program as defined in Requirement 2.

D. Compliance

1. **Compliance Monitoring Process**

    1.1. Compliance Monitoring Responsibility

    Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for three years.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and the Generator Owner that owns a generation Protection System, shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program provided was incomplete as required in R1, but records indicate maintenance and testing did occur within the identified intervals for the portions of the program that were documented.

2.2. Level 2: Documentation of the maintenance and testing program provided was complete as required in R1, but records indicate that maintenance and testing did not occur within the defined intervals.

2.3. Level 3: Documentation of the maintenance and testing program provided was incomplete, and records indicate implementation of the documented portions of the maintenance and testing program did not occur within the identified intervals.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
1	December 1, 2005	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. 3. Changed “Timeframe” to “Time Frame” in item D, 1.2.	01/20/05

A. Introduction

1. Title: Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program

2. Number: PRC-008-0

3. Purpose: Provide last resort system preservation measures by implementing an Under Frequency Load Shedding (UFLS) program.

4. Applicability:

4.1. Transmission Owner required by its Regional Reliability Organization to have a UFLS program

4.2. Distribution Provider required by its Regional Reliability Organization to have a UFLS program

5. Effective Date: April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.

R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner's and Distribution Provider's UFLS equipment maintenance and testing program contains the elements specified in Reliability Standard PRC-007-0_R1.

M2. Each Transmission Owner and Distribution Provider shall have evidence that it provided the results of its UFLS equipment maintenance and testing program's implementation to its Regional Reliability Organization and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (within 30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Undervoltage Load Shedding System Maintenance and Testing**

2. **Number:** PRC-011-0

3. **Purpose:** Provide system preservation measures in an attempt to prevent system voltage collapse or voltage instability by implementing an Undervoltage Load Shedding (UVLS) program.

4. **Applicability:**

   4.1. Transmission Owner that owns a UVLS system

   4.2. Distribution Provider that owns a UVLS system

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include:

R1.1. The UVLS system identification which shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have documentation that its UVLS equipment maintenance and testing program conforms with Reliability Standard PRC-011-0_R1.

M2. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have evidence it provided documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program as specified in Reliability Standard PRC-011-0_R2.

D. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Special Protection System Maintenance and Testing**

2. **Number:** PRC-017-0

3. **Purpose:** To ensure that all Special Protection Systems (SPS) are properly designed, meet performance requirements, and are coordinated with other protection systems. To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected.

4. **Applicability:**

   4.1. Transmission Owner that owns an SPS

   4.2. Generator Owner that owns an SPS

   4.3. Distribution Provider that owns an SPS

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include:

R1.1. SPS identification shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

C. Measures

M1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place that includes all items in Reliability Standard PRC-017-0_R1.

M2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have evidence it provided documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization. Each Region shall report compliance and violations to NERC via the NERC Compliance Reporting process.

Timeframe:
On request (30 calendar days.)

1.2. Compliance Monitoring Period and Reset Timeframe

Compliance Monitor: Regional Reliability Organization.

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing
Formal Comment Period Open Aug 15 – Sept 28, 2011
Ballot Pool Window Open Through Sept 14, 2011
Initial Ballot and Non-Binding Poll: Sept 19 – 28, 2011

Now available at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

The Standards Committee has authorized posting the SAR for Project 2007-17 Protection System Maintenance and Testing, along with the draft standard PRC-005-2 — Protection System Maintenance and associated implementation plan, for a formal 45-day comment period.

PRC-005-2 was posted for a recirculation ballot that ended June 30, 2011. The standard narrowly failed to achieve ballot pool approval, and in accordance with the Standard Processes Manual, the project has been reinitiated. An initial ballot and concurrent non-binding poll will be conducted during the last 10 days of the 45-day comment period. A new ballot pool is being formed during the first 30-days of the 45-day comment period. Because the project is not new to stakeholders, the Standards Committee has waived the initial 30-day comment period and asked the drafting team to conduct a webinar during the comment period.

Instructions for Joining the New Ballot Pool for Project 2007-17
The ballot pool windows are open through **8 a.m. Eastern on Wednesday, September 14, 2011**.

Registered Ballot Body members may join the ballot pools to be eligible to vote in the upcoming ballot and non-binding poll at the following page: https://standards.nerc.net/BallotPool.aspx

During the pre-ballot window, members of the ballot pool may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list server for the initial ballot pool is: bp-2007-17_PSMT_IN2_in@nerc.com. The list serve for the non-binding poll is: bp-2007-17_nb_0811_in@nerc.com

Any member who wishes to participate in the non-binding poll of the associated violation risk factor (VRF) and violation severity levels (VSLs) must also join this pool. We have discontinued the practice of automatically populating the ballot pool for the non-binding poll with all those who joined the pool to vote on the standard. Thus, anyone wishing to vote on the standard and also wishes to cast an opinion in the non-binding poll of the VRFs and VSLs must join both ballot pools.

Instructions for Submitting Comments
A formal comment period is open through **8 p.m. Eastern on Wednesday, September 28, 2011.**

Please use this electronic comment form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net.

Documents for this project, including the SAR, a clean copy of PRC-005-2, its Implementation Plan, and Supplemental Reference and FAQ along with an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Redlines have also been posted showing changes made to the standard, implementation plan, and Supplemental Reference and FAQ since the standard was posted for recirculation ballot in June.

The drafting team considered whether revisions to the SAR were needed but did not revise the SAR, so the SAR that is posted is the same SAR that was posted for comment when Project 2007-17 was first initiated, except that the date has been updated.

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a redline of proposed PRC-005-2 that shows the changes to the last approved version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference at:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps – Webinar, Initial Ballot and Non-binding Poll of VRFs and VSLs

The drafting team plans to conduct a webinar during the comment period to review PRC-005-2 and address questions. Additional details will be announced when they are available.

An initial ballot of the revised standard and its associated implementation plan, and a new non-binding poll of the revised VRFs and VSLs will be conducted during the last 10 days of the comment period, beginning on Monday, September 19 through Wednesday, September 28, 2011.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 Protection System Maintenance & Testing
Initial Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Ballot Results for PRC-005-2 Protection System Maintenance
An initial ballot of PRC-005-2 Protection System Maintenance, and a concurrent non-binding poll of the associated VRFs and VSLs, concluded on September 28, 2011.

Voting statistics for the standard are listed below, and the Ballot Results webpage provides a link to the detailed results.

Quorum: 84.86 %
Approval: 61.10 %

Non-binding Poll Results for Associated VRF and VSLs
Of those who registered to participate, 83.13% provided an opinion or abstention; 68.68% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Next Steps
The drafting team will consider all comments received, and decide whether to make additional revisions to the standards.

Project Background
The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

PRC-005-2 was posted for a recirculation ballot that ended June 30, 2011. The standard narrowly failed to achieve ballot pool approval, and in accordance with the Standards Processes Manual, the project has been reinitiated. Because the project is not new to stakeholders, the Standards Committee waived the initial 30-day comment period and directed that the standard be posted for a formal 45-day comment period with an initial ballot conducted during the last ten days of the comment period.

Additional information is available on the project webpage.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

Maintenance and testing of protection systems is the final step in the process that begins with the calculation of settings. The calculation of settings is followed by the application of those settings to the equipment. Maintenance and testing ensures that the settings given to testing personnel have been applied as given. This Standard addresses the Maintenance and Testing of protection systems. It should also address the need to validate the accuracy of the settings given to the field. A statement should be added to the SAR to address this need.
The focus of the industry is on the field procedures necessary to ensure that protection systems are maintained and tested. This includes the verification that settings have been applied correctly. The accuracy of the settings calculated needs to be validated, and that step should be considered for inclusion in this Standard.

APS has been testing batteries nominally every 4 months plus 25% for over 20 years with no adverse consequences. Requiring a maximum of testing every 4 months doesn't allow for any flexibility, would require an additioal 400 tests per year and APS does not consider the 4 months a maximum time limit for battery testing.
Yes
While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. In addition, when technology changes for the better, industry will need the flexibility to optimize use of the new technology. Lastly, the more often protection equipment is taken out of service for testing, the more often the line is vulnerable. The balance between the correct amount of testing and correct amount of time the equipment is in the field and in service is an important consideration when assuring the reliability of the BES. APS suggests the general principles of the following two papers be applied to more equipment types than microprocessor relays with self test capabilities. 1) 'An Improved Model for Protective-System Reliability,' P.M. Anderson and S.K. Agrawal, Power Math Associates, Inc., IEEE Transactions on Reliability, Volume 41, No. 3, September 1992; 2) 'Philosophies for Testing Protective Relays,' J.J. Kumm, et. al., Schweitzer Engineering Laboratory, Inc., 48th Annual Georgia Tech Protective Relaying Conference, May 1994.

No
No
The measures associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. It is suggested that one of these two courses be followed: either a) eliminate the requirement to initate resolution, or b) fully describe what evidence is expected for this part.
Yes
Yes
1) Separating this classification of equipment into its own table is a good idea to make it easier for the owners of this equipment to figure out what they must do. 2) Consider also moving the UVLS note (found in column 1 of Tables 1-4a-d) into the header with the other "UFLS and UVLS note" to simplify the table. The header note could read "Excludes UFLS and UVLS systems - see Table 1-4e for non-distributed UFLS and UVLS systems and see Table 3 for distributed UFLS and UVLS systems"). 3) Table 1-5: Need clarification on "continuity and energization or ability to operate". What does this mean? 4) For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). There are some references to Table 2 (i.e. See Table 2), but does that mean that you have to verify the alarm(s)? We think that the Table 2 details need to be included specifically in Table 3. Or, make it very clear that this test is required for UF and UV schemes.
No
Several additional edits are needed so that the document matches the proposed standard: 1) In Section 5.1.1, page 16, add "and Table 3" in the Figure and at the end of FAQ after figure in that section. 2) In Section 7.1, example #1, a 3 month battery interval is shown 3) In Section 8.1.1, a 3 month interval is shown for communication circuit 4) In Section 15.5.1, several references to "3 month" and "three month" intervals are shown for communication circuits. 5) In Appendix B, the formatting is incorrect for Al McMeekin's company name.
1) For Table 1-1 and Table 3, consider adding "(internal to the relay)" to the microprocessor relay 6 calendar year maintenance activities to clarify that these maintenance activities are not related to items external to the relay).

Saft Comments on NERC Standard PRC-005-2 — Protection System Maintenance Please find herein Saft’s comments to NERC PRC-005-2 regarding ohmic testing of Nickel-Cadmium (NiCad) batteries. As drafted, the proposed NERC Standard PRC-005-2 will lead to the removal of high quality, reliable NiCad battery power units from Protection Systems, which is counter to the NERC stated purpose of PRC-005-2, which is to ‘document and implement programs for the maintenance of all Protection

Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.' There is broad consensus within the battery industry that ohmic testing of Valve Regulated Lead-Acid (VRLA) batteries provides a means for trending the condition of the battery over time. Such a consensus does not exist for Vented Lead-Acid (VLA) batteries, because ohmic measurements are more difficult to trend, thereby providing a go/no-go assessment of the battery's availability at that precise moment in time, rather than a measure of VLA battery condition. Ohmic testing of NiCad batteries provides a similar go/no-go assessment to ohmic testing of VLA batteries. As with VLA batteries, ohmic testing of NiCad batteries does not provide meaningful trending information, but rather provides a status update of battery condition at a specific moment in time. Due to the similar information provided by ohmic testing of VLA and NiCad batteries, Saft recommends that ohmic testing of NiCad batteries be included under the Maintenance Activities for NiCad batteries. Specifically, Saft recommends that NERC add the following language to the Maintenance Activities column in Table 1-4(d), 'Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline', at a maximum maintenance interval of 18 months, as in the requirement for VLA batteries noted in Table 1-4(a).

We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4(a,b,c,d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a reliability Standard includes best maintenance practices it is encroaching on IEEE's ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible.
Yes
No
a. On page 26 of the Supplementary Reference document, it states, "If your PSMP (plan) requires more activities than you must perform and document to this higher standard." This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the

minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, "If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards." In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards".
a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES." b. Section 1.3 requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent test record. An audit should be focused on the present day and not in the past. Is an entity compliant today and not can we find a way to issue a fine for something in the past? An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. Why should they be forced into testing again and incurring additional expense for customers only to have two tests available for an auditor? This does not enhance reliability. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years! Hypothetically, if we have a test record from ten years ago, but we don't have the record from 24 years ago, how does that adversely affect the reliability of the BES today? The standard should focus on – Are we compliant today? c. Table 1-5 requires a maintenance activity to, "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Recommend this be changed to, "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, change the wording to, "Electrically operate each interrupting device every 6 years." While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren't configured to test independently. Isolating one trip coil from the other may include "lifting a wire" that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn't practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don't know which trip coil operated, then we have a "one off" device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation – this is a recipe for a compliance violation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES. d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, including us, monitor our circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) – this ensures the operating linkages aren't

bound and the breaker will operate. We have many maintenance activities performed on devices for the BES that do not require a NERC standard. If a utility chooses not to perform best practice maintenance, customers will experience more frequent and longer outages. The utility will receive customer feedback on outages which should translate into the utility increasing its maintenance. In other words, we don't have to include a functional test as a NERC requirement. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications). e. Recommend NERC provide training specifically on how to audit PRC-005-2 to auditors in all eight Regional Entities. PRC-005 is the most violated standard since enforcement began on June 18, 2007. This is an excellent opportunity for NERC to get all eight regions on the same page for what to audit. NERC provides training on standard auditing guidelines and sample selection, but doesn't provide training on how to audit specific standards. RSAW's and CAN's have been an attempt to get consistency across the regions, but differences are still obvious. NERC is in the perfect position to observe potential violations (PV) from an auditor and as a PV is written that goes beyond the standard or is not in accordance with the initial training; NERC can dismiss the PV and retrain the auditor. Auditors aren't perfect, nor are any of us. Training is a basic tool for the auditor to perform their job properly.

(1) General – defined terms need to be capitalized throughout this standard. (2) Requirement R3 only addresses initiation of resolution to any Unresolved Maintenance Issues. Requirement R3 should require completion of corrective action to deal with Unresolved Maintenance Issues within a reasonable timeframe. (3) Section 1.3, Data Retention, should require each entity to keep all versions of its PSMP that were in effect since its last compliance audit, in order to demonstrate compliance at all relevant times (not just the current version). (4) In the Severe VSL for R2, add "Annually" to the second bullet under part 5. (5) The VSLs for R3 should contain a time frame (annual?). The second part of these VSLs should refer to initiation and completion of resolution of Unresolved Maintenance Issues. (See comment on Requirement R3 above.) (6) Consider making the R3 VSLs based on a

percent of the number of maintenance activities required by the PSMP in a stated time period, rather than on a percent of the total number of Components. (7) There is no maintenance activity listed to verify that protection system component settings meet the design intent of the protection system. In other words, there is no required activity to confirm that the “specified” settings are correct and appropriate. This introduces a potential reliability gap into the Protection System maintenance program. (8) In Table 1-1, the term “acceptable measurement of power system input values” is somewhat vague. A tolerance value or reference to industry standards should be provided. (9) In Table 1-3, the activity should include verifying that the current and voltage signal values are within design tolerances, not just that signal values are present. (10) In Table 1-4(a) Component Attributes – the reference to UFLS systems is missing in the exclusion that refers to UVLS systems. (UFLS is included in Tables 1-4(b) through 1-4(d).) (11) In table 1-4(f), there should be a reference to “alarming” in addition to “monitoring” in the first cell of the next-to-last row. (12) In table 1-4(f), why is the last row limited to VRLA station batteries? Should the same exclusion apply to VLA batteries? (13) In Table 1-5, a “12 calendar year” interval is too long for “Unmonitored control circuitry associated with SPS” and “Unmonitored control circuitry associated with protective functions.” We suggest this be changed to 6 years. Similar unmonitored attributes related to battery maintenance have a 6 calendar year interval. (14) In Table 2, the phrase “location where corrective action can be initiated” is unclear, and we suggest that a more definitive description be used. Also, why is the word “DETECTION” in all-caps? (15) In Table 3, the maintenance activity should include verifying that Protection System Component settings meet the design intent of the Protection System. For example, any reclosing function should be disabled on UFLS and UVLS relay systems. (16) In Table 3, In Table 1-1, the term “acceptable measurement of power system input values” is somewhat vague. A tolerance value or reference to industry standards should be provided. (17) The Implementation Plan is overly long and complicated. Entities (including Regional Entities) will have to track and apply multiple versions of this standard for 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable, recognizing that for some Components no action will be required under the standard for a number of years.

Either term works if defined properly.
Yes
Thank you for making this change. As we pointed out in draft 2, a three month maximum would require a bi-monthly target to allow for contingencies; increasing maintenance from four times a year (per the IEEE battery standards) to six.
Yes
Yes
We are concerned about what exactly “initiate resolution” means in R3. We foresee this being a potential area of disagreement between registrants and CEAs when a registrant believes an open work order suffices and the CEA wants to see schedules or purchase orders. Neither M3 nor the FAQs address this.

1. It will take several years for TVA to implement checkback on 590 carrier blocking sets on the TVA system and not have to perform the PRC 005-2 requirement of verifying functionality every 4 months with no grace period. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 test/year. We are also implementing an extensive PM test in October 2011 which will test 25% of the sets per year and will take readings of SWR, line loss, and receiver margin. 2. TVA disagrees with the requirement to measure internal ohmic values of the station dc supply batteries every 18 months. The interval should be 36 months. Our experience from performing our routine maintenance program including cell impedance testing at 3-year intervals has been that the program is fully adequate in monitoring bank condition. An 18-month interval for internal resistance/impedance testing is an unnecessary burden. 3. Are we required to test the trip circuit between the power transformer sudden pressure relay and the switch house or are we only required to test the trip circuit between the electrical sensing relays and the trip coils of the breakers?

We agree with this change. Smaller utilities, especially in the WECC region, in many cases have large territories to cover with limited resources. In many instances sub-stations are inaccesible during the winter and the 4 month interval will assist these smaller entities in getting the work done.
Yes
Thank you for the opportunity to comment on the draft Standard PRC-005-2 – Protection System Maintenance. While the feedback from the last round of comments is appreciated, we still cannot support the standard as written due to our concerns outlined here. We appreciate the work that NERC has put into a new standard to encapsulate and replace the current PRC-005, PRC-008, PRC-011 and PRC-017. But, we believe that the draft Standard needs one important revision before the NERC Board of Trustees should approve it. Specifically, NERC should revise the draft version of PRC-005-2

so that the beginning of Section 4.2 reads as follows: “4.2. Facilities: Protection Systems that (1) are not facilities used in the local distribution of electricity, (2) are facilities and control systems necessary for operating an interconnected electric energy transmission network, and (3) are any of the following:” This revision is necessary to capture the limits that Congress placed on FERC, NERC, and the Regional Entities in developing and enforcing mandatory reliability standards. Specifically, Section 215(i) of the Federal Power Act provides that the Electric Reliability Organization (ERO) “shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System.” And, Section 215(a)(1) of the statute defines the term “Bulk-Power System” or “BPS” as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.” With this language, Congress expressly limited FERC, NERC, and the Regional Entities’ jurisdiction with regard to local distribution facilities as well as those facilities not necessary for operating a transmission network. Given that these facilities are statutorily excluded from the definition of the BPS, reliability standards may not be developed or enforced for facilities used in local distribution. In Order No. 672, FERC adopted the statutory definition of the BPS. In Order No. 743-A, issued earlier this year, the Commission acknowledged that “Congress has specifically exempted ‘facilities used in the local distribution of electric energy’” from the BPS definition. FERC also held that to the extent any facility is a facility used in the local distribution of electric energy, it is exempted from the requirements of Section 215. In Order No. 743-A, FERC delegated to NERC the task of proposing for FERC approval criteria and a process to identify the facilities used in local distribution that will be excluded from NERC and FERC regulation. The critical first step in this process is for NERC to propose criteria for approval by FERC to determine which facilities are used in local distribution, and are therefore not BPS facilities. The criteria to be developed by NERC must exclude any facilities that are used in the local distribution of electric energy, because all such facilities are beyond the scope of the statutory definition of the BPS, which establishes the limit of FERC and NERC jurisdiction. Accordingly, it is critical that NERC draft the new PRC-005-2 standard to expressly exclude facilities used in local distribution. NERC must also expressly exclude from PRC-005-2 those facilities “not necessary for operating an interconnected electric energy transmission network (or any portion thereof)”. Similar to the local distribution exclusion, the facilities not necessary for operating a transmission network are not part of the BPS and therefore must be expressly excluded from the standard. We understand, but disagree with, the argument that, because the FPA clearly excludes local distribution facilities and facilities necessary for operating an interconnected electric transmission network from FERC, NERC, and Regional Entity jurisdiction, it is not necessary to expressly exclude these facilities again in reliability standards. This approach might be legally accurate, but could lead to significant confusion for entities attempting to implement the new PRC-005-2 standard. There are numerous examples of Regional Entities, particularly WECC, attempting to assert jurisdiction over such facilities, and regulated entities face significant uncertainty as to which facilities they should consider as within jurisdiction. Clarifying FERC, NERC, and Regional Entity jurisdiction in the BES definition, even if such clarification is already provided in the FPA, would avoid such problems under the new PRC-005-2 standard. Again, we appreciate the work NERC has put in so far on a new Standard. We look forward to working within the drafting process to help implement our recommended revision.

No
The definition’s wording is satisfactory, and we agree with the removal of “failure of a component to operate within design parameters”. However, we do not agree with the use of the word “unresolved” within the term itself, as we believe this word may convey that the issue was not known or identified. We suggest replacing “Unresolved Maintenance Issue” with “Corrective Maintenance Issue”.
No
Though we agree with extending the interval from what it was previously, AEP recommends that the interval in Table 1-2 for Communications Systems be increased to 6 months.
Yes

No
With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. However, AEP is uncertain how much weight the documents might carry during audits. We recommend that this additional information be included within the actual standard (for example in an appendix) but in a more compact version. Section 15.7 of the supplementary reference includes the bullet point “No verification of trip path required between the lock-out and/or auxiliary tripping device(s).” This appears to contradict the other bullet points within Section 15.7.
As it stands, if an entity adopts a more stringent maintenance program but fails to meet it, that entity could be found non-compliant despite continuing to abide by the minimum requirements of the standard itself. Entities should have the ability, if they so choose, to include additional maintenance activities or more stringent intervals than specified within the standard without concern of penalty in the event they are unable to accomplish them. In short, entities should only be audited against the requirements stated within the standard. Table 1-3 of the standard lists the minimum required maintenance activities for voltage and current sensing devices as "Verify that current and voltage signal values are provided to the protective relay." Consistent with Table 1-3, Section 15.2.1 of the Supplementary Reference states that an entity “...must verify that the protective relay is receiving the expected values from the voltage and current sensing devices...” The Supplementary Reference further offers examples of how this requirement may be satisfied with most examples referencing the need to verify the signal at each relay in the circuit. We recognize the need to verify a voltage signal at each protective relay, as these devices are wired in parallel and an open circuit at one location may not impact the other devices on the circuit. However, we do not agree that there is a need to verify a current signal at each protective relay. Current devices are wired in series, and an open circuit at any location will impact all other devices on the circuit. For this reason, a single measurement of the current circuit is sufficient. We recommend updating Table 1-3 and the supplementary reference to account for the different physical characteristics of voltage and current circuits. This standard encompasses a very broad range of component types and functionality across broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application. Other standards have applicability for certain thresholds of voltage levels, etc. Why not this standard as well?

Please see the comments submitted by the MRO NSRF.
In reference to the zero tolerance policy evident within PRC-005-2, LES offers the following suggestion: Set up an annual review of a random set sample (20% for example) of Protection System equipment to self-verify compliance. If issues arise, allow the entity the opportunity to correct the issue, make the necessary procedural and/or documentation adjustments and not be considered non-compliant. The idea is to allow entities the opportunity to continually improve their practices and procedures; in essence, allow them to show they are attempting to follow a “culture of compliance”. If habitual problems arise, then non-compliance will be evident. One example that justifies this approach is software glitches or improper programming. As more and more systems become automated, scheduling of maintenance will be done automatically through various types of software.

If a program has even one attribute set incorrectly, it could not function as intended and would potentially set up incorrect intervals for maintenance and testing. It was not intended this way by the entity and they are not intentionally disregarding the standards, but could nevertheless be put in a situation where a maintenance interval is missed. An annual review would catch things like this and allow an entity to continuously improve their program without self-reporting. This concept is expanded from a current draft version of several CIP standards; therefore, it is being at least considered by other drafting teams.

A similar change in interval should be applied to intervals of “6 calendar months".
Yes
Yes
It is not clear to what extent can an entity (or auditor) can rely on information contained within the Supplementary Reference to support their position during an audit. There is a disclaimer at the beginning of the Supplementary Reference stating that “this supplementary reference to PRC-005-2 is neither mandatory nor enforceable.” It seems that interpretation of the draft standard depends heavily upon this Supplementary Reference. At the same time, the Supplementary Reference does not rise to the level of a standard.
1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months. 2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station DC supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program develoepd for the previous standards. 3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself. 4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear. 5. In Table 1-2, there is a maintenance activity related to communication systems to “verify essential signals to and from other Protection System components.” It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or

something else. It is recommended that the requirement be to “verify operation of communictation system inputs and outputs that are essential to proper functioning of the Protection System.” This language is consistent with that used for protective relays in Table 1-1. 6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which ‘performance critera’ are ‘pertinent.’ Additionally, it is unclear if an entity must document the ‘communications technology applied’ and the associated ‘performance criteria’ in its PSMP. 7. In Table 1-4, it is unclear if there is a distinction between the terms ‘resistance’ and ‘ohmic values.’ If there is a distinction, then this distinction should be clarified. 8. In Table 1-4, it is unclear if there is a distinction between the terms ‘battery terminal connection resistance’ and ‘unit-to-unit connection resistance.’ If there is a distinction, then this distinction should be clarified. 9. In Table 1-4, replace the term ‘resistance’ with ‘impedance.’ 10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities. 11. Referring to Table 1-5, no periodic maintenance is required for “control circuitry whose continuity and energization or ability to operate are monitored and alarmed.” It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for “unmonitored control circuitry associated with protective functions.” It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions. 12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements. 13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard. 14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.

The new standard itself, the implementation plan and supplemental reference/FAQ makes up more than 100 pages of material. Granted that several standards are being combined here, still it is simply too involved to monitor. And there is still not enough detail in the standard leaving items which are ambiguous and open to interpretation, and therefore open to fines. In order to remove such interpretation, maintenance documentation will need to be precise and extensive. This will necessitate more and more staff to control and validate data. Adding staff is great but it does not seem to ensure that there is increased reliability.

We understand and disagree with the SDT position on the following recommendation. We do not agree with proposed Section 4.2.1 applicability since it captures only a portion of the previously approved applicability Interpretation (PRC-005-1a) which was developed specifically for PRC-005-1. We suggest the draft standard be revised to conform to the wording in the Interpretation: “Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements.”

BPA agrees that the term “Maintenance Correctable Issue” is an improvement over “Unresolved Maintenance Issue”, however, BPA feels that the idea of a “Maintenance Correctable Issue” is very vague, and would perhaps be better left out of the standard. As written, it is unclear when an issue is a “Maintenance Correctable Issue” and exactly how it has to be dealt with. R3 requires the initiation of resolution of any unresolved maintenance issues.
Yes
Yes
Yes
BPA understands that the VSLs for R3 are based on the percentage of unresolved maintenance issues that an entity has failed to initiate a resolution for. This approach penalizes an entity for having less unresolved maintenance issues. For example, if an entity has only one unresolved maintenance issue and it failed to initiate a resolution for it, it would have failed to initiate a resolution for 100% of its unresolved maintenance issues, which would be a severe VSL. If another entity had 100 unresolved maintenance issues, and it failed to initiate resolution on ten of them, it would have failed to initiate a resolution on 10% of its unresolved maintenance issues, which would be a high VSL. Most likely, the first entity is doing a better job with its maintenance than the second entity, but the first entity receives a more severe penalty. The VSL for R3 is not an accurate measurement of a maintenance program’s effectiveness and needs to be revised. BPA recommends removing the entire “Unresolved Maintenance Issue” topic from the standard. In Table 1-1, it is not clear when a microprocessor relay meets the requirement for internal self-diagnosis and alarming. It is not clear that any microprocessor relay with a relay failure alarm would meet this requirement. BPA believes that it seems like an omission in Table 1-1 for unmonitored microprocessor relays, the verification of settings is not included as a maintenance activity. BPA would also like to recommend clarifying language stating that the owner of the asset is the responsible entity.

The IESO agrees with the revision to the term. However, we observed the inconsistent format of this defined term used throughout the draft standard and would like to point it out to the Drafting Team. The capitalized term “Unresolved Maintenance Issue” is defined on Page 2 and used as a capitalized term in the blue box on Page 5. The defined term was made lowercase and used in other areas of the document as “unresolved maintenance issues” (eg. Page 5 and Page 8). We recommend that the format of this defined term be consistent throughout the draft standard.
Yes
Yes
Yes
The IESO disagrees with the concept that auditors use the standards as minimum requirements and evaluate compliance based on a registered entity’s own governance. We believe that the entity could be found non-compliant with Requirement R3 if they fail to follow the internal maintenance intervals established in their PSMP, even though actual maintenance intervals are no less frequent than the prescribed maximum intervals established in the draft standard. The potential for such a finding will discourage conscientious entities from setting higher internal targets for their planned maintenance and promote compliance with only the minimum requirements of the standard. We therefore propose the following revision to Requirement R3: R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. In the case of time-based maintenance programs, each Transmission Owner, Generator Owner, and Distribution Provider is permitted to deviate from its PSMP provided that actual maintenance intervals do not exceed those specified in Tables 1-1 through 1-5, Table 2 and Table 3. [Violation Risk Factor: High] [Time Horizon: Operations Planning]

No
The reference contains language which makes it a violation should an entity choose a cycle time less than the maximum from the table, and then fail to meet that cycle. (see page 27, "If your PSMP

(plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.") There is no reason to hold a RE in violation if all work is performed within the maximum time from the table - either there was no reliability risk, or the table is incorrect and a reliability risk in itself.
With the development and publication of maximum maintenance and testing intervals (the Tables), there is no longer a reliability need for a RE to identify the associated maintenance intervals for Protection System Components. Further, REs who wish to perform these activities in shorter intervals than those allowed by the standard (See Supplementary Reference, page 27,"If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.")As noted in Question 5, if the entity completes all activities within the maximum interval allowed by the standard, there can be no reliability concern; if there is a reliability issue, then the table interval is incorrect. I would suggest the following changes. 1. Change R1.2 to read "Identify any Protection System component where the RE is using a performance based maintenance interval. No batteries associated with the station DC supply component type of Protection System shall be included in a performance based system". 2. Change R1.3 to read "The intervals for time-based programs are established in Table 1-1 through 1-5, Table 2, and Table 3". 3. Change M1 to add the phrase "for performance-based components" after the words "maintenance intervals". 4. In M1, replace the words "the type of maintenance program applied (time-based, performance based, or a combination of these maintenance methods)' with the words "the identification of any protection system components using performance based intervals".

Our experience with a very large number of communication systems and station dc supplies substantiates an even longer interval as sufficient for reliable Protection Systems.
Yes
Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.
Yes
1) Although the explanation of ‘Restore’ is enlightening on page 12, ‘Restore’ no longer appears in the PS Maintenance definition in the last few drafts. We disagree with the added burden of retaining maintenance records for removed or replaced equipment. This will actually reduce reliability because of the confusion it can cause as to what equipment is providing BES protection. At most, only the last maintenance date of the removed or replaced component should be retained if there’s really a need to

prove that the interval was met regarding the BES protection. 2) Remove 'Reverse power relays' from the list on page 32. They provide thermal of the steam turbine, not electrical protection of the generator.
(1)Measure M3 on page 5 should only apply to 99.5% of the components. Please revise to state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. No one is perfect and it is impractical to imply perfection is achievable. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance".(2)2. An alternate approach regarding the unrealistic perfection of M3 is to correctly recognize that the protection of the primary BES is the objective. Most Protection Systems are redundant by design and the entity needs to be afforded the opportunity to show that a redundant component met the PSMP thereby providing the required protection. The entity should be allowed a reasonable time frame of one calendar increment to maintain the component in question. Our concern stems from the tens of thousands of components in a PSMP, and the reality that rarely but occasionally a data base error or outage scheduling issue may result in a very small number component exceeding their maximum interval. As long as the entity can show that BES protection was sustained and maintains the component quickly (e.g. within one calendar month of discovery), BES reliability has been maintained. (3) Now that FERC has approved the Project 2009-17 Interpretation, please acknowledge more directly in the Supplement that the 'transmission Protection System' that is now approved. NERC interprets "transmission Protection System," as it appears in Requirements R1 and R3 of PRC-004-1 and Requirements R1 and R2 of PRC-005-1, to mean "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directlyfrom the BES."

We do not agree with aspects of the Supplementary Reference document as discussed in Question 6.
1. We remain concerned with the proposed draft version of Requirement R3 as well as the SDT developed statements in the Supplementary Reference & FAQ. The SDT's approach sends industry the wrong message; a message that entities should not go beyond what is in the text of the standards and that in some cases they can even be found non-compliant by failing to meet their own more stringent internal practice. We have sent NERC Staff and Drafting Team leaders a separate document detailing our concerns as well as proposed redlines to the standard. The separately provided document can be viewed as FE's ballot comments. 2. FE supports the standard from a technical standpoint but offer the following additional comments and suggestions: A clarification to the supplementary reference document is necessary regarding Maintenance Activities specified for electromechanical lockout and/or tripping auxiliary devices, as specified in Table 1-5 of the standard. The standard states, "Verify electrical operation of electromechanical trip and auxiliary tripping devices" which must be performed every 6 years. A question was asked during the September 15th Webinar requesting clarification of what "verify electrical operation...." meant. The verbal response

from the SDT member was that this involves verifying that the relay actuates, but does not require verification that its contacts changed state. However, the answer to the question at the bottom of page 29 and top of page 30 in the Supplementary Reference and FAQ (dated July 29, 2011) implies that checking the contacts is necessary. The following statement in the published answer makes this clarification request necessary; “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” This statement implies that if outputs to annunciators and DME inputs do not need to be checked, then the other outputs do need to be checked. Verification of the auxiliary tripping relays appears to be covered in Table 1-5 of the standard under the "Unmonitored control circuitry associated with protective functions" section at 12 calendar years. Thus, we ask the SDT clarify in the supplementary reference the type of maintenance activities required for electromechanical lockout and/or tripping auxiliary devices to satisfy the requirements of Table 1-5 of the standard. Since the standard specifically dictates the output contacts verification for protective relays under Table 1-1, the output contacts of aux tripping relays is left up to interpretation. Therefore, we suggest the following statement be added after “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” on page 30 of the document: “Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the ‘Unmonitored control circuitry associated with protective functions" section’ at 12 calendar years.”

The migration of the UFLS and UVLS requirements to Table 3 is appreciated. The Table 3 Component Attributes in rows 6 and 7 (“Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices” and Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems” respectively) do not identify that the trip coils are excluded. Although row 9 states “Trip coils of non-BES interrupting devices in UFLS or UVLS systems” do not have any period maintenance specified, our recommendation is to annotate rows 6 and 7 to explicitly indicate the trip coils are excluded.
Yes
1. The definition of “Component” in PRC-005-2 Draft 1, states “Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.” However, in Section 15.2 of Supplementary Reference & FAQ it states: “The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.” Please consider reconciling these two sections (definition of “Component” and Section 15.2) to allow the entity to consider a relay as the single component versus the voltage and current sensing devices, and pursuant with Section 15.2 perform the voltage and current checks to the inventoried relays. This approach will ensure that the CT and PT check to each relay is performed. 2. Section 15.2 of Supplementary Reference & FAQ states in the second paragraph “The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.” Please consider revising the last bullet in Section 15.2, paragraph 3 from “Any other method that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable” to “Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.” 3. As shown (see Figure A-2) and discussed in Appendix A of Supplementary Reference & FAQ list, there are four elements that are not verified. Following the identification of the four elements that are not verified, a

practical solution is provided for testing methods on three of the four elements. Please provide a practical solution for the fourth element.

Requirement R3 includes the following: “and initiate resolution of any unresolved maintenance issues”. For clarification it is recommended that the following change be made to this phrase: “initiate resolution of any unresolved Protection System maintenance issues”. Also it is recommended that the following be added to the list in M3: “work management system information”.
Yes
None
Yes
None
Yes
The changes to the “Supplementary Reference” document appear to be acceptable, but the following are suggested as changes to enhance clarity. On page 9 of the Supplementary Reference and FAQ draft the following statement is included: “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.” On page 67, the third sentence of Section 15.3 states: “It includes [referring to control circuitry] the wiring from every trip output to every trip coil.” Later in that section the following is included: “...from a protective relay that are necessary for the correct operation of the protective functions.” While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: “Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested.” On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard

could result in a noncompliance finding even if the maximum intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.
The following comment was submitted in the last comment period: In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: " The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. The consideration of comments response to the above did not completely address the issue that led to the comment. In the Tables in PRC-005-2 there are maintenance items that an entity may not have had in their PRC-005-1 compliance program even though they did have a compliant maintenance program (e.g. battery continuity testing) for that Protection System component. As the transition is made to the PRC-005-2 requirement the above clarification should be made to better define what achievement of PRC-005-2 compliance is for that component. Section 4.2.2 includes UFLS systems installed per the ERO requirements - excluding any additional UFLS systems that a utility has on their system. Section 4.2.3 includes UVLS systems "installed to prevent system voltage collapse or voltage instability for BES reliability". It is assumed that this would only include UVLS systems required by the ERO, but it is not clear as to what is in scope. It is suggested that the wording of 4.2.3 be changed to match the wording in 4.2.2. In the implementation plan in the R2 and R3 requirements plans, in item a. of each there is a parenthetical statement regarding generating plant scheduled outage intervals. A similar parenthetical statement should be added to the b. and c. items of each of these plans. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words "affecting the reliability" be removed from the purpose statement. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months. In the tables for dc Supply the term "unit-to-unit" is used along with "intercell" when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be "intercell". It is recommended that the "unit-to-unit" term be removed to avoid confusion regarding what is to be verified.

