My comment is in regard to the proposed maintenance tasks associated with ohmic testing and capacity testing of lead-acid batteries affected by PRC-005-2. The option is given to the battery use to perform either inter cell/unit ohmmic tests OR battery capacity tests whichever suits the user. The two tests, while related, are not directly interchangeable with one another. Ohmic tests are intended to be used as a tool during battery maintenance inspections to determine the general state of health (condition) of the battery as a whole. Capacity tests are intended to demonstrate the actual capacity of a battery. Ohmic tests cannot be substituted for capacity tests. Alber has pioneered the development of portable and fixed internal resistance test equipment for stationary lead-acid batteries since 1972. Through years of research, testing in real-world applications and development, Alber has conclusively determined that there is a direct relationship between internal cell resistance and capacity. However, because this correlation is not linear, ohmic measurements should not be used to calculate capacity or remaining life. Ohmic measurements should used as a supplement to capacity testing and not as a replacement. These measurements are very valuable in identifying developing problems between the capacity testing intervals and for determining whether a battery string is going to perform its intended mission. IEEE 1188-2005 for VRLA batteries agrees with this and recommends measurement of this parameter once every three months. While not specifically recommended in IEEE 450-2010 for vented lead-acid batteries, ohmic measurements can provide early warning of potential failure and should be performed at least annually. Again, if readings result in doubt that a battery will perform as intended, follow up capacity testing is recommended. A battery discharge test completely simulates the operating environment and therefore conclusively proves that a battery can perform during an emergency. The results of these tests will help set the priority for capacity testing as the user becomes more familiar with their batteries and may assist in extending capacity test intervals. The intention of the proposed NECR PRC-005-2 standard as it relates to the DC supply, and, in particular, the station battery is to increase reliability of the bulk electric system (BES) in north America. In its current draft form, PRC-005-2 proposes the utility may perform internal ohmic measurements or perform capacity, but both tests are not required. It would appear therefore, that the Standards Drafting Team (SDT) has made the assumption that test results obtained from measuring cell internal ohmic values is the same as performing a capacity test. It is not, and to provide the option to perform one test or the other runs counter to industry recommended practices. Such maintenance practices will, in effect, ultimately reduce the reliability of the BES rather than improve it. Periodic capacity testing on a 5 year interval for VLA batteries, and a 2 year interval for VRLA batteries is consistent with IEEE 450-2010 and IEEE 1188-2005 recommended practices respectively. It should be part of a complete maintenance program designed to maximize the DC supply's availability when needed. Respectfully submitted, Richard Tressler Alber Corp.

Specifying “by component type” appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to “by component or component type” when entities determine the maintenance method in their PSMP. Generally, have concerns with all the new definitions except the NERC definition of Protection System. The approach to creating new definitions of plain language in a standard should be avoided.
Yes
We appreciate the work of the drafting team to fulfill the SAR objectives. Flathead generally does not like some of the new definitions proposed by the revised standard, especially R5, “Unresolved Maintenance Issues” is too vague and will be left up to individual auditors to determine compliance. In addition, it appears the drafting team is creating new definitions for plain english in the definition of Protection System Maintenance Program (PSMP). Surely "test, monitor, inspect, calibrate" don't need NERC definitions. Let's leave the definition as "An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored." Suggest deleting "A maintenance program for a specific component includes one or more of the following activities: • Verify— Determine that the component is functioning correctly. • Monitor — Observe the routine in-service operation of the component. • Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. • Inspect — Detect visible signs of component failure, reduced performance and degradation. • Calibrate—Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended erformance requirement." In addition, it appears the component and component type definitions alter the meaning of the NERC approved definition of a protection system. I would suggest the drafting team not try to redefine the NERC-approved definition of Protection system. "Countable Event" definition seems to conflict with standards related to Misoperation of protection system.

Yes
The IESO continues to disagree with the VRF assigned to the new R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.

Sacramento Municipal Utility District
1) SMUD wishes to comment on the requirement to test the trip paths from relays that do not respond to electrical quantities. In two separate sections of the FAQ, the SDT included this new guidance on the trip paths. In section 2.4.1 of the FAQ, the SDT plainly asserts that the trip path from Sudden Pressure Relays (SPR) will now be covered and implies that the trip paths from non-electrically initiated devices might also be covered. In section 2.4.1, the SDT does not provide any guidance on how to determine which trip paths are included, but does provide guidance on how one

might test the trip path. In section 15.3, the SDT finally provides the guidance – control circuits (trip paths) are included if the relay is installed to detect faults on BES Elements. In reviewing the definition of Protection System, SMUD feels the “Control circuitry associated with protective functions…” to be in reference to the “Protective relays which respond to electrical quantities”. The SDT is now applying a new interpretation in which each of the five bullets is considered separately. Furthermore, the SDT appears to be defining “…associated with protective functions…” to mean detecting faults on the BES. What basis can the SDT offer for defining this phrase to mean detecting faults on the BES? Since this same wording is not used in defining the relay, can a relay be covered under the standard, but not its control circuitry? For instance, Out of Step Tripping? Over Excitation? Frequency or Voltage Protection on a generator? These relays respond to electrical quantities, but are not applied to detect faults on BES Elements. SMUD believes this interpretation takes us down a very confusing path. SMUD respectively requests the SDT strike the new wording (as seen on the redlined version) in 2.4.1 and 15.3.

1. Table 3, Row 7: The requirement to “Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices” contradicts Section 15.7, bullet 2 of the Supplementary Reference and FAQ document. In the supplementary reference, the phrase “and/or auxiliary tripping device(s)” has been struck out.
Individual
Ingleside Cogeneration LP
Yes
Ingleside Cogeneration agrees that a Compliance Authority should be alerted to those component types which have been assigned extended maintenance intervals because they use some form of monitoring. We also agree that it is appropriate that the PSMP list the relevant monitoring attributes in these cases, so they can be confirmed to be consistent with the criteria in PRC-005-2’s interval tables.
No
Ingleside Cogeneration LP strongly agrees with the change made to the language in R1 and R3 specifying that compliance is measured against the PRC-005-2’s interval tables wherever time-based methods are used. The intervals were carefully designed to assure an acceptable level of BES reliability, and the regulatory authorities must be prepared to stand by them. Furthermore, a Registered Entity who may establish tighter intervals for their own internal purposes should be encouraged to do so – and without a threat of a violation hanging over their heads. We also agree with the need to add a new requirement (R4) which applies to those entities who choose to use a performance-based system to determine some of their maintenance intervals. It logically maps back to requirement R2 which states that the calculated intervals must be documented in the PSMP. We cannot agree with the language used in R5, which, in its previous form under R3, had specified only that the Protection System owner “initiate resolution” to correct identified unresolved maintenance issues. We were actually comfortable with this language as it was unambiguous that progress did not need to be tracked start-to-finish. We would like to propose adding a phrase that tracks the statement in M5; which we find acceptable. This would result in the following: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate THAT IT HAS UNDERTAKEN <our emphasis> efforts to correct identified Unresolved Maintenance Issues.
No
We do not agree with the assertion in the reference and FAQs that the DC supply and control circuitry for mechanical components are part of a BES Protection System. This is not an accepted norm in the existing Standard as the Project Team claims – only an expansion in scope that was not properly vetted by the industry. If the Compliance Authorities believe that electrical components which support mechanical systems are rightfully part of the BES or BPS, then this has implications far beyond Protection System maintenance. The appropriate place to begin this determination is with Project 2010-17 Defintion of the BES – where it can be fully reviewed by all affected industry stakeholders.
The derivation of the implementation plan apparently incorporates the “requirements” of NERC’s Compliance organization, which has released several CANs on the topic. This is exactly backwards, and has led to at least one CAN which has been withdrawn due to legal overreach. However, the plan as written is very complex. We believe that diagrams of acceptable time frames should be included in the implementation plan so that industry stakeholders can better assess the impact on their maintenance operations.
Individual
Liberty Electric Power LLC
Yes
Yes
Thank you for the change in Requirement 3. This standard now gives clear direction to entities, removes the burden of "created paperwork" intended only for the use of auditors, and removes the compliance jeopardy for holding a program to a higher standard than required.

Yes
Group
DTE Energy
Kent Kujala
No
DECo does not agree. With the exception of station batteries, all components should be tested as a scheme to assure that all components are working together as designed, so the PSMP should not be required for each component type.
Yes
No
DECo does not agree with the 6 year interval for the majority of the Protection System componenets. There are not sufficent problems found on routine maintenance based on a 10 year interval that would justify that significant of a reduction in the maintenance interval. Also, with respect the the station batteries specifically, station batteries, DECo recommends the elimination of the 4 month inspection as annual inspections have been sufficient for early diagnosis of potential issues. Advanced monitoring is not practical at this time as it does not appear that the technology required to forgo the 4 month inspection is readily available.
Group
MRO NSRF
WILL SMITH
Yes
Yes
No
Section 5.1 (second paragrath, under the first bullet) states: "TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components." If this "actual event" can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. Seciton 2.4.1 – Sudden Pressure Relays – This question should be clarified that circuits from only EHV transformers should be considered in scope. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.
• Article 4.2.1 – The NSRF believes that this article should be revised to say "Protection Systems installed for the purpose of protecting BES Elements only and detecting Faults on BES Elements. Protection Systems designed to protect non-BES elements that incidentally open 100 kV and greater breakers are excluded from the scopte of PRC-005-2". This makes it very clear what is included in the scope of the Testing and Maintenance program and what is not. • Change the text of "Standard PRC-005-2 – Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to: "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years" Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). The NSRF believes that as written the testing of "each" trip coil will result in the increased amount of time that the BES is in a less reliable system configuration. The NSRF hopes that the SDT will consider these changes. • The NSRF recommends the statement "Excluding distributed UFLS and distributed UVLS (see Table 3)" be added to the top of Table 1-4(f). • Table 3. There will be many DP's that have distributed UFLS (or UVLS) solely on the distribution system (less than 100 kV). The only item these DP's will have to verify under Table 3 "Protection System dc supply" is the Protection System dc supply voltage. Yet, the definition of Protection System, as it relates to dc supply is "Station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply)". Our interpretation of Table 3 and Section 15.7 of the Supplementary Reference & FAQ document is that a DP need only check the dc supply voltage at the terminals of the relays. If that is the SDT interpretation as well, we recommend revising Table 3 of the standard to reflect that. Table 3 contains issues that need to be addressed in a similar fashion as discussed for non-UFLS and non-UVLS systems, i.e. Table 1-1. Comparison to independent sources is only one way to check for a reliable AC measuring device. It also

appears that monitoring capabilities are not being given any credit in regards to the AC sensing devices, DC supply, or control circuitry themselves. There should be no difference in the way these systems are treated compared to BES Protection Systems. • In Section D Compliance, Article 1.3, paragraph 4 the standard requires documentation be kept for the “. . .two most recent performances of each distinct maintenance activity. . .”. This needs to clarified that it cannot go back before 06/18/07, as evidenced by the suspension of CAN-0008. Also with some of the testing intervals being 12 years, that would dictate a Registered Entity maintain 24 years of records, which is unreasonable. This article should be revised to have documentation for the most current testing interval, if after 06/18/07. • It is understood that lockout relay testing is important as unexercised lockouts can stick and cause regional outages as experienced at Westwing. However, lockout testing by itself is risky and can lead to local outages. If Registered Entities are required to take on the additional risk of testing lockout relays, dispenstation must be granted for outages caused by those tests. The following statement should be included in the standard “No enforcement actions or penalties will result from outages caused by relay testing unless a Registered Entity shows a history of 3 or more test related outages per year for 5 years.” • In the VSL for Table 4 it seems that the phrase “5% or less” should be “not more than 5%”. With the original language it seems like an entity could be found to have an R4 lower VSL violation for “failure” of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive. • The drafting team needs to clarify “maintenance summaries” as stated in Measure M3. This is an ambiguous term that could be interpreted differently amongst entities. If a term such as ‘summary’ is to be utilized within the standard, a clear definition of what the term is, what it pertains to, where it is located, etc. needs to be included. The NSRF recommends that “maintenance summaries” be defined and included in the “Definition of Terms used in Standard” section. • Footnote 1 in the Table sections would be much improved by inserting an example similar to what was provided in Section 8.4 of the Supplemental Reference and FAQ document . • Additional methods of verification should be allowed for AC measurement monitoring other than simply performing comparison to an independent source. For example, a sudden rate of change in calculated relay MW analog value and/or 3Io calculation would give way towards a bad CT and/or path. Loss of potential logic is available in most microprocessor relays today, which is very reliable logic for determining PT/CCVT issues. Consideration should be given to utilities that are capable of performing this type of monitoring in order to allow them to reach that next level of attributes. • Please clarify why input/output verification is excluded from the highest level of monitoring related to communications systems (Table 1-2). The way the monitoring attribute is listed does not provide that these will operate when needed. Recommend language be added similar to the monitoring of inputs and outputs described in the relay section (Table 1-1). • Table 1-3 should take into account the same concepts mentioned above in regards to AC measurement verification in Table 1-1. There are alternative ways to verify these quantities while still ensuring reliable operation. As such, companies should be given the opportunity to implement them. Additionally, credit should be given to circuit monitoring and alarming in AC circuits with electromechanical relays. If a transducer/alarming relay is placed in the circuit and monitoring is alarmed appropriately, the health of the AC sensing device can be determined. This would essentially provide the same level assurance as mentioned with the microprocessor relays. • Clarification is needed on the last row of Table 1-5. Does integrity entail monitoring and alarming of every individual path, if necessary, or is overall integrity sufficient? This statement is once again open to interpretation and leaves the entity at the mercy of the auditor.
Individual
NIPSCO
Per NIPSCO Tech Service Dept : There is a need for NERC to provide a format for maintenance reports. Also, it would help if specific test requirements for relays was provided.

More detail explanation or examples of Efforts on R5 is required
Yes
More detail explanation on Segment is required, the reason of sixty (60) individual components is required for one Segment. More detail explanation on Countable Event is required.
1.3 Evidence Retention. The standard said: For Requirement R2, R3, R4 and R5, the Transmission Owner, Generator Owner and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance. How to count” the most recent performance “. Is this Standard going forward basis? For some of the protection system component, the maximum maintenance interval is 12 years (such as CT, PT or microprocessor relay) on the standard, how to count the two most recent performance?
Group
Tacoma Public Utilities
Kieth Morisette
Yes

Yes
Yes
1. For components that are part of a time-based PSMP, if correction of Unresolved Maintenance Issues takes place before the maximum maintenance interval expires, is it mandatory to demonstrate (document) these efforts to correct identified Unresolved Maintenance Issues? Is the purpose of Requirement R5 only to avoid compliance jeopardy when an entity discovers a problem during maintenance but cannot correct the problem until after the maximum maintenance interval has expired (as discussed in the Supplemental Reference and FAQ document)? Or, is the purpose also to ensure that all Unresolved Maintenance Issues are documented even if they corrected very quickly and within the maximum maintenance intervals and just considered part of routine maintenance (i.e., Unresolved Maintenance Issues not explicitly documented) in a manner similar to recalibrating a relay? 2. Assume that a component under a time-based PSMP is not considered “monitored” per the PSMP, but in actuality it is. If an alarm comes in, indicating a component problem, would the entity have any additional documentation obligations under PRC-005-2 associated with this alarm, provided that all minimum maintenance activities and maximum maintenance intervals associated with the unmonitored component are satisfied? The concern is that, if there are additional documentation obligations, then many entities may disable monitoring in some cases in order to avoid compliance jeopardy. 3. Assume that an entity treats batteries at certain remote communication sites as if they were applicable to PRC-005-2. These sites are not substations or generating facilities but support the broad communication system, including teleprotection functions. Furthermore, these sites have limited access during some times of the year because of heavy snow or ice. It is conceivable that it may not be possible to meet all minimum maintenance activities or all maximum maintenance intervals (4 and 6 calendar months) unless the site is extensively monitored and/or field personnel expose themselves to hazard. Would any allowances be made in these cases? Would these sites even be applicable to PRC-005-2, since they are not part of a “station” DC supply? 4. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. 5. In the Implementation Plan for Requirements R1, R2, and R5, why there is a requirement to “be 100% compliant [with R5] on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals”? The emphasis of this question is on Requirement R5, which pertains to Unresolved Maintenance Issues. 6. In the Implementation Plan for R3 and R4, to be considered “100% compliant with PRC-005-2,” is it only necessary to have completed the applicable minimum maintenance activities one time for the applicable component (which is our assumption)? Or, does being considered 100% compliant under this Implementaiton Plan imply that two instances of the applicable minimum maintenance activities must have been completed for the applicable component?
Group
Imperial Irrigation District (IID)
Jesus Sammy Alcaraz
Yes
No
IID disagree with item c. and does not believe item c increases the reliability of the BES. The maintenance issues will be resolved internally and should not be required as per compliance of the standard.
Yes
Group
Dominion
Louis Slade
Yes
Yes
Dominion understands R3 to mean that the time-based maintenance interval can be less that but not exceed the maximum maintenance intervals in the tables. But that compliance will be based upon the maximum interval. Please confirm that our understanding is correct. Dominion belives the intent of the footnote in Table 1-1 is to ‘start the interval’ on either the 1st day of a calendar year or calendar month. We also believe this will require any entity whose current intervals are based on annual or monthly will have to adjust their intervals to calendar as they transition to PRC-005-2. Please confirm our understanding is correct. We also believe this transition could result in the compliance interval measurement being shorter or longer than it would have been if PRC-005-2 had not been approved. If this is incorrect, please provide examples to provide clarity.