Detailed Description: The phrase "Transmission & Generation Protection Systems" used in paragraph 1 should be "Transmission and generation Protection Systems". "Transmission" and "Protection System" are defined words in the NERC Glossary of Terms; "Generation" is not a defined term and should not be capitalized. Applicable Reliability Principles: Is item 4 [Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.] applicable to Protection System Maintenance?
Yes
No
Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Our experience shows that 6 month battery inspections are more than adequate to maintain system reliability. Manitoba Hydro has more than ten

years of experience using its existing battery inspection intervals, and Manitoba Hydro’s reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro’s battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro’s installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro and may be more than is required for many other utilities. To use a more frequent inspection interval would significantly penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. With the 4 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval.
Yes
No
Page 26: In both the industry webinar discussion and the supplementary reference document, it was indicated that if an entity had more maintenance activities in its plan than the minimum required by PRC-005-2, then an entity would be audited to the "higher standard". We understand that an entity could write some flexibility in its program, as long as the NERC minimums were met. We are concerned that auditing to the "higher standard" could discourage entities from performing maintenance tasks beyond the NERC minimum criteria. The discussion on page 9 indicates that although the relays which respond to mechanical parameters are not included in the scope of PRC-005-2, the associated trip circuits are included. We suggest that neither the relays which respond to mechanical parameters nor their associated trip circuits are within the scope of this standard. References to the tables should be consistently updated to include the new Table 3. “Every 3 calendar months” should be updated throughout the document to “Every 4 calendar months”. For example, Page 23: Example #3 should be revised. In addition, there are a number of grammatical errors in the document, particularly capitalization and punctuation, which make it difficult to read. There are terms which are improperly capitalized implying that they are approved NERC Glossary of Terms definitions when they are not.
-Definition of Protection System Maintenance Program: The definition included in the proposed PRC-005-2 is not the same as the definition provided in the document “Definition for Approval”, which also includes items “Upkeep” and “Restore”. Regarding the words “proper operation of malfunctioning components is restored.”; instead of focusing on the component, we suggest that the definition refer to the restoration of correct function, since some malfunctioning components will not be repairable and will need to be replaced. Although the supplementary document expands on the intended definition of “restore”, this is not evident in the proposed stand-alone definition of Protection System Maintenance Program. Referring instead to restoration of proper Protection System function does not strictly require the restoration of a failed component. Suggested wording: Return the Protection System to correct function and proper operation. -We do not agree with the prescribed phased implementation plan. Entities should be given a single compliance date for each of the maintenance intervals, and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-002-2. For example, if a maximum maintenance interval is 6 calendar years, the implementation plan should only require that “The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.” (item 4c.). The existing standard PRC-005-1 already requires protection systems to be maintained as part of a program. Prescribing how an entity must reach full compliance will provide a negligible improvement in reliability, while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets, and proving compliance for prescribed percentages of assets during the transition period creates unnecessary overhead with no added value. We suggest that items 3a., 3b., 4a., 4b., 5a. and 5b be removed from the implementation plan. -Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-

compliance. Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval (for example, performing a battery inspection at a remote station during severe winter weather) or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for safety and reliability without risking non-compliance. In addition, we disagree with the basis that the Drafting Team has established that grace periods are not permitted because of FERC Order 693 which requires that 'maximum' time intervals are established within PRC-005-2. With grace periods, a maximum time interval obviously becomes the required maintenance interval plus the maximum permitted grace period. So we strongly feel that grace periods can be added to the standard while adhering to the FERC Order. We also disagree with the line of reasoning that the Drafting Team used to establish the maximum maintenance intervals for relays as outlined on page 38 of the Supplementary Reference and FAQ document. To our knowledge, no document has been produced which provides evidence of maximum time intervals that work well for 'maintenance cycles that have been in use in generator plants for decades'. Our Protection Systems Maintenance experience indicates that the proposed intervals are acceptable as nominal time intervals with grace periods, but not as maximum time intervals without grace periods. Without a grace period, the bulk of protection maintenance on a six year maintenance cycle will have to be done one year earlier than previously required, in order to allow for the last year of the maximum interval to be used as the grace period. Manitoba Hydro considers this an unnecessary burden on resources with no benefit to reliability. Manitoba Hydro recommends that grace periods be permitted within PRC-005-2 if an entity can demonstrate a reliability or safety related need for using a grace period. This would require the Drafting Team to develop reliability-related criteria for using a grace period.

ATC provides the following suggestions for change: Page 9, "Is a Sudden Pressure Relay an auxiliary tripping relay? " During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows: Is a Sudden Pressure Relay an auxiliary tripping relay? No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. Page 78, last paragraph: If the same type of ohmic testing is done (impedance, conductance or resistance), modify the FAQ to allow the use of a different manufacturer's test equipment to conduct the testing. Page 80, second paragraph: "The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning." Insert the following: "A reading taken from the battery charger panel meter will meet this requirement." "The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits." Insert the following. "A reading taken from the battery charger panel meter will meet this requirement."
a) Change the text of "Standard PRC-005-2 – Protection System Maintenance" Table 1-5 on page 19, Row 1, Column 3 to: "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternatively, "Electrically operate each interrupting device every 6

years" Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). b) Change the text of "Standard PRC-005-2 – Protection System Maintenance" Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years" The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. c)ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC is recommending a negative ballot since, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

We like the new Table 3, but, have remaining concerns. The standard reaches further into the distribution system than we would like for UFLS and UVLS. We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic.
The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from

applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.

We agree in principle with the change; however, we have identified discrepancies among these tables with respect to the reference to UFLS and UVLS systems. The headings in Tables 1-1 through 1-4(b) and Table 1-5 refer to “Excluding distributed UFLS and UVLS”; Table 1-4(c) refers to “Excluding UFLS and non-distributed UVLS”; while Table 1-4(d) refers to “Excluding UFLS and distributed UVLS.” We believe the drafting team intended for consistency among these tables and that the intent is to exclude distributed UFLS and distributed UVLS schemes as opposed to distributed UFLS and all UVLS schemes. To make this clear we recommend changing the second line in the heading of each of these tables to “Excluding distributed UFLS and distributed UVLS.” Corresponding changes should be made in the “Component Attributes” sections of Tables 1-4(a) through 1-4(e) and to the title of Table 3.
No
We recommend changes to Supplementary Reference. It appears the 3 calendar month interval referenced in the second FAQ in section 7.1 on page 20, Example 1 on page 21, Example 2 on page 22, and on page 23 should be updated to 4 calendar months consistent with the changes to the standard for verification of station dc supply voltage and inspection of electrolyte level and unintentional grounds. We recommend modifying references to UFLS and UVLS to clarify the intervals for distributed systems applies to both UFLS and UVLS similar to the recommended change to the standard in our comment on question 4. See pp. 26, 30, 33, 86, and 87 of the supplementary reference.

The measures associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. It is suggested that one of these two courses be followed: either a) eliminate the requirement to initate resolution, or b) fully describe what evidence is expected for this part.
Yes
Yes
For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). There are some references to Table 2 (i.e. See Table 2), but does that mean that you have to verify the alarm(s)? I think Table 2 details need to be included specifically in

Table 3. Or make it very clear that this test is required for UF and UV schemes.

Requirement 3 and the Supplementary Reference Document indicate that an entity should be held to its internal PSMP (especially for a time based program) even if the plan is more stringent than the NERC standard. This would be a deterrent for initiative and for excellence and punish utilities for going above the standards and performing best practices. It also tends to drive the industry to lowest common denominator practices. R3 and the accompanying Supplementary Reference Document should be appropriately revised to reflect that entities would only be held auditably accountable for the minimum requirements as stated in the standard and associated documents.

Brian Evans-Mongeon
Utility Services, Inc
Yes
We would urge that the SAR be modified to include Validation of Protection System settings. Presently, the standard does not provide for the explicit validation of the settings and it is possible that such mis-settings could be the reason for a misoperation. If a validation of the settings was explicitly called for in the standard, then the misooperation would be less likely to occur for that reason.
Yes
While this helps, we are concerned that during the term of the Unresolved Maintenance Issue is being resolved, a question of compliance to the standard might be pending out. It should be clarified that during this term, compliance to the standard is being satisfied and not deemed to be non-compliant.
No
The standard should provide guidance what tasks need to be accomplished for compliance and not mandates on specifics like this. Registered Entities should be left to determine the appropriate intervals based upon their experience and good utility practices.

See comments under question 6
Comment 1: Western Area Power Administration does not agree with penalizing utilities for implementing maintenance programs that exceed the requirements defined in the NERC Standard PRC-005-2 maintenance tables. Although the intent of the language in the Supplementary Reference and FAQ document may have been to allow evolving maintenance programs to include condition-based and performance based maintenance in their programs, penalizing utilities with more stringent programs will more likely provide a disincentive for program development. Utilities will discontinue any additional maintenance activities that could put them at risk for non-compliance. This will cause maintenance programs to stagnate and new maintenance ideas to improve system reliability to not be implemented. It is the opinion of the Western Area Power Administration that the following text should be removed from the Supplementary Reference and FAQ document and entities should be audited to the minimum requirement of the standard regardless of their individual programs. Recommendation: Remove the following text from the Supplementary Reference & FAQ document: 1. Page 26 - The bullet "If your PSMP (plan) requires more activities then you must perform and document to this higher standard." 2. Page 27 – The bullet "If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard." 3. Page 27 – The paragraph "It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal." Revise R3 of PRC-005-2 and add statement to the Supplementary Reference & FAQ document. 1. R3: Each Transmission Owner, Generator Owner and Distribution Provider shall implement and follow its PSMP plan within the prescribed intervals of Tables 1, 2 and 3. and correct any unresolved maintenance issues. 2. FAQ: Any utility maintaining Protection System equipment that exceeds the requirements and tables because of historical testing data and/or failure documentation should not be held non-compliant or penalized for not meeting its PSMP, as long as they do not exceed the maximum allowable intervals or meet the minimum maintenance activities of the standard. Comment 2: R3 of PRC-005-2 states "Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues." The Western Area Power Administration would like more clarification on potential data request for requirement R3 of PRC-005-2. Because the requirement uses the term initiates resolution, the entity could make the assumption that providing just a list of maintenance request for unresolved maintenance issues will serve to prove compliance. Although it would seem implied that whatever method used to initiate resolution would lead to some type of corrective maintenance, the requirement does not make that absolutely clear. To ensure the maintenance practices are meeting the intent of the requirement, the requirement needs to clarify the expectations for completing corrective maintenance that was initiated to resolve maintenance issues. Recommendation: Add additional clarification to Supplementary Reference & FAQ document to further clarify expectation for this requirement.

No

No
Requirement R3 includes the following: “and initiate resolution of any unresolved maintenance issues”. The addition of unresolved maintenance issues to the standard is not included in the SAR and has the potential to cause confusion and misinterpretation. It is suggested that this phrase be removed.
Yes
We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4(a,b,c,d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a reliability Standard includes best maintenance practices it is encroaching on IEEE’s ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible. We recommend that this time frame be a maximum of 6 Calendar Months which will allow entities to establish their own time frame based on the seasonal changes that occur where the batteries are located.
Yes
No
a. Page 9, “Is a Sudden Pressure Relay an auxiliary tripping relay? “ 1) During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows: i. Is a Sudden Pressure Relay an auxiliary tripping relay? No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. b. On page 26 of the Supplementary Reference document, it states, “If your PSMP (plan) requires more activities than you must perform and document to this higher standard.” This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, “If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards.” In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards”. c. Page 78, last paragraph: If the same type of ohmic testing is done (impedance, conductance or resistance), may a different manufacturer’s test equipment be used for this testing? d. Page 79, second paragraph of “Why verify voltage?”: 1) “The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning.” i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? 2) “The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.” i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? e. Except as noted above, the changes to the “Supplementary Reference” document appear to be acceptable, but the following are suggested as changes to enhance clarity. 1) On page 9 of the Supplementary Reference and FAQ draft the following statement is included: “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.” On page 67, the third sentence of Section 15.3 states: “It includes [referring to control circuitry] the wiring from

every trip output to every trip coil." Later in that section the following is included: "...from a protective relay that are necessary for the correct operation of the protective functions." While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: "Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested." 2) On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard could result in a noncompliance finding even if the maximum intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.
a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES." b. Data Retention, Section 1.3 (concerning R2 and R3) requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent (past) test record. An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years. Recommend retention to be the most current record or all records since the last audit. c. Table 1-5 requires a maintenance activity to, "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Recommend this be changed to, "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, change the wording to, "Electrically operate each interrupting device every 6 years." While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren't configured to test independently. Isolating one trip coil from the other may include "lifting a wire" that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn't practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don't know which trip coil operated, then we have a "one off" device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES. d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, monitor circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) – this ensures the operating linkages aren't bound and the breaker will operate. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a

problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications). e. Change the text of "Standard PRC-005-2 – Protection System Maintenance" Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years". 1) The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. 2) In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. f. In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." A recent compliance application notice (CAN-0012) indicated that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. Please provide clarity on CAN-0012 is applicable to PRC-005-2? g. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words "affecting the reliability" be removed from the purpose statement. h. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months. i. In the tables for dc Supply the term "unit-to-unit" is used along with "intercell" when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be "intercell". It is recommended that the "unit-to-unit" term be removed to avoid confusion regarding what is to be verified. j. The NSRF would like to extend our thanks to the drafting team. The 96 page Supplementary Reference document allows us to discuss these issues before the standard is approved, instead of as a potential violation later. Excellent job!

Yes
Yes
1. The data retention requirement for producing evidence that the entity performed maintenance for the 2 most recent maintenance intervals is excessive. As an example, if a registered entity's maintenance/test interval is 12 years, such entity may be required to keep records for up to 35 years. PacifiCorp recommends a revision to the data retention requirement to provide for either a maximum retention period of 10 years or, in cases in which the interval exceeds 10 years, the most recent maintenance/test cycle only. 2. The requirement to identify all PTs is very onerous and not needed to verify maintenance compliance and therefore serves a limited reliability benefit. PacifiCorp believes that, as long as a registered entity can demonstrate that it can verify that all CTs/PTs providing input into a Protection System have been tested and maintained according to its established procedures, then a separate and independent requirement to maintain a list of these devices is not necessary. As an example, if an entity performed their protection system maintenance on a "scheme" basis, and as part of that maintenance documentation identified all CT's and PT's providing input into the scheme and verified their accuracy, then having a "master list" would provide no benefit. A list of all CT's

associated with one device such as a circuit breaker would have little value in this case as these CT's may provide input into multiple relay schemes and would not be maintained on an individual circuit breaker basis.

Yes
Yes
No
There are some changes that are needed to the document. On Page 19, the second question refers to R1.4. There is no R1.4 in the standard. We assume that document is intended to refer to part 1.4 under R1. This needs to be clarified and corrected. The reference document creates an improper incentive to eliminate best practices and utilize the maximum time intervals established in the standard. The document states that an entity will be subject to compliance violations if it has a maintenance and testing program with time intervals that are more stringent than the maximum time intervals in the standard and it does not meet its more stringent intervals. This would hold true even if the registered entity meets the maximum intervals established in the standard. To reduce compliance risk, registered entities will be incented to increase its time intervals to the maximum allowed by the standard. This is contrary to supporting reliability. Penalizing entities for failing to meet their more stringent plan requirements is also contrary to guidance provided by the Commission. Doug Curry, General Counsel of Lincoln Electric System, spoke to the Commission at the November 18, 2010 FERC technical conference on reliability monitoring, enforcement and compliance about his company's experience with the vegetation management standard. They exceeded the requirements for annual inspections by including six aerial patrols each year but were found in violation of the standard and paid penalties when they did not complete but one aerial patrol in the first five months of the year. The auditors concluded that the company's ground patrol fully satisfied the minimum requirements of the standard. In the end, LES removed the aerial inspections from the vegetation management plan. The Commissioners acknowledged that this was contrary to their goal of an adequate level of reliability and agreed that an entity should not be penalized for failing to meet their more stringent requirements when they meet the standard requirements. On Page 34, the FAQ about commissioning does not appear to be consistent with CAN-0011. While we believe the reference document is more correct, the drafting team should compare the advice given in the reference document to that in the CAN to ensure that it is not conflicting. Given that NERC is in the process of revising all of the CANs, the best approach may simply be to add a statement referencing the CAN-0011 for further information. Comments about "gaming the PBM system" regarding restoring segment performance should be removed from the reference document. Comments like these indicate intent by a registered entity to manipulate the compliance process. Only after a thorough investigation can such intent be determined. Thus, there shouldn't be a presumption that registered entities will attempt this. Better comments would be to focus on the consistency that the three year period provides in determining segment performance. In section 12.1 on page 58, the reference document discusses out of service equipment. NERC recently issued a lesson learned on removing unused relaying equipment on August 10, 2011. The drafting team may wish to reference that lesson learned in the reference document.

ITC Holdings
No

Yes
Yes
Yes
Yes
ITC Holdings continues to object to the requirement to exercise auxiliary relays on a 6 year interval. We repeat our previous comments as follows: “It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplementary Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in a such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle.” Previous responses from the SDT were: “The SDT believes that the appropriate interval for electromechanical devices such as aux or lockout relays should remain at 6 years, as these devices contain “moving parts” which must be periodically exercised to remain reliable” ITC requests that the statistical basis for the 6 year interval be published. If it is not clear that lockout relays and other auxiliary relays must be exercised on a 6 year interval, then the requirement should be changed to 12 years.

Michelle D'Antuono
Igleside Cogeneration LP
No
Yes
The original term inferred that the problem detected was correctible through follow-up maintenance – which is not always the case. The term “Unresolved Maintenance Issue” is more appropriate.
Yes
Ingleside Cogeneration LP agrees that the intervals on the activities in question should be extended to 4 calendar months. However on Page 20 of the Supplementary Reference document, the calculation of the next due date using units of “calendar months” is inconsistent with the calculation using a “calendar year”. In the case of “calendar years”, an activity must take place somewhere between Jan 1 and Dec 31. For “four calendar months”, a follow-up activity must be performed within four months from the completion of the prior one. We believe that “four calendar months” should be calculated in the same manner as a “calendar year”. This means that an activity should take place at least once between January 1 and April 30; and repeated once during May 1 through August 31, and again between September 1 and December 31. The pattern would continue in ongoing years. Not only is this method consistent with the “calendar year” derivation, it allows the most flexibility in scheduling – especially if an unexpected event causes a delay. The vast majority of the maintenance activities will still take place at four months plus or minus a week or two; with an occasional outlier that adds minimal risk to reliability.
Yes
We believe that distributed UFLS and UVLS relay systems have a very different operating purpose than those that are not distributed. It is appropriate to separate the maintenance activities and intervals for these relay systems.
Yes
Ingleside Cogeneration LP found the Supplementary Reference document to be helpful, thorough, and technically accurate. The only suggestion we have is that demonstrated adherence to the Reference should be admissible of evidence of compliance at an audit or spot check. Today, all References have no official regulatory standing – which seems to defeat the purpose of developing them to begin with.
Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel

performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test.

Armin Klusman
CenterPoint Energy
No
For the “Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices”, the Table 3 requirement is to “Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that wire checking a panel is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing. In addition, CenterPoint Energy recommends the requirement in Table 3 to “Verify that current and/or voltage signal values are provided to the protective relays” every 12 years be revised to “No periodic maintenance specified”. Likewise, we recommend the requirement in Table 3 to “Verify Protection System dc supply voltage” every 12 years be revised to “No periodic maintenance specified”. Preventive maintenance tasks such as the three above are unnecessary for distributed UFLS and UVLS system components. The overriding performance, or “risk-based”, NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount.
No
CenterPoint Energy appreciates that there is now only one document, instead of the two originally proposed. However, we question the name of the document which shows “Supplemental Reference and FAQ”. The use of “Supplemental Reference” could infer it contains requirements not found in the PRC-005-2 standard. Also, we suggest that NERC standardize on the names of documents associated with standards and other NERC initiatives. CenterPoint Energy recommends the name of the document be “Technical Reference”.
For the “Unmonitored control circuitry associated with protective functions”, the Table 1-5 requirement is to “Verify all paths of the trip circuits through the trip coil(s) of the circuit breakers or other interrupting devices” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping. Likewise, CenterPoint Energy recommends the requirement in Table 1-5 to “Verify all paths of the control circuits essential for proper operation of the SPS” every 12 years be revised to “No periodic maintenance specified”.

Oncor Electric Delivery Company LLC
No
Yes
Yes

Yes
Yes
Oncor would like to see the “Supplementary Reference & FAQ” expanded to provide examples of what documentation would satisfy that the entity is compliant with initiating “resolution of any unresolved maintenance issues.” Also it would be helpful to all entities if the Drafting Team would expand on what, if any, tracking of the resolution of an unresolved maintenance issue is required. Oncor believes that keeping track of the initiation of “resolution of any unresolved maintenance issues” is necessary but that the standard does not currently address retention requirements related to this compliance obligation.
PRC-005-2 is a vast improvement over the vagueness of the existing standard (PRC-005-1), that the new standard makes compliance much easier than the present standard. The new standard recognizes the advances in relay technology and reliability, particularly the benefits of microprocessor based relays. The standard also provides greater flexibility on its implementation while recognizing the benefits of a performance based methodology, particularly as it relates to battery testing. The revised standard eliminates the requirement for a “summary of maintenance and testing procedures” which was vague and provided no real value to the registered entities. Operational and administrative efficiencies can be realized by consolidating the relay testing and maintenance requirements into one standard (PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0)

Yes
This change has no impact on how Springfield Utility Board currently operates.
Yes
This change has no impact on how Springfield Utility Board currently operates.
Yes
Although numerous tables can become overwhelming to navigate, it is far less ambiguous if specific systems are spelled out in separate and distinct tables.
Yes
Because Springfield Utility Board's (SUB) current maintenance and testing program is time-based, the revised "Supplementary Reference" document does not impact SUB operations. SUB agrees with the document changes because the changes result in alernatives for entitities, rather than being prescriptive.

Gerry Schmitt
BGE
No
No comment.
No
No comment about the change itself, but the terms were not consistently applied in the Supplemental Reference Manual (see last comment).
Yes
BGE appreciates the SDT demonstrating flexibility by extending these maintenance intervals.
No
Although BGE does not disagree with moving the distributed UFLS/UVLS maintenance activities and intervals into the new Table-3, BGE requests further clarification from the SDT on how to correctly interpret the headings and content of this table.
No
While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning “Our maintenance plan calls…” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, “How do I achieve a grace period without being out of compliance?” the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out-of-compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance – compliance management, scheduling, operational preference, etc.
When the term “Maintenance Correctable Issue” was revised to “Unresolved Maintenance Issue”, it appears that the PRC-005-2 Protection System Maintenance / Supplementary Reference and FAQ document was not properly updated to reflect this change. There are inconsistencies throughout the entire document were the old term is still showing up instead of the new term, and vice versa.

Constellation Power Generation
Yes
Although Constellation Power Generation agrees with some of the refinements prescribed in the SAR, there are a few items of concern. Constellation Power Generation agrees that “the requirements should reflect the inherent differences between various protection system technologies,” however the requirements should not mandate different testing methods and testing intervals based on that technology. The Registered Entity should be given the latitude to address different technologies through its PSMP, and the requirements should reflect that.
No
As R3 is currently written, Constellation Power Generation is concerned that this requirement may decrease the reliability of the BES under certain circumstances. The severity of the “deficiency” found will dictate the method and timing of a “follow up correction action”. For a generator, the corrective action may not be “initiated” until the next planned outage, which may be a few years. However, R3 suggests that to comply, a generation site may have to extend an outage or take a forced and unplanned outage, to perform the corrective action. This would decrease the available resources in a given BA’s footprint and potentially decrease the reliability of the BES.

No
Moving the UFLS and UVLS systems from Tables 1-1 through 1-5 into a separate Table 3 is a useful improvement in illustrating the requirements. However, our objection is not really with the format, it is will the content of the Tables. From a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive and we are concerned that they may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. In the worst case, the specifics dictated in the Tables may move Entities away from more stringent PSMPs that are currently in practice. For this reason, Constellation suggests that the drafting team revisit the concept of the Tables to better balance to convey useful guidance without creating a compliance requirement that may be contrary to improved reliability. The Registered Entity should be given more flexibility to dictate how a protection system component should be tested, and at what frequency. Lastly, the technical manpower and compliance documentation demands to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any small generation entity would use it.

Consideration of Comments

Protection System Maintenance and Testing – Project 2007-17

The Protection System Maintenance and Testing Drafting Team would like to thank all commenters who submitted comments on the first draft of the PRC-005-2 standard for Protection System Maintenance and Testing (Project 2007-17). This standard and its associated documents were posted for a 45-day public comment period from August 15, 2011 through September 29, 2011. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 48 sets of comments, including comments from approximately 147 different people and approximately 98 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

SAR:

The SDT made several changes to the SAR. The proposed title of the standard was changed to 'Protection System Maintenance'; Reliability Principle item #4 was removed as it does not apply to the standard; and the 'Transmission and Generation' descriptor of Protection Systems was removed from the Detailed Description area of the SAR.

Applicability:

The SDT revised Applicability 4.2.5.4 to indicate that, for generator-connected station service transformers, only the Protection Systems that trip the generator, either directly or via a lockout relay, are included in the standard.

Requirements:

Requirement R1 part 1.3 has been removed.

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_20110825.pdf.

The SDT split Requirement R3 into three separate requirements for better clarity.

Requirement R3 has been revised so that, for time-based programs, entities must comply with the standard's tables rather than their PSMP. Requirement R3 now reads:

> **R3.** Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.

Requirement R4 has been added to address performance-based maintenance. The new Requirement R4 is as follows:

> **R4.** Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System components that are included within the performance-based program.

Requirement R5 has been added to address Unresolved Maintenance Issues. The definition of the term 'Unresolved Maintenance Issues' has been enhanced for additional clarity, and now reads:

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.*

The new Requirement R5 is as follows:

> **R5**. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.

Measures

The SDT revised and drafted new measures to comport with the requirements.

Tables

Most commenters seemed to agree in general that the restructured Tables added clarity and some commenters offered suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" document to address various comments.

In Table 1-5 (Component Type - Control Circuitry Associated With Protective Functions), the SDT removed the auxiliary relays from the 6 year periodic maintenance associated with electromechanical lockout devices, and included them in the 12 year periodic maintenance associated with the unmonitored control circuitry associated with protective functions.

Table 1-4(f) was modified to more accurately represent the monitoring attributes and related activities for monitored Vented Lead-Acid and Valve-Regulated Lead-Acid batteries.

Implementation Plan

Minor clarifying changes were made to the Implementation Plan.

VLSs:

Changes were made to the make the VSLs conform to the new and changed requirements.

Supplementary Reference Document

Changes were made to the "Supplementary Reference and FAQ" document, corresponding to all changes to the standard.

Unresolved Minority Views:

- A few commenters continued to object to the establishment of maximum allowable intervals for the maintenance of various Protection System component types. The SDT continued to respond that FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals.

- Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.

- Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.

- Several commenters continued to question the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT obtained a position from NERC legal staff, and cited this position in responding that these devices are indeed within NERC's authority because they are installed for the reliability of the BES.

- A few commenters questioned the inclusion of the direct current (dc) control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is included because the dc control circuitry is associated with protective functions.

- A few commenters objected to the language in the Data Retention section regarding the retention of the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

1. **Do you have any comments regarding the existing SAR for this project?**

Summary Consideration: In response to the comments, the SDT made several changes to the SAR.

1. **The proposed title of the standard was changed to 'Protection System Maintenance.'**
2. **Reliability Principle item #4 was removed as it does not apply to the standard.**
3. **The 'Transmission and Generation' descriptor of Protection Systems was removed from the Detailed Description area of the SAR.**

Several comments were offered, suggesting that the SAR address validating the accuracy of settings calculations provided to the field test personnel. The SDT declined to modify the SAR because they believe validating the accuracy of settings as provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard.

Several comments were offered, suggesting that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology." The SDT declined to modify the SAR because they believe the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	Yes	Maintenance and testing of protection systems is the final step in the process that begins with the calculation of settings. The calculation of settings is followed by the application of those settings to the equipment. Maintenance and testing ensures that the settings given to testing personnel have been applied as given. This Standard addresses the Maintenance and Testing of protection systems. It should also address the need to validate the accuracy of the settings given to the field. A statement should be added to the SAR to address this need.
Response: Thank you for your comment. You are correct in your observation that the standard, as established in the project scope, addresses the maintenance and testing of Protection Systems. The SDT believes validating the accuracy of settings as		

Organization	Yes or No	Question 1 Comment
provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard. Thus, the SDT does not believe that the SAR should be modified.		
ZGlobal Engineering and Energy Solutions	Yes	Table 1-4(a-c) excludes distributed UFLS and UVLS for batteries but references Table 3. Table 3 does not mention an interval for batteries. Is this an error?
Response: Thank you for your comment. In Table 3 we address the dc supply for tripping only non-BES interrupting devices as part of the UFLS and UVLS system. Table 3 explicitly limits the activities and intervals for station dc supply (relative to distributed UVLS/UFLS) to verifying the Protection System dc supply voltage every 12 calendar years, and requires nothing beyond that for station batteries in this application. This is not an error within the standard.		
Utility Services, Inc	Yes	We would urge that the SAR be modified to include Validation of Protection System settings. Presently, the standard does not provide for the explicit validation of the settings and it is possible that such mis-settings could be the reason for a misoperation. If a validation of the settings was explicitly called for in the standard, then the misoperation would be less likely to occur for that reason.
Response: Thank you for your comment. The SDT believes validating the accuracy of settings as provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard. Thus, the SDT does not believe that the SAR should be modified. If this becomes a "Misoperation" problem for the entity, NERC Reliability Standard PRC-004-2 requires the entity to develop and implement a Corrective Action Plan to address the cause of the Misoperation.		
Constellation Power Generation	Yes	Although Constellation Power Generation agrees with some of the refinements prescribed in the SAR, there are a few items of concern. Constellation Power Generation agrees that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology. The Registered Entity should be given the latitude to address different technologies through its PSMP, and the requirements should reflect that.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comment. The SDT believes the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.		
Constellation Energy Commodities Group	Yes	Although Constellation Energy Commodities Group agrees with some of the refinements prescribed in the SAR, there are a few items of concern. Constellation Energy Commodities Group agrees that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology. The Registered Entity should be given the latitude to address different technologies through its PSMP, and the requirements should reflect that.
Response: Thank you for your comment. The SDT believes the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.		
Saft America, Inc.	Yes	
Manitoba Hydro	No	**1.** Detailed Description: The phrase "Transmission & Generation Protection Systems" used in paragraph 1 should be "Transmission and generation Protection Systems". "Transmission" and "Protection System" are defined words in the NERC Glossary of Terms; "Generation" is not a defined term and should not be capitalized. **2.** Applicable Reliability Principles: Is item 4 [Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.] applicable to Protection System Maintenance?
Response: Thank you for your comment.		

Organization	Yes or No	Question 1 Comment
1. The SAR has been modified in consideration of your comment. The SDT removed the "Transmission & Generation" descriptors from the sentence. 2. The SAR has been modified in consideration of your comment. The Applicable Reliability Principle 4 has been unchecked as it is not applicable to this standard.

Response: Thank you for your comment.		

2. In response to comments, the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue". Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Most commenters agreed with the change in the term from "Maintenance Correctable Issue" to "Unresolved Maintenance Issue", with some offering further suggestion for improvement and clarification. Several commenters expressed concern that, without further clarity, auditors may confuse initiation of resolution for an issue with completion of the activities necessary to ultimately resolve the issue, but the SDT believes that this term (and its use within the Standard) is unequivocal. In response to comments, the SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 (shown below) and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.

Requirement R5 now reads:

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.

Organization	Yes or No	Question 2 Comment
Occidental Chemical	Affirmative Ballot	In response to comments, the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue". Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. The original term inferred that the problem detected was correctible through follow-up maintenance – which is not always the case. The term "Unresolved Maintenance Issue" is more appropriate.
Response: Thank you for your comment and your Affirmative Ballot.		
Independent Electricity System	Yes	The IESO agrees with the revision to the term. However, we observed the inconsistent format of this defined term used throughout the draft standard and would like to point it out to the Drafting Team. The capitalized term "Unresolved Maintenance Issue" is defined on Page 2 and used as a capitalized term in the blue box on Page 5. The defined term was made

Organization	Yes or No	Question 2 Comment
Operator		lowercase and used in other areas of the document as “unresolved maintenance issues” (eg. Page 5 and Page 8). We recommend that the format of this defined term be consistent throughout the draft standard.
Response: Thank you for your comment. The SDT has capitalized the term throughout the standard for consistency.		
MidAmerican Energy Company	Yes	1. Requirement R3 includes the following: “and initiate resolution of any unresolved maintenance issues”. For clarification it is recommended that the following change be made to this phrase: “initiate resolution of any unresolved Protection System maintenance issues”. 2. Also it is recommended that the following be added to the list in M3: “work management system information”.
Response: Thank you for your comment. **1. The SDT observes that your concern is addressed by the Applicability of the standard (specifically addressing Protection Systems), and that the change you suggest is unnecessary.** **2. The language of Measure M3 specifies “*may include but is not limited to dated maintenance records …*” and could include records and information from a work management system without excluding other maintenance records an entity might have outside a work management system.**		
Utility Services, Inc	Yes	While this helps, we are concerned that during the term of the Unresolved Maintenance Issue is being resolved, a question of compliance to the standard might be pending out. It should be clarified that during this term, compliance to the standard is being satisfied and not deemed to be non-compliant.
Response: Thank you for your comment. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
Igleside	Yes	The original term inferred that the problem detected was correctible through follow-up

Organization	Yes or No	Question 2 Comment
Cogeneration LP		maintenance -which is not always the case. The term "Unresolved Maintenance Issue" is more appropriate.
Response: Thank you for your comment.		
Springfield Utility Board	Yes	This change has no impact on how Springfield Utility Board currently operates.
Response: Thank you for your comment.		
Dominion	Yes	
FirstEnergy	Yes

Bonneville Power Administration	No	BPA agrees that the term “Maintenance Correctable Issue” is an improvement over “Unresolved Maintenance Issue”, however, BPA feels that the idea of a “Maintenance Correctable Issue” is very vague, and would perhaps be better left out of the standard. As written, it is unclear when an issue is a “Maintenance Correctable Issue” and exactly how it has to be dealt with. R3 requires the initiation of resolution of any unresolved

Organization	Yes or No	Question 2 Comment
		maintenance issues.
Response: Thank you for your comment. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.**		
MRO's NERC Standards Review Forum	No	Requirement R3 includes the following: "and initiate resolution of any unresolved maintenance issues". The addition of unresolved maintenance issues to the standard is not included in the SAR and has the potential to cause confusion and misinterpretation. It is suggested that this phrase be removed.
Response: Thank you for your comment. The SAR was developed and submitted by the NERC System Protection and Control Task Force (SPCTF) who later prepared and submitted the Technical Reference "Protection System Maintenance" as a guide for the SDT to use in developing PRC-005-2. In crafting the elements of PRC-005-2, the SDT has endeavored to follow the SAR, which directs addressing FERC Order 693 directives; recommendations from the SPCTF Assessment of Standards PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0; and consideration of stakeholder comments received during the development of the Version 0 and Phase III & IV standards. **In the Detailed Description section of the SAR, bullet point four recommends the SDT define the terms "maintenance programs" and "testing programs" while recognizing other terms may be necessary for clarity. The SPCTF Assessment further recommends that PRC-005-2 "…should clarify that two goals are being covered: The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers' design specifications throughout the service life" and the "testing portion should… verify the functional performance of protection systems". Additionally, in the SPCTF Technical Reference "Protection System Maintenance", the term "maintenance" is defined as "An ongoing program by which Protection System function is proved, and restored if needed."** **The SDT developed and defined the term "Protection System Maintenance Program" (PSMP) and its elements (which includes the testing portion) to achieve the goal of the recommendations of the SAR, SPCTF Assessment, and guidance given in the SPCTF Technical Reference. Consistent with this guidance, a PSMP is defined in PRC-005-2 as "An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored." The term "Unresolved Maintenance Issue" defines those things identified as needing follow-up action in order to restore them to proper**		

Organization	Yes or No	Question 2 Comment
operation. This may include repair or replacement activities that cannot be performed during the periodic PSMP activity through which the deficiency was discovered. Demonstrating the entity has initiated resolution of these issues might then include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… For clarity, the SDT has included these examples in the associated Measure for this requirement in the current draft. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.**		
Southern Company Generation	No	The measure associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. It is suggested that one of these two courses be followed: either a) eliminate the requirement to initiate resolution, or b) fully describe what evidence is expected for this part.
Response: Thank you for your comment. The SDT believes that an effective PSMP must include correction of deficiencies, but management of completion of any Unresolved Maintenance Issues is a complex topic which may involve a wide variety of activities (with varying completion timelines). The associated Measure lists examples of what may be effective evidence (more examples have been added); specific evidence, for any specific situation, will vary based on the particulars of that situation. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
American Electric Power	No	The definition's wording is satisfactory, and we agree with the removal of "failure of a component to operate within design parameters". However, we do not agree with the use of the word "unresolved" within the term itself, as we believe this word may convey that the issue was not known or identified. We suggest replacing "Unresolved Maintenance Issue" with "Corrective Maintenance Issue".
Response: Thank you for your comment. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		

Organization	Yes or No	Question 2 Comment
Southern Company Transmission	No	The measure associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. It is suggested that one of these two courses be followed: either a) eliminate the requirement to initiate resolution, or b) fully describe what evidence is expected for this part.