Group
Texas Reliability Entity
Don Jones
Yes
No
New requirement R5 states that an entity shall “demonstrate efforts” to correct identified Unresolved Maintenance Issues. This falls short of requiring completion of any corrective actions for the unresolved maintenance issue. We suggest rewording to “Each Transmission Owner, Generator Owner, and Distribution Provider shall develop a corrective action plan and work timetable to address identified Unresolved Maintenance Issues. The Registered Entity shall complete resolution of Unresolved Maintenance Issues within the time frame identified in the Entity corrective action plan.” If R5 is modified, then M5 and the VSL should also be modified accordingly.
1. The Implementation Plan is still overly long and complicated. Registered Entities and Regional Entities will have to track and apply multiple versions of this standard for up to 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable at any given time, recognizing that for some Components no action will be required under the standard for a number of years. 2. Referring to R3, R4 and M1 (and other places), it is redundant to add “Protection System” to describe “Components “or “Component Types” based on the “local definitions” provided. Alternatively, the defined term could be changed to “Protection System Component” and used consistently. 3. In Table 1-3, the activity should include verifying that the current and voltage signal values are within tolerances, not just that signal values are present. The minimum activity should include a ratio check and/or burden check of current transformers. Suggest revising to state “Verify that current and/or voltage signal values provided to the protective relays are within the accuracy tolerance of the voltage and current sensing device”. 4. In the VSL for R2, we are assuming that the “4% within three years” is a 4% failure rate based on Attachment A, but that is unclear. We suggest clarifying this language to match Attachment A language. 5. What is the basis for the 4% failure rate limit in Attachment A? It would appear that a 4% failure rate is high for protective relays. Does the SDT have a technical justification supporting the selection of 4% as the applicable limit? 6. In Attachment A, item 4 in the “maintain the technical justification” section needs clarification. It can be assumed that the phrase ”for the greater of either the last 30 Components maintained or all Components maintained in the previous year” is referring to Components within a specific Segment, but more specific language may be needed. Also, are the references to “prior year” and “previous year” intended to refer to calendar years or 365 days preceding the analysis? 7. In Attachment A, item 5 in the “maintain the technical justification” section needs clarification. We suggest adding a timeframe for the “experience 4% or more Countable Events” phrase. Does this refer to any 12-month period? Additionally, the determination of a timeframe for “4% of the Segment population” is needed. Example- If there are 100 Components in a performance-based Segment in Year 1 and I add an additional 100 Components in Year 2, is the 4% based on 100 or 200?

Yes
Yes
We recommend the word “Protection” be deleted from the definition of Component to make the defined term Component be a generic term. If that word is not deleted then we recommend the term used in the standard “Protection System Component” be changed to “Component” since as defined a Component is a Protection System piece of equipment. Component – A Component is any individual discrete piece of equipment included in a System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed

Under section 1.3 Evidence Retention we feel like documentation of the last two performances of each distinct maintenance activity should be limited to the last one. This is due to the amount of documentation being recorded as well as for certain components there is a 12 year maximum interval. Would you have to store this information for 24 years? This could also violate the NERC ruling that was just made on a CAN 008 that stated you do not have to show intervals earlier than June 18th 2007. Suggested alternate language “ For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous audit date, whichever is longer, but not prior to June 18th 2007.”

1. Regarding the functional test required every 3 months for “unmonitored communication systems” in Table 1-2 of the PRC-005-2 Draft. TVA feels that a Maximum Maintenance Interval for the Functional Test should be every 12 months until auto-checkback has been fully implemented by the utility. 2. The Implementation Plan for PRC-005-2 Step 4 on Page 2 states: “The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.” TVA feels that this is not sufficient time to implement full auto-checkback capability at some utilities. The time schedule of twelve (12) months should be forty-eight (48) months following applicable regulatory approvals. 3. TVA has many excitation transformers directly connected to the generator bus, configured such that a fault on the excitation transformer will cause a generator trip. Is the intent that the revised standard will include these transformers in the applicability? Would they be included by section 4.2.5.1? 4. TVA (Rusty Hardison) has forwarded a slide presentation with six questions to the PRC-005-2 Draft Team requesting consideration as input to the Frequently Asked Questions document accompanying the standard. Thank you for considering.

Yes
Yes
Table 1-4(a) Vented Lead-Acid (VLA) Batteries: ATCO Electric has a number of remote substations that are difficult to access frequently. The requirement for a 4 calendar month inspection for electrolyte level is too frequent. (i) Does alarm/monitor technology exist for electrolyte level in battery design today? For in-service battery systems, if battery alarm/monitor technology exists, a capital project is required to retrofit each battery system and this kind of retrofit work could be detrimental to both the battery design life as well as the battery reliability. (ii) The electrolyte level requirement would become achievable if electrolyte level inspection was moved to the 18 calendar months category, or if the 4 calendar months frequency was increased to 8 calendar months. Table 1-4(b) Valve Regulated Lead Acid (VRLA) Batteries: ATCO Electric has a number of remote substations that are difficult to access frequently. The requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category. Table 1-5 Control Circuitry When a breaker is opened, there is no indication on which trip coil is actually operated. How do market participants demonstrate compliance for "verify that each trip coil is able to operate..."? The verification of trip coil health is done during breaker maintenance with various maintenance durations that maybe longer than 6 years depending on breaker types. The requirement of "verify electrical operation of electromechanical lockout devices" introduces high risk of human error outages to the BES system and diminishes the reliability gain from performing this activity. The drafting team should consider lockout relay failure rates, onerous tasks of blocking each trip contacts in many BES elements' tripping circuits, imposed risk, required resources in the overall reliability benefit gained by performing the lockout relay maintenance.

American Electric Power
No

R1.1 binds you to the activities in the table, but our system is comprised of elements (such as a Plant Control Systems), that are not included in the table. As a result, it is not clear how an entity could develop an SPS that satisfies both the requirement and our sytem.
No
R3: Table 1-5 notes a “mitigating device” as part of component attributes. Such a phrase could be open to interpretation and needs to be clearly defined. Table 1-3, Maintenance Activities – there is nothing specifically regarding accuracy. Suggest incorporating the definition of “verify” as used in the FAQ or perhaps something similar to “verify values are as expected”. R5: We understand the drafting team’s desire to deal with unresolved maintenance issues, however it is not clear how the adequacy of resolving those issues would be determined by an auditor. If these kinds of efforts are going to be scrutinized, there needs to be some sort of boundaries established so that it is clear how unresolved maintenance issues would be evaluated.
No
Though the guidance provided in these documents may appear to be beneficial, we are troubled that despite the time spent on them by the drafting team, and the voluminous nature of the references, that the information contained in them essentially fades away upon approval of the standard. Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might help prevent the need for future CANs and interpretation requests.
PRC-005-2 is intended to supersede the existing standard PRC-017-0 "Special Protection System Maintenance and Testing". As it is currently written, an Entity with a Special Protection System will be required by R1 to select either a time-based, performance-based or combination maintenance method for the Entity's SPS. Since Special Protection Systems are not frequently installed, it is unlikely that an Entity will be able to meet the requirement of R2 and Attachment A that the Segment population contain 60 components for all components of the SPS. This will require the Entity to utilize the time-based maintenance method for at least some components in the SPS. Under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems by their nature may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are not included in the NERC definition of Protection System.
Individual
Manitoba Hydro
No
Please see comments provided in Question 4.
Yes
Yes
Manitoba Hydro is voting negative for the following reasons: 1 - Battery inspection and verification interval - Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Manitoba Hydro has more than ten years of experience using its existing battery inspection intervals and Manitoba Hydro’s reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro’s battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro’s installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro and may be more than is required for many other utilities. To use a more frequent inspection interval would penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. It would also potentially adversely affect reliability by diverting resources away from projects that are critical to reliability to meet this maintenance interval. In addition, the 4 month time period proposed for basic battery verification and inspection interval is not aligned with the more detailed 18 month battery verification and inspection interval which will result in additional and unnecessary site visits and maintenance activities. As well, Manitoba Hydro does not feel that the SDT has provided sufficient technical basis to support a 4 month battery inspection and verification interval and requests that further justification and external reference be provided. 2 - PBM not permitted for batteries - Manitoba Hydro disagrees with the SDT’s basis for not permitting the use of PBM for batteries. The reasons provided by the SDT for disallowing them are that batteries are perishable and involve chemical reactions. However, it is our understanding that many other industries rely on performance based maintenance programs when dealing with similar equipment. We would appreciate an external reference or source which supports the claim that equipment with these characteristics cannot have a performance based maintenance system applied to them. 3 - Phased Implementation Plan - Manitoba Hydro maintains its position that prescribing how an entity must reach full compliance with PRC-005-2 will provide a negligible improvement in reliability while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets and proving compliance for the prescribed percentages of assets during the transition period creates

unnecessary overhead with no added value. We suggest that the requirement to demonstrate the percentage of assets currently under PRC-005-1 vs. PRC-005-2 be removed, that entities should be given a single compliance date for each of the maintenance intervals and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-005-2, and that NERC measures progress on reaching PRC-005-2 intervals using means other than Compliance measures such as industry surveys. 4 - Data Retention Requirements - The data retention requirements are too uncertain for two reasons. First, the requirement to “provide other evidence” if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what ‘other evidence’, besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit.

Please see our comments and suggested changes to the Supplemental Reference and FAQ document in Question 4.
FE asks that the team clarify the intent of certain aspects of the applicability section: Sec. 4.2.5.4 - For transformers supplying unit auxiliaries, protective functions that provide for transferring of auxiliaries without tripping the generating unit should not be included. Also, we believe that the term "station service transformer" is being used inaccurately. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, “Protection Systems for generator-connected station service transformers for generators that are part of the BES.” Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. But since a station service transformer, by definition (IEEE Std. 505), is "a transformer that supplies power from a station high voltage bus to the station auxiliaries and also to the unit auxiliaries during unit startup or shutdown or when the unit auxiliaries transformer is not available, or both." [Ed. note: a.k.a. Start-Up Transformer or Cranker], the terminology "generator-connected station service transformer" is confusing and easily subject to misinterpretation. Also, there needs to be consistency of use of terms between the standard and its Supplementart Refererence document. On pages 32 and 33 of the FAQ, the following questions and their respective answers should be consistent with use of terms and replace “station service” with “auxiliary” as follows: FAQ Question - Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected auxiliary transformer to meet the requirements of this Maintenance Standard. FAQ Question - In the case where a plant does not have a generator connected auxiliary transformer such that it is normally fed from a system connected auxiliary transformer, is it still the drafting team’s intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) auxiliary transformer will result in a trip of a BES generating facility? Therefore, for consistency between the reference FAQ document and the standard, we suggest that “station service” be replaced with “auxiliary” in 4.2.5.4 and read as follows: “Protection Systems for generator-connected auxiliary transformers used on generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.”

No
We agree with the intent of the Supplement changes but believe that they are either incomplete or need clarification.

Therefore, we provide the specifics as follow : (a) Page 93, Revise Section 15.7 Distributed UFLS (i) Change Table 1-2 to 1-3.(ii)Inculde ‘Verify operation…and/or auxiliary tripping device’ to agree with Table 3. (b) Please identify BES Elements in Supplementary Reference Figure 2. (c) Remove ‘Reverse power relays’ from the bulleted list on the top section of page 33. They provide thermal of the steam turbine, and they may protect CTG speed reduction gear teeth, but neither of these are electrical protection of the generator. (d) Please add Interval FAQ to address a component minimum maintenance activity that is not in the present PRC-005-1 program. (i) : “How is interval proven for a component minimum maintenance activity that is not in the present PRC-005-1 program? For example, suppose the present program continuously monitors a communication system, say audio tones, and personnel respond to alarms; this approach presently have basis that is sufficient. (ii) Table 1-2 requires two maintenance activities every 12 calendar years: 1) verify channel meets performance criteria; and 2) verify essential I/O. The entity is required to perform these minimum maintenance activities one time in the first 13 years after regulatory approval. The 12 year interval is proven by the date of the PRC-005-2 maintenance activity and the date of your PRC-005-1 program applicable for the previous maintenance. After the second time the PRC-005-2 maintenance activity is performed, appropriately sometime in year 14 to 25 after regulatory approval, then interval will be proven by the dates of the two PRC-005-2 maintenance activities.” (e) Page 17 We disagree with retention of maintenance records for replaced equipment as this can cause confusion. At most the last maintenance date could be retained to prove interval between it and the test date of the replacement equipment that provides like-kind protection. (f)Page 36, FAQ ‘initial date for maintenance’ answer is inconsistent with CAN-0011. Though the CAN applies to PRC-005-1, it should be consistent with NERC’s position on this. (g) Page 71, Please remove ‘The trip path from a sudden pressure device is a part of the Protection System control circuitry…’ because the actuating relay does not respond to electrical quantities. This is just one example of the many gotcha’s that will no doubt arise in enforcement. (h) If a capacitor trip device is an example of a non-battery based station DC supply, then please provide a FAQ to convey it.
(a) R3 & R4: Change VRF to “Medium” for the following reasons: (i) Consistency with existing standards that PRC-005-2 replaces. Per the VRF_Standards_Applicability_Matrix_2012-03-01, PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (ii) We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (iii) Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events are extremely rare. (iv) Either change VRF to Medium, or double the percentage ranges applied to each component type across VSLs. We strongly believe that the SDT needs to retune these to match the experienced risk, which has been extremely low. (b) Measure M3 on page 6 should only apply to 99.5% of the components. Please revise to state: “Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated….” We believe that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is “non-performance”. (c) Measure M5 – add ‘internal inventory / parts request, trouble investigation assignment, trouble repair report’ as examples of an entity undertaking efforts with internal parts and/or labor resources. (d) Augment R3 and R4 VSL with a ‘number based limit for populations up to 100 components’ for comparable treatment of small entities. For example, for Lower VSL restate as ‘…the responsible entity failed to maintain from one to five Components if total Components is less than 100; or 5% or less of the total Components if total exceeds 99 included within a specific Protection System Component Type…’. Otherwise a small entity could unfairly incur a Severe violation for the same number of Components that a larger entity would incur a Lower VSL. (i) Similarly, Moderate numbers should be 6 to 10; High 11 to 15; and Severe 16 or more if the total Components of a certain Component Type that is less than 100. (e) Augment R5 VSL with percentage based limits for comparable treatment of larger entities. For example, for Lower VSL restate as ‘The responsible entity failed to undertake efforts to correct 5 or less Unresolved Maintenance Issues if total of such issues in the audit period is less than 100; or 5% or less if total of such issues in the audit period exceeds 99.’ (i) Similarly, Moderate numbers should be >5% to 10%; High >10% to 15%; and Severe more than 15% if the total Unresolved Maintenance Issues in the audit period exceeds 99. (f) Please number all pages of the standard. They are missing from pages with tables. (g) Please add a title to the table following Table 3. Is it a continuation of Table 3?
Group
PNGC Comment Group
Ron Sporseen
No
Specifying “by component type” appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to “by component or component type” when entities determine the maintenance method in their PSMP.
Yes
The PNGC comment group agrees with this change. Removing the jeopardy associated with more stringent intervals will make it less risky for entities to tighten intervals in their PSMP.
Yes

We thank the SDT for their hard work and will be voting "yes" on this project. However, we have 5 specific comments independent of the questions above and we've listed them in order of priority: 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the “NERC Guidance (Below), this seems to be a contradiction given the language of “…more than one”. a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Modedrate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required performance. We suggest changing the language for “Lower VSL” for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained… Or For Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained… 2. The PNGC comment group disagrees with the “Evidence Retention” requirements for the standard. In the current version for R2-R5, entities are required to: “…keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.” The PNGC comment group believes that keeping documentation for one previous maintenance activity or since the last audit, whichever is longer, should be sufficient. Keeping the two most recent instances of an acitivity with a maximum maintenance interval of 12 years could mean planning for up to 35 years or so of evidence retention. With the longer of “since the last audit” or “at least one maintenance interval” as the minimum retention requirement the CEA should have sufficient basis to determine compliance. 3. The PNGC comment group believes R5, “Unresolved Maintenance Issues” is too vague and will be left up to individual auditors to determine compliance. This requirement appears ripe for misapplication and future CANs on the topic. Good utility practice will ensure that maintenance issues are corrected as a primary function of our members is to provide the most reliable service possible. The SDT lists several possible examples of evidence in M5 but we believe that more specificity is needed for evidence requirements or the requirement should be removed. We understand the importance of “maintenance” of protection systems and that when maintenance issues cannot be immediately addressed there needs to be follow up. We believe notation of the maintenance issue during the inspection should be sufficient for compliance. By including the examples in the associated measure for the requirement, we believe the SDT has confused the issue. In our opinion M5 should indicate that evidence of notation of the issue is all that is required (meaning acknowledging of the issue on the inspection form). Further, in your response to entity comments during the last comment period on this topic, you stated, “The SDT believes that an effective PSMP must include correction of deficiencies…”. This statement implies that the standard must cover the correction of deficiencies to completion. There could be very long time frames associated with maintenance including management budget decisions, equipment purchase lead times and personnel scheduling for follow up work. Some issues could potentially require years of tracking within this standard creating an unnecessary compliance risk for the entity. We believe the SDT has met the intent of order 693 if a maintenance activity is initiated. The completion of the initiated maintenance activity should be outside the bounds of the standard and the standard should clearly state this. 4. We also find issues with the “Definitions of Terms Used in Standard” Specifically, the definition of “Component” seems to confuse the subject unnecessarily. We suggest simplifying the definition by breaking out the control circuitry and votage and current sensing device examples. That is a lot of material to cover in what should be a simple definition of “Component”. 5. Also we believe the definitions of the 5 behaviours under the PSMP definition are unnecessary. We believe that indicating that the PSMP involves some or all of the 5 activities without trying to define them is fine. For example, your definition of “Inspect” states: Detect visible signs of component failure, reduced performance and degradation. But what if you find no failure, reduced performance or degradation? Have you not inspected the component? Or what about “verify”? If you determine the componenet is not functioning correctly, have you not verified anything?

Central Lincoln
Yes
: We thank the SDT for removing the extra compliance jeopardy associated with stringent intervals. The extra jeopardy never made sense to us, since it could result in sanctions to one entity and no sanctions to another entity when both followed the same interval with no BES risk presented by either. We are concerned regarding the language of R5. We understand that maintenance without resolution is worthless, but the language here is subjective allowing different auditors to reach differing conclusions whether a sufficiently documented effort has been made. We also note that entities are expected to be continually in compliance with applicable standards, and are expected to self report when they are not. Strictly interpreted, an entity is out of compliance with R5 if there is any time lag between the moment the problem is identified in the field and documentation is produced of an effort taken to resolve it. We suggest the inclusion of a reasonable time limit.
No
The Supplemental Reference and FAQ apparently has not kept up with definition changes and uses uncapitalized

“component” “Protection System components”. Please use capitals if defined terms are intended.
Central Lincoln appreciates the good work the SDT has done. We believe this particular team has actually listened to our comments and made changes where needed. Thanks.

Page 20 states that every 18 months "battery ohmic values to station battery baseline (if performance tests are not opted)" should be changed to add comment that ohmic values, while permissible as a tool, should not be taken to validate the actual capacity, thus the reliability of the battery. If capacity is an issue due to questionable ohmic values shown, a decision must be made to [1] perform a capacity test following one of the three methodologies recorded in IEEE 450 or IEEE 1188; [2] make a decision to replace the battery string depending upon the number of cells with quesitonable ohmic values shown, the age of the battery string, and the critical nature of the station in question; or [3] accept the risk that the battery may or may not perform as intended due to the lack of a true knowledge of the battery capacity (See IEEE Letter to Al McMeekin). Every 18 calendar months verify/inspect the following: "Cell Condition of all individual battery cells (where visible) should add "or as frequently as recommended in the battery manufacturer's operating instructions." Every 6 years: perform or verify the following: "Battery Performance Test (if internal ohmic tests are not opted)" should be changed to read "Battery Performance Test (if ohmic tests are not conducted or if ohmic test values show that a degraded situation with the cells call into question whether the battery will perform to "design requirements." this should be repeated where referenced in additional examples (VLA, VRLA, Ni-Cd)
The NERC Standard should incorporate suggestions made in a letter provided to the NERC Drafting Team along w/ a specific Task Force Report commissioned by the IEEE Stationary Battery Committee.

Page 20 of the Supplemental Reference and FAQ document in Example 1 states that "Every 18 months verify/inspect the following: o Battery bank ohmic values to station battery baseline (if performance tests are not opted). A sentence should be added stating: "ohmic values, while useful as a tool to determine continuity and condition of individual cells, should not be taken to validate the actual capacity or reliability of the battery string. If capacity is an issue due to questionable ohmic values shown, a decision must be made to [1] perform a capacity test following one of the methodologies prescribed in IEEE 450, 1188, or 1106; [2] make a decision to replace the battery string depending upon the number of cells with questionable ohmic values, the age of the battery string, and the critical nature of the functional entity operating station in question; or [3] accept the risk that the battery may or may not perform as intended due to the lack of a true knowledge of the battery capacity (see IEEE Stationary Battery Committee letter to Al McMeekin and the NERC SDT). In this same example on page 20, Every 18 months . . . bullet 5: "Cell condition of all individual battery cells (where visible)," words should be added in 2nd parenthesis "(18 months or as frequently as recommended in the battery manufacuter's operating and maintenance instructions." On page 21 of the Supplemental Guide, Example 1 states: "Every 6 calendar years perform or verify the following:" 1st bullet: "Battery performance test (if internal ohmic tests are not opted)." Recommend that this should be changed to say: "Battery Performance Test (if internal ohmic tests are not opted or if ohmic test values show that a degraded situatioj with the cells call into question whether the battery will perform to 'design requirements'." This language should be incorporated into all following examples that reference batteries, whether VLA, VRLA or Ni-Cd. On page 73 of the Supplemental Reference there is a detailed discussion under Section 15.4 regarding continuity. In the 3rd paragraph reference is made to "not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to

verifying that there is a continuous path from the positive terminal of the station battery to the negative terminal. Without verifying continuit of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger." This argument is carried forward on page 74 of the Supplemental guide under the paragraph titled in bold: "What did the PSMT SDT mean by "continuity" of the dc supply. The problem with this whole section is that while there are statement presented that are true in the limited context of continuity, nevertheless have the ability to mislead the reader into thinking that continuity can be equated to capacity. This is evidenced by the reference to "open circuit." While open circuit conditions are more critical to a VRLA, the issue is not only whether there is continuity or open circuit, but whether the battery still maintains sufficient capacity to hold up the load under a worst-case condtion if exercised in that event. The most effective and accepted way at the present time is via a capacity test (Again, see letter to Al McMeekin and the SDT from the IEEE Stationary Battery Committee).
Major comments have been addressed in Question 3.
Individual
US Bureau of Reclamation
No
The requirement R1 states that the PSMP must identify how the component is to be maintained, using time based or performance based or a combination. While R1 requires a PSMP, there is no measure that the PSMP is used for acutally maintaining the components, other than for documenting which maintenance method is being used. The purpose of R1 is therefore administrative. Since there is no measure for the use of the PSMP, why is the entity required to develop the PSMP as defined? There is no VSL for R1 which requires that the entity establish a PSMP. Since there is no severity level associated a PSMP that does not contain one of the required activities it supports elimination of the definition of PSMP. PSMP definition is also weak and does not match with the VSL that the PSMP identify the maintenance method of the protection system component types. The definition is that PSMP which must include: "A maintenance program for a specific component includes one or more of the following activities: • Verify— Determine that the component is functioning correctly. • Monitor — Observe the routine in-service operation of the component. • Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. • Inspect — Detect visible signs of component failure, reduced performance and degradation. • Calibrate—Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement." Since requirement 1 essentially only requires identification of which maintenance method is to be used, there is no need for the definition. It no longer matters how the device's functionality is determined as long as it is performed on a time based or performance based method. This approach may be lowering the reliability level associated with the protection system maintenance. Since the definition of PSMP is that only one of the 5 activities is needed, is seems that one could select to "Monitor" the in-service operation of the component on a time base and no further action is needed. So that could mean observe that the relay has power and was not misoperating every six years and maintenance is performed. A PSMP is as defined does not help the reliability. It would be better require the PSMP include as a minimum all five activities defined as well as defining the maintenance method used (time based, performance based, or a combination). There needs to be a requirement that the PSMP needs to be developed. Then Requirement 1 would be to implement the PSMP.
No
The Requirement R5 indicates the entity has to "demonstrate" efforts to correct identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP.
Yes
Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. Re The definition of Components: The standard defined what constitutes a control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.

NextEra Energy, Inc.
Verifying electrolyte levels of vented lead acid (VLA) batteries every four (4) calendar months is excessive and will not promote the reliability of the bulk electric system (BES). The maximum maintenance interval should be twelve (12) calendar months. Today's lead-calcium and lead-selenium-low antimony batteries do not experience rapid water loss as compared to the legacy lead-antimony batteries and if battery cells should crack from positive plate growth, twelve (12) calendar months is more than adequate to detect electrolyte leakage before cell failure. Verifying that unmonitored communication systems are functional every four (4) calendar months is excessive and will not promote the reliability of the BES. The maximum maintenance interval should be twelve (12) calendar months. Based on our operating experience, twelve (12) calendar months is sufficient to detect communication failures without affecting the reliability of the BES.

Essential Power, LLC
Yes
No
The change to R3 is too restrictive, and removes the registered entity's ability to better define its own intervals based on its own experience and system characteristics. The comments regarding a CEA's enforcement of an RE's more stringent internal intervals is not indicative of an issue with the Requirement, but with the way in which it is enforced.
a. This DRAFT Standard is written as a prescriptive 'procedure' and not as a 'Standard'. The SDT should revise the Standard to address the goal, or intent, rather prescribing how entities should meet the Standard. b. Inclusion of non-BES elements within the Standard falls outside of NERC's jurisdiction, as defined in the EPA 2005. The SDT should remove these elements from the Standard. c. The inclusion of dc circuitry for equipment that is itself not covered under the Standard is not logical and does not contribute to reliability. The SDT should remove this from the Standard.

Since auditors will be able to request documentation necessary to validate the inclusion of the device within the appropriate level of monitoring, why does the program document require listing level of moniotoring and component attributes? (Concerned about the burden of maintaining lists of components in a program document that are alike but have different levels of monitoring. Ex: Monitored and unmonitored microprocessor relays) For identification of the relevant monitoring attributes applied can a single specification document suffice for similar relay types such as one document for SEL relays? For trip circuit monitoring can a standard document be used for a group of similar schemes?
No
The FAQ attempts to clarify the intent of "demonstrate efforts to correct", however, there is no explanation as to why this new term is preferable to the more concise "initiate resolution" term that was developed and agreed upon over the last year. In the supplementary reference and FAQ document there is a request for clarification and it is reprinted below. Please clarify what is meant by "…demonstrate efforts to correct an unresolved maintenance issue…"; why not measure the completion of the corrective action? Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to

complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. I agree with this response and specifically the last sentence. This indicates that R5 “demonstrating efforts to correct unresolved issues” is too open ended and subjective and cannot be applied by enforcement in a consistent way. R5 should be removed from the standard.
No
Section D 1.3 Evidence Retention – Do not agree with requirement to keep the two most recent performances of each distinct maintenance activity. Should not require records previous to last audit. What is the point of keeping records up to twenty years? FAQ page 7 and 77 now include discussion about how sudden pressure relays are “presently” excluded because they do not meet the definition of a protection system and a method of component verification does not exist. This part I agree with. The problem is that they go on to explain that the DC control circuitry from the Sudden Pressure relay is part of a protection system. This I disagree with. It’s clear that the Standards Drafting Team is attempting a compromise to address direction from FERC Docket No. RM10-5-000. This approach however, sets a bad precedence. A trip path from a non-protection system component should not be classified as a protection system trip path. The removal of grace periods and the comments in the FAQ that it will be up to the Auditor to determine if a test was not done due to extraordinary circumstances (example: Communications can’t be tested due to the line out from a storm and under repair) is not acceptable. The SDT needs to come up with guidelines for these situations and not leave it up to each auditor to determine what is acceptable.
The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES Please provide the basis for the requirement of functional trip checks? Are there recorded instances that an “event” would have been avoided if functional trip checks had been performed? Suggest for monitored microprocessor relays in Table 1-1 and 3 to verify “settings are as specified that are essential to the proper functioning of the protection system”. Many settings are not essential. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. All functional tests should be moved to the minimum frequency of 12 years to minimize this unknown but present risk.

ATC recommends that the SDT change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 21, Row 1, Column 3 to: “Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years” Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). ATC continues to recommend a negative ballot since we believe that the testing of “each” trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element.The interpretation states: The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)” Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the

distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.
Individual
CenterPoint Energy
Yes
Yes
Yes
CenterPoint Energy recommends retaining an option to utilize technology for monitoring trip coil continuity as an alternative to the maintenance activity in Table 1-5. The Table 1-5 requirement to "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating devices (regardless of any monitoring of the control circuitry)" appears to address breaker maintenance, instead of Protection System Controls. In the Supplementary Reference and FAQ, monitoring is described as greatly reducing the time between a component failure and discovery of that failure. For the “Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (Excludes non-BES trip coils)”, the Table 3 requirement is to “Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes this to be a commissioning task, not a preventive maintenance task. A preventive maintenance task, such as the above, is unnecessary for distributed UFLS and UVLS system components. The overriding performance, or “risk-based”, NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount. For the “Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays”, the Table 1-5 requirement is to “Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. Alternatively, CenterPoint Energy recommends specifically excluding panel wiring and requiring only cabling between panels and interrupting devices be verified. Requiring trip path verification to include panel wiring complicates maintenance while focusing on a component that is not subject to age-related degradation in addition to, historically, not being a source of protection system failures. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping.
Individual
ReliabitliyFirst
ReliabilityFirst votes in the negative for this standard primarily due to the language in Requirement R5. The language in Requirement R5 is subjective and non-measurable in its present state. ReliabilityFirst offers the following comments for consideration. 1. Definition of “Component” a. The language stating “discrete piece of equipment” within the first sentence is unclear and open ended. ReliabilityFirst suggests the following modified language for the first sentence in the definition of “Component”: “A Component is a piece of equipment that is one of the five specific element included in a Protection System, including but not limited to a protective relay or current sensing device.” 2. Definition of “Unresolved Maintenance Issue” a. There may be instances when a deficiency is identified and corrected during the maintenance itself. For further clarity and to address this circumstance, ReliabilityFirst recommends the following modification for consideration: “A deficiency identified during a maintenance activity that could not be corrected and causes the component to not meet the intended performance and requires follow-up corrective action.” 3. Facilities Section 4.2.1 a. This is too limited or selective in only including Protection Systems that are installed on BES Elements to strictly detect Faults. There are a number of relays that are installed to detect non-Fault but abnormal conditions such as power swings/out of step and overvoltage that should not be excluded from a maintenance program. ReliabilityFirst recommends the following language for consideration: “Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)” 4. Facilitates Section 4.2.2 a. It is unclear what requirements the phrase “installed per ERO underfrequency load-shedding requirements.” is referring to. Is it NERC UFLS Requirements, Regional UFLS Requirements, etc.? To be consistent with section 4.2.3, ReliabilityFirst

recommends the following for consideration: “Protection Systems used for underfrequency load-shedding systems installed to arrest declining frequency, for BES reliability. 5. Requirement R3 a. For time-based maintenance program(s), there is no safeguard if more than 4% Countable Events are experienced during a maintenance interval. ReliabilityFirst recommends adding an new Subpart 3.1 (similar to the language for performance-based in Attachment A): “3.1 If the Components in a Protection System Segment maintained through a time-based PSMP experience 4% or more Countable Events, develop, document, and implement a Corrective Action Plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.” 6. Requirement R5 a. Requirement R5 has language which states “…shall demonstrate efforts to correct…”. ReliabilityFirst believes this language is subjective and non-measurable. It will be difficult in determining what amount of demonstration an entity will need to provide in order to be compliant. There is also no timeframe in which the correction needs to be completed (is it 30 days or 30 years?). ReliabilityFirst believes measurable language such as “shall correct” or “shall have and implement a Corrective Action Plan” should be incorporated within the requirement. 7. Table 1-2 a. For “Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function” ReliabilityFirst believes the maintenance interval is too short. Carrier communication failures are a major cause of Misoperations. Many have automatic checkback and are monitored but continue to fail during Fault conditions. ReliabilityFirst recommends a maintenance interval of 6 years. b. For “Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied” ReliabilityFirst believes a maintenance interval should be required. ReliabilityFirst recommends a maintenance interval of 12 years. 8. Table 1-3 a. For “Any voltage and current sensing devices not having monitoring attributes of the category below.” ReliabilityFirst recommends a maintenance interval of 6 years. b. For “Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value…” ReliabilityFirst believes the concept of never having to do any testing just because you have continuous monitoring is fundamentally flawed in this table as well as 1-5 and 2. Continuous monitoring and measurement comparison cannot test everything, such as loss of ground, multiple grounds and turn-to-turn failures, and monitoring itself can fail. ReliabilityFirst recommends a maintenance interval of 12 years. 9. Table 1-5 a. ReliabilityFirst recommends adding “auxiliary tripping devices” to Electromechanical lockout devices in row 2 of Table 1-5. If lockout relays are maintained every six years auxiliary tripping devices should be as well. ReliabilityFirst recommends the following language for considerations: “Electromechanical lockout devices and auxiliary tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).”