BGE	No	No comment about the change itself, but the terms were not consistently applied in the Supplemental Reference Manual (see last comment).
Response: Thank you for your comment. The SDT has further reviewed and revised the Supplementary Reference and FAQ document to facilitate consistent use of the terms.		
Constellation Power Generation	No	As R3 is currently written, Constellation Power Generation is concerned that this requirement may decrease the reliability of the BES under certain circumstances. The severity of the “deficiency” found will dictate the method and timing of a “follow up correction action”. For a generator, the corrective action may not be “initiated” until the next planned outage, which may be a few years. However, R3 suggests that to comply, a generation site may have to extend an outage or take a forced and unplanned outage, to perform the corrective action. This would decrease the available resources in a given BA’s footprint and potentially decrease the reliability of the BES.
Response: Thank you for your comment. **PRC-005-2 only requires the entity “… *<u>initiate</u> resolution*” of the issue found. The SDT recognizes that performance of the activities**		

Organization	Yes or No	Question 2 Comment
necessary to <u>resolve</u> an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.		
Constellation Energy Commodities Group	No	As R3 is currently written, Constellation Energy Commodities Group is concerned that this requirement may decrease the reliability of the BES under certain circumstances. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.**		
PNGC Comment Group	No	
Central Lincoln		Either term works if defined properly.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment.		

3. In response to comments, the SDT revised the previous "3 calendar months" interval to "4 calendar months" for communications systems and station dc supply. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Most commenters agreed with the change; however, several commenters suggested further extension of these intervals. The SDT did not make any further changes to those intervals, explaining their belief that the established intervals are appropriate maximum intervals for this continent-wide standard. A few commenters continued to object to the establishment of maximum allowable intervals as specified in FERC Order 693; the SDT did not adopt any related suggestions, and instead reminded the commenters of FERC's directives.

Organization	Yes or No	Question 3 Comment
CPS Energy	Affirmative Ballot	The 4 month maintenance and testing interval for station DC supply is too short based on programs that have been in service for many years where twelve months have been proven as reliable for operation.
Response: Thank you for your comments **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present (per Table 1-4f).**		
Occidental Chemical	Affirmative Ballot	In response to comments, the SDT revised the previous "3 calendar months" interval to "4 calendar months" for communications systems and station dc supply. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. Ingleside Cogeneration LP agrees that the intervals on the activities in question should be extended to 4 calendar months. However on Page 20 of the Supplementary Reference document, the calculation of the next due date using units of "calendar months" is inconsistent with the calculation using a "calendar year". In the case of "calendar years", an activity must take place somewhere between Jan 1 and Dec 31. For "four calendar months", a follow-up activity must be performed within four months from the completion of the prior one. We believe that "four

Organization	Yes or No	Question 3 Comment
		calendar months" should be calculated in the same manner as a "calendar year". This means that an activity should take place at least once between January 1 and April 30; and repeated once during May 1 through August 31, and again between September 1 and December 31. The pattern would continue in ongoing years. Not only is this method consistent with the "calendar year" derivation, it allows the most flexibility in scheduling – especially if an unexpected event causes a delay. The vast majority of the maintenance activities will still take place at four months plus or minus a week or two; with an occasional outlier that adds minimal risk to reliability.
Response: Thank you for your comments. **Section 7.1 of the Supplementary Reference and FAQ document has been modified in consideration of your comment.**		
Wisconsin Electric Power Co. Wisconsin Electric Power Marketing	Affirmative Ballot	Focusing on batteries which are required to be done on a time-based maintenance program: 1. The big picture is that it is not just testing anymore - there are many more mandated tasks to be performed - Table 1-4(a). - Verifications & inspections are now part of the plan criteria, and have been moved from 3 months to a 4 month maximum interval. 2. We would like to see clarification on what is meant by the extent of 4 months. Is it by the end of the same calendar day or the previous calendar day, four months later; or is it 120 days or what? Could plan to manage to every 3 months, but not greater than 4 months. Same for Battery testing - manage to 1 year, but not greater than 18 months. 3. What is meant by battery continuity? Is battery float current an acceptable test methodology? It is not defined as clearly as an "impedance" or "resistance" test.
Response: Thank you for your comments. **1. The SDT believes that all of the maintenance activities within the "definition" of PSMP and as listed in the Tables are necessary components of an effective PSMP. Testing alone cannot assure that the Protection System components are in good working order.** **2. Section 7.1 of the Supplementary Reference and FAQ document provides an expanded discussion of this topic, and has been revised to add further clarity.**		

Organization	Yes or No	Question 3 Comment
3. "Continuity" can be tested via several methods, and is described in detail in Section 15.4 of the Supplementary Reference and FAQ document. Battery float current is one of the many methods discussed within the Supplementary Reference Document.		
PNGC Comment Group	Yes	We agree with this change. Smaller utilities, especially in the WECC region, in many cases have large territories to cover with limited resources. In many instances sub-stations are inaccessible during the winter and the 4 month interval will assist these smaller entities in getting the work done.
Response: Thank you for your comment		
MRO's NERC Standards Review Forum	Yes	We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4(a, b, c, d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a Reliability Standard includes best maintenance practices it is encroaching on IEEE's ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible. We recommend that this time frame be a maximum of 6 Calendar Months which will allow entities to establish their own time frame based on the seasonal changes that occur where the batteries are located.
Response: Thank you for your comments. **Station dc supply (including station batteries) must perform properly for the Protection System to function correctly. In order to establish that station batteries are functioning properly, the SDT believes that all of the listed maintenance activities must be performed, within the specified maximum intervals, with due consideration for any monitoring functionality that may be present. The SDT has drawn from the relevant IEEE standards (and other sources) to determine those activities that it has deemed appropriate to assure proper performance of the station battery. The SDT specifically believes that the 4-month maximum interval is proper for these activities for unmonitored DC supply systems and is consistent with the prevailing industry practice.**		
Tacoma Power	Yes	A similar change in interval should be applied to intervals of "6 calendar months".

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments **The SDT believes that the six-month interval is appropriate.**		
Nebraska Public Power District	Yes	We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4 (a, b, c, d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a Reliability Standard includes best maintenance practices it is encroaching on IEEE's ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible.

Manitoba Hydro	No	Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Our experience shows that 6 month battery inspections are more than adequate to maintain system reliability.Manitoba Hydro has more than ten years of experience using its existing battery inspection intervals, and Manitoba Hydro's reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro's battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro's installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro

Organization	Yes or No	Question 3 Comment
		and may be more than is required for many other utilities. To use a more frequent inspection interval would significantly penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. With the 4 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval.
Response: Thank you for your comments. **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present (per Table 1-4f).**		
Arizona Public Service Company	No	APS has been testing batteries nominally every 4 months plus 25% for over 20 years with no adverse consequences. Requiring a maximum of testing every 4 months doesn't allow for any flexibility, would require an additional 400 tests per year and APS does not consider the 4 months a maximum time limit for battery testing.
Response: Thank you for your comments. **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present (per Table 1-4f).**		
Utility Services, Inc	No	The standard should provide guidance what tasks need to be accomplished for compliance and not mandates on specifics like this. Registered Entities should be left to determine the appropriate intervals based upon their experience and good utility practices.
Response: Thank you for your comments **FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum**		

Organization	Yes or No	Question 3 Comment
maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present. If an entity's experience is that some components require less-frequent maintenance than specified in the Tables, a performance-based program in accordance with Requirement R2 and Attachment A is an option unless specifically precluded.		
American Electric Power	No	Though we agree with extending the interval from what it was previously, AEP recommends that the interval in Table 1-2 for Communications Systems be increased to 6 months.
Response: Thank you for your comments **The SDT believes that the revised 4-month maximum interval is proper for unmonitored communications systems.**		
Tennessee Valley Authority	No	

4. **The SDT extracted the maintenance activities and intervals for distributed UFLS and UVLS systems from Table 1-1 through 1-5 and placed them into a new Table 3 to more clearly illustrate the requirements related to these systems. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Most commenters appreciated the break-out of distributed UFLS/UVLS maintenance activities into Table 3. Several commenters, however, continued to object to inclusion of this maintenance within the standard, and some questioned NERC's jurisdiction to address devices installed on the distribution system. The SDT consulted with NERC legal staff on the jurisdiction question, and cited the position from NERC Legal in responding that these devices are indeed within NERC's authority because they are installed for the reliability of the BES. Several commenters also objected to the requirements relating to periodic operation of electromechanical devices, maintenance of voltage and current sensing devices, and/or maintenance of the dc supply within the new Table 3, and the SDT provided responses supporting the SDT's belief that all of these activities are relevant and necessary for inclusion within the standard. Several other commenters suggested formatting changes, most of which were adopted. While considering these comments, the SDT also made assorted clarifying changes to Table 3.

Organization	Yes or No	Question 4 Comment
Occidental Chemical	Affirmative Ballot	The SDT extracted the maintenance activities and intervals for distributed UFLS and UVLS systems from Table 1-1 through 1-5 and placed them into a new Table 3 to more clearly illustrate the requirements related to these systems. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. We believe that distributed UFLS and UVLS relay systems have a very different operating purpose than those that are not distributed. It is appropriate to separate the maintenance activities and intervals for these relay systems.
Response: Thank you for your support.		
Southern Company Generation	Yes	1. Separating this classification of equipment into its own table is a good idea to make it easier for the owners of this equipment to figure out what they must do. 2. Consider also moving the UVLS note (found in column 1 of Tables 1-4a-d) into the header with

Organization	Yes or No	Question 4 Comment
		the other "UFLS and UVLS note" to simplify the table. The header note could read "Excludes UFLS and UVLS systems - see Table 1-4e for non-distributed UFLS and UVLS systems and see Table 3 for distributed UFLS and UVLS systems"). 3. Table 1-5: Need clarification on "continuity and energization or ability to operate". What does this mean? 4. For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). There are some references to Table 2 (i.e. See Table 2), but does that mean that you have to verify the alarm(s)? We think that the Table 2 details need to be included specifically in Table 3. Or, make it very clear that this test is required for UF and UV schemes.
Response: **1. Thank you for your support.** **2. Thank you for your comment, Table 1-4 (a, b, c, d) has been revised accordingly.** **3. This entry in Table 1-5 has been modified to "Control circuitry whose integrity is monitored and alarmed". Section 15.3 of the Supplementary Reference and FAQ document provides additional discussion on this topic.** **4. The SDT has revised the Table 2 for clarity.**		
Ameren	Yes	Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.
Response: Thank you for your suggestion; the SDT has revised the standard.		
Northeast Utilities	Yes	The migration of the UFLS and UVLS requirements to Table 3 is appreciated. The Table 3 Component Attributes in rows 6 and 7 ("Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices" and Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems" respectively) do not identify that the trip coils are excluded. Although row 9 states "Trip coils of non-BES interrupting devices in UFLS or UVLS systems" do not have any period maintenance specified, our recommendation is to

Organization	Yes or No	Question 4 Comment
		annotate rows 6 and 7 to explicitly indicate the trip coils are excluded.
Response: Thank you for support. The SDT has revised Table 3 accordingly.		
MidAmerican Energy Company	Yes	None
Southern Company Transmission	Yes	For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). Flathead Electric Cooperative	Negative Ballot	I appreciate the drafting team's effort to separate requirements for distributed UFLS, however fundamentally it is unclear how mandatory and enforceable requirements can be applied to non-BES elements as there is no statutory authority over local distribution networks.
Response: Thank you for comment. In regards to your concern, the SDT received the following position from NERC Legal: **"While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.** **FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 also covers users, owners, and operators of bulk-power facilities.** **UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES."**		
Lakeland Electric	Negative Ballot	The standard reaches further into the distribution system for UFLS and UVLS. It will be burdensome to present all the evidence of distribution class protection system maintenance and testing at audits.
Response: The existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.		
Beaches Energy	Negative	The standard reaches further into the distribution system than we would like for UFLS and UVLS

Organization	Yes or No	Question 4 Comment
Services	Ballot	(Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection.

Response: Thank you for your comment.

First, the existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.

Second, the UVLS and UFLS systems are included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical devices, such as auxiliary or lockout relays which contain "moving parts", need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.

Organization	Yes or No	Question 4 Comment
Florida Keys Electric Cooperative Assoc.	Negative Ballot	The standard reaches further into the distribution system than we would like for UFLS and UVLS (Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to preform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic.
Response: Thank you for your comment. **First, the existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.** **Second, the UVLS and UFLS systems are included as part of the Project 2007-17 Standard Authorization Request (SAR). Lincoln Electric System	Negative Ballot	Please see comments submitted in addition to the following comment. LES recommends the standard drafting team clarify the expected maintenance activities for BES related batteries that also serve UFLS systems. In particular, what would be the required maintenance activities for a battery bank serving both BES transmission elements and UFLS elements? Table 1.4 clearly

Organization	Yes or No	Question 4 Comment
		excludes UFLS elements and Table 3 indicates it only applies to “non-BES interrupting devices”. As such, if a joint use battery is excluded from Table 1.4 because of its association with UFLS, BES related batteries would have no place in any of the tables.
Response: Thank you for your comment. **The SDT responded to your other comments in the sections where they were submitted.** **A battery bank serving both BES and UFLS/UVLS protection systems would be maintained per table 1-4. A battery bank that serves only distributed UFLS or UVLS system would be maintained per table 3.** **The headers of the various sections of Table 1-4 now exclude station dc supply that is used <u>only</u> for UFLS/UVLS from Table 1-4.**		
CenterPoint Energy	No	1. For the “Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices”, the Table 3 requirement is to “Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that wire checking a panel is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing. 2. In addition, CenterPoint Energy recommends the requirement in Table 3 to “Verify that current and/or voltage signal values are provided to the protective relays” every 12 years be revised to “No periodic maintenance specified”. 3. Likewise, we recommend the requirement in Table 3 to “Verify Protection System dc supply voltage” every 12 years be revised to “No periodic maintenance specified”. Preventive maintenance tasks such as the three above are unnecessary for distributed UFLS and UVLS system components. The overriding performance, or “risk-based”, NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. 1. **While much of the control circuitry associated with a distribution device is regularly exercised, the SDT believes that the control circuitry associated directly with UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so.** 2. **The SDT believes that the voltage/current signals that support proper operation of UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so. The specific degree of this verification is constrained within Table 3 to those activities necessary to assure proper operation of the UFLS/UVLS.** 3. **The SDT believes that the station dc supply that supports only proper operation of UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so. The specific degree of this verification is constrained within Table 3 to only periodic measurement of the dc voltage.**		
BGE	No	Although BGE does not disagree with moving the distributed UFLS/UVLS maintenance activities and intervals into the new Table-3, BGE requests further clarification from the SDT on how to correctly interpret the headings and content of this table.
Response: Thank you for your support. Table 3 has been modified since it was last released for comment. Table 3 should be used to determine maintenance activities and intervals for distributed UFLS and UVLS systems. Distributed systems are further elaborated upon in the Supplementary Reference and FAQ document, Section 15.7.		
Constellation Power Generation	No	Moving the UFLS and UVLS systems from Tables 1-1 through 1-5 into a separate Table 3 is a useful improvement in illustrating the requirements. However, our objection is not really with the format, it is will the content of the Tables. From a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive and we are concerned that they may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. In the worst case, the specifics dictated in the Tables may move Entities away from more stringent PSMPs that are currently in practice. For this reason, Constellation suggests that the drafting team revisit the concept of the Tables to better balance to convey useful guidance without creating a

Organization	Yes or No	Question 4 Comment
		compliance requirement that may be contrary to improved reliability. The Registered Entity should be given more flexibility to dictate how a protection system component should be tested, and at what frequency. Lastly, the technical manpower and compliance documentation demands to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any small generation entity would use it.
Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present. The ability to utilize performance-based maintenance is provided for those entities who wish to pursue it; it is understood that many entities may instead choose to simply implement a PSMP based on the Tables.**		
Constellation Energy Commodities Group	No	Moving the UFLS and UVLS systems from Tables 1-1 through 1-5 into a separate Table 3 is a useful improvement in illustrating the requirements. Florida Municipal Power Agency	No	We like the new Table 3, but, have remaining concerns. The standard reaches further into the distribution system than we would like for UFLS and UVLS. We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic.
Response: Thank you for your comment. **First, the existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.** **Second, the UVLS and UFLS systems are included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical devices, such as auxiliary or lockout relays which contain “moving parts”, need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.**		

Organization	Yes or No	Question 4 Comment
NERC Staff Technical Review	No	We agree in principle with the change; however, we have identified discrepancies among these tables with respect to the reference to UFLS and UVLS systems. The headings in Tables 1-1 through 1-4(b) and Table 1-5 refer to "Excluding distributed UFLS and UVLS"; Table 1-4(c) refers to "Excluding UFLS and non-distributed UVLS"; while Table 1-4(d) refers to "Excluding UFLS and distributed UVLS." We believe the drafting team intended for consistency among these tables and that the intent is to exclude distributed UFLS and distributed UVLS schemes as opposed to distributed UFLS and all UVLS schemes. To make this clear we recommend changing the second line in the heading of each of these tables to "Excluding distributed UFLS and distributed UVLS." Corresponding changes should be made in the "Component Attributes" sections of Tables 1-4(a) through 1-4(e) and to the title of Table 3.
Response: Thank you for your comment. The standard has been modified as you suggest.		
Tennessee Valley Authority	No	

5. The SDT has revised the “Supplementary Reference and FAQ” document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change.

Summary Consideration: Many commenters objected to Requirement R3 and to the explanation that entities would be held to compliance on “either the Tables or their PSMP, whichever is more stringent”. In response to these comments, the SDT modified the standard to remove Requirement R1 part 1.3, and revised Requirement R3 so that, for time-based programs, entities shall comply with the Tables rather than their PSMP. The SDT added Requirement R4 to address performance-based maintenance, and added Requirement R5 to address Unresolved Maintenance Issues. The Supplementary Reference and FAQ document was updated to reflect these changes.

Several commenters questioned the inclusion of the dc control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of “Protection System”; the SDT reiterated its position that this dc control circuitry is indeed included because the dc control circuitry is associated with protective functions. No change was made to the standard based on these comments.

Numerous commenters suggested minor revisions or clarifying text for the Supplementary Reference and FAQ document. These changes were generally adopted.

Organization	Yes or No	Question 5 Comment
Ameren Services	Affirmative Ballot	1. Although the explanation of ‘Restore’ is enlightening on page 12, ‘Restore’ no longer appears in the PS Maintenance definition in the last few drafts. 2. We disagree with the added burden of retaining maintenance records for removed or replaced equipment. This will actually reduce reliability because of the confusion it can cause as to what

Organization	Yes or No	Question 5 Comment
		equipment is providing BES protection. At most, only the last maintenance date of the removed or replaced component should be retained if there's really a need to prove that the interval was met regarding the BES protection. 3. Remove 'Reverse power relays' from the list on page 32. They provide thermal of the steam turbine, not electrical protection of the generator. 4. Now that FERC has approved the Project 2009-17 Interpretation, please acknowledge more directly in the Supplement that the 'transmission Protection System' that is now approved. NERC interprets "transmission Protection System," as it appears in Requirements R1 and R3 of PRC-004-1 and Requirements R1 and R2 of PRC-005-1, to mean "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES". 5. Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.

Response:

1. **Thank you for your suggestion; the SDT has revised the Supplementary Reference and FAQ document to remove the "restore" reference from the definition.**
2. **The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period.**
3. **The SDT agrees that for many steam units, reverse power relays provide alarm only of a condition which could result in eventual overheating of steam turbine components. However, for many combustion turbine generators, a reverse power condition can lead to imminent failure of teeth on the speed reduction gear and thus, reverse power relays on combustion turbine generators are frequently wired as a direct trip to the generator breaker to immediately remove the motoring condition. Furthermore, in the Supplementary Reference document, the preface to the list of relays to which you refer is as follows: "Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:". The SDT was attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included in an**

Organization	Yes or No	Question 5 Comment
entity's PSMP. **4. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.** **5. Thank you for your suggestion; the SDT has revised the standard.**		
Madison Gas and Electric Co.	Affirmative Ballot	Note that the Guidance document over states that an entity will be held accountable for have a more restrictive PMSP than the maximum intervals in attachment 1. Please review FERC Order 693, section 278 which states: "While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, and we do not require that they exceed the Reliability Standards".
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Northeast Power Coordinating Council, Inc.	Affirmative Ballot	An issue was raised here in the Northeast regarding requiring an entity to adhere to their protection system maintenance program, PSMP. If an entity has a maintenance program in place that has shorter intervals, i.e. more stringent than those in the appendix of the standard, and the entity misses completing his maintenance, the entity will be found non-compliant irrespective of the entity to demonstrate they still were within the longer intervals listed in the actual standard. NPCC would suggest that the SDT consider revising this to only result in a non-compliance assessment result if an entity missed the intervals in the appendix of the standard not those specified in their PSMP. The concern is that some entities will forego more stringent programs and revise their documents "downward" in order to ensure compliance at the potential for a reduction in reliability. There is no mechanism currently in place to preclude entities from doing this.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Occidental Chemical	Affirmative Ballot	The SDT has revised the "Supplementary Reference" document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change. Yes. Ingleside Cogeneration LP found the Supplementary Reference document to be helpful, thorough, and technically accurate. The only suggestion we have is that demonstrated adherence to the Reference should be admissible of evidence of compliance at an audit or spot check. Today, all References have no official regulatory standing – which seems to defeat the purpose of developing them to begin with.
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.		
Occidental Chemical	Affirmative Ballot	We need to clarify the following: A transmission owner has established a maintenance cycle which is more stringent (less time between maintenance or test cycles) than the NERC Standard requires. The transmission owner fails to comply fully with the transmission owner's maintenance and testing schedule; however, the maintenance and/or testing is performed within the time frame mandated by the NERC Standard. Must the transmission owner report his failure to comply with his own maintenance/testing program even though the maintenance or testing was completed well within the time frame or interval required by the applicable NERC Standard? Must he transmission owner report such a failure of his own maintenance procedures which are more stringent than the NERC maintenance/testing standard? Will such a self report be considered a non-compliance?
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for		

Organization	Yes or No	Question 5 Comment
time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Oncor Electric Delivery Company LLC	Yes	Oncor would like to see the "Supplementary Reference & FAQ" expanded to provide examples of what documentation would satisfy that the entity is compliant with initiating "resolution of any Unresolved Maintenance Issues." Also it would be helpful to all entities if the Drafting Team would expand on what, if any, tracking of the resolution of an unresolved maintenance issue is required. Oncor believes that keeping track of the initiation of "resolution of any unresolved maintenance issues" is necessary but that the standard does not currently address retention requirements related to this compliance obligation.
Response: Thank you for your comment. The measure related to this requirement has been expanded to include additional suggestions of relevant documentation. There is no tracking requirement listed for the resolution of unresolved maintenance issue, only the initiation of a resolution. The SDT recognizes that performance of the activities necessary to <u>resolve</u> an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. Requiring tracking and deadlines is not within the scope of this standard. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
Springfield Utility Board	Yes	Because Springfield Utility Board's (SUB) current maintenance and testing program is time-based, the revised "Supplementary Reference" document does not impact SUB operations. SUB agrees with the document changes because the changes result in alternatives for entities, rather than being prescriptive.
Response: Thank you for your comment.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP found the Supplementary Reference document to be helpful, thorough, and technically accurate. The only suggestion we have is that demonstrated adherence to the Reference should be admissible of evidence of compliance at an audit or spot check. Today, all References have no official regulatory standing - which seems to defeat the purpose of developing them to begin with.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.		
MidAmerican Energy Company	Yes	The changes to the "Supplementary Reference" document appear to be acceptable, but the following are suggested as changes to enhance clarity. 1. On page 9 of the Supplementary Reference and FAQ draft the following statement is included: "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included." On page 67, the third sentence of Section 15.3 states: "It includes [referring to control circuitry] the wiring from every trip output to every trip coil." Later in that section the following is included: "...from a protective relay that are necessary for the correct operation of the protective functions." While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: "Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested." 2. On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard could result in a noncompliance finding even if the maximum intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.
Response: Thank you for your comment. **1. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is**		

Organization	Yes or No	Question 5 Comment
consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. 2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Ameren	Yes	1. Although the explanation of 'Restore' is enlightening on page 12, 'Restore' no longer appears in the PS Maintenance definition in the last few drafts. 2. We disagree with the added burden of retaining maintenance records for removed or replaced equipment. This will actually reduce reliability because of the confusion it can cause as to what equipment is providing BES protection. At most, only the last maintenance date of the removed or replaced component should be retained if there's really a need to prove that the interval was met regarding the BES protection. 3) Remove 'Reverse power relays' from the list on page 32. They provide thermal of the steam turbine, not electrical protection of the generator.
Response: 1. Thank you for your suggestion; the SDT has revised the Supplementary Reference and FAQ document to remove the "restore" reference from the definition. 2. The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period. 3. The SDT agrees that for many steam units, reverse power relays provide alarm only of a condition which could result in eventual overheating of steam turbine components. However, for many combustion turbine generators, a reverse power condition can lead to imminent failure of teeth on the speed reduction gear and thus, reverse power relays on combustion turbine generators are frequently wired as a direct trip to the generator breaker to immediately remove the motoring condition. Furthermore, in the Supplementary Reference and FAQ document, the preface to the list of relays to which you refer is as follows: "Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not		

Organization	Yes or No	Question 5 Comment
necessarily limited to:". The SDT was attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included in an entity's PSMP.		
Tacoma Power	Yes	It is not clear to what extent can an entity (or auditor) can rely on information contained within the Supplementary Reference to support their position during an audit. There is a disclaimer at the beginning of the Supplementary Reference stating that "this supplementary reference to PRC-005-2 is neither mandatory nor enforceable." It seems that interpretation of the draft standard depends heavily upon this Supplementary Reference. At the same time, the Supplementary Reference does not rise to the level of a standard.
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.

Baltimore Gas & Electric Company	Negative Ballot	BGE's negative ballot is based on our response to Q5: While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning “Our maintenance plan calls…” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, “How do I achieve a grace period without being out of compliance?” the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out of compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance – compliance management, scheduling, operational preference, etc.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
AEP	Negative Ballot	This negative vote is driven primarily by the concerns AEP has regarding the proposed supplementary reference documentation. If an entity adopts a more stringent maintenance program but fails to meet it, that entity could be found non-compliant despite continuing to abide by the minimum requirements of the standard itself. Entities should have the ability, if they so choose, to include additional maintenance activities or more stringent intervals than specified

Organization	Yes or No	Question 5 Comment
		within the standard without concern of penalty in the event they are unable to accomplish them. In addition, AEP is concerned by the volume of information provided in the supplementation documentation, and is uncertain how much weight that documentation might carry during audits. Note: Additional comments are being submitted via electronic form by Thad Ness on behalf of American Electric Power.
Response: Thank you for your comments. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.**		
Manitoba Hydro	Negative Ballot	Maintenance Activities Exceeding NERC Requirements In both the industry webinar discussion and the supplementary reference document, it was indicated that if an entity had more maintenance activities in its plan than the minimum required by PRC-005-2, then an entity would be audited to the "higher standard". We understand that an entity could write some flexibility in its program, as long as the NERC minimums were met. We are concerned that auditing to the "higher standard" could discourage entities from performing maintenance tasks beyond the NERC minimum criteria.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
PJM Interconnection,	Negative	PJM remains concerned with a position taken by the SDT related to statements found within their Supplementary Reference & FAQ as well as the manner in which Requirement R3 has been

Organization	Yes or No	Question 5 Comment
L.L.C.	Ballot Negative Poll	drafted. The SDT's position sends industry the wrong message; a message that entities should not go beyond what is in the text of the standards and that in some cases they can even be found non-compliant by merely failing to meet their own more stringent internal practice. Therefore, PJM is voting NEGATIVE at this time. The NERC reliability standards aim to ensure an Adequate Level of Reliability (ALR). If NERC's reliability standard establishes that an ALR is achieved by a maximum allowable relay maintenance period of every 6 years in a time-based Protection System Maintenance Program (PSMP), then an entity striving to complete its maintenance every 4 years should not be found non-compliant for completing it in 5 years. We have heard NERC say in CAN Webinars and NERC Workshops that "auditors must audit to the standard", however, the position taken by the SDT within their Supplementary Reference and FAQ document and the wording of Requirement R3 is contrary to this position.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
FirstEnergy	No	We do not agree with aspects of the Supplementary Reference document as discussed in Question 6.
Response: Thank you for your comments. Please see our response to your comments in Question 6.		
NERC Staff Technical Review	No	We recommend changes to Supplementary Reference. It appears the 3 calendar month interval referenced in the second FAQ in section 7.1 on page 20, Example 1 on page 21, Example 2 on page 22, and on page 23 should be updated to 4 calendar months consistent with the changes to the standard for verification of station dc supply voltage and inspection of electrolyte level and unintentional grounds. We recommend modifying references to UFLS and UVLS to clarify the intervals for distributed systems applies to both UFLS and UVLS similar to the recommended change to the standard in our comment on question 4. See pp. 26, 30, 33, 86, and 87 of the supplementary reference.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. **1. Thank you for comment; the Supplementary Reference and FAQ document has been changed.** **2. Changes have been made to the standard and its Supplementary Reference and FAQ document.**		
MRO's NERC Standards Review Forum	No	a. Page 9, "Is a Sudden Pressure Relay an auxiliary tripping relay? "1) During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows:i. Is a Sudden Pressure Relay an auxiliary tripping relay? No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. b. On page 26 of the Supplementary Reference document, it states, "If your PSMP (plan) requires more activities than you must perform and document to this higher standard." This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, "If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards." In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards". c. Page 78, last paragraph: If the same type of ohmic testing is done (impedance, conductance or

Organization	Yes or No	Question 5 Comment
		resistance), may a different manufacturer's test equipment be used for this testing? d. Page 79, second paragraph of "Why verify voltage?": 1) "The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning." i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? 2) "The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits." i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? e. Except as noted above, the changes to the "Supplementary Reference" document appear to be acceptable, but the following are suggested as changes to enhance clarity. 1) On page 9 of the Supplementary Reference and FAQ draft the following statement is included: "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included." On page 67, the third sentence of Section 15.3 states: "It includes [referring to control circuitry] the wiring from every trip output to every trip coil." Later in that section the following is included: "...from a protective relay that are necessary for the correct operation of the protective functions." While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: "Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested." 2) On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard could result in a noncompliance finding even if the maximum

Organization	Yes or No	Question 5 Comment
		intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.
Response: Thank you for your comment. **1. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.** **2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **3. Yes. Your concern, of course should be that your results can be trended from test to test. The Supplementary Reference and FAQ document has been changed.** **4. The Supplementary Reference and FAQ document has been changed to add clarity.** **5. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. As to part 2, The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, R1 part 1.3 has been removed; R3 has been revised so that, for time-based programs, entities shall comply with the tables; R4 has been added to address performance-based maintenance, and R5 has been added to address Unresolved Maintenance Issues.**		
ACES Power Collaborators	No	There are some changes that are needed to the document. 1. On Page 19, the second question refers to R1.4. There is no R1.4 in the standard. We assume

Organization	Yes or No	Question 5 Comment
		that document is intended to refer to part 1.4 under R1. This needs to be clarified and corrected. 2. The reference document creates an improper incentive to eliminate best practices and utilize the maximum time intervals established in the standard. The document states that an entity will be subject to compliance violations if it has a maintenance and testing program with time intervals that are more stringent than the maximum time intervals in the standard and it does not meet its more stringent intervals. This would hold true even if the registered entity meets the maximum intervals established in the standard. To reduce compliance risk, registered entities will be incented to increase its time intervals to the maximum allowed by the standard. This is contrary to supporting reliability. Penalizing entities for failing to meet their more stringent plan requirements is also contrary to guidance provided by the Commission. Doug Curry, General Counsel of Lincoln Electric System, spoke to the Commission at the November 18, 2010 FERC technical conference on reliability monitoring, enforcement and compliance about his company's experience with the vegetation management standard. They exceeded the requirements for annual inspections by including six aerial patrols each year but were found in violation of the standard and paid penalties when they did not complete but one aerial patrol in the first five months of the year. The auditors concluded that the company's ground patrol fully satisfied the minimum requirements of the standard. In the end, LES removed the aerial inspections from the vegetation management plan. The Commissioners acknowledged that this was contrary to their goal of an adequate level of reliability and agreed that an entity should not be penalized for failing to meet their more stringent requirements when they meet the standard requirements. 3. On Page 34, the FAQ about commissioning does not appear to be consistent with CAN-0011. While we believe the reference document is more correct, the drafting team should compare the advice given in the reference document to that in the CAN to ensure that it is not conflicting. Given that NERC is in the process of revising all of the CANs, the best approach may simply be to add a statement referencing the CAN-0011 for further information. 4. Comments about "gaming the PBM system" regarding restoring segment performance should be removed from the reference document. Comments like these indicate intent by a

Organization	Yes or No	Question 5 Comment
		registered entity to manipulate the compliance process. Only after a thorough investigation can such intent be determined. Thus, there shouldn't be a presumption that registered entities will attempt this. Better comments would be to focus on the consistency that the three year period provides in determining segment performance. 5. In section 12.1 on page 58, the reference document discusses out of service equipment. NERC recently issued a lesson learned on removing unused relaying equipment on August 10, 2011. The drafting team may wish to reference that lesson learned in the reference document.
Response: Thank you for your comment. **1. The Supplementary Reference and FAQ document has been changed.** **2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **3. The Supplementary Reference and FAQ document has been changed.** **4. The Supplementary Reference and FAQ document has been changed.** **5. The Supplementary Reference and FAQ document has been changed to incorporate a discussion of the cited Lessons Learned.**		
Southern Company Generation	No	Several additional edits are needed so that the document matches the proposed standard: 1) In Section 5.1.1, page 16, add "and Table 3" in the Figure and at the end of FAQ after figure in that section. 2) In Section 7.1, example #1, a 3 month battery interval is shown 3) In Section 8.1.1, a 3 month interval is shown for communication circuit 4) In Section 15.5.1, several references to "3 month" and "three month" intervals are shown for communication circuits. 5) In Appendix B, the formatting is incorrect for Al McMeekin's company name.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The Supplementary Reference and FAQ document has been changed to address each of your suggestions.		
Nebraska Public Power District	No	a. On page 26 of the Supplementary Reference document, it states, "If your PSMP (plan) requires more activities than you must perform and document to this higher standard." This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, "If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards." In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards".
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
American Electric Power	No	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. However, AEP is uncertain how much weight the documents might carry during audits. We recommend that this additional information be included within the actual standard (for example in an appendix) but in a more compact version. Section 15.7 of the supplementary reference includes the bullet point "No verification of trip path

Organization	Yes or No	Question 5 Comment
		required between the lock-out and/or auxiliary tripping device(s).” This appears to contradict the other bullet points within Section 15.7.
Response: Thank you for your comment. **1. Doing as you suggest would make the supporting information within the Supplementary Reference and FAQ document part of the standard and this would add extensive and unnecessary prescription to the standard.** **2. The Supplementary Reference and FAQ document has been changed.**		
Lincoln Electric System	No	Please see the comments submitted by the MRO NSRF.
Response: Please see our response to the comments submitted by the MRO NSRF.		
Liberty Electric Power LLC	No	The reference contains language which makes it a violation should an entity choose a cycle time less than the maximum from the table, and then fails to meet that cycle. (See page 27, "If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.") There is no reason to hold a RE in violation if all work is performed within the maximum time from the table - either there was no reliability risk, or the table is incorrect and a reliability risk in itself.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Manitoba Hydro	No	1. Page 26: In both the industry webinar discussion and the supplementary reference document, it was indicated that if an entity had more maintenance activities in its plan than the minimum required by PRC-005-2, then an entity would be audited to the "higher standard". We understand that an entity could write some flexibility in its program, as long as the NERC minimums were met. We are concerned that auditing to the "higher standard" could

Organization	Yes or No	Question 5 Comment
		discourage entities from performing maintenance tasks beyond the NERC minimum criteria. 2. The discussion on page 9 indicates that although the relays which respond to mechanical parameters are not included in the scope of PRC-005-2, the associated trip circuits are included. We suggest that neither the relays which respond to mechanical parameters nor their associated trip circuits are within the scope of this standard 3. References to the tables should be consistently updated to include the new Table 3. “Every 3 calendar months” should be updated throughout the document to “Every 4 calendar months”. For example, Page 23: Example #3 should be revised. 4. In addition, there are a number of grammatical errors in the document, particularly capitalization and punctuation, which make it difficult to read. There are terms which are improperly capitalized implying that they are approved NERC Glossary of Terms definitions when they are not.
Response Thank you for your comment. **1. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **2. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. American Transmission	No	ATC provides the following suggestions for change:

Organization	Yes or No	Question 5 Comment
Company		1. Page 9, "Is a Sudden Pressure Relay an auxiliary tripping relay? "During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows: Is a Sudden Pressure Relay an auxiliary tripping relay?No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. 2. Page 78, last paragraph:If the same type of ohmic testing is done (impedance, conductance or resistance), modify the FAQ to allow the use of a different manufacturer's test equipment to conduct the testing. 3. Page 80, second paragraph: "The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning." Insert the following: "A reading taken from the battery charger panel meter will meet this requirement." "The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits." Insert the following." A reading taken from the battery charger panel meter will meet this requirement."

Response: Thank you for your comments.

1. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.**
2. **In the Supplementary Reference and FAQ document, the SDT is discussing methods of performing ohmic testing but is not specifying any particular test or test equipment.**

Response: Thank you for your comments. **1. The Supplementary Reference and FAQ document has been changed.** **2. The Supplementary Reference and FAQ document has been changed.**		
CenterPoint Energy	No	CenterPoint Energy appreciates that there is now only one document, instead of the two originally proposed. However, we question the name of the document which shows "Supplemental Reference and FAQ". The use of "Supplemental Reference" could infer it contains requirements not found in the PRC-005-2 standard. Also, we suggest that NERC standardize on the names of documents associated with standards and other NERC initiatives. CenterPoint Energy recommends the name of the document be "Technical Reference".
Response: Thank you for your comment. The Supplementary Reference and FAQ document is explanatory in nature.		
BGE	No	While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning "Our maintenance plan calls..." states that an entity is "out of compliance" if maintenance occurs at a time longer than that specified in the entity's plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, "How do I achieve a grace period without being out of compliance?" the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out-of-compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance - compliance management, scheduling, operational

Organization	Yes or No	Question 5 Comment
		preference, etc.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Constellation Power Generation	No	While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning “Our maintenance plan calls...” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, “How do I achieve a grace period without being out of compliance?” the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out-of-compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance - compliance management, scheduling, operational preference, etc. The discussion of “grace period” may be best clarified as a term to include in an entity’s PSMP that grants entities the flexibility to maintain compliance if testing occurs between an entity’s plan interval and the bright-line interval.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Constellation Energy	No	While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning

Organization	Yes or No	Question 5 Comment
Commodities Group		"Our maintenance plan calls..." states that an entity is "out of compliance" if maintenance occurs at a time longer than that specified in the entity's plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, "How do I achieve a grace period without being out of compliance?" the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out-of-compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Response: Please see our response to your comments in Question 6.		
Tennessee Valley Authority	No	

6. **If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them in the comment section.**

Summary Consideration:

Many commenters objected to Requirement R3 and to the explanation that entities would be held to compliance on "either the Tables or their PSMP, whichever is more stringent". In response to these comments, the SDT modified the standard to remove Requirement R1 part 1.3, and revised Requirement R3 so that, for time-based programs, entities shall comply with the Tables rather than their PSMP. The SDT added Requirement R4 to address performance-based maintenance, and added Requirement R5 to address Unresolved Maintenance Issues. The Supplementary Reference and FAQ document was updated to reflect these changes.

Several commenters questioned the inclusion of the dc control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is indeed included because the dc control circuitry is associated with protective functions.

Several comments were offered objecting that the VSLs establish that any non-compliance is a violation, and that "perfection is unrealistic". The SDT responded that the VSL Guidelines do not provide for an entity to be out of performance to some degree without incurring a violation.

Several comments were offered regarding "Unresolved Maintenance Issues". Some of these comments suggested that the entity should be required to resolve such issues, rather than initiating resolution. Others offered concerns regarding the definition of this term itself or the related VSLs. The SDT revised the definition to: "A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, and requires follow-up corrective action." The VSLs for the old Requirement R3 (new Requirement R5) were revised from graduated "%" to graduated "hard counts" of violations. The SDT also clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.

Other comments were offered regarding Data Retention, generally objecting to retaining the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

Several commenters questioned the verification of lockout and auxiliary relays every 6 years. The SDT explained their rationale for this requirement relative to lockout relays, and did move the auxiliary relays to the 12-year control circuitry verification.

Several comments were offered on the Implementation plan, resulting in several clarifying changes.

Many comments were offered, questioning the Applicability of the standard relative to the recently-approved Interpretation of “transmission Protection System”. The SDT explained that PRC-005-2 does not use this term; thus the interpretation does not apply. The SDT also explained that the Applicability in PRC-005 is correct and that it supports the reliability of the BES.

In response to comments, the SDT revised Applicability 4.2.5.4 to indicate that, for generator-connected station service transformers, only the Protection Systems that trip the generator, either directly or via a lockout relay are included in the standard.

In response to comments, Table 1-4(f) was modified to more accurately represent the monitoring attributes and related activities for monitored Vented Lead-Acid and Valve-Regulated Lead-Acid batteries.

Organization	Yes or No	Question 6 Comment
City of Austin dba Austin Energy	Affirmative Ballot	(1) The following language should be clarified to make it clear that a Registered Entity does not have to include its detailed maintenance procedures in its PSMP: 1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3.
	Affirmative Poll	(2) For a modern digital relay panel, designed with monitored components and electromechanical lockouts, the maintenance interval would otherwise be a maximum of 12 years except that the lockout must be electrically operated every 6 years. We cannot see justification for a separate maintenance activity to just test the lockouts, due to the increased human error associated with testing lockouts and the low likelihood of a lockout failure. We recommend that the lockouts be tested on a 12 year basis, perhaps in association with the “Unmonitored control circuitry associated with protective functions” as found in Table 1-5. By doing so, we feel that the risk of an undesired operation due to human error can be minimized and not degrade system reliability.
		(3) If sudden pressure relays are exempt from the Standard, the DC circuitry for those relays should also be exempt.
		(4) If a Registered Entity has a PSMP that is more stringent than the intervals in PRC-005-2, the Registered Entity should not be considered out of compliance if it fails to meet its internal interval but remains within the interval set forth in PRC-005-2.

Response: Thank you for your comments.

1. **The SDT's intent with the R1.4 wording is to convey that the entity's PSMP must document that the monitoring attributes of any given component type meet the Table-specified monitoring attributes in order to justify exclusion of the maintenance activities and/or the lengthening of maintenance intervals as provided for in the Tables. PRC-005-2 does not have requirements for inclusion of detailed maintenance procedures in an entity's PSMP as the tables within the standard have taken the place of the "summary of maintenance and testing procedures" required by R1.2 of PRC-005-1.**
2. **The SDT believes that electromechanical lockout relays need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.**
3. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.**
4. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.**

City of Tacoma, Department of Public Utilities, Light Division, dba Tacoma Power	Affirmative Ballot	1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.
		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station DC supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program developed for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to "include all applicable monitoring attributes and related maintenance activities" per the Tables and requires an entity to "implement and follow its PSMP." Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.

		5. In Table 1-2, there is a maintenance activity related to communication systems to "verify essential signals to and from other Protection System components." It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to "verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System." This language is consistent with that used for protective relays in Table 1-1.
		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which 'performance criteria' are 'pertinent.' Additionally, it is unclear if an entity must document the 'communications technology applied' and the associated 'performance criteria' in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms 'resistance' and 'ohmic values.' If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms 'battery terminal connection resistance' and 'unit-to-unit connection resistance.' If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term 'resistance' with 'impedance.'
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.

		11. Referring to Table 1-5, no periodic maintenance is required for “control circuitry whose continuity and energization or ability to operate are monitored and alarmed.” It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for “unmonitored control circuitry associated with protective functions.” It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.
		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.
Response:	**Thank you for your comments.**	
	1. The SDT agrees with your observation and has changed the relevant parts of the implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals.	
	2. The SDT agrees with your observation and has revised the Implementation plan to clarify.	

	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.
	5. The SDT agrees with your suggestion and has changed the standard accordingly.
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.
	7. As utilized on Table 1-4, the term "ohmic value" is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term "ohmic value" is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term "resistance" as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.

	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.
	14. As timing is critical to proper Protection System function, timers are considered protective relays.

Ameren Services	Affirmative Ballot	Measure M3 on page 5 should only apply to 99.5% of the components. Please revise to state: “Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated….” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. No one is perfect and it is impractical to imply perfection is achievable. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is “non-performance”. An alternate approach regarding the unrealistic perfection of M3 is to correctly recognize that the protection of the primary BES is the objective. Most Protection Systems are redundant by design and the entity needs to be afforded the opportunity to show that a redundant component met the PSMP thereby providing the required protection. The entity should be allowed a reasonable time frame of one calendar increment to maintain the component in question. Our concern stems from the tens of thousands of components in a PSMP, and the reality that rarely but occasionally a data base error or outage scheduling issue may result in a very small number component exceeding their maximum interval. As long as the entity can show that BES protection was sustained and maintains the component quickly (e.g. within one calendar month of discovery), BES reliability has been maintained.
Response: Thank you for comment. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RRO to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.**		

City of Austin dba Austin Energy	Affirmative Ballot	1. The following language should be clarified to make it clear that a Registered Entity does not have to include its detailed maintenance procedures in its PSMP: "all applicable monitoring attributes and related maintenance activities ". Reference: R1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3. 2. For a modern digital relay panel, designed with monitored components and electromechanical lockouts, the maintenance interval would otherwise be a maximum of 12 years except that the lockout must be electrically operated every 6 years. We cannot see justification for a separate maintenance activity to just test the lockouts, due to the increased human error associated with testing lockouts and the low likelihood of a lockout failure. We recommend that the lockouts be tested on a 12 year basis, perhaps in association with the "Unmonitored control circuitry associated with protective functions" as found in Table 1-5. By doing so, we feel that the risk of an undesired operation due to human error can be minimized and not degrade system reliability. 3. If sudden pressure relays are exempt from the Standard, the DC circuitry for those relays should also be exempt.

Response: Thank you for your comments.

1. **The SDT's intent with the Requirement R1.4 (new Requirement R1.2) wording is to convey that the entity's PSMP must document that the monitoring attributes of any given component type meet the Table-specified monitoring attributes in order to justify exclusion of the maintenance activities and/or the lengthening of maintenance intervals as provided for in the Tables. PRC-005-2 does not have requirements for inclusion of detailed maintenance procedures in an entity's PSMP as the tables within the standard have taken the place of the "summary of maintenance and testing procedures" required by R1.2 of PRC-005-1.**
2. **The SDT believes that electromechanical lockout relays need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.**
3. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is**

omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.		
International Transmission Company Holdings Corp	Affirmative Ballot	While voting "Affirmative" on this ballot, ITC continues to have concerns with testing intervals. These comments have been submitted via the Comment Form associated with this project.
Response: Thank you for your affirmative vote. Please see our responses to our comments elsewhere in this report.		
Occidental Chemical	Affirmative Ballot	If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here. Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test.
Response: Thank you for your comment and affirmative vote. **There are less intrusive ways to verify channel performance that do not require disconnecting communication terminations. It is up to the entity to determine specific maintenance techniques.**		

Oncor Electric Delivery	Affirmative Ballot	PRC-005-2 is a vast improvement over the vagueness of the existing standard (PRC-005-1), that the new standard makes compliance much easier than the present standard. The new standard recognizes the advances in relay technology and reliability, particularly the benefits of microprocessor based relays. The standard also provides greater flexibility on its implementation while recognizing the benefits of a performance based methodology, particularly as it relates to battery testing. The revised standard eliminates the requirement for a "summary of maintenance and testing procedures" which was vague and provided no real value to the registered entities. Operational and administrative efficiencies can be realized by consolidating the relay testing and maintenance requirements into one standard (PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0)
Response: Thank you for your comment and affirmative vote.		
Public Utility District No. 2 of Grant County	Affirmative Ballot	We are ok with this standard, however, we would like to see some recognition of the use of non-calendar based maintenance practices such as predictive maintenance practices or condition based maintenance practices. When you use one of those methodologies for the basis for your plant maintenance it is very labor intensive to interpret those results to a calendar based requirement.
Response: Thank you for your comment and affirmative vote. **Please see Sections 5, 6, and 7 of the Supplementary Reference and FAQ for a discussion of how the SDT has attempted to incorporate condition-based maintenance practices (utilizing installed monitoring capabilities) and performance-based maintenance practices within PRC-005-2.**		
Tacoma Public Utilities	Affirmative Ballot	1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.

		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station dc supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program develoepd for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.
		5. In Table 1-2, there is a maintenance activity related to communication systems to “verify essential signals to and from other Protection System components.” It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to “verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.” This language is consistent with that used for protective relays in Table 1-1.

		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which 'performance criteria' are 'pertinent.' Additionally, it is unclear if an entity must document the 'communications technology applied' and the associated 'performance criteria' in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms 'resistance' and 'ohmic values.' If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms 'battery terminal connection resistance' and 'unit-to-unit connection resistance.' If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term 'resistance' with 'impedance.'
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.
		11. Referring to Table 1-5, no periodic maintenance is required for "control circuitry whose continuity and energization or ability to operate are monitored and alarmed." It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for "unmonitored control circuitry associated with protective functions." It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.

		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.
Response:	Thank you for your comments.	
	1. The SDT agrees with your observation and has changed the relevant parts of the implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals	
	2. The SDT agrees with your observation and has revised the Implementation plan to clarify.	
	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.	
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.	
	5. The SDT agrees with your suggestion and has changed the standard accordingly.	
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.	

	7. As utilized on Table 1-4, the term “ohmic value” is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term “ohmic value” is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term “resistance” as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.
	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.

	14. As timing is critical to proper Protection System function, timers are considered protective relays.	
Wisconsin Electric Power Co. Wisconsin Electric Power Marketing	Affirmative Ballot	Do we need to track the maintenance of another owner's Protection System Component which is part of my Protection System? For example, if our Protection System includes and trips another owner's circuit breaker, do we need to track maintenance and testing for that circuit breaker?
Response: Thank you for your comment and affirmative ballots. **The owner is responsible for the maintenance of Protection System Components. You do not need to track the maintenance of other owner's Protection System Components.**		
Beaches Energy Services	Negative Ballot	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer".

		2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.

Response: Thank you for your comments.

1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.**
2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**

Florida Municipal Power Pool	Negative Ballot	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer", e.g., if the standard says an interval is 6 years, then, through business practice we can shorten actual maintenance and testing intervals to something like 4 years to allow ourselves a 2 year buffer to catch equipment that may have been missed due to difficulty in scheduling outages and the like. Does not cause us to vote negative.
	Negative Poll	2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard. Causes us to vote Negative.

Response: Thank you for your comments. 1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.** 2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**		
Constellation Power Source Generation, Inc.	Negative Ballot Negative Poll	Constellation Power Generation is voting against the approval of this standard because, from a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive. Constellation Power Generation is concerned that the Tables may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. In the worst case, the specifics dictated in the Tables may move Entities away from more stringent PSMPs that are currently in practice. For this reason, Constellation Power Generation suggests that the drafting team revisit the concept of the Tables to better convey useful guidance without creating a compliance requirement that may be contrary to improved reliability. The Registered Entity should be given more flexibility to dictate how a protection system component should be tested, and at what frequency. Furthermore, the technical manpower and compliance documentation demands to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any small generation entity would use it. Please refer to Constellation Power Generation's submitted comments for other issues identified with this standard.
Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance.**		

Duke Energy/ Fort Pierce Utilities Authority	Negative Ballot	Duke Energy disagrees with the wording in the Applicability section 4.2.1. The wording change from PRC-005-2 draft 4 to PRC-005-2 draft 5 expands the reach of the standard to relaying schemes that detect faults on the BES but are not intended to provide protection for the BES. Duke Energy's standard protection scheme for dispersed generation at retail stations would be subject to the standard due to the changes in section 4.2.1. These protection schemes are design to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the definition used in PRC-005-1A Appendix 1 "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Lakeland Electric	Negative Ballot	First Concern is that evidence of maintenance and testing at this level will be very difficult to obtain, track and report. Second is the word exercise - what is really meant by this. This may be difficult or impossible to do without impacting or tripping the circuit. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17).
Response: Thank you for your comments 1. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Nonetheless, the SDT agrees that significant effort will be necessary to implement these requirements and to prove compliance.** 2. **The SDT is unsure to which utilization of the word "exercise" you refer.** 3. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		
Illinois Municipal Electric Agency	Negative Ballot	IMEA greatly appreciates SDT efforts to address/resolve issues, improve PRC-005, and consolidate various PRC Reliability Standards. However, IMEA is voting Negative based on the inconsistency between the current Applicability language and the PRC-004 and PRC-005 interpreation (Project 2009-17) recently approved by FERC. IMEA supports comments submitted by Florida Municipal Power Agency which address this inconsistency, and encourages the SDT to address this issue which is important to municipal entities.

Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**		
Consumers Energy	Negative Ballot	R3 continues to have "...initiate resolution of unresolved maintenance issues." Initiate means to start or set going, it does not mean closure of the item. If a remediation project is initiated and not closed out in a timely manner an auditor could penalize an entity based on what the auditor considers timely. We suggest definitive language indicating closure of the unresolved maintenance issue. Also, it would be beneficial to specify time frame for closing the issue.
Response: Thank you for your comment. **PRC-005-2 only requires the entity "… initiate resolution" of the issue found. The SDT recognizes that performance of the activities necessary to resolve an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.**		

Florida Keys Electric Cooperative Assoc.	Negative Ballot	The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Independent Electricity System Operator	Negative Ballot	The IESO disagrees with the concept that auditors use the standards as minimum requirements and evaluate compliance based on a registered entity's own governance. We believe that the entity could be found non-compliant with Requirement R3 if they fail to follow the internal maintenance intervals established in their PSMP, even though actual maintenance intervals are no less frequent than the prescribed maximum intervals established in the draft standard. The potential for such a finding will discourage conscientious entities from setting higher internal targets for their planned maintenance and promote compliance with only the minimum requirements of the standard. We therefore propose the following revision to Requirement R3: R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. In the case of time-based maintenance programs, each Transmission Owner, Generator Owner, and Distribution Provider is permitted to deviate from its PSMP provided that actual maintenance intervals do not exceed those specified in Tables 1-1 through 1-5, Table 2 and Table 3. [Violation Risk Factor: High] [Time Horizon: Operations Planning]
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Florida Municipal Power Agency	Negative Ballot	We have three remaining concerns. The second concern leads us to recommend a negative vote.

	Negative Poll	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer", e.g., if the standard says an interval is 6 years, then, through business practice we can shorten actual maintenance and testing intervals to something like 4 years to allow ourselves a 2 year buffer to catch equipment that may have been missed due to difficulty in scheduling outages and the like. Does not cause us to vote negative.
		2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard. Causes us to vote Negative.

		3. The standard reaches further into the distribution system than we would like for UFLS and UVLS (Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic. Borderline concerning whether this causes us to vote Negative or not. As a result, FMPA recommends a Negative vote with the second and third comments, emphasizing that it is the second comment that causes us to vote negative but we also would like the 3rd comment addressed. Feedback appreciated. Vote and comments are due next Wednesday, 9/28.

Response: Thank you for your comments 1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.** 2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ Document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.** 3. **UVLS and UFLS systems are required to be included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical lockout relays require periodic operation. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.**		
Lakeland Electric	Negative Poll	The "Applicability" section is not consistent with Tri-State PRC-005 interpretation.
Response: Thank you for your comments **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Liberty Electric Power LLC	Negative Ballot	With the development and publication of maximum maintenance and testing intervals (the Tables), there is no longer a reliability need for a RE to identify the associated time-based maintenance intervals for Protection System Components. Further, REs who wish to perform these activities in shorter intervals than those allowed by the standard risk non-compliance (See Supplementary Reference, page 27,"If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.")If the entity completes all activities within the maximum interval allowed by the standard, there can be no reliability concern; if there is a reliability issue, then the table interval is incorrect. I would suggest the following changes.
		1. Change R1.2 to read "Identify any Protection System component where the RE is using a performance based maintenance interval. No batteries associated with the station DC supply component type of Protection System shall be included in a performance based system"
		2. Change R1.3 to read "The intervals for time-based programs are established in Table 1-1 through 1-5, Table 2, and Table 3".
		3. Change M1 to add the phrase "for performance-based components" after the words "maintenance intervals".
		4. In M1, replace the words "the type of maintenance program applied (time-based, performance based, or a combination of these maintenance methods") with the words "the identification of any protection system components using performance based intervals".
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues. The Measures have also been revised.		
Manitoba Hydro	Negative Ballot	Manitoba Hydro is voting negative for the following reasons:

		1. Grace Periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-compliance. Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval (for example, performing a battery inspection at a remote station during severe winter weather) or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for safety and reliability without risking non-compliance. In addition, we disagree with the basis that the Drafting Team has established that grace periods are not permitted because of FERC Order 693 which requires that 'maximum' time intervals are established within PRC-005-2. With grace periods, a maximum time interval obviously becomes the required maintenance interval plus the maximum permitted grace period. So we strongly feel that grace periods can be added to the standard while adhering to the FERC Order. We also disagree with the line of reasoning that the Drafting Team used to establish the maximum maintenance intervals for relays as outlined on page 38 of the Supplementary Reference and FAQ document. To our knowledge, no document has been produced which provides evidence of maximum time intervals that work well for 'maintenance cycles that have been in use in generator plants for decades'. Our Protection Systems Maintenance experience indicates that the proposed intervals are acceptable as nominal time intervals with grace periods, but not as maximum time intervals without grace periods. Without a grace period, the bulk of protection maintenance on a six year maintenance cycle will have to be done one year earlier than previously required, in order to allow for the last year of the maximum interval to be used as the grace period. Manitoba Hydro considers this an unnecessary burden on resources with no benefit to reliability. Manitoba Hydro recommends that grace periods be permitted within PRC-005-2 if an entity can demonstrate a reliability or safety related need for using a grace period. This would require the Drafting Team to develop reliability-related criteria for using a grace period.

		2. Phased Implementation Plan Manitoba Hydro does not agree with the prescribed phased implementation plan. Entities should be given a single compliance date for each of the maintenance intervals, and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-005-2. For example, if a maximum maintenance interval is 6 calendar years, the implementation plan should only require that "The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption." (item 4c.). The existing standard PRC-005-1 already requires protection systems to be maintained as part of a program. Prescribing how an entity must reach full compliance will provide a negligible improvement in reliability, while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets, and proving compliance for prescribed percentages of assets during the transition period creates unnecessary overhead with no added value. We suggest that items 3a., 3b., 4a., 4b., 5a. and 5b be removed from the implementation plan and that NERC measure progress on reaching PRC-005-2 intervals using means other than Compliance measures such as industry surveys.

Response: Thank you for your comments.

1. **FERC Order 693 directs NERC to establish maximum allowable intervals. The SDT believes a "grace period" process as you describe would not satisfy this directive. In essence, by specifying maximum allowable intervals the SDT is leaving the establishment of normal maintenance intervals and grace periods to the entities discretion and to what works best for their scheduling needs and program flexibility. Alternatively, if the SDT believes that 6 calendar years is the maximum allowable interval for a given maintenance activity, it could have done as you suggested and defined a 4 year "normal" interval with a 2 year grace period for a maximum allowable interval of 6 years. The SDT believes the management of normal maintenance intervals and grace periods is best left to the entity's PSMP and thus chose only to specify the maximum allowed interval within which entities must comply. Note that if data is available to prove reliability is maintained, performance-based maintenance is available to achieve longer maintenance intervals.**
2. **The SDT believes that it is not practical for all entities to rapidly transition all of their Protection Systems to the new program, especially with some component types on maintenance intervals of up to 12 years. Nonetheless, all in-scope Protection Systems must be maintained by either a PRC-005-1 program or a PRC-005-2 program. The SDT believes the phased approach mapped out in the Implementation plan is practical. If an entity wishes to implement PRC-005-2 on a more rapid rate than laid out in the Implementation plan to lessen the complexity of documentation requirements, they are free to do so.**

Muscatine Power & Water	Negative Ballot	1. Section D.1.3, in Data Retention, requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable and problematic requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent test record. A compliance audit should be focused on the present day and not in the past. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent test results, we could conceivably have to retain a relay test record for up to 24 years! Hypothetically, if we have a test record from ten years ago, but we do not have the record from 12 years before that, how does that adversely affect the reliability of the BES today? The standard should focus on – Is the Entity compliant TODAY?
		2. Table 1-5 requires a maintenance activity to, "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Recommend this be changed to, "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Alternately, change the wording to, "Electrically operate each interrupting device every 6 years." While requiring each trip coil to operate the breaker sounds good in theory, however, it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and are not configured to test independently. Isolating one trip coil from the other may include "lifting a wire" that may not get landed properly when the test is complete. Using an actual event only tests one coil and we may not know which coil tripped the device. The current language is a recipe for a compliance violation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.
		3. In the tables for dc Supply the term "unit-to-unit" is used along with "intercell" when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450), the standard terminology seems to be "intercell". It is recommended that the "unit-to-unit" term be removed to avoid confusion regarding what is to be verified.

Response: Thank you for your comments. **1. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities. Obviously, Compliance Monitors should not expect entities to be able produce records for maintenance performed prior to there being requirements for that maintenance to be performed.** **2. The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.** **3. The term "unit-to-unit" is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar.**		
NorthWestern Energy	Negative Ballot	I recommend a no vote please see my comments below. 1. For Table 1-5 Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices 6 calendar years Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device. Provisions need to be added to allow non-tripping checks of coils on the BES element that will Trip load. If I am reading the purposed correct the circuit switcher feeding distribution banks at or above 100kV will need to be tripped taking out load. 2. It was my understanding the IEEE standard 450 allowed for 7 year load test interval for VLA and NiCad batteries the standard calls out for 6 years. It appears that the standard has been recently updated and should be verified. My last objection is Table 1-2 3. Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below. 4 calendar months Verify that the communications system is functional. 4 calendar months is excessive on annual maint and will discourage communications assisted tripping when not absolutely needed. 1 year is a more reasonable and doable timeline.

Response: Thank you for your comments. **1. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." If the Protection System in question is not protecting a BES component, it is not applicable to this standard. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.** **2. IEEE 450 only pertains to VLA batteries. IEEE 1106 pertains to NiCad batteries. The SDT believes that the 6 calendar year interval specified in PRC-005-2 is appropriate.** **3. The SDT believes that performing this maintenance activity at 4 month intervals is proper for unmonitored communications systems.**		
Seattle City Light	Negative Ballot	Regarding Voltage and Current Sensing Device Maintenance & Testing Activities: Table 1-3 of the standard lists the minimum required maintenance activities for voltage and current sensing devices as "Verify that current and voltage signal values are provided to the protective relay." Consistent with Table 1-3, Section 15.2.1 of the Supplementary Reference states that an entity "...must verify that the protective relay is receiving the expected values from the voltage and current sensing devices..." The Supplementary Reference further offers examples of how this requirement may be satisfied with most of the examples reference the need to verify the signal at each relay in the circuit. We recognize the need to verify a voltage signal at each protective relay, as these devices are wired in parallel and an open circuit at one location may not impact the other devices on the circuit. However, we do not agree that there is a need to verify a current signal at each protective relay. Current devices are wired in series; an open circuit at any location will impact all other devices on the circuit. For this reason, a single measurement of the current circuit is sufficient. We recommend updating Table 1-3 and the supplementary reference to account for the different physical characteristics of voltage and current circuits.
Response: Thank you for your comment. **An open circuit is not the only failure mechanism for a CT secondary circuit. Grounded CT secondary wiring can result in situations where accurate current is present in the part of the secondary circuit upstream of the ground but current would be shunted to ground and might not pass through devices downstream of the ground. Entities should not interpret PRC-005-2 as specifying "how" to test but rather that PRC-005-2 only specifies "what" to test.**		

Seminole Electric Cooperative, Inc.	Negative Ballot	We recommend the SDT consider an interval of 12 calendar years for the component in row 3, of Table 1-5 on page 19 of the standard. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We sincerely hope that the SDT will consider these changes.
Response: Thank you for your comments. **The SDT believes it is possible to manage the risks that you describe and that performance of this testing will be an overall benefit to the reliability of the BES. It is the majority opinion of the subject matter experts forming the SDT that testing of electromechanical devices with moving parts such as lockout relays be performed on a 6 year interval. Entities may use the PBM process to extend this interval if they desire.**		
Tennessee Valley Authority	Negative Ballot	It will take several years for TVA to implement checkback on 590 carrier blocking sets on the TVA system and not have to perform the PRC 005-2 requirement of verifying functionality every 4 months with no grace period. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We are also implementing an extensive PM test in October 2011 which will test 25% of the sets per year and will take readings of SWR, line loss, and receiver margin.
Response: Thank you for your comment. **The SDT believes that performing this maintenance activity at 4 month intervals will benefit the reliability of the BES. The Implementation plan allows for 15 months after regulatory approvals for entities to implement the program per PRC-005-2. You may also find performance-based maintenance (per Requirement R2) useful.**		

Utility Services, Inc.	Negative Ballot	While we generally agree with most of the proposal, we are concerned about the need to address validate of Protection System settings in the standard. We believe that there should be an explicit requirement on validating the settings to ensure that misoperations don't occur due to incorrect settings being programmed into the devices. Reliability will be enhanced if misoperations can be avoided due to the explicit check on the accuracy of the settings.
Response: Thank you for your comment. **Rows 1 and 2 of Table 1-1 currently require verification that relay settings are as specified.**		
Westar Energy	Negative Ballot	Westar agrees in general with most of the changes and modifications included in the proposed Standard. Specifically, the change from 3 to 4 calendar months in Table 1-4. 1. However, we believe that the terms Distributed and Non-Distributed need to be more clearly defined. 2. Clarification is also needed on an entities ability to use fault initiated trips as evidence for Table 1-5 - Control Circuitry.
Response: Thank you for your comments. **1. Please see Section 8.1.1 on pg 25-26 of the Supplementary Reference and FAQ document for discussions of the terms "distributed" and "non-distributed".** **2. Please see paragraph 7 in Section 8.1.2 of the Supplementary Reference and FAQ document for further discussion of this topic.**		
Xcel Energy, Inc.	Negative Ballot	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

Xcel Energy, Inc.	Negative Ballot	I appreciate the effort the SDT has invested in bringing PRC-005 to ballot and refer them to comments submitted by FirstEnergy. I agree with FE that PRC-005 encourages entities to set a low bar when developing protective system maintenance programs and will penalize those with robust programs that miss self-imposed schedules or targets.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Tennessee Valley Authority	Negative Ballot	1. It will take several years for TVA to implement checkback on 590 carrier blocking sets on the TVA system and not have to perform the PRC 005-2 requirement of verifying functionality every 4 months with no grace period. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We are also implementing an extensive PM test in October 2011 which will test 25% of the sets per year and will take readings of SWR, line loss, and receiver margin.
		2. TVA disagrees with the requirement to measure internal ohmic values of the station dc supply batteries every 18 months. The interval should be 36 months. Our experience from performing our routine maintenance program including cell impedance testing at 3-year intervals has been that the program is fully adequate in monitoring bank condition. An 18-month interval for internal resistance/impedance testing is an unnecessary burden.
		3. Are we required to test the trip circuit between the power transformer sudden pressure relay and the switch house or are we only required to test the trip circuit between the electrical sensing relays and the trip coils of the breakers?

Response: Thank you for your comments. 1. **The SDT feels that performing this maintenance activity at 4 month intervals will benefit the reliability of the BES. The Implementation Plan allows for 15 months after regulatory approvals for entities to implement the program per PRC-005-2. You may also find that performance-based maintenance (per Requirement R2) useful.** 2. **The SDT believes the required 18 month interval is better in line with accepted industry practice. Please note that for VLA batteries, an entity may entirely avoid internal ohmic measurements by implementing a VLA maintenance program using 18 month visual inspections and 6 yr capacity tests.** 3. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.**		
Northeast Power Coordinating Council		The focus of the industry is on the field procedures necessary to ensure that protection systems are maintained and tested. This includes the verification that settings have been applied correctly. The accuracy of the settings calculated needs to be validated, and that step should be considered for inclusion in this Standard.
Response: Thank you for comment. **Validating the accuracy of settings calculations is more properly a design function and not a maintenance function. The SDT agrees that validating relays are left with the intended settings programmed in is important; as such, Row 1 and Row 2 of Table 1-1 require that settings be verified to be as specified.**		

PNGC Comment Group		Thank you for the opportunity to comment on the draft Standard PRC-005-2 - Protection System Maintenance. While the feedback from the last round of comments is appreciated, we still cannot support the standard as written due to our concerns outlined here. We appreciate the work that NERC has put into a new standard to encapsulate and replace the current PRC-005, PRC-008, PRC-011 and PRC-017. But, we believe that the draft Standard needs one important revision before the NERC Board of Trustees should approve it. Specifically, NERC should revise the draft version of PRC-005-2 so that the beginning of Section 4.2 reads as follows: “4. 2. Facilities:Protection Systems that (1) are not facilities used in the local distribution of electricity, (2) are facilities and control systems necessary for operating an interconnected electric energy transmission network, and (3) are any of the following:”This revision is necessary to capture the limits that Congress placed on FERC, NERC, and the Regional Entities in developing and enforcing mandatory reliability standards. Specifically, Section 215(i) of the Federal Power Act provides that the Electric Reliability Organization (ERO) “shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System.” And, Section 215(a)(1) of the statute defines the term “Bulk-Power System” or “BPS” as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.” With this language, Congress expressly limited FERC, NERC, and the Regional Entities’ jurisdiction with regard to local distribution facilities as well as those facilities not necessary for operating a transmission network. Given that these facilities are statutorily excluded from the definition of the BPS, reliability standards may not be developed or enforced for facilities used in local distribution. In Order No. 672, FERC adopted the statutory definition of the BPS. In Order No. 743-A, issued earlier this year, the Commission acknowledged that “Congress has specifically exempted ‘facilities used in the local distribution of electric energy’” from the BPS definition. FERC also held that to the extent any facility is a facility used in the local distribution of electric energy, it is exempted from the requirements of Section 215. In Order No. 743-A, FERC delegated to NERC the task of proposing for FERC approval criteria and a process to identify the facilities used in local distribution that will be excluded from NERC and FERC regulation. The critical first step in this process is for NERC to propose criteria for approval by FERC to determine which facilities are used in local distribution, and are therefore not BPS facilities. The criteria to be developed by NERC must exclude any facilities that are used in the local distribution of electric energy, because all such facilities are beyond the scope of the statutory definition of the BPS, which establishes the limit of FERC and NERC jurisdiction. Accordingly, it is critical that NERC draft the new PRC-005-2 standard to expressly exclude facilities used in local distribution. NERC must also expressly exclude from PRC-005-2 those facilities “not necessary for operating an interconnected electric energy transmission network (or any portion thereof)”. Similar to the local distribution exclusion, the facilities not necessary for operating a transmission network are not part of the BPS and therefore must be expressly excluded from the standard. We understand, but disagree with, the argument that, because the FPA clearly excludes local distribution facilities and facilities necessary for operating an interconnected electric transmission network from FERC, NERC, and Regional Entity jurisdiction, it is not necessary to expressly exclude these facilities again in reliability standards. This approach might be legally accurate, but could lead to significant confusion for entities attempting to implement the new PRC-005-2 standard. There are numerous examples of Regional Entities, particularly WECC, attempting to assert jurisdiction over such facilities, and regulated entities face significant uncertainty as to which facilities they should consider as within jurisdiction. Clarifying FERC, NERC, and Regional Entity jurisdiction in the BES definition, even if such clarification is already provided in the FPA, would avoid such problems under the new PRC-005-2 standard. Again, we appreciate the work NERC has put in so far on a new Standard. We look forward to working within the drafting process to help implement our recommended revision.

Response: Thank you for your comment.

Other than the requirement relating expressly to UFLS/UVLS Protection Systems, the Applicability currently expressly addresses Protection Systems applied for the purpose of detecting BES faults.

To the degree that such Protection Systems may be located on non-BES components, and as the Applicability addresses UFLS/UVLS systems, the SDT has received the following position from NERC Legal:

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 covers users, owners, and operators of bulk-power facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES.

Bonneville Power Administration		1. BPA understands that the VSLs for R3 are based on the percentage of unresolved maintenance issues that an entity has failed to initiate a resolution for. This approach penalizes an entity for having less unresolved maintenance issues. For example, if an entity has only one unresolved maintenance issue and it failed to initiate a resolution for it, it would have failed to initiate a resolution for 100% of its unresolved maintenance issues, which would be a severe VSL. If another entity had 100 unresolved maintenance issues, and it failed to initiate resolution on ten of them, it would have failed to initiate a resolution on 10% of its unresolved maintenance issues, which would be a high VSL. Most likely, the first entity is doing a better job with its maintenance than the second entity, but the first entity receives a more severe penalty. The VSL for R3 is not an accurate measurement of a maintenance program's effectiveness and needs to be revised. BPA recommends removing the entire "Unresolved Maintenance Issue" topic from the standard. 2. In Table 1-1, it is not clear when a microprocessor relay meets the requirement for internal self-diagnosis and alarming. It is not clear that any microprocessor relay with a relay failure alarm would meet this requirement. 3. BPA believes that it seems like an omission in Table 1-1 for unmonitored microprocessor relays, the verification of settings is not included as a maintenance activity. 4. BPA would also like to recommend clarifying language stating that the owner of the asset is the responsible entity.

Response: Thank you for your comments. 1. **The SDT believes that, if a component cannot be returned to “good working order” during the performance of the maintenance program as defined within the entity’s criteria, the maintenance program must include those actions necessary to restore the component (and thus the Protection System) to good working order. Therefore, the topic of “Unresolved Maintenance Issues” cannot be removed from the standard. The VSL for the old Requirement R3 (now Requirement R5) has been revised to indicate gradations on the actual count of violations of this requirement, rather than percentages.** 2. **Microprocessor relay failure alarms meet this requirement as long as the alarm is sent back to a location where corrective action can be initiated.** 3. **The first maintenance activity listed on Table 1-1 is to validate that relay settings are as specified and this statement is applicable to unmonitored microprocessor relays. The activity has been revised to clarify.** 4. **The preface paragraphs for R1, R2, R3, R4, and R5 each state that the Transmission Owner, Generator Owner, and Distribution Provider are responsible for implementation of the associated requirements.**		
FirstEnergy		1. We remain concerned with the proposed draft version of Requirement R3 as well as the SDT developed statements in the Supplementary Reference & FAQ. The SDT's approach sends industry the wrong message; a message that entities should not go beyond what is in the text of the standards and that in some cases they can even be found non-compliant by failing to meet their own more stringent internal practice. We have sent NERC Staff and Drafting Team leaders a separate document detailing our concerns as well as proposed redlines to the standard. The separately provided document can be viewed as FE’s ballot comments.