We agree with the changes to R3 and the new R4 requirement but disagree with the wording change in the new R5 requirement. The difference between “initiate resolution” and “demonstrate efforts to correct identified unresolved maintenance issues” is very unclear. Please clarify the SDT’s intent with this subtle wording change. In our opinion, it would be fairly obvious if an entity met a requirement to “initiate resolution” and, thus, this would be easily measurable requirement. It seems that the phrase “demonstrate efforts to correct identified unresolved maintenance issues” will be open to more auditor judgement as to what constitutes adequate efforts to correct a deficiency and thus makes the measurement of meeting this requirement far more arbitrary. If this is not the intent, then why bother with the wording change? Furthermore, CEAs should realize that entities already have strong financial incentives in correcting identified unresolved maintnance issues to minimize the risk of costly equipment damage or equally costly outages of critical equipment. Delays in correcting identified unresolved maintenance issues are seldom driven by cost avoidance and are more likely driven by the time it takes to develop, engineer and/or procure a better solution to a problem. Prompt band-aid type fixes are not necessarily desirable fixes and the wording of R5 should not promote the band-aid approach to the correction of a problem.

• Duke Energy votes “Negative” because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the Successive Ballot but prior to the Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but are not intended to provide protection for the BES. FERC’s September 26, 2011 Order in Docket No. RD11-5 approved NERC’s interpretation of PRC-005-1 R1 and R2, stating: “The interpretation clarifies that the Requirements are “applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES.” This interpretation is consistent with the Commission’s understanding that a “transmission Protection System” is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices.” The SDT’s response to our comment directed us to Section 2.3 of the Supplementary Reference And FAQ Document which states “There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard.” We agree with that statement, but question why the SDT insists on changing Section 4.2.1 to include devices that detect Faults on the BES but which do not provide protection for the BES? Duke Energy’s standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following definition: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)”. • We also note that the Lower VSLs for R3 and R4 include violations for “5% or less”, and R5 for “5 or less” which mandates perfection. We believe that the consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability.” We suggest that a range of 0.5% to 5% would be more reasonable.

As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity’s calculated mean time between failure, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT’s current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program .

BPA believes that R5 is not worded in such a way that it can be easily or consistently audited.
Yes
BPA believes that PRC-005-2 achieves the goal of reducing redundancy and overlap within the PRC standards by consolidating four existing standards into one. BPA's comments are focused on improving the clarity and audit-ability of the proposed standard. Regarding Section D1.3 “Evidence Retention”, BPA suggests that the entire first paragraph be removed because for all the instances that follow the first paragraph there is a requirement to keep evidence obtained since the last audit. Therefore, there are no instances where the evidence retention period is shorter than the time since the last audit, and the first paragraph is not necessary. Furthermore, the first paragraph introduces the idea of “other evidence” for which there is no explanation. It is unclear what could be used for evidence other than the items described in the Measures. The idea of “other evidence” should not be introduced without an explanation of what that evidence might be, so this is another reason for removing the first paragraph. Regarding requirements R2 and R4, BPA believes that these two requirements should be combined into a single requirement with two parts. Since both of these requirements deal with performance-based maintenance, it would simplify the standard and improve the flow if they were to be combined. Regarding Table 1-4(f), it is unclear if all of the conditions on the left side need to be met before any of the reduced maintenance activities on the right side are allowed, or if there is a one-on-one relationship between an item on the left and the adjacent item on the right. BPA suggests that the table be reconfigured to clarify the relationship between the conditions on the left and the activities on the right.

1: The definition of “Protection System” in this version of PRC-005-2 includes “station dc supply associated with protective functions…” as a Protection System component. Page 83 of the FAQ document accompanying the draft standard provides further clarification that the batteries covered under PRC-005-2 are those that “supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System.” This statement in the FAQ is much more limiting than the definition of Protection System and may create confusion concerning registered entities’ compliance obligations. For example, a registered entity may have one battery / charger system in a station that supplies DC voltage to communication equipment, including that utilized in transfer trip communication, while a separate battery (typically operating at a different DC voltage) is utilized for relay / trip coil operation. In this case, it is unclear whether the battery / charger system utilized for transfer trip communication is subject to the requirements of the standard. PacifiCorp recommends that NERC or the SDT reconcile this apparent inconsistency in the FAQ document. 2: In Tables 1-4(a) thru 1-4(d), the maximum maintenance interval of four calendar months includes inspection “for unintentional grounds.” PacifiCorp seeks clarification on whether this maintenance activity is intended to target the detection of unintentional grounds on the battery bank / rack itself, or a ground located anywhere on the entire DC wiring system. 3: The Violation Severity Level (“VSL”) for R5 - which ranges from a failure to correct 5 or less (“Lower” VSL) to greater than 15 (“Severe” VSL) Unresolved Maintenance Issues – fails to adequately account for the cumulative amount of equipment a registered entity is required to maintain pursuant to PRC-005-2. A better alternative approach may be to base the VSL on the cumulative percentage of Unresolved Maintenance Issues that an entity fails to address and correct. Such an approach would be more consistent with the VSLs for R3 and R4, which are based on a percentage of the total scheduled maintenance. This approach more fairly and reasonably addresses the covered

maintenance activities relative to the approach in the VSLs for R5. which are based on a strict count and therefore independent of the cumulative amount of maintenance activities performed by a registered entity. PacifiCorp recommends that the SDT develop an alternative method for determining VSLs for R5 that reflects the scope of an entity's maintenance activities and the resulting Unresolved Maintenance Issues managed by an entity.

PNM Resources
Yes
Yes
Yes
PNM Resources appreciate the outstanding work of the SDT! We offer two comments for consideration by the SDT. 1) We believe that the 6 Calendar Month battery cell/unit internal ohmic value measurement for VRLA Batteries may be more frequent than we believe is necessary to maintain reliability. PNM has witnessed no significant failure patterns with VRLA batteries in our system and we currently do impedance testing of all Transmission Station Batteries on a 2-year basis. 2) We also believe that system constraints could arise that will make it difficult to "verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices" as specified in Table 1-5 for "unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays". Thank you for your consideration.

LADWP notices that the terms "Unresolved Maintenance Issue" and "maintenance-correctable issue" are used in several places. We recognize that "Unresolved Maintenance Issue" is defined as a deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action. Please define "maintenance-correctable issue" and clarify the differences between the two terms.

1. The maximum maintenance intervals in PRC-005-2 of 4 calendar months and 18 calendar months are not compatible with computerized maintenance-planning programs based on periodicity rather than elapsed time from the previous check. This situation could be addressed in a conservative fashion by performing work quarterly instead of at 4-month intervals, and annually in place of 18-month periods, which also provides often-needed flexibility as to scheduling the tasks. Inspections performed in April for Q2 and September for Q3 would not meet NERC's 4 calendar month criterion, however, and a similar problem exists for annual checks. The more-stringent compliance jeopardy cited above has therefore not been fully addressed. We recommend changing the 4 calendar months and 18 calendar months intervals to quarterly and annually respectively. 2. We consider addition of the expression, "causes the component to not meet the intended performance," to the previous draft's definition of Unresolved Maintenance Issues (UMIs) to constitute a step backwards, because of the unavoidable subjectivity involved in deciding whether or not a battery or other protection system device is unable to perform as intended. A battery with some "sparkle" on the plates due to sulfation would still be able to perform adequately, for example, making this an issue to watch but not an UMI. It is impractical to provide strict, quantitative, UMI-threshold performance limits for every piece of equipment in a Protection System and every situation that may arise, however. The concept of an UMI has some appeal from a common-sense point of view; but as a regulation it is impractical and, given the breadth of the topic at hand, is likely to remain so regardless of alternative phrasing that might be attempted.
No
We recommend that the final sentence of M3 and M4 be changed to, "Any of the following constitutes sufficient evidence: dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, dated work orders, or other equivalent documentation," and that the slightly different final sentence of M5 be similarly changed.
Although we have provided some suggested changes in these comments, PPL Generation entities voted in favor of this

version. We thank the SDT for the effort on this project and believe that the SDT has developed a revision that improves on many aspects of the existing version of PRC-005.

Section 5.1 (second paragrath, under the first bullet) states: “TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.” If this “actual event” can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. Seciton 2.4.1 – Sudden Pressure Relays – This question should be clarified that circuits from only EHV transformers should be considered in scope. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.
• Article 4.2.1 –The NSRF believes that this article should be revised to say”Protection Systems installed for the purpose of protecting BES Elements only and detecting Faults on BES Elements. Protection Systems designed to protect non-BES elements that incidentally open 100 kV and greater breakersare excluded from the scopte of PRC-005-2”. This makes it very clear what is included in the scope of the Testing and Maintenance program and what is not. • Change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 21, Row 1, Column 3 From “Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device” to: “Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years” Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). The NSRF believes that as written the testing of “each” trip coil will result in the increased amount of time that the BES is in a less reliable system configuration. The NSRF hopes that the SDT will consider these changes. • The NSRF recommends the statement “Excluding distributed UFLS and distributed UVLS (see Table 3)” be added to the top of Table 1-4(f). • Table 3. There will be many DP’s that have distributed UFLS (or UVLS) solely on the distribution system (less than 100 kV). The only item these DP’s will have to verify under Table 3 “Protection System dc supply” is the Protection System dc supply voltage. Yet, the new definition of Protection System, as it relates to dc supply is ”Station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply)”. Our interpretation of Table 3 and Section 15.7 of the Supplementary Reference & FAQ document is that a DP need only check the dc supply voltage at the terminals of the relays. If that is the SDT interpretation as well, we recommend revising Table 3 of the standard to reflect that. Table 3 contains issues that need to be addressed in a similar fashion as discussed for non-UFLS and non-UVLS systems, i.e. Table 1-1. Comparison to independent sources is only one way to check for a reliable AC measuring device. It also appears that monitoring capabilities are not being given any credit in regards to the AC sensing devices, DC supply, or control circuitry themselves. There should be no difference in the way these systems are treated compared to BES Protection Systems. • In Section D Compliance, Article 1.3, paragraph 4 the standard requires documentation be kept for the “. . .two most recent performances of each distinct maintenance activity. . .”. This needs to clarified that it cannot go back before 06/18/07, as evidenced by the suspension of CAN-0008. Also with some of the testing intervals being 12 years, that would dictate a Registered Entity maintain 24 years of records, which is unreasonable. This article should be revised to have documentation for the most current testing interval, if after 06/18/07. • It is understood that lockout relay testing is important as unexercised lockouts can stick and cause regional outages as experienced at Westwing. However, lockout testing by itself is risky and can lead to local outages. If Registered Entities are required to take on the additional risk of testing lockout relays, dispenstation must be granted for outages caused by those tests. The following statement should be included in the standard “No enforcement actions or penalties will result fromoutages caused by relay testing unless a Registered Entity shows a history of 3 or more test related outages per year for 5 years.” • In the VSL for Table 4 it seems that the phrase “5% or less” should be “not more than 5%”. With the original language it seems like an entity could be found to have an R4 lower VSL violation for “failure” of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive. • The drafting team needs to clarify “maintenance summaries” as stated in Measure M3. This is an ambiguous term that could be interpreted differently amongst entities. If a term such as ‘summary’ is to be utilized within the standard, a clear definition of what the term is, what it pertains to, where it is located, etc. needs to be included.The NSRF recommends that “maintenance

summaries" be defined and included in the "Definition of Terms used in Standard" section. • Footnote 1 in the Table sections would be much improved by inserting an example similar to what was provided in Section 8.4 of the Supplemental Reference and FAQ document . • Additional methods of verification should be allowed for AC measurement monitoring other than simply performing comparison to an independent source. For example, a sudden rate of change in calculated relay MW analog value and/or 3Io calculation would give way towards a bad CT and/or path. Loss of potential logic is available in most microprocessor relays today, which is very reliable logic for determining PT/CCVT issues. Consideration should be given to utilities that are capable of performing this type of monitoring in order to allow them to reach that next level of attributes. • Please clarify why input/output verification is excluded from the highest level of monitoring related to communications systems (Table 1-2). The way the monitoring attribute is listed does not provide that these will operate when needed. Recommend language be added similar to the monitoring of inputs and outputs described in the relay section (Table 1-1). • Table 1-3 should take into account the same concepts mentioned above in regards to AC measurement verification in Table 1-1. There are alternative ways to verify these quantities while still ensuring reliable operation. As such, companies should be given the opportunity to implement them. Additionally, credit should be given to circuit monitoring and alarming in AC circuits with electromechanical relays. If a transducer/alarming relay is placed in the circuit and monitoring is alarmed appropriately, the health of the AC sensing device can be determined. This would essentially provide the same level assurance as mentioned with the microprocessor relays. • Clarification is needed on the last row of Table 1-5. Does integrity entail monitoring and alarming of every individual path, if necessary, or is overall integrity sufficient? This statement is once again open to interpretation and leaves the entity at the mercy of the auditor.