		2. FE supports the standard from a technical standpoint but offer the following additional comments and suggestions: A clarification to the supplementary reference document is necessary regarding Maintenance Activities specified for electromechanical lockout and/or tripping auxiliary devices, as specified in Table 1-5 of the standard. The standard states, “Verify electrical operation of electromechanical trip and auxiliary tripping devices” which must be performed every 6 years. A question was asked during the September 15th Webinar requesting clarification of what “verify electrical operation....” meant. The verbal response from the SDT member was that this involves verifying that the relay actuates, but does not require verification that its contacts changed state. However, the answer to the question at the bottom of page 29 and top of page 30 in the Supplementary Reference and FAQ (dated July 29, 2011) implies that checking the contacts is necessary. The following statement in the published answer makes this clarification request necessary; “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” This statement implies that if outputs to annunciators and DME inputs do not need to be checked, then the other outputs do need to be checked. Verification of the auxiliary tripping relays appears to be covered in Table 1-5 of the standard under the "Unmonitored control circuitry associated with protective functions" section at 12 calendar years. Thus, we ask the SDT clarify in the supplementary reference the type of maintenance activities required for electromechanical lockout and/or tripping auxiliary devices to satisfy the requirements of Table 1-5 of the standard. Since the standard specifically dictates the output contacts verification for protective relays under Table 1-1, the output contacts of aux tripping relays is left up to interpretation. Therefore, we suggest the following statement be added after “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” on page 30 of the document: “Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the ‘Unmonitored control circuitry associated with protective functions" section’ at 12 calendar years.”

Response: Thank you for your comments. **1. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **2. Output contacts and auxiliary tripping relays that are not part of a trip path or essential for proper operation of an SPS need not be tested per this standard. The Supplementary Reference and FAQ document will be revised as you suggest.**		
Southwest Power Pool Standards Review Group		1. Please update Appendix B, Drafting Team Members, of the Supplementary Reference document. 2. We request that the detail for the breaker failure protection for generator protection in the bulleted list at the bottom of page 31 and the top of page 32 of the Supplementary Reference document be removed. We are not sure what the SDT is looking for here since there are several types of breaker failure protection. 3. We ask that Section 4.2.5.4 of the draft standard under the Facilities be modified to read 'Protection Systems that trip the generator for generator-connected station service transformers for generators that are part of the BES.' 4. We suggest that Section 1.3 Data Retention be rewritten to provide clarification that no data prior to the date of the last audit need be retained.

Response: Thank you for your comments. **1. The list of SDT members has been updated.** **2. The preface to the list of relays to which you refer is as follows: “Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:”. The SDT was merely attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included.** **3. In consideration of your comment and those of others received, the SDT has revised Section 4.2.5.4 as requested.** **4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**		
Florida Municipal Power Agency		The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.

Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		
Pepco Holdings Inc & Affiliates		Requirement 3 and the Supplementary Reference Document indicate that an entity should be held to its internal PSMP (especially for a time based program) even if the plan is more stringent than the NERC standard. This would be a deterrent for initiative and for excellence and punish utilities for going above the standards and performing best practices. It also tends to drive the industry to lowest common denominator practices. R3 and the accompanying Supplementary Reference Document should be appropriately revised to reflect that entities would only be held auditably accountable for the minimum requirements as stated in the standard and associated documents.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
MRO's NERC Standards Review Forum		a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES."

		b. Data Retention, Section 1.3 (concerning R2 and R3) requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent (past) test record. An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years. Recommend retention to be the most current record or all records since the last audit.
		c. Table 1-5 requires a maintenance activity to, “Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Recommend this be changed to, “Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, change the wording to, “Electrically operate each interrupting device every 6 years.” While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren’t configured to test independently. Isolating one trip coil from the other may include “lifting a wire” that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn’t practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don’t know which trip coil operated, then we have a “one off” device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.

		d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, monitor circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) - this ensures the operating linkages aren't bound and the breaker will operate. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications).
		e. Change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years". 1) The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years.2) In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays.

		f. In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." A recent compliance application notice (CAN-0012) indicated that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. Please provide clarity on CAN-0012 is applicable to PRC-005-2?
		g. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words "affecting the reliability" be removed from the purpose statement
		h. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months
		i. In the tables for dc Supply the term "unit-to-unit" is used along with "intercell" when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be "intercell". It is recommended that the "unit-to-unit" term be removed to avoid confusion regarding what is to be verified.
		j. The NSRF would like to extend our thanks to the drafting team. The 96 page Supplementary Reference document allows us to discuss these issues before the standard is approved, instead of as a potential violation later. Excellent job!

Response: Thank you for your comments.

a) The SDT has modified paragraph 4.2.5.4 as you suggest.

b) In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.

c) The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.

d) The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.

e) The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such.

f) The CAN cited applies to PRC-005-1, not PRC-005-2. The SDT intends that the Implementation plan associated with PRC-005-2 will govern compliance to PRC-005-2 during the transition to the new standard.

g) The purpose of the standard expresses the general intent of the standard, and is further clarified by the Applicability.

h) The SDT believes that the 6-month interval is appropriate for these activities.

i) The term “unit-to-unit” is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar. The SDT does not believe this terminology causes wide spread confusion.

j) Thank you.

Arizona Public Service Company		While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. In addition, when technology changes for the better, industry will need the flexibility to optimize use of the new technology. Lastly, the more often protection equipment is taken out of service for testing, the more often the line is vulnerable. The balance between the correct amount of testing and correct amount of time the equipment is in the field and in service is an important consideration when assuring the reliability of the BES. APS suggests the general principles of the following two papers be applied to more equipment types than microprocessor relays with self test capabilities. 1) 'An Improved Model for Protective-System Reliability,' P.M. Anderson and S.K. Agrawal, Power Math Associates, Inc., IEEE Transactions on Reliability, Volume 41, No. 3, September 1992;2) 'Philosophies for Testing Protective Relays,' J.J. Kumm, et. al., Schweitzer Engineering Laboratory, Inc., 48th Annual Georgia Tech Protective Relaying Conference, May 1994.
Response: Thank you for your comments. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. Wherever possible, the SDT has provided entities with the flexibility to utilize capabilities of emerging technologies by using condition-based maintenance where effective, and also by using performance-based maintenance should an entity wish to modify their intervals based on past performance.		
Southern Company Generation		1) For Table 1-1 and Table 3, consider adding "(internal to the relay)" to the microprocessor relay 6 calendar year maintenance activities to clarify that these maintenance activities are not related to items external to the relay).
Response: Thank you for your comments. Since the component type being addressed is the protective relay itself, it seems that the clarification you request is unnecessary.		

Tacoma Power		1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.
		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station DC supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program developed for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.

		5. In Table 1-2, there is a maintenance activity related to communication systems to “verify essential signals to and from other Protection System components.” It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to “verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.” This language is consistent with that used for protective relays in Table 1-1.
		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which ‘performance criteria’ are ‘pertinent.’ Additionally, it is unclear if an entity must document the ‘communications technology applied’ and the associated ‘performance criteria’ in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms ‘resistance’ and ‘ohmic values.’ If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms ‘battery terminal connection resistance’ and ‘unit-to-unit connection resistance.’ If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term ‘resistance’ with ‘impedance.’
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.

		11. Referring to Table 1-5, no periodic maintenance is required for "control circuitry whose continuity and energization or ability to operate are monitored and alarmed." It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for "unmonitored control circuitry associated with protective functions." It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.
		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.

Response:	**Thank you for your comments.**
	1. The SDT agrees with your observation and has changed the relevant parts of the Implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals.
	2. The SDT agrees with your observation and revised the Implementation plan to clarify.

	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.
	5. The SDT agrees with your suggestion and has changed the standard accordingly.
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.
	7. As utilized on Table 1-4, the term "ohmic value" is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term "ohmic value" is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term "resistance" as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.

	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.
	14. As timing is critical to proper Protection System function, timers are considered protective relays.

Progress Energy		1. Standard, Table 1-4(a), second sentence under Component Attributes, should state "Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded...." As written, the statement does not include the phrase "UFLS and." I believe it should. 2. Supplemental, Section 13, 2nd paragraph, first sentence should state: "...device match the minimum requirements listed in Tables 1 and 3."
Response: Thank you for your comments. **1. The SDT agrees. Table 1-4(a) has been modified as you suggest; this text has been relocated to the header of the table.** **2. The SDT agrees and has modified the Supplementary Reference and FAQ document as you suggest.**		

Western Area Power Administration		Comment 1:Western Area Power Administration does not agree with penalizing utilities for implementing maintenance programs that exceed the requirements defined in the NERC Standard PRC-005-2 maintenance tables. Although the intent of the language in the Supplementary Reference and FAQ document may have been to allow evolving maintenance programs to include condition-based and performance based maintenance in their programs, penalizing utilities with more stringent programs will more likely provide a disincentive for program development. Utilities will discontinue any additional maintenance activities that could put them at risk for non-compliance. This will cause maintenance programs to stagnate and new maintenance ideas to improve system reliability to not be implemented. It is the opinion of the Western Area Power Administration that the following text should be removed from the Supplementary Reference and FAQ document and entities should be audited to the minimum requirement of the standard regardless of their individual programs. Recommendation: Remove the following text from the Supplementary Reference & FAQ document:1. Page 26 - The bullet “If your PSMP (plan) requires more activities then you must perform and document to this higher standard.” 2. Page 27 - The bullet “If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.” 3. Page 27 - The paragraph “It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity’s more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity’s PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.” Revise R3 of PRC-005-2 and add statement to the Supplementary Reference & FAQ document.1. R3: Each Transmission Owner, Generator Owner and Distribution Provider shall implement and follow its PSMP plan within the prescribed intervals of Tables 1, 2 and 3. and correct any unresolved maintenance issues.2. FAQ: Any utility maintaining Protection System equipment that exceeds the requirements and tables because of historical testing data and/or failure documentation should not be held non-compliant or penalized for not meeting its PSMP, as long as they do not exceed the maximum allowable intervals or meet the minimum maintenance activities of the standard.

		Comment 2:R3 of PRC-005-2 states "Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues." The Western Area Power Administration would like more clarification on potential data request for requirement R3 of PRC-005-2. Because the requirement uses the term initiates resolution, the entity could make the assumption that providing just a list of maintenance request for unresolved maintenance issues will serve to prove compliance. Although it would seem implied that whatever method used to initiate resolution would lead to some type of corrective maintenance, the requirement does not make that absolutely clear. To ensure the maintenance practices are meeting the intent of the requirement, the requirement needs to clarify the expectations for completing corrective maintenance that was initiated to resolve maintenance issues. Recommendation: Add additional clarification to Supplementary Reference & FAQ document to further clarify expectation for this requirement.

Response: Thank you for your comments.

1. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.**
2. **Additional clarification has been added to the Supplementary Reference and FAQ document. Additional examples have also been added to the Measure for this Requirement.**

PacifiCorp		1. The data retention requirement for producing evidence that the entity performed maintenance for the 2 most recent maintenance intervals is excessive. As an example, if a registered entity's maintenance/test interval is 12 years, such entity may be required to keep records for up to 35 years. PacifiCorp recommends a revision to the data retention requirement to provide for either a maximum retention period of 10 years or, in cases in which the interval exceeds 10 years, the most recent maintenance/test cycle only. 2. The requirement to identify all PTs is very onerous and not needed to verify maintenance compliance and therefore serves a limited reliability benefit. PacifiCorp believes that, as long as a registered entity can demonstrate that it can verify that all CTs/PTs providing input into a Protection System have been tested and maintained according to its established procedures, then a separate and independent requirement to maintain a list of these devices is not necessary. As an example, if an entity performed their protection system maintenance on a "scheme" basis, and as part of that maintenance documentation identified all CT's and PT's providing input into the scheme and verified their accuracy, then having a "master list" would provide no benefit. A list of all CT's associated with one device such as a circuit breaker would have little value in this case as these CT's may provide input into multiple relay schemes and would not be maintained on an individual circuit breaker basis.

Response: Thank you for your comments.

1. **In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**
2. **The SDT does not believe the current standard contains a "separate and independent requirement to maintain a list of these devices". As your comment correctly indicates, if an entity can provide evidence that the inputs from all CTs and PTs are accurately being received by the associated relays for in scope Protection Systems, this is acceptable. It is up to the entity to best determine how to track this – whether by a "master list" of CTs and/or PTs, on a "scheme" basis, by physical location of the instrument transformer, or some other effective tracking method.**

Saft America, Inc.		Saft Comments on NERC Standard PRC-005-2 - Protection System Maintenance - Please find herein Saft's comments to NERC PRC-005-2 regarding ohmic testing of Nickel-Cadmium (NiCad) batteries. As drafted, the proposed NERC Standard PRC-005-2 will lead to the removal of high quality, reliable NiCad battery power units from Protection Systems, which is counter to the NERC stated purpose of PRC-005-2, which is to 'document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.' There is broad consensus within the battery industry that ohmic testing of Valve Regulated Lead-Acid (VRLA) batteries provides a means for trending the condition of the battery over time. Such a consensus does not exist for Vented Lead-Acid (VLA) batteries, because ohmic measurements are more difficult to trend, thereby providing a go/no-go assessment of the battery's availability at that precise moment in time, rather than a measure of VLA battery condition. Ohmic testing of NiCad batteries provides a similar go/no-go assessment to ohmic testing of VLA batteries. As with VLA batteries, ohmic testing of NiCad batteries does not provide meaningful trending information, but rather provides a status update of battery condition at a specific moment in time. Due to the similar information provided by ohmic testing of VLA and NiCad batteries, Saft recommends that ohmic testing of NiCad batteries be included under the Maintenance Activities for NiCad batteries. Specifically, Saft recommends that NERC add the following language to the Maintenance Activities column in Table 1-4(d), 'Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline', at a maximum maintenance interval of 18 months, as in the requirement for VLA batteries noted in Table 1-4(a).

Response: Thank you for your comments.

The SDT disagrees. The SDT is aware of studies that indicate a correlation between ohmic measurements and battery condition (or remaining life) for VLA and VRLA batteries when trended against a baseline ohmic measurement taken when the battery was new. These same studies concluded no such correlation exists for NiCad batteries. We are unaware of any published studies that conclude otherwise for NiCad batteries. The standard does not favor one technology over another but simply allows flexibility in testing techniques when the attributes of a technology allow for technically justifiable application of that flexibility and achieve the objective of the standard.

Nebraska Public Power District		a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES."
		b. Section 1.3 requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent test record. An audit should be focused on the present day and not in the past. Is an entity compliant today and not can we find a way to issue a fine for something in the past? An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. Why should they be forced into testing again and incurring additional expense for customers only to have two tests available for an auditor? This does not enhance reliability. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years! Hypothetically, if we have a test record from ten years ago, but we don't have the record from 24 years ago, how does that adversely affect the reliability of the BES today? The standard should focus on - Are we compliant today?

		c. Table 1-5 requires a maintenance activity to, "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Recommend this be changed to, "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, change the wording to, "Electrically operate each interrupting device every 6 years." While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren't configured to test independently. Isolating one trip coil from the other may include "lifting a wire" that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn't practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don't know which trip coil operated, then we have a "one off" device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation - this is a recipe for a compliance violation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.

		d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, including us, monitor our circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) - this ensures the operating linkages aren't bound and the breaker will operate. We have many maintenance activities performed on devices for the BES that do not require a NERC standard. If a utility chooses not to perform best practice maintenance, customers will experience more frequent and longer outages. The utility will receive customer feedback on outages which should translate into the utility increasing its maintenance. In other words, we don't have to include a functional test as a NERC requirement. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications).

		e. Recommend NERC provide training specifically on how to audit PRC-005-2 to auditors in all eight Regional Entities. PRC-005 is the most violated standard since enforcement began on June 18, 2007. This is an excellent opportunity for NERC to get all eight regions on the same page for what to audit. NERC provides training on standard auditing guidelines and sample selection, but doesn't provide training on how to audit specific standards. RSAW's and CAN's have been an attempt to get consistency across the regions, but differences are still obvious. NERC is in the perfect position to observe potential violations (PV) from an auditor and as a PV is written that goes beyond the standard or is not in accordance with the initial training; NERC can dismiss the PV and retrain the auditor. Auditors aren't perfect, nor are any of us. Training is a basic tool for the auditor to perform their job properly.
Response: Thank you for your comments **a) The SDT has modified paragraph 4.2.5.4 as you suggest.** **b) In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.** **c) The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.** **d) The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.** **e) The SDT will forward this comment to NERC Compliance for their consideration.**		
Exelon		
Texas		(1) General - defined terms need to be capitalized throughout this standard.

Reliability Entity		(2) Requirement R3 only addresses initiation of resolution to any Unresolved Maintenance Issues. Requirement R3 should require completion of corrective action to deal with Unresolved Maintenance Issues within a reasonable timeframe.
		(3) Section 1.3, Data Retention, should require each entity to keep all versions of its PSMP that were in effect since its last compliance audit, in order to demonstrate compliance at all relevant times (not just the current version).
		(4) In the Severe VSL for R2, add "Annually" to the second bullet under part 5.
		5) The VSLs for R3 should contain a time frame (annual?). The second part of these VSLs should refer to initiation and completion of resolution of Unresolved Maintenance Issues. (See comment on Requirement R3 above.)
		(6) Consider making the R3 VSLs based on a percent of the number of maintenance activities required by the PSMP in a stated time period, rather than on a percent of the total number of Components.
		(7) There is no maintenance activity listed to verify that protection system component settings meet the design intent of the protection system. In other words, there is no required activity to confirm that the "specified" settings are correct and appropriate. This introduces a potential reliability gap into the Protection System maintenance program.
		(8) In Table 1-1, the term "acceptable measurement of power system input values" is somewhat vague. A tolerance value or reference to industry standards should be provided.
		(9) In Table 1-3, the activity should include verifying that the current and voltage signal values are within design tolerances, not just that signal values are present.
		(10) In Table 1-4(a) Component Attributes - the reference to UFLS systems is missing in the exclusion that refers to UVLS systems. (UFLS is included in Tables 1-4(b) through 1-4(d).)

		(11) In table 1-4(f), there should be a reference to "alarming" in addition to "monitoring" in the first cell of the next-to-last row
		(12) In table 1-4(f), why is the last row limited to VRLA station batteries? Should the same exclusion apply to VLA batteries?
		(13) In Table 1-5, a "12 calendar year" interval is too long for "Unmonitored control circuitry associated with SPS" and "Unmonitored control circuitry associated with protective functions." We suggest this be changed to 6 years. Similar unmonitored attributes related to battery maintenance have a 6 calendar year interval.
		(14) In Table 2, the phrase "location where corrective action can be initiated" is unclear, and we suggest that a more definitive description be used. Also, why is the word "DETECTION" in all-caps?
		(15) In Table 3, the maintenance activity should include verifying that Protection System Component settings meet the design intent of the Protection System. For example, any reclosing function should be disabled on UFLS and UVLS relay systems.
		(16) In Table 3, In Table 1-1, the term "acceptable measurement of power system input values" is somewhat vague. A tolerance value or reference to industry standards should be provided.
		(17) The Implementation Plan is overly long and complicated. Entities (including Regional Entities) will have to track and apply multiple versions of this standard for 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable, recognizing that for some Components no action will be required under the standard for a number of years.

Response:	**Thank you for your comments.**
	1. The SDT will attempt to properly capitalize defined terms throughout the standard.

	2. The SDT specifically chose the phrase "initiate resolution" because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues or what documentation might be sufficient to provide proof that effective corrective action has been initiated. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.
	3. The SDT agrees with your observation and has modified the data retention requirements accordingly.
	4. The SDT agrees with your observation and has modified VSL for Requirement R2 accordingly.
	5. The percentages relate to the number of violations of the respective requirement reported within the compliance monitoring period relative to the number of components within that component type. PRC-005-2 only requires the entity "… initiate resolution" of the issue found. The SDT recognizes that performance of the activities necessary to resolve an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. It is for this reason the SDT crafted the requirement to only require initiation of the process.
	6. The SDT disagrees. The entity must complete all required activities on any specific component in order to be compliant, regardless of the number of activities scheduled for that component.
	7. The SDT believes that adequacy of settings is more properly a design issue and should not be included in a maintenance standard.

	8. The SDT believes it is more appropriate for entities themselves to establish acceptance criteria that meet the performance requirements necessary for the proper operation of their Protection Systems.
	9. The action, "verify" is specified within the PSMP definition as "Determine that the component is functioning correctly." Therefore, the SDT believes that the suggested change is unnecessary.
	10. The SDT agrees. Table 1-4(a) has been modified as you suggest. The modified text has been moved to the header of the tables.
	11. The SDT agrees. Table 1-4(f) has been modified as you suggest.
	12. The SDT agrees. Table 1-4(f) has been modified as you suggest.
	13. The SDT disagrees and believes that the 12 year requirement for SPS's is in alignment with the Table 1-5 row 4 requirement for testing of unmonitored trip paths for control circuitry with protective function in other Protection Systems.
	14. Based on a lack of other comments received on this topic, the SDT believes that this description has sufficient clarity. The word "detection" on Table 2 has been corrected to lower case font.
	15. The first row of Table 3 requires that settings be verified to be as specified. The SDT believes this to be a proper maintenance function but that the determination of the adequacy of settings (or, for that matter, design criteria) is more properly a design issue and should not be included in a maintenance standard.
	16. The SDT believes it is more appropriate for entities themselves to establish acceptance criteria that meet the performance requirements necessary for the proper operation of their Protection Systems.

		17. The SDT disagrees. It is not practical for all entities to rapidly transition all of their protection systems to the new program, especially with some component types on maintenance intervals of up to 12 years. Nonetheless, all in scope Protection Systems must either be being maintained by either a PRC-005-1 program or a PRC-005-2 program. The SDT believes the graded approach mapped out in the Implementation plan is practical. Finally, if in order to lessen the complexity of documentation requirements, an entity wishes to implement PRC-005-2 on a more rapid rate than laid out in the Implementation plan, they are free to do so.
Central Lincoln		We are concerned about what exactly "initiate resolution" means in R3. We foresee this being a potential area of disagreement between registrants and CEAs when a registrant believes an open work order suffices and the CEA wants to see schedules or purchase orders. Neither M3 nor the FAQs address this.
Response: Thank you for your comment. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues or what documentation might be sufficient to provide proof that an entity is correcting these issues.**		
Dynegy Inc.		For Facilities listed under 4.2, are Reserve Auxiliary Transformers supposed to be included?

Response: Thank you for your comment.

No, Reserve Auxiliary Transformers or system connected station service transformers were intentionally removed from the Applicability in a previous draft. Generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. and are thus included. Reserve auxiliary or system connected station service transformers Protection Systems will not directly result in the trip of a generator and as such are omitted from the Applicability of the standard.

American Electric Power		1. As it stands, if an entity adopts a more stringent maintenance program but fails to meet it, that entity could be found non-compliant despite continuing to abide by the minimum requirements of the standard itself. Entities should have the ability, if they so choose, to include additional maintenance activities or more stringent intervals than specified within the standard without concern of penalty in the event they are unable to accomplish them. In short, entities should only be audited against the requirements stated within the standard. Table 1-3 of the standard lists the minimum required maintenance activities for voltage and current sensing devices as "Verify that current and voltage signal values are provided to the protective relay." 2. Consistent with Table 1-3, Section 15.2.1 of the Supplementary Reference states that an entity "...must verify that the protective relay is receiving the expected values from the voltage and current sensing devices..." The Supplementary Reference further offers examples of how this requirement may be satisfied with most examples referencing the need to verify the signal at each relay in the circuit. We recognize the need to verify a voltage signal at each protective relay, as these devices are wired in parallel and an open circuit at one location may not impact the other devices on the circuit. However, we do not agree that there is a need to verify a current signal at each protective relay. Current devices are wired in series, and an open circuit at any location will impact all other devices on the circuit. For this reason, a single measurement of the current circuit is sufficient. We recommend updating Table 1-3 and the supplementary reference to account for the different physical characteristics of voltage and current circuits. 3. This standard encompasses a very broad range of component types and functionality across broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application. Other standards have applicability for certain thresholds of voltage levels, etc. Why not this standard as well?

Response: Thank you for your comments.

1. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.
2. An open circuit is not the only failure mechanism for a CT secondary circuit. Grounded CT secondary wiring can result in situation where accurate current is present in the part of the secondary circuit upstream of the ground but current would be shunted to ground and might not pass through devices downstream of the ground.   Entities should not interpret PRC-005-2 as specifying "how" to test but rather that PRC-005-2 only specifies "what" to test. Entities are free to determine creative ways to fulfill requirements.
3. VSLs characterize "how bad did you miss a requirement", rather than on the impact to the BES. The percentages indicated in the VSLs follow demarcation guidelines given by NERC to Standard Drafting Teams. With the magnitude of the total number of Protection System components for many entities likely to be very large, exceeding 5% of that total equates to failing to perform maintenance and testing on a (potentially) large number of components, and should be reflected by a Severe VSL. The SDT further believes that this standard should be applied uniformly to the applicable facilities, rather than stratifying it to reflect different system voltages.

Lincoln Electric System		In reference to the zero tolerance policy evident within PRC-005-2, LES offers the following suggestion: Set up an annual review of a random set sample (20% for example) of Protection System equipment to self-verify compliance. If issues arise, allow the entity the opportunity to correct the issue, make the necessary procedural and/or documentation adjustments and not be considered non-compliant. The idea is to allow entities the opportunity to continually improve their practices and procedures; in essence, allow them to show they are attempting to follow a "culture of compliance". If habitual problems arise, then non-compliance will be evident. One example that justifies this approach is software glitches or improper programming. As more and more systems become automated, scheduling of maintenance will be done automatically through various types of software. If a program has even one attribute set incorrectly, it could not function as intended and would potentially set up incorrect intervals for maintenance and testing. It was not intended this way by the entity and they are not intentionally disregarding the standards, but could nevertheless be put in a situation where a maintenance interval is missed. An annual review would catch things like this and allow an entity to continuously improve their program without self-reporting. This concept is expanded from a current draft version of several CIP standards; therefore, it is being at least considered by other drafting teams.
Response: Thank you for your comments. **The NERC criteria for VSLs do not permit any level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 provides for an escalating degree of severity for increasing degrees of non-compliance.**		
NIPSCO		The new standard itself, the implementation plan and supplemental reference/FAQ makes up more than 100 pages of material. Granted that several standards are being combined here, still it is simply too involved to monitor. And there is still not enough detail in the standard leaving items which are ambiguous and open to interpretation, and therefore open to fines. In order to remove such interpretation, maintenance documentation will need to be precise and extensive. This will necessitate more and more staff to control and validate data. Adding staff is great but it does not seem to ensure that there is increased reliability.

Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance.**		
Entergy Services		We understand and disagree with the SDT position on the following recommendation. We do not agree with proposed Section 4.2.1 applicability since it captures only a portion of the previously approved applicability Interpretation (PRC-005-1a) which was developed specifically for PRC-005-1. We suggest the draft standard be revised to conform to the wording in the Interpretation: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements."
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Independent Electricity System Operator		The IESO disagrees with the concept that auditors use the standards as minimum requirements and evaluate compliance based on a registered entity's own governance. We believe that the entity could be found non-compliant with Requirement R3 if they fail to follow the internal maintenance intervals established in their PSMP, even though actual maintenance intervals are no less frequent than the prescribed maximum intervals established in the draft standard. The potential for such a finding will discourage conscientious entities from setting higher internal targets for their planned maintenance and promote compliance with only the minimum requirements of the standard. We therefore propose the following revision to Requirement R3:R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. In the case of time-based maintenance programs, each Transmission Owner, Generator Owner, and Distribution Provider is permitted to deviate from its PSMP provided that actual maintenance intervals do not exceed those specified in Tables 1-1 through 1-5, Table 2 and Table 3. [Violation Risk Factor: High] [Time Horizon: Operations Planning]
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		

Liberty Electric Power LLC		With the development and publication of maximum maintenance and testing intervals (the Tables), there is no longer a reliability need for a RE to identify the associated maintenance intervals for Protection System Components. Further, REs who wish to perform these activities in shorter intervals than those allowed by the standard (See Supplementary Reference, page 27,"If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.")As noted in Question 5, if the entity completes all activities within the maximum interval allowed by the standard, there can be no reliability concern; if there is a reliability issue, then the table interval is incorrect. I would suggest the following changes.1. Change R1.2 to read "Identify any Protection System component where the RE is using a performance based maintenance interval. No batteries associated with the station DC supply component type of Protection System shall be included in a performance based system".2. Change R1.3 to read "The intervals for time-based programs are established in Table 1-1 through 1-5, Table 2, and Table 3".3. Change M1 to add the phrase "for performance-based components" after the words "maintenance intervals".4. In M1, replace the words "the type of maintenance program applied (time-based, performance based, or a combination of these maintenance methods)' with the words "the identification of any protection system components using performance based intervals".
Response Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		

Ameren		(1)Measure M3 on page 5 should only apply to 99.5% of the components. Please revise to state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. No one is perfect and it is impractical to imply perfection is achievable. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance". (2) An alternate approach regarding the unrealistic perfection of M3 is to correctly recognize that the protection of the primary BES is the objective. Most Protection Systems are redundant by design and the entity needs to be afforded the opportunity to show that a redundant component met the PSMP thereby providing the required protection. The entity should be allowed a reasonable time frame of one calendar increment to maintain the component in question. Our concern stems from the tens of thousands of components in a PSMP, and the reality that rarely but occasionally a data base error or outage scheduling issue may result in a very small number component exceeding their maximum interval. As long as the entity can show that BES protection was sustained and maintains the component quickly (e.g. within one calendar month of discovery), BES reliability has been maintained. (3) Now that FERC has approved the Project 2009-17 Interpretation, please acknowledge more directly in the Supplement that the 'transmission Protection System' that is now approved. NERC interprets "transmission Protection System," as it appears in Requirements R1 and R3 of PRC-004-1 and Requirements R1 and R2 of PRC-005-1, to mean "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."

Response: Thank you for your comments.

1. The NERC criteria for VSLs do not permit any level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 provides for an escalating degree of severity for increasing degrees of non-compliance.
2. Regarding redundancy, the SDT believes that it is important that redundant components be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment. It should be noted that misoperations not only occur for failure to operate for valid faults but also operation of a protection system for an invalid, non-fault condition. It is important that both components be maintained within the specified intervals to help preclude this second type of misooperation – e.g., over tripping of relays.
3. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.

Northeast Utilities		1. The definition of "Component" in PRC-005-2 Draft 1, states "Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component." However, in Section 15.2 of Supplementary Reference & FAQ it states: "The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample." Please consider reconciling these two sections (definition of "Component" and Section 15.2) to allow the entity to consider a relay as the single component versus the voltage and current sensing devices, and pursuant with Section 15.2 perform the voltage and current checks to the inventoried relays. This approach will ensure that the CT and PT check to each relay is performed. Section 15.2 of Supplementary Reference & FAQ states in the second paragraph "The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample." Please consider revising the last bullet in Section 15.2, paragraph 3 from "Any other method that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable" to "Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample." 2. As shown (see Figure A-2) and discussed in Appendix A of Supplementary Reference & FAQ list, there are four elements that are not verified. Following the identification of the four elements that are not verified, a practical solution is provided for testing methods on three of the four elements. Please provide a practical solution for the fourth element.

Response: Thank you for your comments.

1. **The SDT does not believe a discrepancy exists. CTs and PTs or other current and voltage sensing devices are indeed Protection System Components. Section 15.2 of the Supplementary Reference and FAQ document is describing a maintenance activity that is to be performed to validate proper function of that Component type. The Supplementary Reference and FAQ document has been revised to clarify.**
2. **Appendix A to the Supplementary Reference and FAQ document (with the imbedded figures) is intended to provide an example of the application of monitoring to minimize maintenance activities and maximize maintenance intervals, but is not intended to be a comprehensive treatise of the subject.**

MidAmerican Energy Company		1. The following comment was submitted in the last comment period: In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: " The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. The consideration of comments response to the above did not completely address the issue that led to the comment. In the Tables in PRC-005-2 there are maintenance items that an entity may not have had in their PRC-005-1 compliance program even though they did have a compliant maintenance program (e.g. battery continuity testing) for that Protection System component. As the transition is made to the PRC-005-2 requirement the above clarification should be made to better define what achievement of PRC-005-2 compliance is for that component.
		2. Section 4.2.2 includes UFLS systems installed per the ERO requirements - excluding any additional UFLS systems that a utility has on their system. Section 4.2.3 includes UVLS systems "installed to prevent system voltage collapse or voltage instability for BES reliability". It is assumed that this would only include UVLS systems required by the ERO, but it is not clear as to what is in scope. It is suggested that the wording of 4.2.3 be changed to match the wording in 4.2.2.
		3. In the implementation plan in the R2 and R3 requirements plans, in item a. of each there is a parenthetical statement regarding generating plant scheduled outage intervals. A similar parenthetical statement should be added to the b. and c. items of each of these plans.

		4. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words “affecting the reliability” be removed from the purpose statement.
		5. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months.
		6. In the tables for dc Supply the term “unit-to-unit” is used along with “intercell” when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be “intercell”. It is recommended that the “unit-to-unit” term be removed to avoid confusion regarding what is to be verified.

Response: Thank you for your comments. 1. **The SDT agrees with your comment and has modified the Implementation plan to better indicate that, for activities being added to an entity's program as part of PRC-005-2 implementation, evidence will be available to show only a single performance of the activity until a full maintenance interval has transpired following initial implementation.** 2. **Entities are required to install UFLS per PRC-007; there are no standards which require entities to install UVLS. However, if entities choose to install UVLS to meet minimum system performance requirements, several standards (including the current PRC-011 and the proposed PRC-005-2) apply. Section 4.2.3 is specifically intended to address these UVLS.** 3. **The SDT provided the allowance for generator plants to allow them until their first maintenance outage to begin program implementation. It is believed that the entity would then likely perform all maintenance on the protection system for a given generator, GSU and, if so equipped, generator connected station auxiliary transformer during that maintenance window. It seems unlikely that an entity would perform maintenance on only a portion of a protection system. Thus, the SDT concludes that inclusion of the parenthetical to the 2nd and 3rd bullets would only add confusion and provide little or no benefit to generator plants in the implementation of their program.** 4. **The purpose of the standard expresses the general intent of the standard, and is further clarified by the Applicability.** 5. **The SDT believes that a 6-month interval is appropriate for these activities.** 6. **The term "unit-to-unit" is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar. The SDT does not believe this terminology causes wide spread confusion.**		
Manitoba Hydro		-Definition of Protection System Maintenance Program: The definition included in the proposed PRC-005-2 is not the same as the definition provided in the document "Definition for Approval", which also includes items "Upkeep" and "Restore".
Response: Thank you for your comments. **The SDT agrees with your observation and will review the associated documents to attain consistency.**		

American Transmission Company		a) Change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 19, Row 1, Column 3 to: "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternatively, "Electrically operate each interrupting device every 6 years." Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). b) Change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years" The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years.In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. c) ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC is recommending a negative ballot since, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

Response: Thank you for your comments. a) **While the SDT agrees with much of your observation about circuit breaker operations, this standard applies to Protection System maintenance and per the Protection System definition does not include the entire circuit breaker. As such we are limited to exercising the trip coils and seeing that they have the intended effect on the interrupting device. A simple cycling of the breaker should have minimal impact on the scheduling of the entities breaker maintenance program.** b) **The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.** c) **As noted above, the SDT has modified Table 1-5 to remove other auxiliary relays, etc, from the 6-year activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification. However, the SDT believes that the other activities addressed in your comment need to be performed as reflected in Table 1-5.**		
Southern Company Transmission		Table 1-5: Need clarification on "continuity and energization or ability to operate". What does this mean?
Response: Thank you for comment. **This entry in Table 1-5 has been modified to "Control circuitry whose integrity is monitored and alarmed". Section 15.3 of the Supplementary Reference and FAQ document provides additional discussion on this topic.**		
Utility Services, Inc		Thank you for the opportunity to address the new documentation and for your efforts.
Response: Thank you for comment.		

ITC Holdings		ITC Holdings continues to object to the requirement to exercise auxiliary relays on a 6 year interval. We repeat our previous comments as follows: "It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplementary Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle." Previous responses from the SDT were: "The SDT believes that the appropriate interval for electromechanical devices such as aux or lockout relays should remain at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable." ITC requests that the statistical basis for the 6 year interval be published. If it is not clear that lockout relays and other auxiliary relays must be exercised on a 6 year interval, then the requirement should be changed to 12 years.
Response: Thank you for your comments. **The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification as you have suggested.**		
Ingleside Cogeneration LP		Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test.

Response: Thank you for your comments. **There are less intrusive ways to verify channel performance that do not require disconnecting communication terminations. It is up to the entity to determine specific maintenance techniques.**		
CenterPoint Energy		For the "Unmonitored control circuitry associated with protective functions", the Table 1-5 requirement is to "Verify all paths of the trip circuits through the trip coil(s) of the circuit breakers or other interrupting devices" every 12 calendar years. CenterPoint Energy recommends this requirement be revised to "No periodic maintenance specified". CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping. Likewise, CenterPoint Energy recommends the requirement in Table 1-5 to "Verify all paths of the control circuits essential for proper operation of the SPS" every 12 years be revised to "No periodic maintenance specified".
Response: Thank you for your comments. **The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.**		
Oncor Electric Delivery Company LLC		PRC-005-2 is a vast improvement over the vagueness of the existing standard (PRC-005-1), that the new standard makes compliance much easier than the present standard. The new standard recognizes the advances in relay technology and reliability, particularly the benefits of microprocessor based relays. The standard also provides greater flexibility on its implementation while recognizing the benefits of a performance based methodology, particularly as it relates to battery testing. The revised standard eliminates the requirement for a "summary of maintenance and testing procedures" which was vague and provided no real value to the registered entities. Operational and administrative efficiencies can be realized by consolidating the relay testing and maintenance requirements into one standard (PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0).
Response: Thank you for your comments.		

City of Austin dba Austin Energy		If a Registered Entity has a PSMP that is more stringent than the intervals in PRC-005-2, the Registered Entity should not be considered out of compliance if it fails to meet its internal interval but remains within the interval set forth in PRC-005-2.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
BGE		When the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue", it appears that the PRC-005-2 Protection System Maintenance / Supplementary Reference and FAQ document was not properly updated to reflect this change. There are inconsistencies throughout the entire document were the old term is still showing up instead of the new term, and vice versa.
Response: Thank you for your comments. **The SDT has attempted to correct the terminology inconsistencies you have mentioned between the Standard and the Supplementary Reference and FAQ document.**		
VRFs/VSLs		
Xcel Energy, Inc.	Negative Ballot	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

Ameren Services	Negative Poll	The VRF for R3 should be Low. Many entities presently do not perform some of the specified maintenance activities on some of their components. The risk to the BES is quite low as proven by the extremely reliable BES performance. We are not aware of such omissions in Protection System performance leading to widespread outages, cascading or uncontrolled separation. This coupled with NERC's insistence on 100% perfect completion of all maintenance for even the Lower VSL leads to an inappropriate and unjustified VRF/VSL combination.
Response: The VRF value of "high" stems from consideration of an entity not performing any maintenance and testing of their Protection System. Specifically, a "high" VRF, for a planning time horizon requirement, addresses violations of requirements that could directly cause or contribute to BES instability, separation, or cascading. While not every failure to properly perform maintenance WILL do these things, they can very well contribute to them, as evidenced by involvement of Protection Systems in every recent significant BES disturbance.		
Flathead Electric Cooperative	Negative Poll	do not believe the severe VSL should apply to distributed UFLS
Response: The VSL is a measure of the completeness of the execution of a requirement. Where a binary evaluation of compliance with a particular requirement is prescribed, the NERC VSL guidelines require the violation level to be severe. If the compliance can be demonstrated to be partially complete, a graduated violation severity level is allowed. The NERC Criteria for setting Violation Severity Levels states that it is preferable to have four VSLs for each requirement.		
Independent Electricity System Operator	Negative Poll	The IESO continues to disagree with the High VRF for R3 which asks for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.

Response: The VRF value of "high" stems from consideration of an entity not performing any maintenance and testing of their Protection System. Specifically, a "high" VRF, for a planning time horizon requirement, addresses violations of requirements that could directly cause or contribute to BES instability, separation, or cascading. While not every failure to properly perform maintenance WILL do these things, they can very well contribute to them, as evidenced by involvement of Protection Systems in every recent significant BES disturbance.		
Liberty Electric Power LLC	Negative Poll	The percentage structure on unresolved maintenance issues presents problems. Smaller entities are unlikely to ever have more than a handful of unresolved issues, meaning a single failure to initiate would automatically be a High VSL. There would also be a disincentive to close out issues from fear that "resolving" them could potentially increase a violation level on a discovered issue.
Response: The VSLs relating to Unresolved Maintenance Issues have been revised to graduated VSLs using a count of violations, rather than a percentage.		
Xcel Energy, Inc.	Negative Poll	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

END OF REPORT

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing Drafting Team – Nomination Period Open

September 1-23, 2011

The Standards Committee is seeking additional industry experts to serve on the Protection System Maintenance and Testing Drafting Team. While anyone may submit a nomination to participate on this team, the specific focus of this solicitation is to add members that represent smaller entities. This team is drafting revisions to PRC-005-1 Transmission and Generation Protection System Maintenance and Testing.

Nominees should have experience in developing, managing, or supporting a maintenance program or a testing program for one or more of the following:

- Generator protection systems
- Transmission protection systems
- Under-frequency load shedding equipment
- Under-voltage load shedding equipment
- Special protection systems

If you are interested in serving on this drafting team, please complete this nomination form **by September 23, 2011**.

Further details are included on the Project 2007-17 project page:
Project 2007-17 Protection System Maintenance

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Andy Rodriquez (via email) or at (404) 446-9741 or Wendy Sandberg (via email) or at (404) 446-9735.

RELIABILITY | ACCOUNTABILITY

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.

Description of Current Draft:

This is the second draft of the Standard. This standard merges previous standards PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and successive ballot.	March – April, 2012
2. Drafting Team Responds to Comments	May – June, 2012
3. Conduct recirculation ballot	June, 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion

on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

Countable Event – A Component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner

4.1.2 Generator Owner

4.1.3 Distribution Provider

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers used on generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

> ***Component Type*** *- Any one of the five specific elements of the Protection System definition.*

1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented Protection System Maintenance Program in accordance with Requirement R1.

For each Protection System Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System Components included within its time-based program in accordance with Requirement R3. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaints

1.3. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System Component Type.

For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	The responsible entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entities' PSMP failed to include the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to less than 4% within three years.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to less than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to less than 4% within five years OR 3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				• Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or less Unresolved Maintenance Issues.	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
		Unresolved Maintenance Issues.	Unresolved Maintenance Issues.	Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program...

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — July 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.

Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3
Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays
Excluding distributed UFLS and distributed UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) **Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Devices for SPS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used only for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic measurement and evaluation relative to baseline of battery cell/unit internal ohmic values is required to verify the station battery can perform as designed.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3) **Note:** Table requirements apply to all Control Circuitry Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 calendar years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with SPS.	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **Segment** population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.*

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.
5. If the Components in a Protection System Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee ~~approves~~approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.

Description of Current Draft:

This is the ~~first~~second draft of the Standard. This standard merges previous standards ~~PRC-005-1,~~ PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined ~~45~~30-day comment and successive ballot.	~~September – October, 2011~~March – April, 2012
2. ~~Conduct initial ballot~~Drafting Team Responds to Comments	~~October, 2011~~May – June, 2012
3. ~~Drafting Team Responds to Comments~~Conduct recirculation ballot	~~November – December, 2011~~June, 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency ~~that cannot be corrected~~identified during ~~the performance of the~~ a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a ~~segment~~Segment. A ~~segment~~Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A ~~component~~Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit ~~component~~Component is ~~very~~ dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit ~~components~~Components. Another example of where the entity has some discretion on determining what constitutes a single ~~component~~Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single ~~component~~Component.

Countable Event – A ~~component~~Component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action~~,~~ or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System ~~component~~Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission ~~Owners~~Owner

4.1.2 Generator ~~Owners~~Owner

4.1.3 Distribution ~~Providers~~Provider

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting ~~faults~~Faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via ~~generator~~ lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers ~~for~~used on generators ~~that~~which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: ~~Long Term~~Operations Planning]*

The PSMP shall:

~~1.1. Address all Protection System **component types.**~~

~~1.2.~~1.1. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System ~~component type.~~Component Type. All batteries associated with the station dc supply ~~component type~~Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

Component Type - Any one of the five specific elements of the Protection System definition.

~~1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5, Table 2, and Table 3.~~

~~1.4.~~1.2. Include ~~all~~the applicable ~~monitoring~~monitored Component attributes ~~and related maintenance activities~~ applied to each Protection System ~~component type~~Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

~~**Unresolved Maintenance Issue** - *A deficiency that cannot be corrected during the performance of the maintenance activity and requires follow-up corrective action.*~~

an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider ~~shall implement and follow its PSMP and initiate resolution of any **unresolved maintenance issues**.~~ that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

***Unresolved Maintenance Issue** - A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

~~***Component Type** - Any one of the five specific elements of the Protection System definition.*~~

R5. Each Transmission Owner, Generator Owner, and

Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a ~~current~~ documented Protection System Maintenance Program ~~that addresses all component types of its Protection Systems, as required by~~in accordance with Requirement R1.

For each Protection System ~~component type~~Component Type, the documentation shall include the type of maintenance ~~program~~method applied (time-based, performance-based, or a combination of these maintenance methods), ~~maintenance activities, maintenance intervals, and, for component types~~and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

~~M1.~~ For Component Types that use monitoring to extend the ~~intervals,~~ maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate ~~monitoring~~monitored Component attributes as specified in ~~Requirement R1, Parts 1.~~Tables 1-1 through 1~~.4.~~ -5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses ~~a~~ performance-based maintenance ~~program~~intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to ~~equipment~~Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has ~~implemented the~~maintained its Protection System ~~Maintenance Program and initiated resolution of unresolved maintenance issues~~Components included within its time-based program in accordance with Requirement R3~~, which~~. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance ~~Monitoring Responsibility~~Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance ~~Audits~~Audit
Self-~~Certifications~~Certification
Spot Checking
Compliance ~~Violation Investigations~~Investigation
Self-Reporting
Complaints

1.3. ~~Data~~Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to ~~demonstrate~~show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System ~~component type~~Component Type.

~~**Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*~~

For Requirement R2, Requirement R3, Requirement R4, and Requirement ~~R3~~R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System ~~**components**~~Components, or all performances of each distinct maintenance activity for the Protection System ~~component~~Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last ~~periodic~~ audit ~~report~~records and all requested and submitted subsequent ~~compliance~~audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one ~~component type~~Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.~~2~~1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	~~The responsible entity's PSMP failed to address one component type included in the definition of 'Protection System' (Part 1.1)~~ ~~OR~~ The responsible entity's PSMP failed to specify whether two ~~component types~~Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.~~2~~1)	The responsible ~~entity's PSMP failed to address two component types included in the definition of 'Protection System' (Part 1.1)~~ ~~OR~~ ~~The responsible entity's~~entities' PSMP failed to include ~~station batteries in a time-based program (Part 1.2)~~ ~~OR~~ ~~The responsible entity failed to include all maintenance activities or intervals relevant for the identified~~the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3~~. (Part 1.3 and 1.4)~~ where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity ~~has not established~~failed to establish a PSMP. OR ~~The responsible entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1)~~ ~~OR~~ The responsible entity failed to specify whether three or more ~~component types~~Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.~~2~~1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but ~~has:~~ ~~1)~~ ~~Failed~~failed to reduce ~~countable events~~Countable Events to less than 4% within three years. ~~OR~~	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but ~~has~~ failed to reduce ~~countable events~~Countable Events to less than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but ~~has~~: 1) Failed to establish the ~~entire~~ technical justification described within Requirement R2 for the initial use of the performance-based PSMP

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	~~2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment.~~			OR 2) Failed to reduce ~~countable events~~Countable Events to less than 4% within five years OR 3) ~~Failed to annually document program activities, results, maintenance dates, or countable events for over 5% of components in any individual segment~~ ~~OR~~ ~~4)~~ Maintained a ~~segment~~Segment with less than 60 ~~components~~Components OR ~~5~~4) Failed to: • Annually update the list of ~~components~~Components, OR • ~~Perform~~Annually perform maintenance on the greater of 5% of the segment population or 3 ~~components~~Components, OR • Annually analyze the program activities and results for each ~~segment~~Segment.
R3	~~The responsible entity has failed to implement and follow scheduled program on 5% or less of total Protection System components.~~ ~~OR~~	~~The responsible entity has failed to implement and follow scheduled program on greater than 5%, but no more than 10% of total Protection System components.~~	~~The responsible entity has failed to implement and follow scheduled program on greater than 10%, but no more than 15% of total Protection System components.~~	~~The responsible entity has failed to implement and follow scheduled program on greater than 15% of total Protection System components.~~

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	~~The responsible entity has failed to initiate resolution on 5% or less of unresolved maintenance issues.~~For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	~~OR~~ ~~The responsible entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of unresolved maintenance issues.~~For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	~~OR~~ ~~The responsible entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of unresolved maintenance issues.~~For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	~~OR~~ ~~The responsible entity has failed to initiate resolution on greater than 15% of unresolved maintenance issues.~~For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or less Unresolved Maintenance Issues.	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10 Unresolved Maintenance Issues.	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15 Unresolved Maintenance Issues.	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program…

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — July 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed.
For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error~~.~~ (See Table 2~~)~~). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure~~.~~ (See Table 2~~)~~). • Alarming for change of settings~~.~~ (See Table 2~~)~~).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential ~~signals~~ to ~~and from other~~proper functioning of the Protection System ~~components~~.

Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function~~.~~ (See Table 2~~)~~).	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential ~~signals~~ to ~~and from other~~proper functioning of the Protection System~~ components~~.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3
Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.

Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a)
Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries
Excluding distributed UFLS and distributed UVLS (see Table 3)

Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). ~~Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UVLS systems are excluded (see Table 1-4(e)).~~	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). ~~Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).~~	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(c) Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and ~~non-~~distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). ~~Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).~~	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). ~~Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).~~	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting ~~Device~~Devices for SPS, non-distributed UFLS, and non-distributed UVLS ~~and UFLS~~ systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used only for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS ~~and UFLS~~ system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure~~.~~ (See Table 2~~)~~).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2~~)~~).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2~~)~~).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2~~)~~).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2~~)~~).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2~~)~~).		No periodic verification of the intercell and terminal connection resistance is required.
Any ~~lead acid battery based~~Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station ~~dc supply~~battery with internal ohmic value monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2~~)~~).		~~.~~No periodic measurement and evaluation relative to baseline of battery cell/unit internal ohmic values is required to verify the station battery can perform as designed ~~.~~.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ~~Ohmic~~ohmic value~~.~~ (See Table 2~~)~~).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3) **Note:** Table requirements apply to all Control Circuitry ~~components~~Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
~~Unmonitored control circuitry associated with SPS~~Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	~~12~~6 calendar years	Verify ~~all paths of the control circuits essential for proper~~electrical operation of ~~the SPS~~electromechanical lockout devices.
~~Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.~~Unmonitored control circuitry associated with SPS.	~~6~~12 calendar years	Verify ~~electrical~~all paths of the control circuits essential for proper operation of ~~electromechanical trip and auxiliary devices~~the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry ~~whose continuity~~associated with protective functions and ~~energization~~ /or ~~ability to operate are~~SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of ~~DETECTION~~detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. ~~•~~ Acceptable measurement of power system input values~~.~~ •

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error~~.~~ (See Table 2~~)~~). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure~~.~~ (See Table 2~~)~~). Alarming for change of settings~~.~~ (See Table 2~~)~~).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping ~~only~~ non-BES interrupting devices ~~as part of~~used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices~~.~~ (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems~~.~~ (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices~~.~~ (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of ~~components~~Components included in each designated ~~segment~~Segment of the Protection System ~~component~~Component population, with a minimum **~~segment~~Segment** population of 60 ~~components~~Components.
2. Maintain the ~~components~~Components in each ~~segment~~Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the ~~segment~~Segment are available for a minimum of 30 individual ~~components~~Components of the ~~segment~~Segment.
3. Document the maintenance program activities and results for each ~~segment~~Segment, including maintenance dates and ~~countable events~~Countable Events for each included ~~component~~Component.
4. Analyze the maintenance program activities and results for each ~~segment~~Segment to determine the overall performance of the ~~segment~~Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each ~~segment~~Segment such that the ~~segment~~Segment experiences **~~countable events~~Countable Events** on no more than 4% of the ~~components~~Components within the ~~segment~~Segment, for the greater of either the last 30 ~~components~~Components maintained or all ~~components~~Components maintained in the previous year.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a ~~segment~~Segment. A ~~segment~~Segment must contain at least sixty (60) individual components.*

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System ~~components~~Components and ~~segments~~Segments and/or description if any changes occur within the ~~segment~~Segment.
2. Perform maintenance on the greater of 5% of the ~~components~~Components (addressed in the performance based PSMP) in each ~~segment~~Segment or 3 individual ~~components~~Components within the ~~segment~~Segment in each year.

3. For the prior year, analyze the maintenance program activities and results for each ~~segment~~Segment to determine the overall performance of the ~~segment~~Segment.
4. Using the prior year's data, determine the maximum allowable maintenance interval for each ~~segment~~Segment such that the ~~segment~~Segment experiences ~~countable events~~Countable Events on no more than 4% of the ~~components~~Components within the ~~segment~~Segment, for the greater of either the last 30 ~~components~~Components maintained or all ~~components~~Components maintained in the previous year.
5. If the ~~components~~Components in a Protection System ~~segment~~Segment maintained through a performance-based PSMP experience 4% or more ~~countable events~~Countable Events, develop, document, and implement an action plan to reduce the ~~countable events~~Countable Events to less than 4% of the ~~segment~~Segment population within 3 years.

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing
PRC-005-02

Standards Involved
Approval:

- PRC-005-2 – Protection System Maintenance and Testing

Retirements:

- PRC-005-1a – Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
- PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:
Revised definition of "Protection System"

Background:
The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.
5. The Implementation Schedule set forth in this document facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in approximately equally-distributed steps over those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets the requirements of PRC-005-2 in accordance with this implementation plan.

While entities are transitioning to the requirements of PRC-005-2, each entity must be prepared to identify:

- All of its applicable Protection System components.
- Whether each component has last been maintained according to PRC-005-2 or under PRC-005-1a, PRC-008-0, PRC-011-0, or PRC-017-0, or a combination thereof.

For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

The existing Standards PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following applicable regulatory approval of PRC-005-2 in all jurisdictions.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption.

Implementation Plan for Requirements R3 and R4:

1. For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption.
2. For Protection System component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.
3. For Protection System component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption.

4. For Protection System component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption.

5. For Protection System component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption.

Applicability:

This standard applies to the following functional entities:

- Transmission Owner
- Generator Owner
- Distribution Provider

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02

Standards Involved

Approval:

- PRC-005-2 – Protection System Maintenance and Testing

Retirements ~~(phased to coincide with each entity's implementation of PRC-005-2 as specified in the Implementation Plan for Requirements R1 through R3 later in this document)~~:

- ~~PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing~~
- PRC-005-1a – Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
- PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

Revised definition of "Protection System"

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities~~for the first time~~. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately ~~in compliance~~compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.

3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~twelve~~ twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.

5. The Implementation Schedule set forth in this document ~~further requires~~ facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in ~~roughly~~ approximately equally-distributed steps over ~~the maintenance~~those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance ~~follow the protection system maintenance and testing program it used to perform maintenance and testing to comply~~ with ~~PRC-005-1,~~ PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 ~~(for the Protection System components identified in PRC-005-2 Tables 1-1 through 1-5, Table 2, and Table 3)~~ until that ~~Transmission Owner, Generator Owner or Distribution Provider~~entity meets ~~initial compliance~~the requirements of PRC-005-2 ~~for maintenance of the same Protection System component,~~ in accordance with ~~the phasing specified below~~this implementation plan.

~~For audits that are conducted d~~Wuring ~~the time period when~~ hile entities are ~~modifying~~ transitioning ~~their existing protection system maintenance and testing programs to become compliant with~~to the ~~maintenance activities and intervals specified in~~requirements of PRC-005-2, each ~~responsible~~ entity must be prepared to identify:

- All of its applicable ~~protection~~ Protection ~~system~~ System components.
- ~~For each component, w~~Whether ~~maintenance of that~~ each component ~~is being addressed~~has last been maintained according to PRC-005-2 or under ~~PRC-005-1,~~ PRC-005-1a, PRC-008-0, PRC-011-0, or PRC-017-0, or a combination thereof.

~~Evidence that each component has been maintained under the relevant requirements.~~For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

The existing Standards ~~PRC-005-1,~~ PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following ~~the latter of 156 months following~~ applicable regulatory approval of PRC-005-2 in all ~~jurisdictions~~ jurisdictions~~or 168 months following Board of Trustees adoption of PRC-005-2~~.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 ~~and~~ R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-~~one~~ four (~~21~~24) months following NERC Board of Trustees adoption.

Implementation Plan for Requirements ~~R2 and~~ R3 and R4:

~~Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 and R3 which use this defined term.~~

1. For Protection System component~~s~~ maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen ~~15~~ (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty ~~24~~ (30) months following NERC Board of Trustees adoption.
2. For Protection System component~~s~~ maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.
3. For Protection System component~~s~~ maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption.

4. For Protection System ~~components~~ component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption.

5. For Protection System ~~components~~ component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption.

Applicability:

This standard applies to the following functional entities:

- Transmission Owner~~s~~
- Generator Owner~~s~~
- ~~Distribution Provider~~s

Standard Authorization Request Form

Title of Proposed Standard:	Protection System Maintenance (Project 2007-17)
Request Date:	May 7, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: System Protection and Controls Task Force (Attachment A)	☐	New Standard
Primary Contact: Charles Rogers	X	Revision to existing Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs PRC-011-0 — UVLS System Maintenance and Testing PRC-017-0 — Special Protection System Maintenance and Testing
Telephone (517) 788-0027 Fax (517) 788-0917	X	Withdrawal of existing Standard
E-mail:cwrogers@cmsenergy.com	☐	Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of standard PRC-005 should remain "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

In Order 693, the Federal Energy Regulatory Commission directed that changes be made to these standards.

These standards should be consolidated into a single standard to reduce the costs of compliance and a number of technical short comings in these standards should be corrected to provide reliable performance when responding to abnormal system conditions.

Brief Description (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

Revise PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, to consolidate PRC-005-1, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs; PRC-011-0 — UVLS System Maintenance and Testing; and PRC-017-0 — Special Protection System Maintenance and Testing into a single maintenance and testing standard. Standards PRC-008-0, PRC-011-0, and PRC-017-0 would then be withdrawn.

The revised PRC-005 standard should address the issues raised in the FERC Order 693, the issues raised by stakeholders during the development of Version 0 and Phase III & IV standards (Attachment D), and the issues addressed in the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" (Attachment B) The revised standard should also address the comments submitted by stakeholders during the development of Version 0, and Phase III & IV and should reflect improvements identified in the Reliability Standards Review Guidelines. (Attachment C)

Detailed Description:

The PRC-005, 008, 011, and 017 reliability standards are intended to assure that Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generator Owner, and Distribution Provider to ensure the Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

- Applicable to PRC-017 — Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between various protection system technologies.
- Applicable to all four standards — The terms "maintenance programs" and "testing programs" should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.
- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor.

The revised standard should also include the general improvements identified in the attached Reliability Standard Review Guidelines (Attachment C) and should address the comments submitted by stakeholders (Attachment D).

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☒	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

NERC SPCTF Assessment of Standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

DRAFT 1.0
March 8, 2007

A Technical Review of Standards

Prepared by the
System Protection and Controls Task Force
of the
NERC Planning Committee

Table of Contents

This report and its attendant Standards Authorization Request were approved by the Planning Committee on March 21, 2007, for forwarding to the Standards Committee.

Introduction

When the original scope for the System Protection and Control Task Force was developed, one of the assigned items was to review all of the existing PRC-series Reliability Standards, to advise the Planning Committee of our assessment, and to develop Standards Authorization Requests, as appropriate, to address any perceived deficiencies.

This report presents the SPCTF's assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing. The report includes the SPCTF's understanding of the intent of this standard and contains specific observations relative to the existing standard.

The SPCTF sees the parallel intent for each of the PRC-005, PRC-008, PRC-011, and PRC-017 as being maintenance and testing standards for different protective systems. In fact, PRC-005 & PRC-008, and PRC-011 & PRC-017 have very similar format respectively. Since all protective relay systems require some means of maintenance and testing, it would seem that all protective system maintenance and testing could be included in one standard regardless of scheme type. The SPCTF recommends that these four standards be reduced to one standard covering the issues detailed for PRC-005 on maintenance and testing.

These four standards were developed primarily by translating the requirements of an earlier Phase I Planning Standard; thus they have not been previously subjected to a critical review of the Requirements.

Executive Summary

Reliability standards PRC-005, 008, 011, and 017 are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Only PRC-005 will be commented on in detail although the other three standards have the same concerns.

SPCTF concluded that:

- Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."
- Applicable to PRC-017 — Part of the stated purpose in PRC-017 states: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is, the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between different technologies of protection systems.
- Applicable to all four standards — The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.

- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor.

Assessment of PRC-005-1

Purpose

To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

A review of PRC-005 indicates that this standard is intended to assure that all affected entities have adequate maintenance and testing programs for their Protection Systems to ensure reliability. SPCTF agrees with the Purpose statement of PRC-005-1.

General Comments

The SPCTF offers the following general comments:

- None of the requirements within PRC-005-1 specifically indicate what minimum attributes should be included in protective system maintenance and testing procedures.
- For interval-based procedures, no allowable maximum interval is prescribed.
- None of the requirements in the existing PRC-005-1 reflect condition-based or performance-based maintenance and testing criteria.

Standard PRC-005 should clarify that two goals are being covered:

- The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers’ design specification throughout the service life.
- The testing portion should have requirements that verify that the functional performance of the protection systems is consistent with the design intent throughout the service life.

Applicability

Applicability 4.3 suggests that the definition of a Protection System in the Glossary of Terms should

> **4.1.** Transmission Owners
>
> **4.2.** Generation Owners
>
> **4.3.** Distribution Providers that owns a transmission Protection System

clarify how a Distribution Provider may be the owner of a transmission Protection System.

Requirements

R1

> **R1.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:
>
> **R1.1.** Maintenance and testing intervals and their basis.
>
> **R1.2.** Summary of maintenance and testing procedures.

The following clarifications should be made to Requirement R1:

1. How is the phrase "that affect the reliability of the BES" to be interpreted? The standard should clearly specify which Protection Systems are subject to the requirements.
2. The standard should clearly specify which components of the Generation Protection System are subject to the requirements.

The following clarifications should be made to Subparts R1.1 & R1.2:

1. Interval-based, condition-based, or performance-based maintenance and testing minimum criteria should be established within R1.1, including, but not limited to the following:
   a. For time-based maintenance and testing programs, maximum maintenance intervals should be specified.
   b. For condition-based or performance-based maintenance and testing programs, the program should have sufficient justification and documentation.
2. Definitions should be established for the terms "maintenance programs" and "testing programs."
3. A minimum set of attributes to be included in maintenance and testing programs should be established within R1.2.

R2

> **R2.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:
>
> **R2.1.** Evidence Protection System devices were maintained and tested within the defined intervals.
>
> **R2.2.** Date each Protection System device was last tested/maintained

The following clarification should be made to requirement R2:

- The appropriate entity should have their Protection System maintenance program and testing program and associated documentation, including maintenance records and testing records, available to its Regional Reliability Organization and NERC during audits or upon request within 30 days.

FERC Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

In the October 20, 2006 Notice of Proposed Rulemaking for adoption of NERC Standards (Docket Number RM06-16-000), the Federal Energy Regulatory Commission commented on these four standards and proposed changes. The observations and proposals are excerpted from the NOPR and included below.

PRC-005-1

> The Commission proposes to approve PRC-005-1 as mandatory and enforceable. In addition, we propose to direct that NERC develop modifications to the Reliability Standard as discussed below.
>
> Proposed Reliability Standard PRC-005-1 does not specify the criteria to determine the appropriate maintenance intervals, nor do it specify maximum allowable maintenance intervals for the protections systems. The Commission therefore proposes that NERC include a requirement that maintenance and testing of these protection systems must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-005-1 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.

PRC-008-0

The Commission notes that the commenters generally share staff's concern that the proposed Reliability Standard does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protection systems. The Commission agrees and proposes to require NERC to modify the proposed Reliability Standard to include a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of relay used and the impact on the reliability of the Bulk-Power System.

Accordingly, the Commission proposes to approve Reliability Standard PRC-008-0 as mandatory and enforceable. In addition, the Commission proposes to direct that NERC submit a modification to PRC-008-0 that includes a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval appropriate to the relay type and the potential impact on the Bulk-Power System.

PRC-011-0

PRC-011-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes that NERC include a Requirement that maintenance and testing of these UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of the relay used and the impact of these UFLS on the reliability of the Bulk-Power System.

The Commission believes that Reliability Standard PRC-011-0 serves an important purpose in requiring transmission owners and distribution providers to implement their UVLS equipment maintenance and testing programs. Further, the proposed Requirements are sufficiently clear and objective to provide guidance for compliance.

Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-011-0 that includes a requirement that maintenance and testing of UVLS programs must be carried out within a maximum allowable interval appropriate to the applicable relay and the impact on the reliability of the Bulk-Power System.

PRC-017-0

> PRC-017-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes to require NERC to include a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used and the impact of these special protection system programs on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation’s Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-017-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-017-0 that: (1) includes a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used; and (2) identifies the impact of these special protection system programs on the reliability of the Bulk-Power System.

Other Activities Related to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

These four Standards are contained in several projects and draft SARs as part of the “Draft Reliability Standards Development Plan: 2007–2009”, which was approved by the NERC Board of Trustees.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the Standards Development Plan, and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

Conclusions and Recommendations

PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 require additions, clarifications, and definitions to insure that the Protection Systems are properly maintained and tested.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the “Draft Reliability Standards Development Plan: 2007–2009,” and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

SPCTF submits the attached SAR for that purpose of consolidating PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 into a single standard to the Planning Committee for endorsement.

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replace existing 'levels of non-compliance.') The violation severity levels must be applied for each requirement and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: more than 95% but less than 100% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: more than 85% but less than or equal to 95% compliant.
- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: more than 70% but less than or equal to 85% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: 70% or less compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan. The effective date should be linked to the NERC BOT adoption date.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

PRC-005-0 — Transmission Protection System Maintenance and Testing

Version 0 Comments:

- This section should not move forward in Version 0. More procedure/data oriented, not really stand alone "standard" material but more tools or reference material for executing a standard
- R3-1.a – should breakers and switches be included in the list?
- M3-2 – what kind of evidence?
- M3-2 The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

Phase III & IV Comments:

- PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term.
- Need to add language to ensure the Regional Requirements focus on the most impactive scenarios
- Modify applicability to clarfify that the requirements are applicable to the following:
- All protection systems on the bulk electric system.
- All generation protection systems whose misoperations impact the bulk electric system
- There is no performance requirement or measure of effectiveness of a maintenance program required by the standard

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

Version 0 Comments:

- The language for protection system maintenance and testing programs should be consistent from standard to standard. The requirement in this standard should match Standard 063, Requirement R3-1. This will provide a consistent reporting requirement for all protection system.
- From standard 063.3: The Transmission Owner, Generator Owner and Distribution Provider that owns a transmission protection system shall have a transmission protection system maintenance and testing program in place. The program(s) shall include:
- From Standard 067.3: The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

PRC-011-0 — UVLS System Maintenance and Testing

Version 0 Comments:

- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.
- UVLS : Under voltage load shedding should not be a requirement for all parties. Those who have shunt reactors can meet the objective by not shedding load but by shedding shunt reactors. Flexibility in achieving the desired goal is appropriate.

PRC-017-0 — Special Protection System Maintenance and Testing

Version 0 Comments:

- In f, it needs to be changed to require that the last two dates of testing and maintenance are kept. This is necessary to verify an action that is required bi-annually or bi-monthly.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

Standard Authorization Request Form

Title of Proposed Standard: ~~Transmission and Generation Protection System Maintenance and Testing~~Protection System Maintenance (Project 2007-17)	
Request Date:	May 7, 2007

SAR Requestor Information	SAR Type (*Check a box for each one that applies.*)	
Name: System Protection and Controls Task Force (Attachment A)	☐	New Standard
Primary Contact: Charles Rogers	X	Revision to existing Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs PRC-011-0 — UVLS System Maintenance and Testing PRC-017-0 — Special Protection System Maintenance and Testing
Telephone (517) 788-0027 Fax (517) 788-0917	X	Withdrawal of existing Standard
E-mail: cwrogers@cmsenergy.com	☐	Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of standard PRC-005 should remain "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

In Order 693, the Federal Energy Regulatory Commission directed that changes be made to these standards.

These standards should be consolidated into a single standard to reduce the costs of compliance and a number of technical short comings in these standards should be corrected to provide reliable performance when responding to abnormal system conditions.

Brief Description (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

Revise PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, to consolidate PRC-005-1, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs; PRC-011-0 — UVLS System Maintenance and Testing; and PRC-017-0 — Special Protection System Maintenance and Testing into a single maintenance and testing standard. Standards PRC-008-0, PRC-011-0, and PRC-017-0 would then be withdrawn.

The revised PRC-005 standard should address the issues raised in the FERC Order 693, the issues raised by stakeholders during the development of Version 0 and Phase III & IV standards (Attachment D), and the issues addressed in the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" (Attachment B) The revised standard should also address the comments submitted by stakeholders during the development of Version 0, and Phase III & IV and should reflect improvements identified in the Reliability Standards Review Guidelines. (Attachment C)

Detailed Description:

The PRC-005, 008, 011, and 017 reliability standards are intended to assure that ~~Transmission & Generation~~ Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, ~~Generation~~ Generator Owner, and Distribution Provider to ensure the ~~Transmission & Generation~~ Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

- Applicable to PRC-017 — Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between various protection system technologies.
- Applicable to all four standards — The terms "maintenance programs" and "testing programs" should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.
- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor.

The revised standard should also include the general improvements identified in the attached Reliability Standard Review Guidelines (Attachment C) and should address the comments submitted by stakeholders (Attachment D).

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐ ☒	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☒	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

NERC SPCTF Assessment of Standards:

- **PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing**
- **PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs**
- **PRC-011-0 — UVLS System Maintenance and Testing**
- **PRC-017-0 — Special Protection System Maintenance and Testing**

DRAFT 1.0
March 8, 2007

A Technical Review of Standards

Prepared by the
System Protection and Controls Task Force
of the
NERC Planning Committee

Table of Contents

This report and its attendant Standards Authorization Request were approved by the Planning Committee on March 21, 2007, for forwarding to the Standards Committee.

Introduction

When the original scope for the System Protection and Control Task Force was developed, one of the assigned items was to review all of the existing PRC-series Reliability Standards, to advise the Planning Committee of our assessment, and to develop Standards Authorization Requests, as appropriate, to address any perceived deficiencies.

This report presents the SPCTF's assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing. The report includes the SPCTF's understanding of the intent of this standard and contains specific observations relative to the existing standard.

The SPCTF sees the parallel intent for each of the PRC-005, PRC-008, PRC-011, and PRC-017 as being maintenance and testing standards for different protective systems. In fact, PRC-005 & PRC-008, and PRC-011 & PRC-017 have very similar format respectively. Since all protective relay systems require some means of maintenance and testing, it would seem that all protective system maintenance and testing could be included in one standard regardless of scheme type. The SPCTF recommends that these four standards be reduced to one standard covering the issues detailed for PRC-005 on maintenance and testing.

These four standards were developed primarily by translating the requirements of an earlier Phase I Planning Standard; thus they have not been previously subjected to a critical review of the Requirements.

Executive Summary

Reliability standards PRC-005, 008, 011, and 017 are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Only PRC-005 will be commented on in detail although the other three standards have the same concerns.

SPCTF concluded that:

- Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."
- Applicable to PRC-017 — Part of the stated purpose in PRC-017 states: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is, the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between different technologies of protection systems.
- Applicable to all four standards — The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.

- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor.

Assessment of PRC-005-1

Purpose

To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

A review of PRC-005 indicates that this standard is intended to assure that all affected entities have adequate maintenance and testing programs for their Protection Systems to ensure reliability. SPCTF agrees with the Purpose statement of PRC-005-1.

General Comments

The SPCTF offers the following general comments:

- None of the requirements within PRC-005-1 specifically indicate what minimum attributes should be included in protective system maintenance and testing procedures.
- For interval-based procedures, no allowable maximum interval is prescribed.
- None of the requirements in the existing PRC-005-1 reflect condition-based or performance-based maintenance and testing criteria.

Standard PRC-005 should clarify that two goals are being covered:

- The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers' design specification throughout the service life.
- The testing portion should have requirements that verify that the functional performance of the protection systems is consistent with the design intent throughout the service life.

Applicability

Applicability 4.3 suggests that the definition of a Protection System in the Glossary of Terms should

> **4.1.** Transmission Owners
>
> **4.2.** Generation Owners
>
> **4.3.** Distribution Providers that owns a transmission Protection System

clarify how a Distribution Provider may be the owner of a transmission Protection System.

Requirements

R1

> **R1.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:
>
> **R1.1.** Maintenance and testing intervals and their basis.
>
> **R1.2.** Summary of maintenance and testing procedures.

The following clarifications should be made to Requirement R1:

1. How is the phrase "that affect the reliability of the BES" to be interpreted? The standard should clearly specify which Protection Systems are subject to the requirements.
2. The standard should clearly specify which components of the Generation Protection System are subject to the requirements.

The following clarifications should be made to Subparts R1.1 & R1.2:

1. Interval-based, condition-based, or performance-based maintenance and testing minimum criteria should be established within R1.1, including, but not limited to the following:
   a. For time-based maintenance and testing programs, maximum maintenance intervals should be specified.
   b. For condition-based or performance-based maintenance and testing programs, the program should have sufficient justification and documentation.
2. Definitions should be established for the terms "maintenance programs" and "testing programs."
3. A minimum set of attributes to be included in maintenance and testing programs should be established within R1.2.

R2

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained

The following clarification should be made to requirement R2:

- The appropriate entity should have their Protection System maintenance program and testing program and associated documentation, including maintenance records and testing records, available to its Regional Reliability Organization and NERC during audits or upon request within 30 days.

FERC Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

In the October 20, 2006 Notice of Proposed Rulemaking for adoption of NERC Standards (Docket Number RM06-16-000), the Federal Energy Regulatory Commission commented on these four standards and proposed changes. The observations and proposals are excerpted from the NOPR and included below.

PRC-005-1

The Commission proposes to approve PRC-005-1 as mandatory and enforceable. In addition, we propose to direct that NERC develop modifications to the Reliability Standard as discussed below.

Proposed Reliability Standard PRC-005-1 does not specify the criteria to determine the appropriate maintenance intervals, nor do it specify maximum allowable maintenance intervals for the protections systems. The Commission therefore proposes that NERC include a requirement that maintenance and testing of these protection systems must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.

Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation’s Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-005-1 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.