Jason Marshall
Yes
Is the use of parentheticals within another set of parentheticals in Part 1.1 intentional? It is unusual to do this and a little confusing.
Yes
We agree the changes will benefit reliability by allowing a registered entity to have shorter maintenance cycles without the potential for compliance violations associated with missing their shorter maintenance cycle. Requirement R5 should be modified to focus on what is to be accomplished. As it is written now, the requirement is essentially focused on compliance by using "shall demonstrate efforts". Compliance is about demonstrating or presenting evidence that the requirement has been met. The purpose of the requirement is to correct Unresolved Maintenance issues. We suggest changing the wording to: "shall initiate resolution of Unresolved Maintenance Issues."
Yes
The first part of definition of a Countable Event should be modified as follows: "The failure of a Component such that it requires repair or replacement…". As it is currently worded, it is technically counting the Component as the Countable Event and not the failure of the component. Considering that the other two items that are Countable Events are conditions and misoperations, it seems appropriate to make failure the Countable Event. Application of this standard to UFLS is problematic as worded in Section 4.2.2. The UFLS are only applicable if "installed per ERO underfrequency load-shedding requirements". Technically, no UFLS fits this description because there are no ERO requirements to have a UFLS. PRC-006-0 was never approved by the Commission and is not enforceable. The Commission considered it a "fill-in-the-blank" standard. While PRC-006-1 corrects the "fill-in-the-blank" issues and was approved by the NERC BOT November 4, 2010, the Commission has yet to act on it. The data retention requirement for the Protection System Maintenance Program documentation seems excessive. The Data Retention section states that all versions since the last compliance audit must be maintained. Since TOs, GOs, and DPs are all on six year audit cycles, this would require maintaining this documentation for six years. Is this really necessary? The length could become even greater once NERC implements registered entity assessments that could shorten or lengthen the periods between compliance audits. The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C – Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of "the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date". While it may have been intended to apply to both clauses, the "since the previous scheduled audit date" only applies to the second clause. Since some of the maintenance activities have intervals of 12 years, this would require the registered entity to retain documentation for 24 years which cannot be audited since it is outside the audit window per the Rules of Procedures. At a minimum, we suggest clarifying that the documentation must not be maintained past the day after the last audit completion date. In the fourth paragraph of the Data Retention section, Component is not used consistently. It is used in both singular and plural form. It seems like it should be one or the other. Requirement R1 VSLs: For the High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

Yes
No
The standard does not provide basis for the enumerated “maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.” An example of such an approach is the Standard Technical Specifications in use by the nuclear power industry; e.g., NUREG 1432, volume 2. While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. When technology changes for the better, industry will need the flexibility to optimize use of the new technology while still maintaining an appropriate level of reliability. Lack of defined bases for intervals will prevent technically sound revision to maintenance practices.
No
Either the FAQ or the Standard should define the bases for each interval mandated. See the response to question 2 for further details.
Individual
EPRI
No
My comments are not to the point of dividing the requirements but the guidance in the PSMP tables are not technically valid for maintaining stationary battery cells. Internal ohmic measurements are related to the condition of an individual cell and not a battery bank. Also, there is not a direct correlation to ohmic measurements and battery or cell capacity. Ohmic measurements can provide an indication of a problem cell and point to a cell that should be tested. There also seems to be a misconception as to the type of capacity test that should be required. There are typically two types of tests done on batteries: service tests and performance tests Service test are done to determine a a battery (group of cells) can meet its duty cycle whereas, a performance test is intended to test a battery against the manufacturers curve to make a determination of when the battery should be replaced. A battery could technically still met its duty cycle but have reduced capacity. This simply means that the sizing was done properly, maintenace is timely, and there should be a timely replacement of the cells.

No
see comments in question 1
The drafting time should see the opinion of the IEEE Stationary Battery Committee before this standard is rolled out for implementation.
Individual
Constellation/Exelon
No
While we are fine with the structural change to separate the requirements out further, we have concerns with the content of the requirements. R5/M5 • M5 needs further clarity to reflect the intended compliance obligation for R5. In previous comments, Constellation expressed concern that compliance obligation for R5 implied a greater level of completion in attending to an identified “deficiency.” We pointed out that the severity of the “deficiency” found will dictate the method and timing of a “follow up correction action”. In response to the comment, the SDT stated that “PRC-005-2 only requires the entity “… initiate resolution” of the issue found.” The SDT revision of R5 and M5 is an improvement; however, changes to M5 are needs to clarify that efforts to correct do not require demonstration that those efforts have concluded. • A revision to the language will clarify the SDT intent. Please consider use of the following language: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall correct or initiate resolution of identified Unresolved Maintenance Issues. [Violation Risk Factor: Medium] [Time Horizon: Operations Planning] M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has initiated resolution of, or corrected, identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence for initiated resolution may include but is not limited to work orders for future resolution, project schedules for future resolution, or other documentation of future plans. The evidence for corrected Unresolved Maintenance Issues may include but is not limited to replacement Component orders, invoices, return material authorizations (RMAs) or purchase orders.
Constellation/Exelon thanks the drafting team for the hard work on the PRC-005 standard. The standard language made significant progress; however, below are outstanding issues of concern: Table 1-3 • Table 1-3 should not include current transformers (CTs). The tests mandated by this draft seeks to measure that a signal is “provided to the protective relay” however, for CT’s this test merely confirms that a signal is sent, not that it reached the correct protective relay. • The maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays should be left to the discretion of the Generator Owner. In order to meet the required activity specified in PRC-005-2

draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse affect on the reliability of the BES. Such testing is not recommended by suppliers. Battery Testing • The Tables describing battery testing could be consolidated into less granular breakdown and thus alleviate some of the associated compliance burden and avoid potential confusion. • Further to battery testing, given the quantity of batteries and the shorter interval cycles, the four calendar month requirement for batteries is too rigid as a firm four months. Similar to how a definition of annual can have a boundary such as within 9 to 16 months, battery testing intervals should allow a boundary such as “three times per year and not more than 6 months between each and average intervals not exceeding four months.” • Please confirm that references throughout Standard to battery/batteries relate to the entire battery bank and not to the individual battery cells unless specifically mentioned. Similarly, battery charger maintenance activity should relate to the battery charger in its entirety and not to individual parts or components. Auto Synchronizing Systems and Relays • The drafting team should clarify in the language that testing of auto synchronizing systems and relays is excluded. Applicability • To make 4.2.5.4 under Facilities more clear, please remove the term “generator-connected”. • When the SDT changed the original PRC-005 applicability language from “…affecting the reliability of the BES…” to the new 4.2.1 language “…that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)”, they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read “…and trips an interrupting device that interrupts current supplied directly from the BES.” By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005. Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1 language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement: “The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.” Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1: “Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements.” This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. Evidence Retention • It is not necessary and is undesirable to reiterate the language from the NERC Rules of Procedure (Appendix 4C 3.1.4.2) in the standard. Stating such language in two places is redundant and future changes to this section of the Rules of Procedure language will create compliance conflict. • While this language may be recommended for inclusion as new boilerplate-type language for NERC standards and may be used in other recently revised standards, the potential conflict should be taken into account and avoided for PRC-005. The first paragraph in section 1.3 should be removed. • Further, the standard language should dictate data retention relevant to the standard activities and not merely default to the time period in between audits. The Rules of Procedure language enables CEAs to confirm compliance for the full audit period, but the Standard retention language allow for a more reasoned obligation for evidence retention. Specific to this standard, two or three years of evidence for certain components, such as battery tests, is sufficient to demonstrate an entity’s PSMP program. • On a positive note, standardizing the requested evidence information is helpful.

Yes
No
The change made to R3 was a good move. Entities should be allowed the flexibility to build grace periods into their maintenance programs to assist them in meeting common national standards for maintenance activities and intervals. If possible, elimination of all possible uncertainty in the auditability of requirement R5 is desired. We prefer eliminating this requirement R5 altogether to the proposed draft that includes a requirement to demonstrate efforts to correct identified unresolved maintenance issues.
Yes

For the 18 month / 6 year activities, it is technically incorrect to allow equivalency between internal ohmic measurements and performance testing. This view is not substantiated by industry experience, documentation, or standards. Additionally, it should be specified to the auditor that the intervals for the battery maintenance are relevant to the component, not the application. This means that if a battery is replaced just before a required 6 year performance test, the 6 year interval for the performance test is reset.

Kansas City Power & Light
Todd Moore
Yes
Yes
Yes
For clarity, change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 21, Row 1, Column 3 to: “Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.”. Or alternately, “Electrically operate each interrupting device every 6 years”. Countable Event as proposed is somewhat unclear. Recommend the following language: Countable Event – A Component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to any other reason are not included in Countable Events.

Consideration of Comments

Project 2007-17
Protection System Maintenance and Testing

The Project 2007-17 Protection System Maintenance and Testing Standard Drafting Team thanks all commenters who submitted comments on PRC-005-2. These documents were posted for a 30-day public comment period from February 28, 2012 through March 28, 2012. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 56 sets of comments, including comments from approximately 118 different people from approximately 98 companies representing 9 of the 10 Industry Segments, as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Definitions:

The SDT revised the "Inspect" element of the definition of Protection System Maintenance Program (PSMP) to: "Examine for signs of component failure, reduced performance or degradation."

The definition of the term 'Unresolved Maintenance Issue' has been enhanced for additional clarity. The definition now reads: "A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action."

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The definition of Countable Event was modified to: "A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events." This change was acknowledged in Attachment A.

Applicability:

The SDT revised Applicability Clause 4.2.5.4 to: "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."

Requirements:

A minor editorial change was made to Requirement R1 to remove the nested parentheticals.

Tables

In Table 1-2, the interval for the second portion of the first row of the table was changed from six years to 12 years, and extensive changes were made to the last row of the table.

Several activities within Table 1-4a, Table 1-4b, Table 1-4c, Table 1-4d, and Table 1-4f, relating to verification that the station battery can perform properly, were modified with the assistance of representatives of the IEEE Stationary Battery Committee.

Measures

Measure M5 has been revised to include: "…project schedules with completed milestones …"

VSLs

In the High VSL for R1, "entities'" was corrected to "entity's".

The VSLs for Requirement R2 were modified from "reduce Countable Events to less than 4%" to "reduce Countable Events to no more than 4%".

Supplementary Reference Document

Complementary changes were made to the Supplementary Reference Document corresponding to all changes to the standard.

Unresolved Minority Views:

- A few commenters continued to object to the establishment of maximum allowable intervals for the maintenance of various Protection System component types. The SDT continued to respond that FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals comments and minimum maintenance activities. The SDT believes that the intervals established within the tables are appropriate as continent-wide maximum allowable intervals.

- Several commenters were concerned that an entity has to be “perfect” in order to be compliant; the SDT responded that NERC standards currently allow no provision for any degree of non-performance relative to the requirements.

- Several commenters continued to question NERC’s propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT obtained a position from NERC legal staff, and cited this position in responding that these devices are, indeed, within NERC’s authority because they are installed for the reliability of the BES.

- A few commenters questioned the inclusion of the dc control circuitry for sudden pressure relays, even though the relays themselves are excluded from the definition of “Protection System;” the SDT reiterated its position that this dc control circuitry is included because the dc control circuitry is associated with protective functions.

- A few commenters objected to the language in the Data Retention section regarding the retention of the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

- Several commenters suggested removal of Requirement R5, and others expressed concerns regarding Requirement R5 and Unresolved Maintenance Issues. The SDT explained its rationale for the requirement as drafted; and made a minor change to Unresolved Maintenance Issues, as detailed above.

1. **In response to comments, the PSMTSDT revised Requirement R1 to state that an entity's Protection System Maintenance Program (PSMP) shall include, for each Protection System component type, an identification of the maintenance method(s) used, and the identification of the relevant monitoring attributes applied. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Many commenters were in agreement with this change.

Comments were offered that the definition of PSMP is incongruous with its use in Requirement R1; the SDT disagreed, and noted that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program, and is the foundation for the standard.

Other comments questioned why Requirement R1 includes the applicable level of monitoring for a Component when this is also listed in the Component attributes within the tables; the SDT explained that the discussion in Requirement R1 is to assure that the monitoring is present to support the intervals and activities used.

The SDT responded to concerns regarding the use, within Requirement R1, of "Component Type" by noting that this term allows entities latitude in how they define their PSMP.

Other commenters noted that Requirement R1 does not require that entities maintain their Components; and is, therefore, administrative and should have a lower VRF. The SDT responded that Requirement R1 is the foundation of the standard; and, therefore, the VRF is appropriate.

The SDT accepted a suggestion to remove the imbedded parenthetical within Requirement R1.

Several comments were submitted that were unrelated to this question.

Organization	Yes or No	Question 1 Comment
Pacific Gas and Electric Company	Negative	PG&E thanks the drafting team for their efforts. PG&E agrees with overall changes to the standard and sees the current draft as an improvement over the prior draft, on which PG&E voted affirmative. PG&E however will vote negative on the current ballot due to recent experience and trouble with trying to implement the intercell connection resistance test for NiCad batteries as specified in Table 1-4c of PRC-005-2. PG&E has experienced trouble trying to implement the "Battery intercell or unit-to-unit connection resistance" maintenance activity for certain NiCad battery types. In

Organization	Yes or No	Question 1 Comment
		these cases the battery post was not exposed and was entirely covered by the intercell strap. The battery post protruded minimally from the battery and could not be accessed with a probe. PG&E requests clarification on this requirement and that provision be provided to accommodate existing battery systems without requiring modification to the battery system. Modification of the battery system to access the battery post places a hardship on the battery owner, may compromise the battery design, and ultimately may require replacing the battery to allow fulfilling the maintenance requirement. One solution may be to allow measuring intercell connection resistance from the battery post bolt when the battery post is not accessible. While this is not the optimal approach, it may still be effective since the presence of corrosion would likely show up between both the battery post and bolt and also between the bolt and intercell strap. Trending the resistance from bolt-to-bolt may still be effective in determining an increasing resistance from post-to-post. PG&E suggests the following language: Table 1-4c Verify - Battery intercell or unit-to-unit connection resistance where battery post is accessible. Where battery post is not accessible measure intercell or unit-to-unit connection resistance from bolt-to-bolt or nearest connection to the battery post.
Response: Thank you for your comment. The SDT believes that the Maintenance Activities in Table 1-4c are explicit as to the required activity and are necessary to ensure the integrity of the station battery. The SDT believes the activity you discuss is not an effective method to satisfy the intent of the requirement in Table 1-4c; and the team suggests that you consult the manufacturer of your battery system to investigate how to meet the requirement.		
Seminole Electric Cooperative, Inc.	Negative	Seminole recommends the SDT re-consider an interval of 12 calendar years for the component in row 2, of Table 1-5. The maximum maintenance interval for "Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less stable system configuration. Increasing the time the BES is in

Organization	Yes or No	Question 1 Comment
		a less stable system configuration also increases the probability of a low frequency, high impact event occurring. We believe that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. It appears that the SDT is trying to address a specific type of lockout relay with the 6 year interval that consists of a longer operating rod lockout that is subject to binding when called upon to operate. Why is it necessary to include all lockout relays when only a very specific segment of all lockout relays is subject to this one problem? Maybe a unique category of these specific types of lockouts, subject to operating rod binding should be specified at 6 years, with other lockouts not subject to this problem using a common interval like other protective components of 12 years. We sincerely hope that the SDT will consider these positive changes.
Response: Thank you for your comment. The SDT believes that electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils), regardless of the manufacturer, need to be electrically operated to prove the capability of the device to change state. The application of lockouts is typically associated with equipment limited having remote backup protection (Generators/Transformers) or higher system consequences if remote backup is called upon to operate (Buses/Breakers). A failure of a lockout to function results in decreased stability and has a higher outage impact. These tests need to be accomplished at least every six years, unless PBM methodology is applied. The contacts on the 86 that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.		
Tampa Electric Co.	Negative	The requirement to periodically test Control circuits will negatively impact reliability. The possibility of lifted wires being properly re-landed or test links being left open following testing will cause more misoperations than the finding of failed devices prevents. The outages required to do the testing will limit available transmission capability and therefore affect markets negatively for no reliability enhancement.
Response: Thank you for your comment. The SDT believes that periodic testing of control circuits is a vital part of assuring proper		

Organization	Yes or No	Question 1 Comment
operation of a protective relay system. There are several methods of accomplishing this testing. Where portions of the circuit are isolated for testing, procedures should be in place to assure proper restoration of the circuit.		
Tennessee Valley Authority	Negative	1. Regarding the functional test required every 3 months for “unmonitored communication systems” in Table 1-2 of the PRC-005-2 Draft. TVA feels that a Maximum Maintenance Interval for the Functional Test should be every 12 months until auto-checkback has been fully implemented by the utility. 2. The Implementation Plan for PRC-005-2 Step 4 on Page 2 states: “The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.” TVA feels that this is not sufficient time to implement full auto-checkback capability at some utilities. The time schedule of twelve (12) months should be forty-eight (48) months following applicable regulatory approvals
Response: Thank you for your comments. 1) The SDT believes the four-month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status. 2) The Implementation Plan is intended to facilitate implementation of the standard, not to facilitate modifications to meet the requirements of the standard.		
U.S. Bureau of Reclamation	Negative	1. The definition for PSMP is incongruous with the use of the PSMP in Requirement R1. Requirement R1, including the Measure and VSL focus on the identification of maintenance method of the Component types and not that the PSMP is in fact being used for maintenance of the component. 2. The requirement R5 indicates the entity has to "demonstrate" efforts to correct