PRC-008-0

The Commission notes that the commenters generally share staff's concern that the proposed Reliability Standard does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protection systems. The Commission agrees and proposes to require NERC to modify the proposed Reliability Standard to include a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of relay used and the impact on the reliability of the Bulk-Power System.

Accordingly, the Commission proposes to approve Reliability Standard PRC-008-0 as mandatory and enforceable. In addition, the Commission proposes to direct that NERC submit a modification to PRC-008-0 that includes a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval appropriate to the relay type and the potential impact on the Bulk-Power System.

PRC-011-0

PRC-011-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes that NERC include a Requirement that maintenance and testing of these UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of the relay used and the impact of these UFLS on the reliability of the Bulk-Power System.

The Commission believes that Reliability Standard PRC-011-0 serves an important purpose in requiring transmission owners and distribution providers to implement their UVLS equipment maintenance and testing programs. Further, the proposed Requirements are sufficiently clear and objective to provide guidance for compliance.

Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-011-0 that includes a requirement that maintenance and testing of UVLS programs must be carried out within a maximum allowable interval appropriate to the applicable relay and the impact on the reliability of the Bulk-Power System.

PRC-017-0

> PRC-017-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes to require NERC to include a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used and the impact of these special protection system programs on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-017-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-017-0 that: (1) includes a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used; and (2) identifies the impact of these special protection system programs on the reliability of the Bulk-Power System.

Other Activities Related to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

These four Standards are contained in several projects and draft SARs as part of the "Draft Reliability Standards Development Plan: 2007–2009", which was approved by the NERC Board of Trustees.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the Standards Development Plan, and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

Conclusions and Recommendations

PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 require additions, clarifications, and definitions to insure that the Protection Systems are properly maintained and tested.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the "Draft Reliability Standards Development Plan: 2007–2009," and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

SPCTF submits the attached SAR for that purpose of consolidating PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 into a single standard to the Planning Committee for endorsement.

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replace existing 'levels of non-compliance.') The violation severity levels must be applied for each requirement and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: more than 95% but less than 100% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: more than 85% but less than or equal to 95% compliant.
- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: more than 70% but less than or equal to 85% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: 70% or less compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan. The effective date should be linked to the NERC BOT adoption date.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

PRC-005-0 — Transmission Protection System Maintenance and Testing

Version 0 Comments:

- This section should not move forward in Version 0. More procedure/data oriented, not really stand alone "standard" material but more tools or reference material for executing a standard
- R3-1.a – should breakers and switches be included in the list?
- M3-2 – what kind of evidence?
- M3-2 The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

Phase III & IV Comments:

- PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term.
- Need to add language to ensure the Regional Requirements focus on the most impactive scenarios
- Modify applicability to clarfify that the requirements are applicable to the following:
- All protection systems on the bulk electric system.
- All generation protection systems whose misoperations impact the bulk electric system
- There is no performance requirement or measure of effectiveness of a maintenance program required by the standard

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

Version 0 Comments:

- The language for protection system maintenance and testing programs should be consistent from standard to standard. The requirement in this standard should match Standard 063, Requirement R3-1. This will provide a consistent reporting requirement for all protection system.
- From standard 063.3: The Transmission Owner, Generator Owner and Distribution Provider that owns a transmission protection system shall have a transmission protection system maintenance and testing program in place. The program(s) shall include:
- From Standard 067.3: The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

PRC-011-0 — UVLS System Maintenance and Testing

Version 0 Comments:

- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.
- UVLS : Under voltage load shedding should not be a requirement for all parties. Those who have shunt reactors can meet the objective by not shedding load but by shedding shunt reactors. Flexibility in achieving the desired goal is appropriate.

PRC-017-0 — Special Protection System Maintenance and Testing

Version 0 Comments:

- In f, it needs to be changed to require that the last two dates of testing and maintenance are kept. This is necessary to verify an action that is required bi-annually or bi-monthly.
- The "shall have evidence" phrase is vague and may be unnecessary considering that the requesting entity should know if its requested information is supplied.

The new proposed definition of Protection System reads as follows:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

NERC

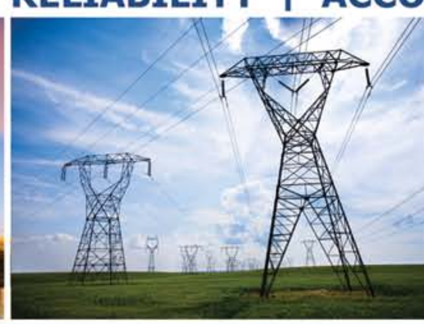
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Supplementary Reference and FAQ - Draft

PRC-005-2 Protection System Maintenance

January 17, 2012

RELIABILITY | ACCOUNTABILITY



3353 Peachtree Road NE
Suite 600, North Tower
Atlanta, GA 30326
404-446-2560 | www.nerc.com

Table of Contents

1. Introduction and Summary

Note: This supplementary reference to PRC-005-2 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems.
These standards are:

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"...*affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to Protection Systems for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

The BES definition is presently under going the process of revision.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse.

This Standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. This Standard covers protective relays that use electrical quantity measurements to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: since PRC-017 will be superseded by PRC-005-2, then if a Special Protection System (previously covered by PRC-017) incorporates automatic closing of breakers, then the SPS related closing devices must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This Standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.) Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are presently excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1a, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of any trip circuit that is a part of a Protection System. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not presently cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters. There is an expectation that fault pressure relays and other non-electrically initiated devices may become part of some maintenance standard. This Standard presently covers trip paths. It might seem incongruous to test a trip path without a present requirement to test the device and thus be arguably more work for nothing. But, one simple test to verify the integrity of such a trip path could be (but is not limited to) a voltage presence test as a dc voltage monitor might do if it were installed monitoring that same circuit.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a “lock-out”. Thus the software-latch 86 that replaces an electro-mechanical 86 does not require routine trip testing. Any trip circuitry associated with the “soft 86” would still need applicable verification activities performed but the actual “86” does not have to be “electrically operated” or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 Table 2 and Table 3 (collectively the “Tables”), and the various components of the definition established for a “Protection System Maintenance Program”, PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of “Restore” in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the Standard does require that the entity “shall demonstrate efforts to correct any identified unresolved maintenance issues”. Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

Please clarify what is meant by “…demonstrate efforts to correct an unresolved maintenance issue…”; why not measure the completion of the corrective action?

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (TMB) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

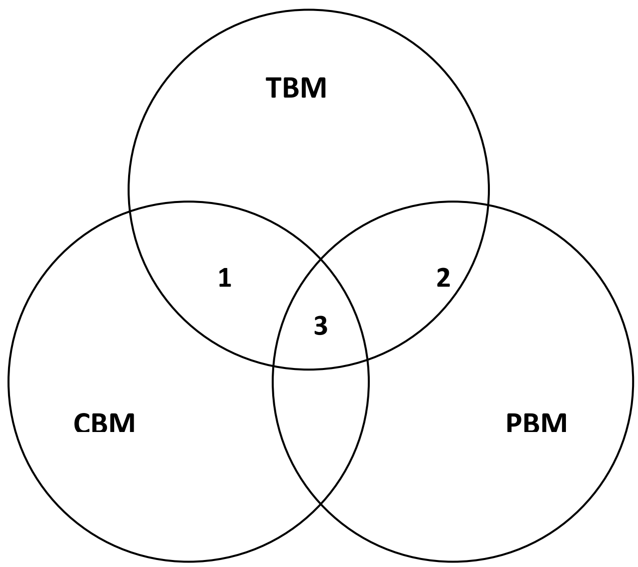
Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



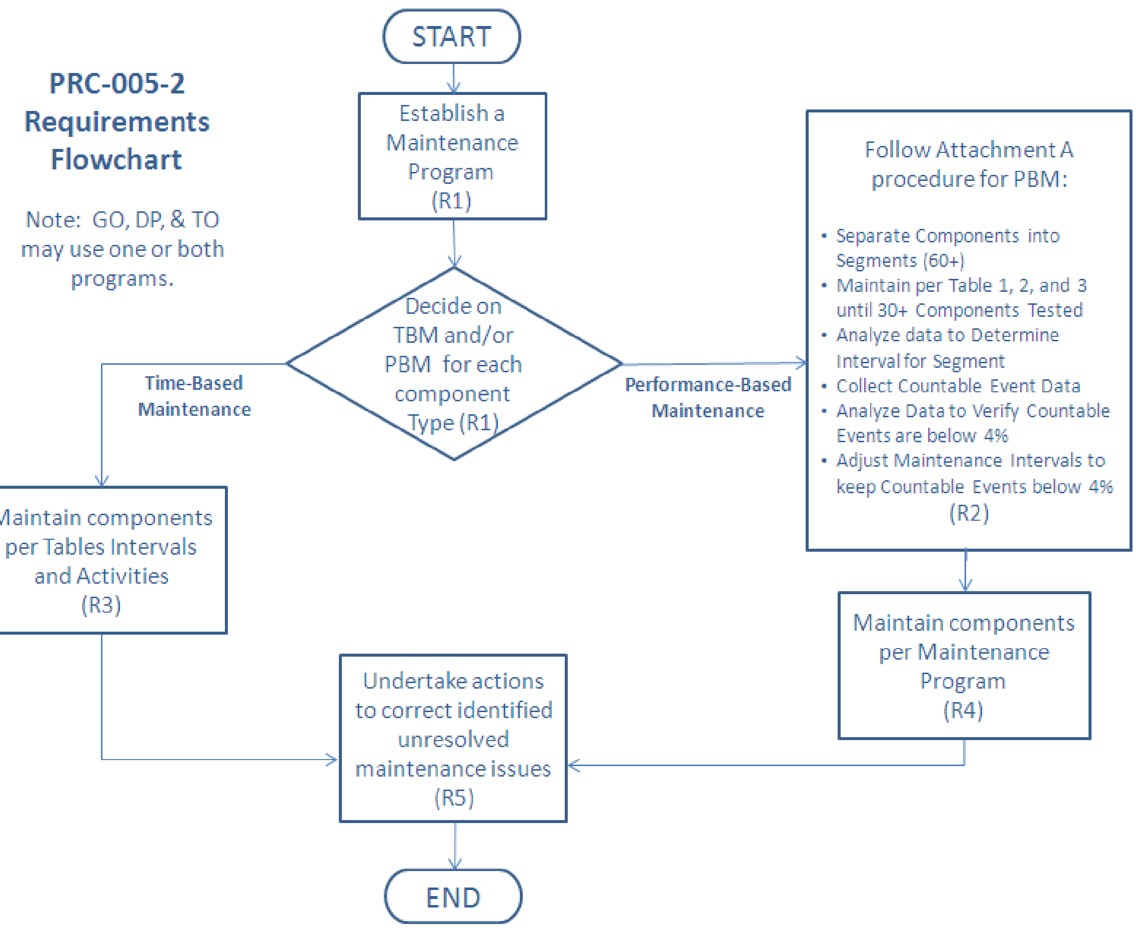
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a "flow chart" of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables .

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct any identified unresolved maintenance issues. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. **Non-invasive Maintenance:** The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. **Virtually Continuous Monitoring:** CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

To use the extended time intervals available through Condition Based Maintenance simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1 (Part 1.4) of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a “One Calendar Year Interval”, the next event would have to occur on or before December 31, 2010.

Please provide an example of “4 Calendar Months”.

If a maintenance activity is described as being needed every 4 Calendar Months then it is performed in a (given) month and due again 4 months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a 4-month inspection was performed in January is due in May, but if performed in March (instead of May) would still be due four months later therefore the activity is due again July. Basically every "4Calendar Months" means to add 4 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2 , the particular components have maximum activity intervals of:

Every 4 calendar months,inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity

- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

<u>Every 6 calendar years</u>, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

<u>Every 12 calendar years</u>, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored control circuitry associated with protective functions" section'
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”) and Table 2 (“Alarming Paths and Monitoring”), the particular components have maximum activity intervals of:

<u>Every 4 calendar months</u>, inspect:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

<u>Every 18 calendar months</u>, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

<u>Every 6 calendar years</u>, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

<u>Every 12 calendar years</u>, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the ‘Unmonitored control circuitry associated with protective functions" section’
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components shall have maximum activity intervals of:

Every 4 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified

- Operation of the microprocessor’s relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the ‘Unmonitored control circuitry associated with protective functions" section’
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years or when an unresolved maintenance issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2 and Table 3 in the Standard, specify maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various subsystems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

Distributed UFLS and UVLS systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits.
    - Table 2, is for alarms; this was broken out to simplify the other tables.
    - Table 3 is for components which make-up distributed UFLS and UVLS systems.
- Next look within that Table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance Based Maintenance (PBM) plan requires <u>more activities</u> then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your Performance Based Maintenance plan requires activities <u>more often</u> than the Tables maximum then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 4 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. If an entity has a Performance Based Maintenance program then that plan must be followed even if the plan proves to be more stringent than the minimums laid out in the Tables.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).
7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.
8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.
9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor based relays. For relay maintenance departments that choose to test microprocessor based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?

As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?

Since components of the SPS, UFLS, and UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest.

We believe that the 4-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections the 4-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

According to R3, if you have a time-based maintenance program then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables. According to R4, if your device in question is part of a Performance Based Maintenance program then you will be in violation of the standard if you fail to meet your PSMP even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays

- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: “Company A” has a maintenance plan that requires its electromechanical protective relays be tested every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within “Company A’s” stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the “Calendar Year” language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3. This VSL is written to compare missed components to total components. In this case 2 components out of 100 were missed or 2 %.

How do I achieve a "grace period" without being out of compliance?

According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded. The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting

utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for “time-interval extensions” or “grace periods” to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. “Maximum time intervals” by their very term negates any “time-interval extension” or “grace periods”. To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was “…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…” The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$\mathrm{B} = \mathrm{z}\sqrt{\frac{\pi(1-\pi)}{\mathrm{n}}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%

z = 1.96 (This equates to a 95% confidence level)

π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue as a countable event within the relevant component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme". Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes", all of which have three current signals supplied from bushing CT's and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT's and voltage signals from PT's built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified unresolved maintenance issues.

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified unresolved maintenance issues..." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an unresolved maintenance issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; (including but not limited to the following) by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

While relays that do not respond to electrical quantities are presently excluded from this standard, their control circuits are included if the relay is installed to detect faults on BES Elements. Thus, the control circuit of a BES transformer sudden pressure relay should be verified every 12 years assuming its integrity is not monitored. While a sudden pressure relay control circuit is included within the scope of PRC-005-2, other alarming relay control circuits, i.e. SF-6 low gas, are not included even though they may trip the breaker being monitored.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3)

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.

- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?
Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

<u>Battery Charger</u> - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

<u>Station Battery</u> - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

<u>Emerging Technologies</u> - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.
- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (Valve-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.

For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Of course, a measurement of "Conductance" from one manufacturer in a given year could be trended against a measurement of "Conductance" from a different manufacturer's device. This would be true for any unit measurements whether it is conductance, impedance, resistance, voltage, amperage, etc.

Although many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings or a combination of the two. There are test methods, presently, that can read post termination resistances and resistance values between external posts, there are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?

Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to “individual cells” some “units” or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980’s several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery’s current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer’s ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manufacturer’s equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life. A consistent measurement device should not be confused with a requirement to always stay with the same manufacturer. After all volts are volts, impedance is impedance, etc. It is just important to not expect to get consistent “Impedance” data if you switch to a “Conductance” measuring device in the middle of your trending program.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for “cell/unit internal ohmic measurements (impedance, conductance and resistance)” and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, “depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell’s capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs “an accurate measure of the overall battery capacity” they should “perform a battery capacity test.”

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station’s battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level.

Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell. Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the "perform as designed 6 month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be performed on any communications-assisted trip scheme regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 4-month inspection of communications-assisted trip scheme equipment?

The 4-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes

this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and Distributed UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current sensing devices have the same maintenance activity and interval as Table 1-2. DC systems need only have their voltage read at the relay every twelve years. Control circuits have the following maintenance activities every twelve years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however the part of the trip path control circuitry between the load shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

There are times when a Protection System component will be used on a BES device as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System component) will be subject to the Tables of the Standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS …

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 also covers users, owners, and operators of bulk-power facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

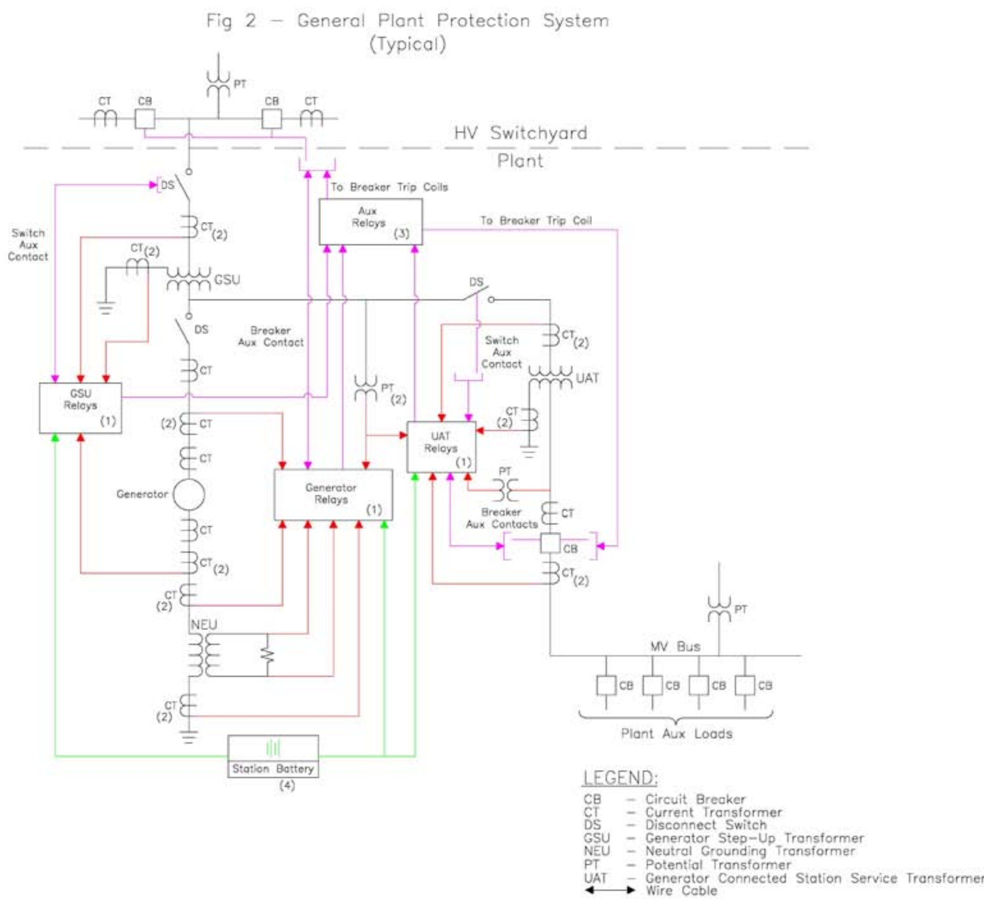
Figure 2: Typical Generation System



For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

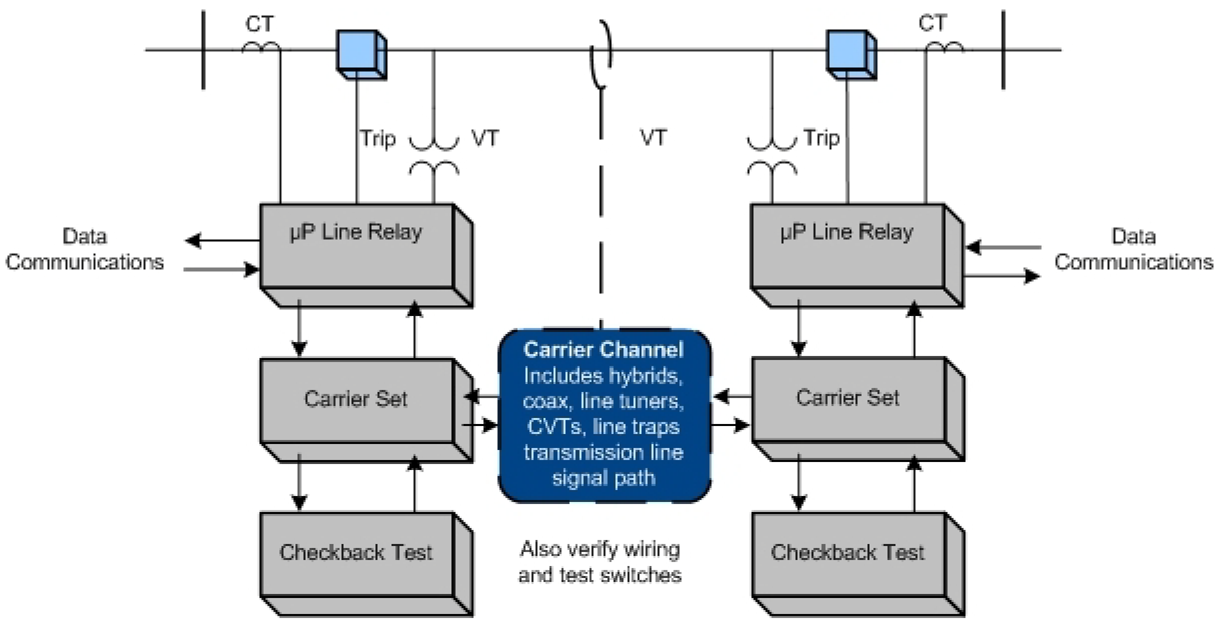
Appendix A

Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

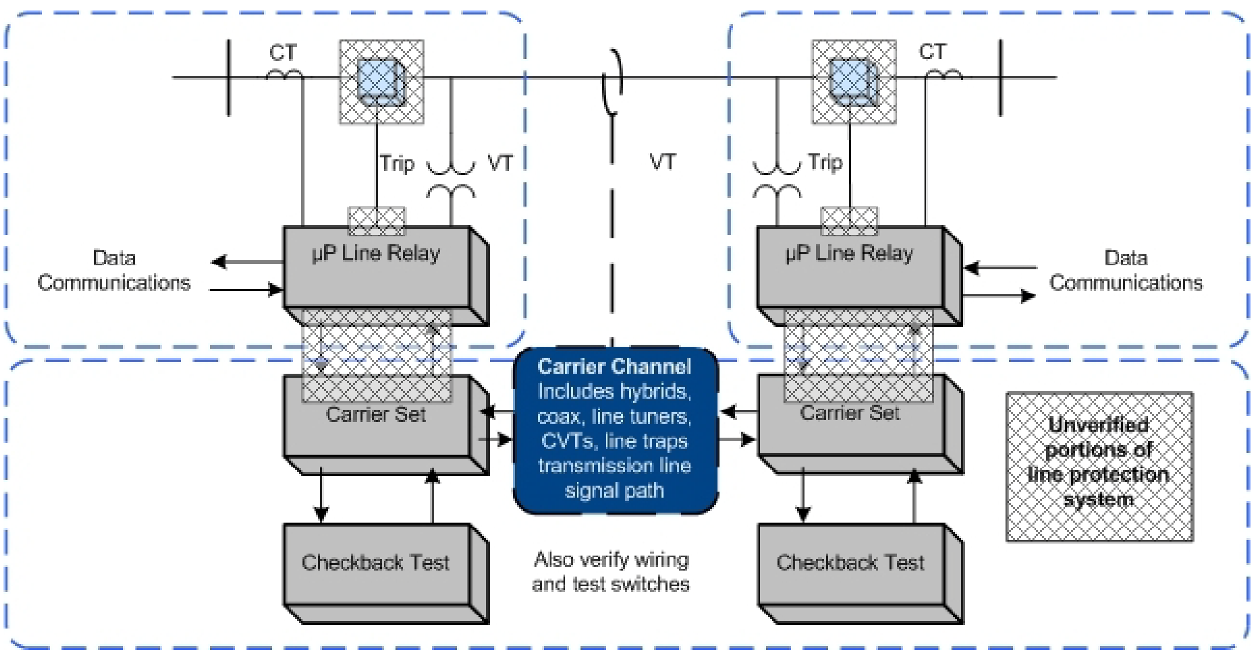
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones.

Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

1. Introduction and Summary

Note: This supplementary reference to PRC-005-2 is neither mandatory nor enforceable.

~~1. Introduction and Summary~~

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems.

These standards are:

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to ~~relays~~Protection Systems for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

The BES definition is presently undergoing revision.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse.

This Standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. ~~As stated in Requirement R1,~~ This Standard covers protective relays that use electrical quantity measurements ~~of electrical quantities~~ to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: since PRC-017 will be superseded by PRC-005-2, then if a Special Protection System (previously covered by PRC-017) incorporates automatic closing of breakers, then the SPS related closing devices ~~are part of the SPS and~~ must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This Standard addresses ~~only devices "~~Protection Systems that are ~~applied on, or are designed to provide protection~~installed for the purpose of detecting Faults on BES~~."~~ Elements (lines, buses, transformers, etc.) Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are presently excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1a, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of ~~the~~any trip circuit that is a part of a Protection System. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not presently cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters. There is an expectation that fault pressure relays and other non-electrically initiated devices may become part of some maintenance standard. This Standard presently covers trip paths. It might seem incongruous to test a trip path without a present requirement to test the device and thus be arguably more work for nothing. But, one simple test to verify the integrity of such a trip path could be (but is not limited to) a voltage presence test as a dc voltage monitor might do if it were installed monitoring that same circuit.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a "lock-out". Thus the software-latch 86 that replaces an electro-mechanical 86 does not require routine trip testing. Any trip circuitry associated with the "soft 86" would still need applicable verification activities performed but the actual "86" does not have to be "electrically operated" or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- ~~Restore — Return malfunctioning components to proper operation.~~

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 Table 2 and Table ~~2~~3 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; ~~R3~~R5 of the Standard does require that the entity "~~initiate resolution of~~shall demonstrate efforts to correct any identified unresolved maintenance issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

Please clarify what is meant by "…demonstrate efforts to correct an unresolved maintenance issue…"; why not measure the completion of the corrective action?

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (~~TBM~~TMB) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

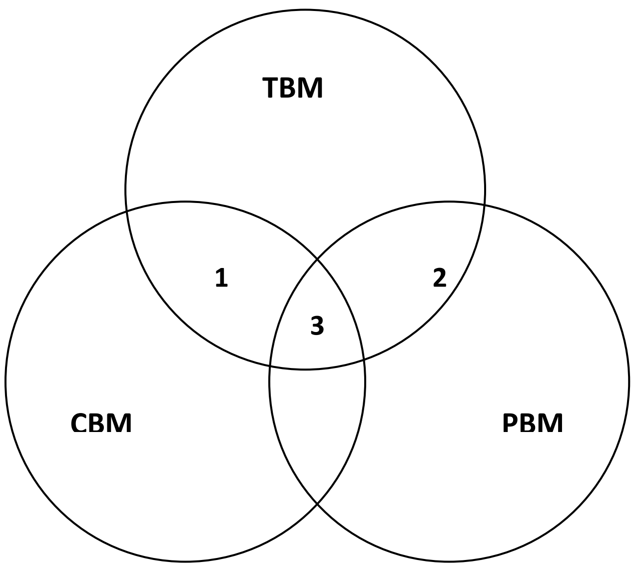
Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the Standard.

We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables ~~1-1 through 1-5~~.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (~~R3~~R5) (in essence) state "…shall ~~implement and follow its PSMP …" if not then actions must be initiated~~demonstrate efforts to correct ~~the deviance.~~any identified unresolved maintenance issues. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. **Non-invasive Maintenance:** The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. **Virtually Continuous Monitoring:** CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

To use the extended time intervals available through Condition Based Maintenance simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1 (Part 1.4) of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

~~7.~~ Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval", the next event would have to occur on or before December 31, 2010.

Please provide an example of "~~3~~4 Calendar Months".

If a maintenance activity is described as being needed every ~~3~~4 Calendar Months then it is performed in a (given) month and due again ~~3~~4 months later. For example a battery bank is inspected in month number 1 then it is due again ~~in~~before the end of the month ~~number 4~~number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of ~~April~~May. Another example could be that a ~~3~~4-month inspection was performed in January is due in ~~April~~May, but if performed in March (instead of ~~April~~May) would still be due ~~three~~four months later therefore the activity is due again ~~June~~July. Basically every "~~3 Calendar~~4Calendar Months" means to add ~~3~~4 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2 , the particular components have maximum activity intervals of:

Every ~~3~~4 calendar months, ~~verify~~inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays~~ and auxiliary relays~~, electrical operation of electromechanical trip ~~and auxiliary devices~~

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored control circuitry associated with protective functions" section'
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every ~~3~~4 calendar months, ~~verify~~inspect:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays~~ and auxiliary relays~~, electrical operation of electromechanical trip ~~and auxiliary devices~~
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- ~~Verify that~~ Current and voltage signal values are provided to the protective relays

- ~~Verify that~~ Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- ~~Verify~~ All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored control circuitry associated with protective functions" section'
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components shall have maximum activity intervals of:

Every ~~3~~4 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- ~~Cell~~ Condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays~~ and auxiliary relays~~, electrical operation of electromechanical trip ~~and auxiliary devices~~

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored control circuitry associated with protective functions" section'
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years or when ~~a~~ an unresolved maintenance issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2 and Table 3 in the Standard, ~~specifies~~specify maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted ~~line~~transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation ~~station layout.~~Protection System. The various subsystems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

Distributed UFLS and UVLS systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
  - Table 1-1 is for protective relays,
  - Table 1-2 is for the associated communications systems,
  - Table 1-3 is for current and voltage sensing devices,
  - Table 1-4 is for station dc supply and
  - Table 1-5 is for control circuits. ~~There is an additional table,~~
  - Table 2, ~~which brings~~is for alarms ~~into the maintenance arena~~; this was broken out to simplify the other tables.
  - ~~Table 3 presents the maintenance activities and intervals for protective relays, current and voltage sensing devices, station dc supply, and control circuitry for~~Table 3 is for components which make-up distributed UFLS and UVLS systems.
- Next look within that Table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your ~~PSMP (~~Performance Based Maintenance (PBM) plan ~~)~~ requires more activities then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your ~~PSMP (plan)~~Performance Based Maintenance plan requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system;

this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every ~~3~~4 months.

- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. ~~(Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal~~ If an entity has a Performance Based Maintenance program then that plan must be followed even if the plan proves to be more stringent than the minimums laid out in the Tables.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver

dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.
6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).
7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.
8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.
9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor based relays. For relay maintenance departments that choose to test microprocessor based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?

As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?

Since components of the SPS, UFLS, and UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. ~~The BES and an entity's bottom line both suffer.~~

We believe that the 4-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team ~~believes~~, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections the 4-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

~~You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.~~

According to R3, if you have a time-based maintenance program then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables. According to R4, if your device in question is part of a Performance Based Maintenance program then you will be in violation of the standard if you fail to meet your PSMP even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss

of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) ~~and auxiliary tripping relays (94)~~ (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or ~~94~~auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electromechanical protective relays be tested~~, for routine scheduled tests,~~ every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

~~Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.~~

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3. This VSL is written to compare missed components to total components. In this case 2 components out of 100 were missed or 2 %.

How do I achieve a "grace period" without being out of compliance?

According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded. The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting

utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for “time-interval extensions” or “grace periods” to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. “Maximum time intervals” by their very term negates any “time-interval extension” or “grace periods”. To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was “…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…” The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set ~~to12~~to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity’s use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is “the sampling distribution of the sample mean can be approximated by a normal probability distribution.” The Central Limit Theorem states: “In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> “… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> “If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation.” (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> “The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> “… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection.” (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a “Pass/Fail” format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%

z = 1.96 (This equates to a 95% confidence level)

π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

~~This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.~~

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue ~~with~~as a countable event within the relevant component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; ~~this is there to prevent an entity from "gaming the system".~~ an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry.~~The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry.~~ Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements.*~~**Segment** – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements.~~ *Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement;~~ this is there to prevent an entity from “gaming the system”.~~ an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme". Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry.~~The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry.~~ Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements.*~~And in Attachment A (PBM) the definition of Segment:~~

~~**Segment** – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements.*~~ *Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes", all of which have three current signals supplied from bushing CT's and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT's and voltage signals from PT's built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement;~~ this is there to prevent an entity from “gaming the system”.~~ an entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval ~~Chosen~~Chose

1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based ma
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the ~~maintenance correctable~~ issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this Standard applies, even if they also perform DME functions.

~~12.~~ Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. ~~R3~~R5 states ~~(the entity must):~~

~~R3~~R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall ~~implement and follow its PSMP and initiate resolution of~~demonstrate efforts to correct any identified unresolved maintenance issues.

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (~~R3) (in essence~~R5) state "…shall ~~implement and follow its PSMP and initiate resolution of~~demonstrate efforts to correct any identified unresolved maintenance issues..." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity ~~could very well ask for documentation showing~~might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to ~~a~~an unresolved maintenance issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; (including but not limited to the following) by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other ~~methods~~method that ~~provide documentation that~~ verifies the ~~expected transformer values as applied to the inputs~~input to the protective ~~relays are acceptable~~relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If ~~these devices~~the lock-out relays (86) are electromechanical type components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

While relays that do not respond to electrical quantities are presently excluded from this standard, their control circuits are included if the relay is installed to detect faults on BES Elements. Thus, the control circuit of a BES transformer sudden pressure relay should be verified every 12 years assuming its integrity is not monitored. While a sudden pressure relay control circuit is included within the scope of PRC-005-2, other alarming relay control circuits, i.e. SF-6 low gas, are not included even though they may trip the breaker being monitored.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil~~, auxiliary relay that carries trip current to a trip coil,~~ and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3)

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.

- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?
Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.
- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (Valve-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.

For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Of course, a measurement of "Conductance" from one manufacturer in a given year could be trended against a measurement of "Conductance" from a different manufacturer's device. This would be true for any unit measurements whether it is conductance, impedance, resistance, voltage, amperage, etc.

Although many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, ~~sulphuric~~sulfuric acid, is consumed and the concentration of the ~~sulphuric~~sulfuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings or a combination of the two. There are test methods, presently, that can read post termination resistances and resistance values between external posts, there are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries “informative” annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries “informative” annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery’s cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?

Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manfacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life. A consistent measurement device should not be confused with a requirement to always stay with the same manufacturer. After all volts are volts, impedance is impedance, etc. It is just important to not expect to get consistent "Impedance" data if you switch to a "Conductance" measuring device in the middle of your trending program.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, "depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity" they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning~~.~~; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level.

Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell. Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the "~~capacity~~perform as designed 6 month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be performed on any communications-assisted trip scheme regardless of the vintage of technology.The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every ~~three~~four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.

- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the ~~3~~4-month inspection of communications-assisted trip scheme equipment?

The ~~3~~4-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes

this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked ~~Question~~Questions:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and Distributed UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current sensing devices have the same maintenance activity and interval as Table 1-2. DC systems need only have their voltage read at the relay every twelve years. Control circuits have the following maintenance activities every twelve years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out ~~and/or auxiliary tripping device(s)~~ used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device~~(s)~~.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS~~/~~ and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however the part of the trip path control circuitry between the load shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

There are times when a Protection System component will be used on a BES device as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System component) will be subject to the Tables of the Standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS …

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 also covers users, owners, and operators of bulk-power facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

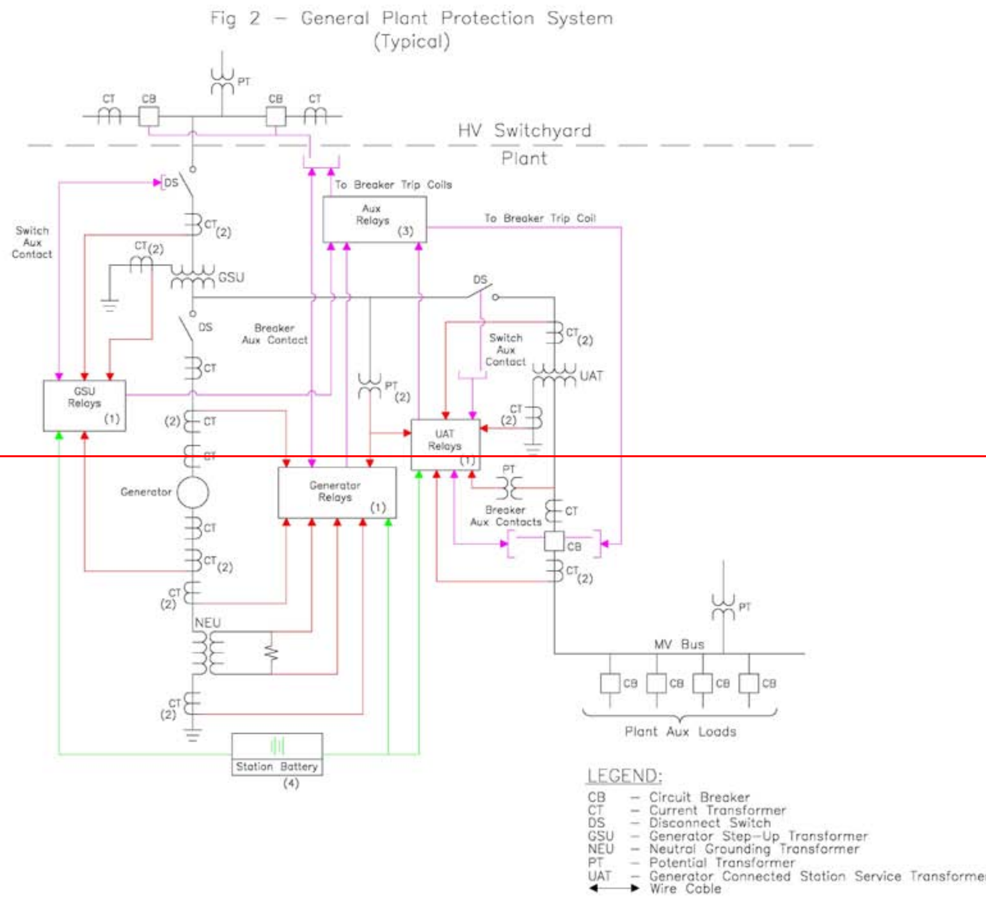
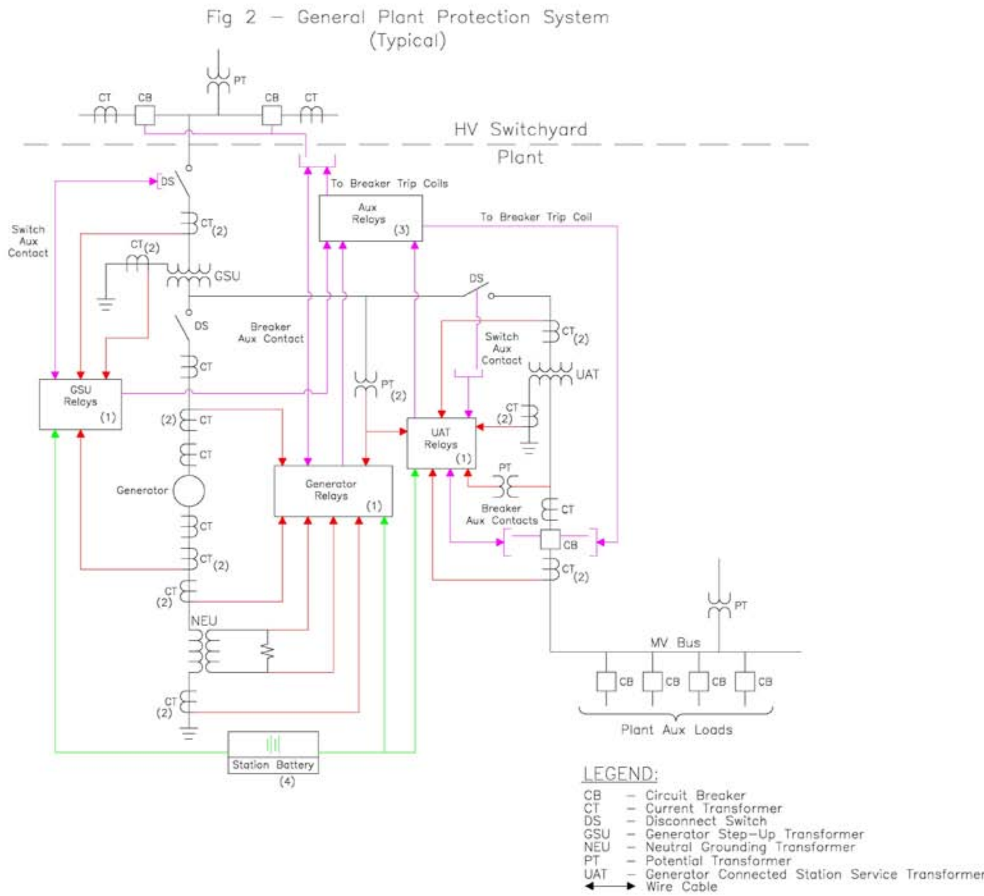
Figure 2: Typical Generation System





For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

Appendix A

Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

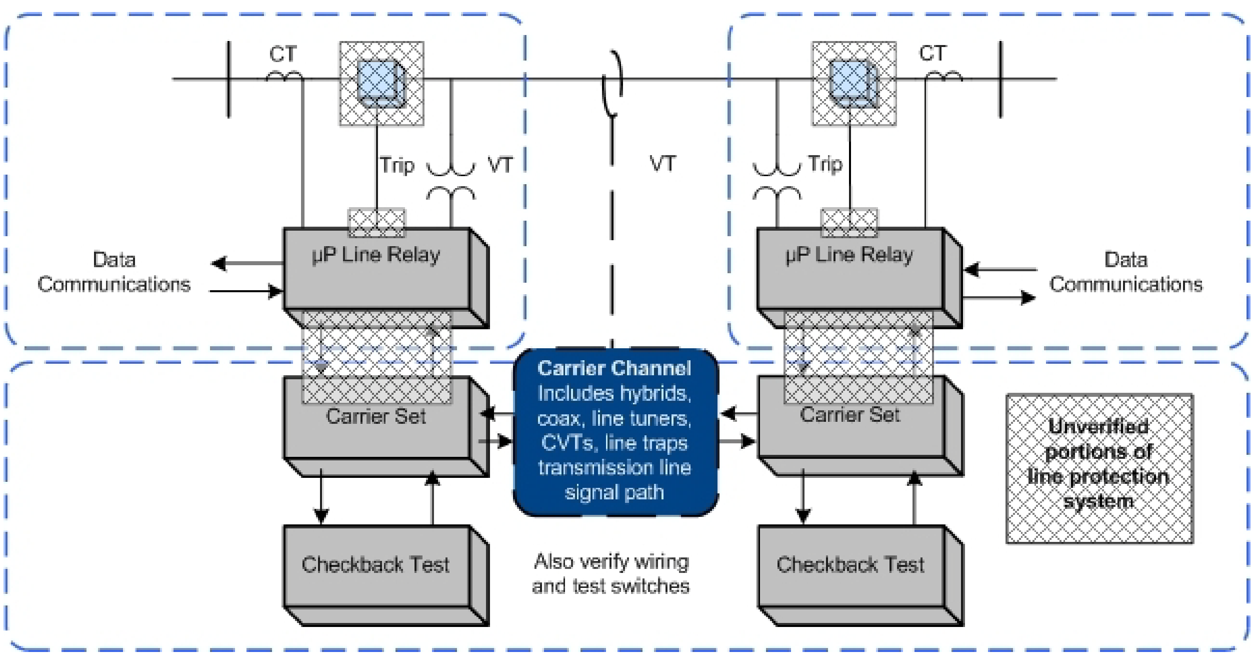
a

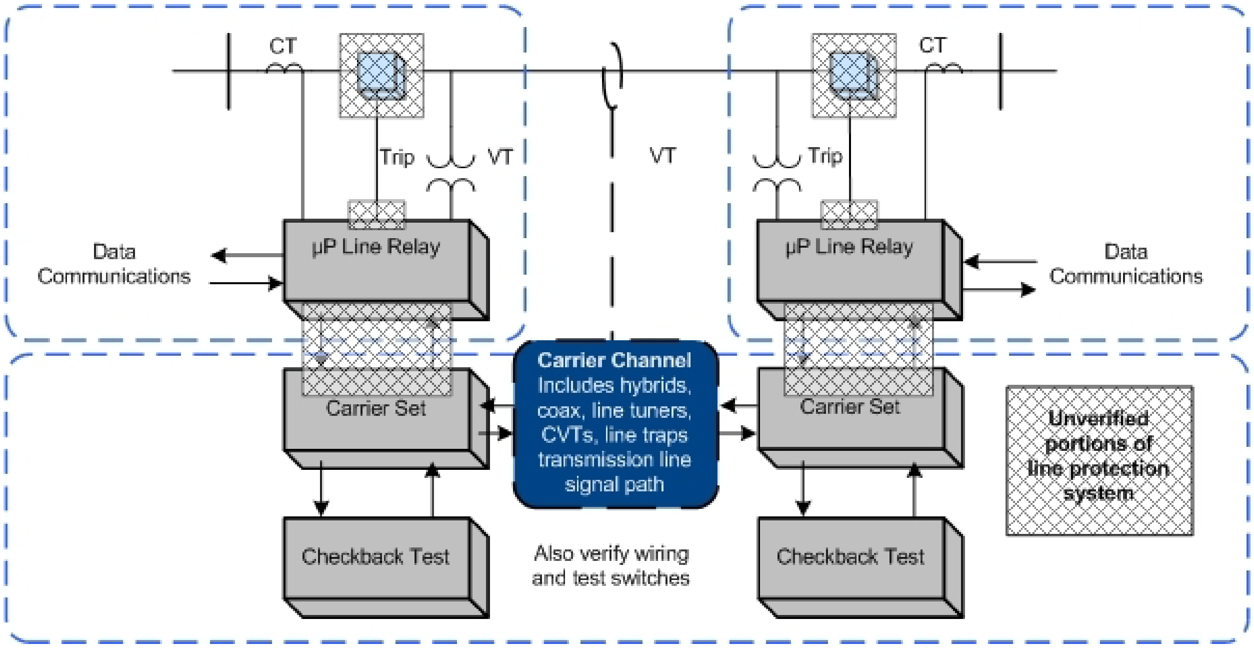
other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2





The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Technical Justification

PRC-005-2 Protection System Maintenance

The purpose of the proposed PRC-005-2 Reliability Standard is to document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. The proposed Reliability Standard further combines the legacy Reliability Standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0, as these legacy Reliability Standards have similar reliability goals and requirements. This purpose is consistent with NERC's goal to create and implement reliability standards that enable or support at least one of the eight, defined Reliability Principles. The requirements of the proposed PRC-005-1 Reliability Standard directly support the following Reliability Principles:

> Reliability Principle 1 – Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
>
> Reliability Principle 7 – The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis.

The existing PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 Reliability Standards, as assessed by the NERC System Protection and Control Task Force (SPCTF) in its report of March 8, 2007, contain several fundamental flaws within the requirements. Within this assessment, the SPCTF asserts, for all four standards, that:

"The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.""

And further recommends that:

- *"The standards should clearly state which power system elements are being addressed."*
- *"The requirements should reflect the inherent differences between different technologies of protection systems."*
- *"The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity."*
- *"The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to*

have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor," and

- *The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 … be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.*

Relative to PRC-005-1, the Federal Energy Regulatory Commission (FERC), in Order 693 further directed in paragraph 1476:

"… the Commission directs the ERO to develop a modification to PRC–005–1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System. We further direct the ERO to consider FirstEnergy's and ISO–NE's suggestion to combine PRC–005–1, PRC–008–0, PRC–011–0, and PRC–017–0 into a single Reliability Standard through the Reliability Standards development process."

FERC offered, in paragraphs 1492, 1517, and 1547, similar directives regarding PRC-008-0, PRC-011-0, and PRC-017-0, respectively.

With the development of the proposed PRC-005-2 Reliability Standard, the Standard Drafting Team (SDT) for Project 2007-17 – Protection System Maintenance, has followed the observations and recommendation of the NERC SPCTF assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. The SDT also addressed FERC's directives from Order 693. The SDT accomplishes this by:

1. Merging the reliability objectives of the four legacy standards.
2. Establishing minimum acceptable maintenance activities and accompanying maximum allowable maintenance intervals, reflecting various technologies of the components being addressed.
3. Providing entities the flexibility to implement condition-based maintenance by adjusting the minimum acceptable maintenance activities and maximum allowable maintenance intervals to reflect condition monitoring of the various Protection System components, and
4. Providing requirements for effective implementation of a performance-based maintenance program.

The proposed PRC-005-2 Reliability Standard includes five requirements that:

1. Combines the reliability goals of developing detailed tables of minimum maintenance activities and maximum maintenance intervals for all five component types addressed within the NERC definition of Protection System. These tables include adjustments to those activities and intervals to reflect the benefits of any condition monitoring that may be present.

2. Requires, within Requirement R1, that entities using a time-based maintenance program (which includes condition-based maintenance) shall establish a Protection System Maintenance Program (PSMP) that conforms to the tables described above.
3. Establishes, within Requirement R2, the opportunity and requirements for establishment of a performance-based maintenance program for those entities that have (or wish to develop) sufficient performance observations for their Protection System components such that they may determine maintenance intervals other than those specified within the tables while maintaining the level of reliability prescribed within the Standard.
4. Requires, within Requirements R3 and R4, that entities fully implement their PSMP as determined pursuant to Requirement R1 for time-based maintenance programs and Requirement R2 for performance-based maintenance programs, respectively.
5. Further requires, within Requirement R5, that entities initiate resolution of any issues discovered during maintenance that cause the entities to be unable to return the associated components to good working order. The SDT elected to not require that entities complete the resolution of these issues, as the time required to effectively resolve the problems may vary widely depending on the scope of that resolution.

The proposed PRC-005-2 Reliability Standard provides a comprehensive set of requirements and associated information (within the tables) that define a strong PSMP. Entities that monitor the actual condition of their Protection System components are further empowered to utilize the monitoring to improve the efficiency and effectiveness of their PSMP, and those entities that have extensive performance data regarding their Protection System components to utilize that performance data to further improve the efficiency and effectiveness of their PSMP.

Requirement R1:

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. *Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.*

1.2. *Include the applicable monitoring attributes applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System components.*

Background and Rationale

Establishment of a Protection System Maintenance Program as directed by Requirement R1 is needed to detect and correct plausible age- and service-related degradation of Protection System components. To ensure reliability of the Bulk Electric System, it is important that a Protection System continue to function as designed over its service life.

Requirement R1 establishes that entities develop a comprehensive maintenance program for Protection System components addressing the elements specified in the Protection System Maintenance Program definition:

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

  A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the directives of FERC Order 693 even more effectively than the strictly time-based tests of the same system components.

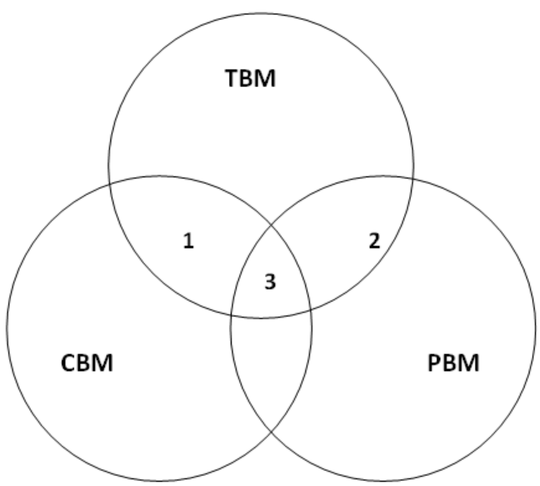
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a

relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

The PSMP shall:

R1, Part 1.1 **Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type.**

R1, Part 1.1 gives entities the flexibility to choose between the various methods listed above to maintain their Protection System equipment.

All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

R1, Part 1.2 Include the applicable monitoring attributes applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System components.

It is necessary for entities to specify the monitoring attributes utilized in their PSMP to demonstrate the existence of the monitoring elements which permit using the extended maintenance intervals established in Tables 1-1 through 1-5, Table 2, and Table 3 of the standard.

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. Making use of the extended intervals by employing component monitoring minimizes human performance errors. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Requirement R2:

Overview

Requirement 2, stated below, deals with Performance Based Maintenance. The requirement refers to Attachment A. Rather than simply list Attachment A, the requirements of Attachment A are listed below with a technical justification discussion for each. The criteria within Attachment A are largely based on application of statistical analysis theory.

Requirement R2

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Background and Rationale

Performance Based Maintenance (PBM) is included in PRC-005-2 to allow utilities to adjust maintenance intervals based on their individual experience with equipment types and manufacture. The utility must create a segment of components with similar manufacture and model characteristics of statistically significant size.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Based on equipment failure(s) and out-of-tolerance(s), called countable events, in any given year, the utility then sets its maintenance interval to keep the countable events below 4%. Performance Based Maintenance is discussed at length in Section 9.1 of the Supplemental Reference for PRC-005-2. Many of the technical justifications shown below come from of the Supplemental Reference. Each requirement of Attachment A will now be listed and individually discussed.

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.

   A sample size requirement can be estimated using the bound on the Error of

Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:
B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4% (see number 5 below)
Using the equation above, n=59.0. The Standard Drafting Team chose to use the round number of 60 for the requirement.

2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.

   An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.

   This requirement needs little justification. To analyze system performance, the activities and results must be documented.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.

   This requirement states the obvious for a program that is based on the performance results of the segment.

5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

The Performance Based Maintenance (PBM) program ensures no more than a 4% failure rate for each segment of a component type. The 4% number was developed using the following:

- General experience of the Standard Drafting Team (SDT) based on open discussions of past performance.
- Test results provided by Consumers Energy for the years 1998-2008 showing a yearly average of 7.5% out-of-tolerance relay test results and a yearly average of 1.5% defective rate.
- Two failure analysis reports from Tennessee Valley Authority (TVA) where TVA identified problematic equipment based on a noticeably higher failure of a certain relay type (failure rate of 2.5%) and voltage transformer type (failure rate of 3.6%).

In addition to the number "30" discussion from number 2 above, the Error of Distribution formula discussed in number 1 above allows the number of components that should be included in a sample size for evaluation of the appropriate testing interval to be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:
B = 5%
z = 1.44 (85% confidence level)
π = 4%
Using the equation above, n=31.8. The Standard Drafting Team chose to use the round number of 30.

6. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.

   Annually was chosen as a reasonable time frame to update component segments due to component installation, replacement, and retirement.

7. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.

   Note: this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

   This requirement ensures that a utility keeps a flow of recent data to use in its annual analysis. The Standard Drafting Team felt that 20 years was the maximum time that should be allowed before a component should be checked or maintained. The minimum number of three allows for the same 20 years interval based on the minimum segment population of 60 (60/3=20).
8. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

Annually was chosen as a reasonable time frame to allow for collection of new data to update the program's performance analysis.

9. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

   Refer to number 5 above.

10. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

    The 4% number is discussed in number 5 above. Three years was chosen by the Standard Drafting Team because it allows time to modify the program and for the effects of a modified program to be observed.

Requirement R3:

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance programs shall maintain its Protection System components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R3 requires the implementation of the minimum maintenance activities and maximum allowable maintenance intervals as elucidated in Requirement R1 and the tables within the standard.

Requirement R4:

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance programs in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System components that are included within the performance-based program. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R4 requires the implementation of an entity's Protection System Maintenance Program established pursuant to Requirement R2.

Requirement R5:

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

***Unresolved Maintenance Issue** - A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.*

Background and Rationale

The reliability objective of this requirement is to assure that Protection System components are returned to working order following the discovery of failures or malfunctions during scheduled maintenance. The maintenance activities specified in the Tables 1-1 through 1-5, Table 2, and Table 3 do not present any requirements related to restoration; therefore Requirement R5 of the Standard was developed to require the entity to "demonstrate efforts to correct identified unresolved maintenance issues".

The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action has been initiated. Therefore Requirement R5 requires only the entity demonstrate efforts to correct the unresolved maintenance issues.

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose to require the entity to “demonstrate efforts to correct …” because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity.

During the period of time that the Protection System is operating in a degraded mode, NERC Standard PRC-001-1 requires that operating entities be informed of any Protection System failures that reduce reliability, and several NERC IRO-series and TOP-series standards require that operating entities operate the system in a manner that assures reliability while recognizing any system degradation.

Project 2007-17 Protection System Maintenance and Testing Mapping Document

Mapping Document Showing Translation of PRC-005-1a – Transmission and Generation Protection System Maintenance and Testing, PRC-008-0- Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 - Undervoltage Load Shedding System Maintenance and Testing, and PRC-017-0 - Special Protection System Maintenance and Testing into PRC-005-2 – Protection System Maintenance.

Table of Issues and Directives

Project 2007-17 Protection System Maintenance and Testing

Table of Issues and Directives Associated with PRC-005-2			
Source	**Directive Language (including pg #)**	**Disposition**	**Section and/or Requirement(s)**
FERC Order 693	1475. In addition, for the reasons discussed in the NOPR, the Commission directs the ERO to develop a modification to PRC-005-1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.	Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 2 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.	Requirement R3, Requirement R4, Tables 1-1 through 1-5, and Table 2, Attachment A
FERC Order 693	1475. We further direct the ERO to consider FirstEnergy's and ISO-NE's suggestion to combine PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 into a single Reliability Standard through the Reliability Standards development process.	These suggestions were adopted. The SDT is combining the four legacy standards into one.	NA

Table of Issues and Directives Associated with PRC-005-2			
Source	**Directive Language (including pg #)**	**Disposition**	**Section and/or Requirement(s)**
FERC Order 693	1492. In addition, the Commission directs the ERO to develop a modification to PRC-008-0 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.	Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 3 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.	Applicability 4.2.2, Requirement R3, Requirement R4, Tables 1-1 through 1-5, and Table3.
FERC Order 693	1516. The Commission believes that the proposal is presently part of the process. The Commission approves Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, the Commission directs the ERO to submit a modification to PRC-011-0 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.	Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, Table 2, and Table 3 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.	Applicability 4.2.3, Requirement R3, Requirement R4, Tables 1-1 through 1-5, Table 2, and Table 3.

Version 0 Team	Definition of evidence required	Requirement R3 states that the program must be implemented. Evidence that the program is implemented is included in the Measure M3.	M1, M2, M3, M4, and M5 all contain examples of evidence
Version 0 Team	Consistent wording from standard to standard required	The SDT is combining the four legacy standards into one.	NA

Table of Issues and Directives Associated with PRC-005-2			
Source	**Directive Language (including pg #)**	**Disposition**	**Section and/or Requirement(s)**
Version 0 Team	Exemptions for those with shunt reactors	UV Relays on shunt reactors is not UVLS; these relays would be included as pertinent to relays "applied on or to protect the BES".	NA
Version 0 Team	Define evidence	Requirement R3 states that the program must be implemented. Evidence that the program is implemented is included in the Measure M3.	M1, M2, M3, M4, and M5 all contain examples of evidence
Version 0 Team	Need to retain two dates	The Standard requires that data be retained for the last two maintenance intervals or to the last audit, whichever is longer.	See data retention clause
Version 0 Team	Define evidence	Requirement R3 states that the program must be implemented. Evidence that the program is implemented is included in the Measure M3.	M1, M2, M3, M4, and M5 all contain examples of evidence

Table of Issues and Directives Associated with PRC-005-2			
Source	**Directive Language (including pg #)**	**Disposition**	**Section and/or Requirement(s)**
NERC Audit Observation Team	How do you verify compliance for cts/pts? How do you audit these within a scheduled maintenance program? As part of the procedure, most have accepted visual inspection. Some entities state that testing of the relays verify functionality of the ct/pt.	Verification activities in Table 1-3 establish the activities required for the voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices.	Specific activities for current and voltage transformers have been defined within Table 1-3
NERC Audit Observation Team	How do you verify DC control power? All regions require functional testing of the breaker. This should include functional relay & station battery checks, including breaker tripping, not just a visual inspection.	Specific verification activities are established in Table 1-4.	Specific activities for maintenance of dc control circuitry have been defined within Table 1-4. These activities include periodic verification of proper functioning of the dc control circuitry.
NERC Audit Observation Team	Determine what on schedule means. Is an entity who maintained/tested 95% of their relays at the same level of non-compliance as an entity who maintained/tested 10% of their relays?	The VSL for maintenance program implementation (Requirement R3) establishes different VSLs depending on the degree to which the program is implemented.	The VSLs for Requirement R3, Requirement R4 have been "phased" such that an entity that

Table of Issues and Directives Associated with PRC-005-2			
Source	**Directive Language (including pg #)**	**Disposition**	**Section and/or Requirement(s)**
			“misses” only a few required activities will be at a lower VSL than entities that “miss” many such activities.
NERC Audit Observation Team	As applicable, each TO, DP and GOP shall have a protection system maintenance and testing program for protection systems that affect the reliability of the BES. Does this include major equipment like circuit breakers and transformers?	Maintenance of **Protection Systems** on all BES equipment is included within this standard. Circuit breakers and power transformers are not included in the definition of Protection System; instrument transformers are included within the definition.	See definition of Protection System.
Fill in the Blank Team	Okay if PRC-006 is fixed	Applicability section of PRC-005-2 (4.2.2) establishes applicability to UFLS established in accordance with ERO requirements.	Applicability 4.2.2, Requirement R3, Requirement R4, Tables 1-1 through 1-5, and Table 3

Table of Issues and Directives Associated with PRC-005-2

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Project 2007-17 – PRC-005-2: Protection System Maintenance

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-2 — Protection System Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria - Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC Violation Risk Factor Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management

- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard
The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards
The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005-2 Protection System Maintenance is a revision of PRC-005-1a Transmission and Generation Protection System Maintenance and Testing with the stated purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. PRC-008-0 Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 Undervoltage Load Shedding System Maintenance and Testing and PRC-017-0 Special Protection System Maintenance and Testing are also being replaced by merging them into PRC-005-2 in accordance with suggestions from FERC Order 693. PRC-005-2 also establishes maximum allowable maintenance intervals as directed by FERC in Order 693 in their discussion of the legacy standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

PRC-005-2 has five (5) requirements that incorporate and enhance the intent of the requirements of PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. Several Tables of minimum maintenance activities and maximum maintenance intervals are also included to addresses FERC's directives from Order 693. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Protection System components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement-to-requirement comparison of VRFs is irrelevant. When developing VRFs for the requirements of PRC-005-2, the Standard Drafting Team carefully considered the NERC criteria for developing VRFs, as well as the FERC VRF guidelines. Therefore, PRC-005-2 Requirements R3 and R4 are assigned a VRF of High, while Requirements R1, R2, and R5 are assigned VRFs of Medium.

PRC-005-2 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-2 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-2 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - Violation Severity Levels

Violation Severity Levels (VSLs) define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

Violation severity levels should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on Violation Severity Levels

In its June 19, 2008 Order on Violation Severity Levels, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-2 Requirement R1.

VRF and VSL Justifications – PRC-005-2, R1			
Proposed VRF	**Medium**		
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF..		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.		
Proposed VSL			
Lower	**Moderate**	**High**	**Severe**
The responsible entity's PSMP failed to specify whether one component type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entity's PSMP failed to specify whether two component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entities' PSMP failed to include the applicable monitoring attributes applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-	The responsible entity failed to establish a PSMP. NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R2	
Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R3	
Proposed VRF	**High**
NERC VRF Discussion	Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only Reliability Standards with similar goals are those being replaced by this standard, and the High VRF assignment for this requirement is consistent with the assigned VRFs for companion requirements in those existing standards.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL			
Lower	**Moderate**	**High**	**Severe**
For Protection System components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total components included within a specific Protection System component type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total components included within a specific Protection System component type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total components included within a specific Protection System component type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total components included within a specific Protection System component type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.

VRF and VSL Justificati3ons – PRC-005-2, R3	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R3	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R4	
Proposed VRF	**High**
NERC VRF Discussion	Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.

FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only Reliability Standards with similar goals are those being replaced by this standard, and the High VRF assignment for this requirement is consistent with the assigned VRFs for companion requirements in those existing standards.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL			
Lower	**Moderate**	**High**	**Severe**
For Protection System components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System component type in accordance with their performance-based PSMP.	For Protection System components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System component type in accordance with their performance-based PSMP.	For Protection System components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System component type in accordance with their performance-based PSMP.	For Protection System components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System component type in accordance with their performance-based PSMP.

VRF and VSL Justifications – PRC-005-2, R4	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R4	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R5	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to initiate resolution of an unresolved maintenance issue for a Protection System component could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only requirement within approved Standards, PRC-004-2a Requirements R1 and R2 contain a similar requirement and is assigned a HIGH VRF. However, these requirements contain several subparts, and the VRF must address the most egregious risk related to these subparts, and a comparison to these requirements may be irrelevant. PRC-022-1 Requirement R1.5 contains only a similar requirement, and is assigned a MEDIUM VRF. FAC-003-2 Requirement R5 contains only a similar requirement, and is assigned a MEDIUM VRF.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to initiate resolution of an unresolved maintenance issue for a Protection System component could directly affect the electrical state or the capability of the bulk power system.

VRF and VSL Justifications – PRC-005-2, R5			
Proposed VRF	**Medium**		
	However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.		
Proposed VSL			
Lower	**Moderate**	**High**	**Severe**
The responsible entity failed to undertake efforts to correct 5 or less unresolved maintenance issues.	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10 unresolved maintenance issues.	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15 unresolved maintenance issues.	The responsible entity failed to undertake efforts to correct greater than 15 unresolved maintenance issues.

VRF and VSL Justifications – PRC-005-2, R5	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This is a new Requirement; consequently, there is no prior level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R5	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

Project 2007-17 Protection System Maintenance and Testing

Please **DO NOT** use this form. Please use the electronic comment form on the project page at the link below to submit comments on the second draft of the PRC-005-2 standard for Protection System Maintenance and Testing. Comments must be submitted by **March 28, 2012.** If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:

This project recently failed to receive two-thirds weighted stakeholder approval on the most recent initial ballot of PRC-005-2. The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) has made several changes to PRC-005-2 based on comments received from industry. The changes include:

- Revised Requirement R1 to state that an entity's Protection System Maintenance Program (PSMP) shall include for each Protection System component type: an identification of the maintenance method(s) used, and the identification of the relevant monitoring attributes applied.
- Separated Requirement R3 into three requirements:
    - Requirement R3 now requires an entity utilizing a time-based program to maintain its Protection System components in accordance with the maximum maintenance intervals listed in the Tables. This change removes the compliance jeopardy associated with an entity having more stringent intervals (in its PSMP) than those listed in the Tables.
    - Requirement R4 (new) requires an entity utilizing a performance-based program to maintain its Protection System components in accordance with its performance-based Protection System Maintenance Program.
    - Requirement R5 (new) requires an entity to demonstrate efforts to correct identified unresolved maintenance issues. The previous language in Requirement R3 directed that an entity initiate resolution.

- Modified the VSLs to reflect the changes listed above.
- The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised within comments.

The PSMT SDT is posting this standard for a formal 30-day comment period and successive ballot.

For questions 1-3, please provide specific comments related to the individual question. Please reserve question 4 for general comments not related to questions 1-3.

1. In response to comments, the PSMTSDT revised Requirement R1 to state that an entity's Protection System Maintenance Program (PSMP) shall include, for each Protection System component type, an identification of the maintenance method(s) used, and the identification of the relevant monitoring attributes applied. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

   ☐ Yes

   ☐ No

   Comments:

2. As a result of the changes to Requirement R1, the previous Requirement R3 was separated into three requirements:

   a. Requirement R3 now requires that an entity utilizing a time-based program maintain its Protection System components in accordance with the maximum maintenance intervals listed in the Tables. This change removes the compliance jeopardy associated with an entity having more stringent intervals (in its PSMP) than those listed in the Tables.

   b. Requirement R4 (new) requires an entity utilizing a performance-based program maintain its Protection System components in accordance with its performance based Protection System Maintenance Program

   c. Requirement R5 (new) requires an entity to demonstrate efforts to correct identified unresolved maintenance issues. The previous language in Requirement R3 directed that an entity initiate resolution.

   Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

   ☐ Yes

   ☐ No

   Comments:

3. The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised. Do you agree with the changes? If you do not agree, please provide specific suggestions for improvement.

   ☐ Yes

   ☐ No

   Comments:

4. If you have any other comments on this Standard that you **have not already provided in response to the prior questions**, please provide them here.

   Comments:

A. Introduction

1. **Title:** **Transmission and Generation Protection System Maintenance and Testing**

2. **Number:** PRC-005-1

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

4. **Applicability**

   4.1. Transmission Owner.

   4.2. Generator Owner.

   4.3. Distribution Provider that owns a transmission Protection System.

5. **Effective Date:** May 1, 2006

B. Requirements

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained.

C. Measures

M1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have an associated Protection System maintenance and testing program as defined in Requirement 1.

M2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have evidence it provided documentation of its associated Protection System maintenance and testing program and the implementation of its program as defined in Requirement 2.

D. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Monitoring Responsibility

   Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for three years.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and the Generator Owner that owns a generation Protection System, shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program provided was incomplete as required in R1, but records indicate maintenance and testing did occur within the identified intervals for the portions of the program that were documented.

2.2. Level 2: Documentation of the maintenance and testing program provided was complete as required in R1, but records indicate that maintenance and testing did not occur within the defined intervals.

2.3. Level 3: Documentation of the maintenance and testing program provided was incomplete, and records indicate implementation of the documented portions of the maintenance and testing program did not occur within the identified intervals.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
1	December 1, 2005	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. 3. Changed “Timeframe” to “Time Frame” in item D, 1.2.	01/20/05

A. Introduction

1. Title: **Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program**

2. Number: PRC-008-0

3. Purpose: Provide last resort system preservation measures by implementing an Under Frequency Load Shedding (UFLS) program.

4. Applicability:

4.1. Transmission Owner required by its Regional Reliability Organization to have a UFLS program

4.2. Distribution Provider required by its Regional Reliability Organization to have a UFLS program

5. Effective Date: April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.

R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner's and Distribution Provider's UFLS equipment maintenance and testing program contains the elements specified in Reliability Standard PRC-007-0_R1.

M2. Each Transmission Owner and Distribution Provider shall have evidence that it provided the results of its UFLS equipment maintenance and testing program's implementation to its Regional Reliability Organization and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (within 30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Undervoltage Load Shedding System Maintenance and Testing**

2. **Number:** PRC-011-0

3. **Purpose:** Provide system preservation measures in an attempt to prevent system voltage collapse or voltage instability by implementing an Undervoltage Load Shedding (UVLS) program.

4. **Applicability:**

   4.1. Transmission Owner that owns a UVLS system

   4.2. Distribution Provider that owns a UVLS system

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include:

R1.1. The UVLS system identification which shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have documentation that its UVLS equipment maintenance and testing program conforms with Reliability Standard PRC-011-0_R1.

M2. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have evidence it provided documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program as specified in Reliability Standard PRC-011-0_R2.

D. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Special Protection System Maintenance and Testing**

2. **Number:** PRC-017-0

3. **Purpose:** To ensure that all Special Protection Systems (SPS) are properly designed, meet performance requirements, and are coordinated with other protection systems. To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected.

4. **Applicability:**

   4.1. Transmission Owner that owns an SPS

   4.2. Generator Owner that owns an SPS

   4.3. Distribution Provider that owns an SPS

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include:

R1.1. SPS identification shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

C. Measures

M1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place that includes all items in Reliability Standard PRC-017-0_R1.

M2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have evidence it provided documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization. Each Region shall report compliance and violations to NERC via the NERC Compliance Reporting process.

Timeframe:
On request (30 calendar days.)

1.2. Compliance Monitoring Period and Reset Timeframe

Compliance Monitor: Regional Reliability Organization.

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing

Ballot and Non-binding Poll Windows Open Through 8 p.m. Wednesday, Mar. 28, 2012

Now Available

A successive ballot of PRC-005-2 – Protection System Maintenance and Testing and a non-binding poll of the associated VRFs and VSLs, are **open through 8 p.m. Eastern on Wednesday, March 28, 2012.**

Instructions for Balloting

Members of the ballot pool associated with this project may log in and submit their vote for the Standard, and opinion for the non-binding poll by clicking here.

Special Instructions for Submitting Comments with a Ballot

Please note that comments submitted during the formal comment period, ballot, and non-binding poll all use the same electronic form. Therefore, it is NOT necessary for ballot pool members to submit more than one set of comments. Companies or entities with representatives in multiple segments of the ballot pool may submit a single set of comments by identifying themselves as a "group" on the comment form. Likewise, it is **preferable** for a group of separate entities that develop comments jointly to submit the comments as a "group." **The drafting team requests that all stakeholders (ballot pool members as well as other stakeholders) submit all comments through the electronic comment form, and that companies in multiple segments as well as individual entities that develop joint comments with other entities submit their comments as a "group."**

Next Steps

The drafting team will consider all comments and determine what changes to make in response to stakeholder input from the comments.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing

Ballot and Non-binding Poll Windows Open Through 8 p.m. Wednesday, Mar. 28, 2012

Now Available

A successive ballot of PRC-005-2 – Protection System Maintenance and Testing and a non-binding poll of the associated VRFs and VSLs, are **open through 8 p.m. Eastern on Wednesday, March 28, 2012.**

Instructions for Balloting

Members of the ballot pool associated with this project may log in and submit their vote for the Standard, and opinion for the non-binding poll by clicking here.

Special Instructions for Submitting Comments with a Ballot

Please note that comments submitted during the formal comment period, ballot, and non-binding poll all use the same electronic form. Therefore, it is NOT necessary for ballot pool members to submit more than one set of comments. Companies or entities with representatives in multiple segments of the ballot pool may submit a single set of comments by identifying themselves as a "group" on the comment form. Likewise, it is **preferable** for a group of separate entities that develop comments jointly to submit the comments as a "group." **The drafting team requests that all stakeholders (ballot pool members as well as other stakeholders) submit all comments through the electronic comment form, and that companies in multiple segments as well as individual entities that develop joint comments with other entities submit their comments as a "group."**

Next Steps

The drafting team will consider all comments and determine what changes to make in response to stakeholder input from the comments.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing
Formal Comment Period Open February 28 – March 28, 2012
Successive Ballot and Non-binding Poll: March 19 – 28, 2012

Now available

The Protection System Maintenance and Testing drafting team (PSMSDT) has posted its consideration of comments from the formal comment period and initial ballot of PRC-005-2 Protection System Maintenance that ended on September 29, 2011, along with a revised draft of the standard, Supplemental Reference and FAQ, and associated implementation plan for a parallel formal comment period and successive ballot, with a non-binding poll of the associated VRFs and VSLs, are open through **8 p.m. Eastern on Wednesday, March, 28, 2012**.

Documents for this project, including the SAR, clean and redline versions of PRC-005-2, the associated Implementation Plan, and Supplemental Reference and FAQ along with an unofficial copy of the comment form are posted on the project's web page. Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a redline of proposed PRC-005-2 that shows the changes to the last approved version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference.

Instructions for Submitting Comments

A formal comment period is open through **8 p.m. Eastern on Wednesday, March 28, 2012.**

Please use this electronic comment form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net.

Next Steps

A successive ballot of PRC-005-2 and the associated implementation plan, and a non-binding poll of VRFs and VSLs will begin on March 19, 2012 and will end on March 28, 2012 at 8 p.m. Eastern.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.