Organization	Yes or No	Question 1 Comment
		identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP. 3. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 4. Re The definition of Components: The standard defined what constitutes a control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT believes that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program, and is the foundation for the standard. Requirements R3-R4 address implementation of the entity's PSMP. 2. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency, "…cannot be corrected during the maintenance interval." 3. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard. 4. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing of these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
DTE Energy	No	DECo does not agree. With the exception of station batteries, all components should be tested as a scheme to assure that all components are working together as designed, so the PSMP should not be required for each component type.
Response: Thank you for your comment. A PSMP allows for each component within a protective relay scheme to have a differing maintenance interval allowing for unit or station outages. A company's PSMP can perform maintenance on all the components within a particular relay scheme, but that would require the shortest of the maintenance intervals.		
PNGC Comment Group	No	Specifying "by component type" appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to "by component or component

Organization	Yes or No	Question 1 Comment
		type" when entities determine the maintenance method in their PSMP.
Response: Thank you for your comment. The SDT believes that it is acceptable for an entity to subdivide components within a component type, if desired. The SDT does not want to remove that latitude.		
Nebraska Public Power District	No	1. Since auditors will be able to request documentation necessary to validate the inclusion of the device within the appropriate level of monitoring, why does the program document require listing level of monitoring and component attributes? (Concerned about the burden of maintaining lists of components in a program document that are alike but have different levels of monitoring. Ex: Monitored and unmonitored microprocessor relays) 2. For identification of the relevant monitoring attributes applied can a single specification document suffice for similar relay types such as one document for SEL relays? 3. For trip circuit monitoring can a standard document be used for a group of similar schemes?
Response: Thank you for your comments. See Section 6.1 of the Supplementary Reference and FAQ document for a discussion of this topic. 1. The requirement to list component attributes is designed to support a company's program for the maintenance intervals used. 2. The SDT concurs with using a single specification document for similar equipment. 3. The SDT concurs with a standard document for trip circuit monitoring when consistent practices are present.		
Flathead Electric Cooperative, Inc.	No	1. Specifying "by component type" appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to "by component or component type" when entities determine the maintenance method in their PSMP. 2. Generally, have concerns with all the new definitions except the NERC

Organization	Yes or No	Question 1 Comment
		definition of Protection System. The approach to creating new definitions of plain language in a standard should be avoided.
Response: Thank you for your comments. 1. The SDT believes it is acceptable for an entity to subdivide components within a component type, if desired. The SDT does not want to remove that latitude. 2. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard.		
American Electric Power	No	R1.1 binds you to the activities in the table, but our system is comprised of elements (such as a Plant Control Systems), that are not included in the table. As a result, it is not clear how an entity could develop an SPS that satisfies both the requirement and our system.
Response: Thank you for your comment. IEEE defines a relay as: "An electric device designed to respond to input conditions in a prescribed manner and after specified conditions are met to cause contact operation or similar abrupt change in associated electric control circuits." The SDT believes that protective relay functions that are embedded in control systems and/or SPSs are a part of this standard and are, therefore, under the same requirements as dedicated, stand-alone protective relays. It is left to the entity to determine how to align these requirements with operational concerns.		
Manitoba Hydro	No	Please see comments provided in Question 4.
US Bureau of Reclamation	No	The requirement R1 states that the PSMP must identify how the component is to be maintained, using time based or performance based or a combination. While R1 requires a PSMP, there is no measure that the PSMP is used for actually maintaining the components, other than for documenting which maintenance method is being used. The purpose of R1 is therefore administrative. Since there is no measure for the use of the PSMP, why is the entity required to develop the PSMP as defined? There is no VSL for R1 which requires that the entity establish a PSMP. Since there is no severity level associated a PSMP that does not contain one of the required activities it supports elimination of the definition of PSMP. PSMP definition is also weak and does not match with the VSL that the PSMP identify the maintenance method of the protection system component types. The definition is that PSMP

Organization	Yes or No	Question 1 Comment
		which must include: "A maintenance program for a specific component includes one or more of the following activities: o Verify- Determine that the component is functioning correctly. o Monitor - Observe the routine in-service operation of the component. o Test - Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. o Inspect - Detect visible signs of component failure, reduced performance and degradation. o Calibrate- Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement." Since requirement 1 essentially only requires identification of which maintenance method is to be used, there is no need for the definition. It no longer matters how the device's functionality is determined as long as it is performed on a time based or performance based method. This approach may be lowering the reliability level associated with the protection system maintenance. Since the definition of PSMP is that only one of the 5 activities is needed, is seems that one could select to "Monitor" the in-service operation of the component on a time base and no further action is needed. So that could mean observe that the relay has power and was not misoperating every six years and maintenance is performed. A PSMP is as defined does not help the reliability. It would be better require the PSMP include as a minimum all five activities defined as well as defining the maintenance method used (time based, performance based, or a combination). There needs to be a requirement that the PSMP needs to be developed. Then Requirement 1 would be to implement the PSMP.
Response: Thank you for your comments. Requirement R1 requires that the entity establishes a PSMP (with the specified attributes), and is the foundation for the standard; thus, Requirement R1 is not administrative, as without a PSMP, there is nothing on which to base the remainder of the standard. Requirements R3-R4 address implementation of the entity's PSMP.		
ExxonMobil Research and Engineering	No	As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must

Organization	Yes or No	Question 1 Comment
		be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program .
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated."		
EPRI	No	My comments are not to the point of dividing the requirements but the guidance in the PSMP tables are not technically valid for maintaining stationary battery cells. Internal ohmic measurements are related to the condition of an individual cell and not a battery bank. Also, there is not a direct correlation to ohmic measurements and battery or cell capacity. Ohmic measurements can provide an indication of a problem cell and point to a cell that should be tested. There also seems to be a misconception as to the type of capacity test that should be required. There are typically two types of tests done on batteries: service tests and performance tests. Service test are done to determine if a battery (group of cells) can meet its duty cycle whereas, a performance test is intended to test a battery against the manufacturers curve to make a determination of when the battery should be replaced. A battery could technically still meet its duty cycle but have reduced capacity. This simply means that the sizing was done properly, maintenance is timely, and there should be a timely replacement of the cells.
Response: Thank you for your comment. The drafting team agrees with statements by you and others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and		

Organization	Yes or No	Question 1 Comment
the Supplemental Reference and FAQ document has been modified to further elaborate on these concerns.		
Public Utility District No. 1 of Okanogan County	Affirmative	OCPD would like some clarification with regards to the Power Wave concept. Currently in Table 1.1 and Table 3 it states, “Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics." OCPD feels that it might be better stated as simply 60 Hz.
Response: Thank you for your comment. The values for waveform sampling are intended to be verified by referencing a specific manufacturer’s specifications.		
ACES Power Marketing Standards Collaborators	Yes	Is the use of parentheticals within another set of parentheticals in Part 1.1 intentional? It is unusual to do this and a little confusing.
Response: Thank you for your comment. The SDT agrees with your suggestion, and made the following change: “Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System component type.”		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration agrees that a Compliance Authority should be alerted to those component types which have been assigned extended maintenance intervals because they use some form of monitoring. We also agree that it is appropriate that the PSMP list the relevant monitoring attributes in these cases, so they can be confirmed to be consistent with the criteria in PRC-005-2’s interval tables.
Response: Thank you for your comments.

2. As a result of the changes to Requirement R1, the previous Requirement R3 was separated into three requirements:

a. Requirement R3 now requires that an entity utilizing a time-based program maintain its Protection System components in accordance with the maximum maintenance intervals listed in the tables. This change removes the compliance jeopardy associated with an entity having more stringent intervals (in its PSMP) than those listed in the tables.

b. Requirement R4 (new) requires an entity utilizing a performance-based program maintain its Protection System components in accordance with its performance-based Protection System Maintenance Program.

c. Requirement R5 (new) requires an entity to demonstrate efforts to correct identified unresolved maintenance issues. The previous language in Requirement R3 directed that an entity initiate resolution.

Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Many commenters were in agreement with this change.

Numerous comments were offered relative to subject and definition of "Unresolved Maintenance Issues," per Requirement R5. As a result of these comments, the definition of this term was modified to include the phrase, "… cannot be corrected during the maintenance interval…" For those commenters objecting to the concept of Unresolved Maintenance Issues, the SDT explained the rationale behind the concept.

Several comments were submitted that were unrelated to this question.

Organization	Yes or No	Question 2 Comment
Beaches Energy Services	Negative	The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: The applicability as currently stated will sweep in distribution protection: "4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)" Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.

To address your concern, the distribution protective devices and functions cited in this comment are not “installed for the purpose of detecting Faults on BES Elements” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse power relay application described is also not “installed for the purpose of detecting Faults on BES Elements,” (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system.

Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue.</td></tr>
</table>

Organization	Yes or No	Question 2 Comment
Fort Pierce Utilities Authority	Negative	1. The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The applicability as currently stated will sweep in distribution protection: "4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)." Most network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). 2. There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200

Organization	Yes or No	Question 2 Comment
		kV, then the entity would not be able to meet PRC-023 as that standard is currently written. FPUA recommends the SDT should adopt the FERC approved interpretation. 3. Another concern is regarding the sudden pressure relays. These had been out of the scope in all previous draft versions of PRC-005-2 because these do not measure electrical quantities. However, the SDT just added a requirement to test the trip path from the sudden pressure device, arguing that it is captured by the definition of Protection Systems. This inconsistency does not make sense and could create “grey areas” for other devices that can trip for low oil level or high temperature, among others. By their nature, sudden pressure devices are far less reliable than their associated control circuitry. I know of at least one large entity that disables sudden pressure relays on smaller transformers to cut down on nuisance alarms. If it is expected that non-electrically initiated devices may become part of some maintenance standard in the future, I think it would be premature for the SDT to address sudden pressure relays in PRC-005-2. 4. And lastly, page 77 of the Supplementary Reference has some text clarifying the requirement for establishing a baseline test: “For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit.” This guidance does not recognize the fact that

Organization	Yes or No	Question 2 Comment
		some battery manufacturers recommend the baseline tests to be performed at some point in time after the install to allow the cell chemistry to stabilize after the initial freshening charge. The manual from a battery manufacturer (Enersys Powersafe) states that "The initial records are those readings taken after the battery has been in regular float service for 3 months (90 days). These should include the battery terminal float voltage and specific gravity reading of each cell corrected to 77F (25C), all cell voltages, the electrolyte level, temperature of one cell on each row of each rack, and cell-to-cell and terminal connection detail resistance readings. It is important that these readings be retained for future comparison". If an entity follows the manufacturer's recommendation, the above statements would lead an auditor to a finding of non-compliance because internal ohmic tests were not performed prior to placing a new battery string in service. A simple modification to the wording would eliminate the conflict.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.
2. To address your concern, the distribution protective devices and functions cited in this comment are not "installed for the purpose of detecting Faults on BES Elements" and would, therefore, not be subject to PRC-005-2. A relay used primarily for "safety and distribution voltage control reasons" is clearly not "installed for the purpose of detecting Faults on BES Elements." The reverse power relay application described is also not "installed for the purpose of detecting Faults on BES Elements," (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system.

Organization	Yes or No	Question 2 Comment
Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue. 3. DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the "Control circuitry" portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. Activities associated with the schedule submitted in the filing will be included in a final SAR to further develop PRC-005. A draft SAR for a second phase of this project is posted for information only at this time. **4.** The drafting team revised the Supplemental Reference and FAQ document based on your recommendations.		
Imperial Irrigation District (IID)	No	IID disagree with item c. and does not believe item c increases the reliability of the BES. The maintenance issues will be resolved internally and should not be required as per compliance of the standard.
Response: Thank you for your comment. The practice of returning Protection System devices to good working order exists currently as a required element of a sound maintenance program as required by the existing Protection System maintenance and testing standard, PRC-005-1b. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to "…look for relay test results or field records with annotations such as "as-found" readings or pass/fail results; if failed, then adjustments made. The maintenance record for adjustments may be requested".		
Texas Reliability Entity	No	New requirement R5 states that an entity shall "demonstrate efforts" to correct identified Unresolved Maintenance Issues. This falls short of requiring completion of any corrective actions for the unresolved maintenance issue. We suggest rewording to "Each Transmission Owner, Generator Owner, and Distribution Provider shall develop a corrective action plan and work timetable to address identified Unresolved Maintenance Issues. The Registered Entity shall complete resolution of Unresolved Maintenance Issues within the time frame identified in the Entity corrective action plan." If R5 is modified, then M5 and the VSL should also be modified accordingly.
Response: Thank you for your comment.		

Organization	Yes or No	Question 2 Comment
Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “unresolved maintenance issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”		
Nebraska Public Power District	No	The FAQ attempts to clarify the intent of “demonstrate efforts to correct”, however, there is no explanation as to why this new term is preferable to the more concise “initiate resolution” term that was developed and agreed upon over the last year. In the Supplementary Reference and FAQ document there is a request for clarification and it is reprinted below. Please clarify what is meant by “...demonstrate efforts to correct an unresolved maintenance issue...”; why not measure the completion of the corrective action? Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program

Organization	Yes or No	Question 2 Comment
		requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. I agree with this response and specifically the last sentence. This indicates that R5 "demonstrating efforts to correct unresolved issues" is too open ended and subjective and cannot be applied by enforcement in a consistent way. R5 should be removed from the standard.
Response: Thank you for your comment. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
Bonneville Power Administration	No	BPA believes that R5 is not worded in such a way that it can be easily or consistently audited.
Response: Thank you for your comment. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and

yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." Each entity must determine how to document the efforts to correct the Unresolved Maintenance Issue based on the specific issue and choice of remediation.		
PPL Supply NERC Registered Organizations	No	1. The maximum maintenance intervals in PRC-005-2 of 4 calendar months and 18 calendar months are not compatible with computerized maintenance-planning programs based on periodicity rather than elapsed time from the previous check. This situation could be addressed in a conservative fashion by performing work quarterly instead of at 4-month intervals, and annually in place of 18-month periods, which also provides often-needed flexibility as to scheduling the tasks. Inspections performed in April for Q2 and September for Q3 would not meet NERC's 4 calendar month criterion, however, and a similar problem exists for annual checks. The more-stringent compliance jeopardy cited above has therefore not been fully addressed. We recommend changing the 4 calendar months and 18 calendar months intervals to quarterly and annually respectively. 2. We consider addition of the expression, "causes the component to not meet the intended performance," to the previous draft's definition of Unresolved Maintenance Issues (UMIs) to constitute a step backwards, because of the unavoidable subjectivity involved in deciding whether or not a battery or other protection system device is unable to perform as intended. A battery with some "sparkle" on the plates due to sulfation would still be able to

Organization	Yes or No	Question 2 Comment
		perform adequately, for example, making this an issue to watch but not an UMI. It is impractical to provide strict, quantitative, UMI-threshold performance limits for every piece of equipment in a Protection System and every situation that may arise, however. The concept of an UMI has some appeal from a common-sense point of view; but as a regulation it is impractical and, given the breadth of the topic at hand, is likely to remain so regardless of alternative phrasing that might be attempted.
Response: Thank you for your comment. 1. The SDT believes that management issues associated with computerized maintenance management programs can be adapted to provide maintenance triggers consistent with the intervals established in the tables. Many of these systems offer the ability for the user to create custom algorithms to trigger the desired work order, reminder, or alarm, etc. The SDT also believes the four calendar-month and 18-calendar-month intervals are appropriate for the relative Protection System components. An entity may utilize the abbreviated intervals, such as you suggest, as long as they meet the explicit requirements and intervals established in the standard. **2.** The consideration of “meet the intended performance” is an issue for an entity to determine subjectively. This consideration depends heavily upon the nature of observed anomaly and upon the actual intended performance.		
Arizona Public Service Company	No	The standard does not provide basis for the enumerated “maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.” An example of such an approach is the Standard Technical Specifications in use by the nuclear power industry; e.g., NUREG 1432, volume 2. While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. When technology changes for the better, industry will need the flexibility to optimize use of the new technology while still maintaining an appropriate level of reliability. Lack of defined bases for intervals will prevent technically sound revision to maintenance practices.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment. The SDT established the maximum maintenance intervals for each Protection System component subject to the standard based upon research performed by the NERC System Protection and Control Subcommittee and "best practice" input from industry. The base intervals are extended in consideration of modern monitoring capabilities and new technologies. These extended intervals range from "12 calendar years" to "No periodic maintenance specified." Consistent with the FERC directive of intervals being "…appropriate to the type of protection system and its impact on the reliability of the Bulk Power System," the SDT did not provide a "No periodic maintenance specified" extended interval for high reliability impact devices, such as protective relays; but rather stipulates a six-calendar-year interval for unmonitored electromechanical and unmonitored microprocessor relays, and a 12-calendar-year verification of monitored microprocessor relays. Please see Section 8.3 of the Supplementary Reference and FAQ document for a more detailed discussion of this issue.		
Southern Company Generation	No	1. The change made to R3 was a good move. Entities should be allowed the flexibility to build grace periods into their maintenance programs to assist them in meeting common national standards for maintenance activities and intervals. 2. If possible, elimination of all possible uncertainty in the auditability of requirement R5 is desired. We prefer eliminating this requirement R5 altogether to the proposed draft that includes a requirement to demonstrate efforts to correct identified unresolved maintenance issues.
Response: 1. Thank you for your comment and support. 2. Returning Protection System devices to good working order exists currently as a required element of a sound maintenance program subject to the existing Protection System Maintenance and Testing Standard, PRC-005-1b. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to "…look for relay test results or field records with annotations such as "as-found" readings or pass/fail results; if failed, then adjustments made. The maintenance record for adjustments may be requested". Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of		

Organization	Yes or No	Question 2 Comment
this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
Ingleside Cogeneration LP	No	1. Ingleside Cogeneration LP strongly agrees with the change made to the language in R1 and R3 specifying that compliance is measured against the PRC-005-2's interval tables wherever time-based methods are used. The intervals were carefully designed to assure an acceptable level of BES reliability, and the regulatory authorities must be prepared to stand by them. Furthermore, a Registered Entity who may establish tighter intervals for their own internal purposes should be encouraged to do so - and without a threat of a violation hanging over their heads. 2. We also agree with the need to add a new requirement (R4) which applies to those entities that choose to use a performance-based system to determine some of their maintenance intervals. It logically maps back to requirement R2 which states that the calculated intervals must be documented in the PSMP. 3. We cannot agree with the language used in R5, which, in its previous form under R3, had specified only that the Protection System owner "initiate

Organization	Yes or No	Question 2 Comment
		resolution” to correct identified unresolved maintenance issues. We were actually comfortable with this language as it was unambiguous that progress did not need to be tracked start-to-finish. We would like to propose adding a phrase that tracks the statement in M5; which we find acceptable. This would result in the following: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate THAT IT HAS UNDERTAKEN <our emphasis> efforts to correct identified Unresolved Maintenance Issues.
Response: 1. Thank you for your comment and support. 2. Thank you for your comment and support. 3. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. For the Compliance Monitoring Authority to be confident that the corrective action is being implemented, the entity should expect to demonstrate progress toward correcting the Unresolved Maintenance Issue, such as the evidence suggested in Measure M5 (with additional suggested evidence added).		
American Electric Power	No	1. R3: Table 1-5 notes a “mitigating device” as part of component attributes. Such a phrase could be open to interpretation and needs to be clearly defined. 2. Table 1-3, Maintenance Activities - there is nothing specifically regarding accuracy. Suggest incorporating the definition of “verify” as used in the FAQ or perhaps something similar to “verify values are as expected”. 3. R5: We understand the drafting team’s desire to deal with unresolved maintenance issues, however it is not clear how the adequacy of resolving

Organization	Yes or No	Question 2 Comment
		those issues would be determined by an auditor. If these kinds of efforts are going to be scrutinized, there needs to be some sort of boundaries established so that it is clear how unresolved maintenance issues would be evaluated.
Response: Thank you for your comment. 1. The SDT intended that "mitigating devices" address actions of SPSs, which may include activities beyond tripping of interrupting devices. For example, SPSs may perform actions like generation run-back or generation fast-valving. 2. 'Verify" is a term expressed in the PSMP definition, and the use of the term in Table 1-3 indicates that the accuracy needs to be 'whatever is necessary' for proper functioning of the connected relays. 3. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues. Measure M5 suggests some examples of evidence.		
US Bureau of Reclamation	No	The Requirement R5 indicates the entity has to "demonstrate" efforts to correct identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP.
Response: Thank you for your comment. The term within Requirement R5, "… demonstrate efforts …" is intended for both – that the entities are acting to correct the deficiency and also (to prove compliance) maintaining documentation of the activities underway to		

Organization	Yes or No	Question 2 Comment
correct the deficiency. The SDT elected to not require a "**Corrective Action Plan**" as defined in the NERC Glossary of Terms to avoid much of the systemic, ongoing documentation attendant to that term. However, if an entity wishes to use a Corrective Action Plan as defined, that would be an acceptable method of meeting Requirement R5.		
Essential Power, LLC	No	The change to R3 is too restrictive, and removes the registered entity's ability to better define its own intervals based on its own experience and system characteristics. The comments regarding a CEA's enforcement of an RE's more stringent internal intervals is not indicative of an issue with the Requirement, but with the way in which it is enforced.
Response: Thank you for your comment. Requirement R3 still allows entities flexibility within their own Protection System Maintenance and Testing Program (PSMP), and only restricts an entity's establishment of intervals that are greater than those specified in the tables. For example, an entity may choose to establish, in its own PSMP, testing of a specific type or model of electromechanical relay more frequently than the six-calendar-year interval specified in Table 1-1 of PRC-005-2. However, should some issue come up that affects the entity's ability to complete testing of those devices within their programs established interval, but they are able complete the testing within the maximum maintenance interval provided by the standard, the standard explicitly establishes that they will not be found non-compliant for missing their own, more stringent interval.		
Xcel Energy	No	We agree with the changes to R3 and the new R4 requirement but disagree with the wording change in the new R5 requirement. The difference between "initiate resolution" and "demonstrate efforts to correct identified unresolved maintenance issues" is very unclear. Please clarify the SDT's intent with this subtle wording change. In our opinion, it would be fairly obvious if an entity met a requirement to "initiate resolution" and, thus, this would be easily measurable requirement. It seems that the phrase "demonstrate efforts to correct identified unresolved maintenance issues" will be open to more auditor judgment as to what constitutes adequate efforts to correct a deficiency and thus makes the measurement of meeting this requirement far more arbitrary. If this is not the intent, then why bother with the wording change? Furthermore, CEAs should realize that entities already have strong financial incentives in correcting identified unresolved maintenance issues to minimize the risk of costly equipment damage or equally costly outages of critical equipment. Delays in correcting identified

Organization	Yes or No	Question 2 Comment
		unresolved maintenance issues are seldom driven by cost avoidance and are more likely driven by the time it takes to develop, engineer and/or procure a better solution to a problem. Prompt band-aid type fixes are not necessarily desirable fixes and the wording of R5 should not promote the band-aid approach to the correction of a problem.
Response: Thank you for your comment and your support on Requirements R3 and R4. Requirement R5 is expressly focused on allowing entities to resolve deficiencies in an effective manner, rather than performing “band-aid” fixes. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “unresolved maintenance issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”		
ExxonMobil Research and Engineering	No	As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity’s calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT’s current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
EPRI	No	See comments in question 1
Constellation/Exelon	No	While we are fine with the structural change to separate the requirements out further, we have concerns with the content of the requirements. R5/M5 • M5 needs further clarity to reflect the intended compliance obligation for R5. In previous comments, Constellation expressed concern that compliance obligation for R5 implied a greater level of completion in attending to an identified "deficiency." We pointed out that the severity of the "deficiency" found will dictate the method and timing of a "follow up correction action". In response to the comment, the SDT stated that "PRC-005-2 only requires the entity "... initiate resolution" of the issue found." The SDT revision of R5 and M5 is an improvement; however, changes to M5 are needs to clarify that efforts to correct do not require demonstration that those efforts have concluded. • A revision to the language will clarify the SDT intent. Please consider use of the following language: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall correct or initiate resolution of identified Unresolved Maintenance Issues. [Violation Risk Factor: Medium] [Time Horizon: Operations Planning] M5. Each Transmission

Organization	Yes or No	Question 2 Comment
		Owner, Generator Owner, and Distribution Provider shall have evidence that it has initiated resolution of, or corrected, identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence for initiated resolution may include but is not limited to work orders for future resolution, project schedules for future resolution, or other documentation of future plans. The evidence for corrected Unresolved Maintenance Issues may include but is not limited to replacement Component orders, invoices, return material authorizations (RMAs) or purchase orders.
Response: Thank you for your comment. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. Measure M5 has been modified to include “project schedules with completed milestones.”		
Northeast Power Coordinating Council	Yes	
DTE Energy	Yes	
MRO NSRF	Yes	
Tacoma Public Utilities	Yes	
Dominion	Yes	1. Dominion understands R3 to mean that the time-based maintenance interval can be less that but not exceed the maximum maintenance intervals in the tables. But that compliance will be based upon the maximum interval. Please confirm that our understanding is correct. 2. Dominion believes the intent of the footnote in Table 1-1 is to ‘start the interval’ on either the 1st day of a calendar year or calendar month. We also believe this will require any entity whose current intervals are based on annual or monthly will have to adjust their intervals to calendar as they

Organization	Yes or No	Question 2 Comment
		transition to PRC-005-2. Please confirm our understanding is correct. 3. We also believe this transition could result in the compliance interval measurement being shorter or longer than it would have been if PRC-005-2 had not been approved. If this is incorrect, please provide examples to provide clarity.
Response: Thank you for your comment. 1. Yes, your understanding of Requirement R3 is correct. 2. No, your understanding of Footnote 1 at the bottom of the page where Table 1-1 appears in the standard is not correct. The intent of Footnote 1 is to clarify, or define the terms “calendar year” and “calendar month” as they relate to the period in which the next maintenance activity for a particular interval must occur. For example, if an entity performed electromechanical relay testing at Substation A in April of 2010, in accordance with the maximum maintenance interval of six-calendar-years established in Table 1-1, the entity must perform the next round of electromechanical relay testing at Substation A sometime during the calendar-year period beginning January 1, 2016. Please see Section 7.1 of the Supplementary Reference and FAQ document for a more detailed discussion of this issue. 3. If an entity’s maintenance program specifies a maintenance activity occur “30 days” from the previous activity’s performance, it would be possible that a transition to a “calendar month” interval would allow the first performance of the activity after the transition to occur sooner or later than the 30 days previously specified. However, many existing maintenance programs that establish performance of an activity “annually” or “monthly” should not require more than adjusting the language in the program. For instance, if an entity’s current program is to inspect substations “monthly,” they are likely performing those inspections sometime during each calendar month. This practice would be no different with the interval redefined as: “once each calendar month.”		
PNGC Comment Group	Yes	The PNGC comment group agrees with this change. Removing the jeopardy associated with more stringent intervals will make it less risky for entities to tighten intervals in their PSMP.
Response: Thank you for your comment and support.		

Organization	Yes or No	Question 2 Comment
ACES Power Marketing Standards Collaborators	Yes	1. We agree the changes will benefit reliability by allowing a registered entity to have shorter maintenance cycles without the potential for compliance violations associated with missing their shorter maintenance cycle. 2. Requirement R5 should be modified to focus on what is to be accomplished. As it is written now, the requirement is essentially focused on compliance by using "shall demonstrate efforts". Compliance is about demonstrating or presenting evidence that the requirement has been met. The purpose of the requirement is to correct Unresolved Maintenance issues. We suggest changing the wording to: "shall initiate resolution of Unresolved Maintenance Issues."
Response: 1. Thank you for your comment and support of this change. **2.** Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
Liberty Electric Power LLC	Yes	Thank you for the change in Requirement 3. This standard now gives clear direction to entities, removes the burden of "created paperwork" intended only for the use of auditors, and removes the compliance jeopardy for holding a program to a higher standard than required.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment and support.		
TransAlta Centralia Generation LLC	Yes	More detail explanation or examples of Efforts on R5 is required
Response: Thank you for your comment. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." See the Supplementary Reference and FAQ document Section 4.1 for additional discussion.		
Central Lincoln		1. We thank the SDT for removing the extra compliance jeopardy associated with stringent intervals. The extra jeopardy never made sense to us, since it could result in sanctions to one entity and no sanctions to another entity when both followed the same interval with no BES risk presented by either. 2. We are concerned regarding the language of R5. We understand that maintenance without resolution is worthless, but the language here is subjective allowing different auditors to reach differing conclusions whether a sufficiently documented effort has been made. We also note that entities are expected to be continually in compliance with applicable standards, and are expected to self report when they are not. Strictly interpreted, an entity is out of compliance with R5 if there is any time lag between the moment the problem is identified in the field and documentation is produced of an effort taken to resolve it. We suggest the inclusion of a reasonable time limit.

Organization	Yes or No	Question 2 Comment
Response: 1. Thank you for your comment and support. 2. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval," which allows the entity until the end of the maintenance interval to develop an approach for correcting the problem. See the Supplementary Reference and FAQ document Section 4.1 for additional discussion.

3. **The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised. Do you agree with the changes? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Several comments were submitted that were unrelated to this question.

Many commenters offered questions and suggestions related to the content of the Supplementary Reference and FAQ document, which resulted in assorted changes throughout the document.

Organization	Yes or No	Question 3 Comment
Fort Pierce Utilities Authority	Negative	1. The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).” Most network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters

Organization	Yes or No	Question 3 Comment
		worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. FPUA recommends the SDT should adopt the FERC approved interpretation. 2. Another concern is regarding the sudden pressure relays. These had been out of the scope in all previous draft versions of PRC-005-2 because these do not measure electrical quantities. However, the SDT just added a requirement to test the trip path from the sudden pressure device, arguing that it is captured by the definition of Protection Systems. This inconsistency does not make sense and could create "grey areas" for other devices that can trip for low oil level or high temperature, among others. By their nature, sudden pressure devices are far less reliable than their associated control circuitry. I know of at least one large entity that disables sudden pressure relays on smaller transformers to cut down on nuisance alarms. If it is expected that non-electrically initiated devices may become part of some maintenance standard in the future, I think it would be premature for the SDT to address sudden pressure relays in PRC-005-2. 3. And lastly, page 77 of the Supplementary Reference has some text clarifying the requirement for establishing a baseline test: "For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above

Organization	Yes or No	Question 3 Comment
		should be followed at the time of installation to insure the most accurate trending of the cell/unit.” This guidance does not recognize the fact that some battery manufacturers recommend the baseline tests to be performed at some point in time after the install to allow the cell chemistry to stabilize after the initial freshening charge. The manual from a battery manufacturer (Enersys Powersafe) states that “The initial records are those readings taken after the battery has been in regular float service for 3 months (90 days). These should include the battery terminal float voltage and specific gravity reading of each cell corrected to 77F (25C), all cell voltages, the electrolyte level, temperature of one cell on each row of each rack, and cell-to-cell and terminal connection detail resistance readings. It is important that these readings be retained for future comparison”. If an entity follows the manufacturer’s recommendation, the above statements would lead an auditor to a finding of non-compliance because internal ohmic tests were not performed prior to placing a new battery string in service. A simple modification to the wording would eliminate the conflict.

Response: Thank you for your comments.

1. **The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.**

   To address your concern, the distribution protective devices and functions provided as examples in this comment, as pointed out by the commenter, are not “installed for the purpose of detecting Faults on BES Elements,” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse power relay application described is also not “installed for

Organization	Yes or No	Question 3 Comment
the purpose of detecting Faults on BES Elements" (the relays react to changes in power flow direction, which may or may not be due to a Fault), but for the purpose of preventing feedback from the distribution system to the transmission system. Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue. 2. **DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the "Control circuitry" portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. Activities associated with the schedule submitted in the filing will be included in a final SAR to further develop PRC-005. A draft SAR has been posted on the project page for information only.** 3. **The Drafting Team has revised the Supplemental Reference and FAQ document based on your recommendations.**		
DTE Energy	No	
MRO NSRF	No	1. Section 5.1 (second paragraph, under the first bullet) states: "TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components." If this "actual event" can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. 2. Section 2.4.1 - Sudden Pressure Relays - This question should be clarified that circuits from only EHV transformers should be considered in scope. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical.

Organization	Yes or No	Question 3 Comment
		3. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.
Response: Thank you for your comments. 1. **Measure M3 lists possible types of evidence, and states, "is not limited to." Therefore, in-service operations can be provided as evidence.** 2. **This standard applies to the BES and certain transformers less than 345kV are, therefore, included.** 3. **Table 5 Component Type states, "Control Circuitry associated with protective functions…" and, therefore, the circuits you reference are not included.**		
FirstEnergy	No	Please see our comments and suggested changes to the Supplemental Reference and FAQ document in Question 4.
Western Area Power Administration	No	Western Area Power Administration does not agree that the trip path from a sudden pressure device is a part of the protection system control circuitry as stated in the revised Supplementary document. FAQ should be used as guidance and not for compliance.
Response: Thank you for your comment. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1B, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff. The Supplementary Reference and FAQ document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a Reference Document, accompanying the standard. As established in SDT Guidelines, the standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and FAQ document.		
Nebraska Public Power District	No	1. Section D 1.3 Evidence Retention - Do not agree with requirement to keep the two most recent performances of each distinct maintenance activity. Should

Organization	Yes or No	Question 3 Comment
		not require records previous to last audit. What is the point of keeping records up to twenty years? 2. FAQ page 7 and 77 now include discussion about how sudden pressure relays are "presently" excluded because they do not meet the definition of a protection system and a method of component verification does not exist. This part I agree with. The problem is that they go on to explain that the DC control circuitry from the Sudden Pressure relay is part of a protection system. This I disagree with. It's clear that the Standards Drafting Team is attempting a compromise to address direction from FERC Docket No. RM10-5-000. This approach however, sets a bad precedence. A trip path from a non-protection system component should not be classified as a protection system trip path. 3. The removal of grace periods and the comments in the FAQ that it will be up to the Auditor to determine if a test was not done due to extraordinary circumstances (example: Communications can't be tested due to the line out from a storm and under repair) is not acceptable. The SDT needs to come up with guidelines for these situations and not leave it up to each auditor to determine what is acceptable.

Response: Thank you for your comments.

1. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.
2. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing

Organization	Yes or No	Question 3 Comment
elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff. 3. FERC Order 693 directs NERC to establish maximum allowable intervals. Grace periods would not satisfy this directive.		
PPL Supply NERC Registered Organizations	No	We recommend that the final sentence of M3 and M4 be changed to, "Any of the following constitutes sufficient evidence: dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, dated work orders, or other equivalent documentation," and that the slightly different final sentence of M5 be similarly changed.
Response: Thank you for your comment. The SDT believes the measures should not mandate evidence, but provide examples of evidence.		
MRO NSRF	No	1. Section 5.1 (second paragraph, under the first bullet) states: "TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components." If this "actual event" can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. 2. Section 2.4.1 - Sudden Pressure Relays - This question should be clarified that circuits from only EHV transformers should be considered in scope. 3. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. 1. Measure M3 lists possible types of evidence and states "is not limited to." Therefore, 'in-service' operations can be provided as evidence. 2. This standard applies to the BES and certain transformers less than 345kV are, therefore, included. 3. Table 5 Component Type states, "Control Circuitry associated with protective functions…" and, therefore, the circuits you reference are not included.		
Arizona Public Service Company	No	Either the FAQ or the Standard should define the bases for each interval mandated. See the response to question 2 for further details.
Response: Please see the Technical Justification document associated with Project 2007-17. Please also see Section 8.3 of the Supplementary Reference and FAQ document.		
Ingleside Cogeneration LP	No	We do not agree with the assertion in the reference and FAQs that the DC supply and control circuitry for mechanical components are part of a BES Protection System. This is not an accepted norm in the existing Standard as the Project Team claims - only an expansion in scope that was not properly vetted by the industry. If the Compliance Authorities believe that electrical components which support mechanical systems are rightfully part of the BES or BPS, then this has implications far beyond Protection System maintenance. The appropriate place to begin this determination is with Project 2010-17 Definition of the BES - where it can be fully reviewed by all affected industry stakeholders.
Response: Thank you for your comment. The trip path from a sudden pressure device is a part of the Protection System control circuitry. Sudden pressure relays, as opposed to other types of mechanical components, are installed to detect an electrical **fault** condition inside a transformer. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.		

Organization	Yes or No	Question 3 Comment
American Electric Power	No	Though the guidance provided in these documents may appear to be beneficial, we are troubled that despite the time spent on them by the drafting team, and the voluminous nature of the references, that the information contained in them essentially fades away upon approval of the standard. Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might help prevent the need for future CANs and interpretation requests.
Response: Thank you for your comments. The Supplementary Reference and FAQ document provides supporting discussion, but is not part of the standard. The SDT intends that it be posted as a **Reference Document** accompanying the standard. As established in SDT Guidelines, the standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and FAQ document. The Supplementary Reference will be revised in the course of the revision process of the standard.		
Westar Energy	No	1. We believe all of the 4 month intervals can be changed to 6 month intervals and still ensure reliability. It is unclear which equipment Table 1-4(d) applies to. 2. In the heading it says “Excluding distributed UFLS and distributed UVLS”, then the line below that says “non-distributed UFLS system, or non-distributed UVLS systems is excluded”.
Response: Thank you for your comments. 1. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the standard is inappropriate. 2. These are addressing two different items; the first addresses distributed UFLS/UVLS, whether tripping at BES levels or not, and the second addresses non-distributed UFLS/UFLS/SPS that trips only non-BES interrupting devices.		
Ameren	No	We agree with the intent of the Supplement changes but believe that they are either incomplete or need clarification. Therefore, we provide the specifics as

Organization	Yes or No	Question 3 Comment
		follow : (a) Page 93, Revise Section 15.7 Distributed UFLS (i) Change Table 1-2 to 1-3.(ii) Include ‘Verify operation...and/or auxiliary tripping device’ to agree with Table 3. (b) Please identify BES Elements in Supplementary Reference Figure 2. (c) Remove ‘Reverse power relays’ from the bulleted list on the top section of page 33. They provide thermal of the steam turbine, and they may protect CTG speed reduction gear teeth, but neither of these are electrical protection of the generator. (d) Please add Interval FAQ to address a component minimum maintenance activity that is not in the present PRC-005-1 program. (i) : “How is interval proven for a component minimum maintenance activity that is not in the present PRC-005-1 program? For example, suppose the present program continuously monitors a communication system, say audio tones, and personnel respond to alarms; this approach presently have basis that is sufficient. (ii) Table 1-2 requires two maintenance activities every 12 calendar years: 1) verify channel meets performance criteria; and 2) verify essential I/O. The entity is required to perform these minimum maintenance activities one time in the first 13 years after regulatory approval. The 12 year interval is proven by the date of the PRC-005-2 maintenance activity and the date of your PRC-005-1 program applicable for the previous maintenance. After the second time the PRC-005-2 maintenance activity is performed, appropriately sometime in year 14 to 25 after regulatory approval, then interval will be proven by the dates of the two PRC-005-2 maintenance activities.” (e) Page 17 We disagree with retention of maintenance records for replaced equipment as this can cause confusion. At most the last maintenance date could be retained to prove interval between it and the test date of the replacement

Organization	Yes or No	Question 3 Comment
		equipment that provides like-kind protection. (f)Page 36, FAQ 'initial date for maintenance' answer is inconsistent with CAN-0011. Though the CAN applies to PRC-005-1, it should be consistent with NERC's position on this. (g) Page 71, Please remove 'The trip path from a sudden pressure device is a part of the Protection System control circuitry...' because the actuating relay does not respond to electrical quantities. This is just one example of the many gotcha's that will no doubt arise in enforcement. (h) If a capacitor trip device is an example of a non-battery based station DC supply, then please provide a FAQ to convey it.

Response: Thank you for your comments.

a. The SDT modified the Supplementary Reference and FAQ document, as suggested.

b. The applicable facilities for a generator are listed in Section 4.2.5 of the standard. Figure 2 is a visual representation of this.

c. Reverse power relays, as discussed in your comment, do not detect Faults; but if they can trip the generator, they must be maintained per 4.2.5.

d. This issue is addressed in the Implementation Plan for Project 2007-17.

e. The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period.

f. The SDT has provided guidance as it relates to PRC-005-2.

g. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

Organization	Yes or No	Question 3 Comment
h. If the “capacitor trip device” you reference is the stored energy device for the breaker, it would not be included in Table 1-4(d).		
Central Lincoln	No	The Supplemental Reference and FAQ apparently has not kept up with definition changes and uses uncapitalized “component” “Protection System components”. Please use capitals if defined terms are intended.
Response: Thank you for your comment. The SDT modified the Supplementary Reference and FAQ document as suggested.		
BAE Batteries USA	No	Page 20 states that every 18 months "battery ohmic values to station battery baseline (if performance tests are not opted)" should be changed to add comment that ohmic values, while permissible as a tool, should not be taken to validate the actual capacity, thus the reliability of the battery. If capacity is an issue due to questionable ohmic values shown, a decision must be made to [1] perform a capacity test following one of the three methodologies recorded in IEEE 450 or IEEE 1188; [2] make a decision to replace the battery string depending upon the number of cells with questionable ohmic values shown, the age of the battery string, and the critical nature of the station in question; or [3] accept the risk that the battery may or may not perform as intended due to the lack of a true knowledge of the battery capacity (See IEEE Letter to Al McMeekin). Every 18 calendar months verify/inspect the following: "Cell Condition of all individual battery cells (where visible) should add "or as frequently as recommended in the battery manufacturer's operating instructions."Every 6 years: perform or verify the following:"Battery Performance Test (if internal ohmic tests are not opted)" should be changed to read "Battery Performance Test (if ohmic tests are not conducted or if ohmic test values show that a degraded situation with the cells call into question whether the battery will perform to "design requirements."this should be repeated where referenced in additional examples (VLA, VRLA, Ni-Cd)
Response: Thank you for your comment. The drafting team agrees with your statement, and those of others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ document has been modified to further elaborate on these concerns.		
ExxonMobil Research and	No	: As written, the current draft of PRC-005-2 discriminates against smaller entities

Organization	Yes or No	Question 3 Comment
Engineering		that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
TransAlta Centralia Generation LLC	Yes	More detail explanation on Segment is required; the reason of sixty (60) individual components is required for one Segment. More detail explanation on Countable Event is required.
Response: Thank you for your comments. The SDT believes that Segment and Countable Events are clearly stated in the standard. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant.		
City of Austin dba Austin Energy	Yes	The effort expended by the SDT in creating and revising the content of the

Organization	Yes or No	Question 3 Comment
		Supplemental Reference and FAQ is admirable and most appreciated. The guide is a useful reference.
Response: Thank you for your comment and support.		
Los Angeles Department of Water and Power	Yes	LADWP notices that the terms "Unresolved Maintenance Issue" and "maintenance-correctable issue" are used in several places. We recognize that "Unresolved Maintenance Issue" is defined as a deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action. Please define "maintenance-correctable issue" and clarify the differences between the two terms.
Response: Thank you for your comments. “Unresolved Maintenance Issue” replaced the term “maintenance-correctable issue,” and the SDT corrected the Supplementary Reference and FAQ document to reflect the change.		
Progress Energy		1. Table 3, Row 7: The requirement to “Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices” contradicts Section 15.7, bullet 2 of the Supplementary Reference and FAQ document. In the supplementary reference, the phrase “and/or auxiliary tripping device(s)” has been struck out.
Response: Thank you for your comments. The Supplementary Reference and FAQ document has been modified per your suggestion.

4. **If you have any other comments on this Standard that you <u>have not already provided in response to the prior questions</u>, please provide them here.**

Summary Consideration: Several comments were repeated from Questions 1, 2, or 3, and the summary consideration responses are not repeated here.

Numerous commenters suggested minor changes to the definition of the terms "inspect" and "Countable Event." In response, the SDT modified the description of the term, "inspect" within the definition of PSMP. Previously "inspect" was "Examine for signs of component failure, reduced performance or degradation." now "inspect" is "Examine for signs of component failure, reduced performance or degradation." The SDT also modified the definition of Countable Event from "A Component which has failed and requires repair or replacement…" to "A failure of a Component requiring repair or replacement …"

The SDT continued to receive comments regarding the Applicability of the standard. The SDT modified the Applicability Clause 4.2.5.4 to read: "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."

Some commenters questioned the last line in Table 1-2 for Communications Systems. The SDT realized they had several errors in the table – one omitted element and one incorrect interval. The table was corrected.

Several comments were offered regarding the station battery activities in Tables 1-4 (a-f). Representatives of the IEEE Stationary Battery Committee assisted the SDT in making revisions to these tables to address concerns related to ohmic testing of the cell/units.

Several commenters questioned elements of the criteria in Attachment A for performance-based maintenance; the SDT explained the rationale for these criteria, including, where appropriate, the related statistical basis.

Several comments pointed out inconsistencies between the Standard and Supplementary Reference and FAQ. The SDT modified the Standard and Supplementary Reference and FAQ to address these inconsistencies.

A few commenters questioned portions of the standard, or suggested changes that the SDT chose not to adopt. The SDT responded with their rationale. These comments included:

- **NERC should provide a format for test reports, etc.**
- **Include batteries within a performance-based PSMP**
- **Objections to the inclusion of distribution devices that are installed for the benefit of the BES**

- **VSLs permitting entities to experience some small level of non-performance relative to the standard without incurring a violation**
- **VSLs set at inappropriate levels**
- **The inclusion of the control circuitry related to sudden pressure relays, even though sudden pressure relays themselves are not included**
- **Various facets of control circuitry maintenance**
- **Specific intervals or activities within the tables**
- **Evidence retention language**
- **Intervals for lockout relays**
- **Voltage and current sensing devices**

Organization	Yes or No	Question 4 Comment
Northern Indiana Public Service Co.	Negative	A format for maintenance reports and specific test requirements for relays are missing.
Response: Thank you for your comments. The SDT does not believe it is necessary or appropriate to prescribe a specific format for maintenance results or test requirements.		
James A Maenner	Negative	As written, the standard may require DPs to include distribution protection devices designed to isolate and protect distribution facilities from faults on monitored transmission or other BES facilities. Qualifying language should be added differentiate protective systems which control BES and distribution facilities for faults on the BES.
Response: Thank you for your comments. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements, even if they are installed on distribution facilities. UFLS and UVLS devices which are commonly installed on distribution facilities for the purposes of addressing related NERC Standards are included. Protection Systems installed on distribution facilities for the purposes of detecting Faults on distribution facilities are not included.		
SERC Reliability Corporation	Negative	FERC Order 758 includes directives that affect this project. I understand that the

Organization	Yes or No	Question 4 Comment
		SPCS/SAMS group is looking at the technical documents to support additional standards activity but as this project is presented, it does not meet the FERC directives. Otherwise, I could vote affirmatively, but I do have some concerns about how clearly and unambiguously the standards requirements are written. This standard should be a candidate for the RSAW initiative being developed by the Standards Committee.
Response: Thank you for your comments. The Standards Committee has directed the PSMTSDT to finalize PRC-005-2 and present it to the NERC Board of Trustees for adoption, and concurrent with this posting of PRC-005-2 to post for information a draft SAR for a second phase of Project 2007-17 addressing further modifications to PRC-005-2. FERC Order 758 includes directives associated with Maintenance and Testing of Auxiliary and Non-Electrical Sensing Relays, Reclosing Relays, and DC Control Circuitry. Regarding these directives in relation to PRC-005-2: 1. Testing of Auxiliary and Non-Electrical Sensing Relays – The NERC System Protection and Control Subcommittee (SPCS) recently worked with NERC staff to develop an informational filing in response to Order 758. Activities associated with the schedule submitted in the filing will be included in a final SAR to establish a future phase of Project 2007-17 for future development of PRC-005. A draft SAR is posted on the project page for information only. 2. Reclosing relays will be addressed in a second phase of this project, which will produce PRC-005-3. Development of that revision will begin after PRC-005-2 is completed and the NERC SPCS completes the technical documentation regarding reclosing relays. 3. DC Control Circuitry and Components – This draft standard PRC-005-2 includes extensive, specific maintenance activities (with maximum maintenance intervals) related to the DC control circuits.		
Southwest Transmission Cooperative, Inc.	Negative	1. For the Requirement R1's High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. 2. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.
Response: Thank you for your comments.		

Organization	Yes or No	Question 4 Comment
1. The SDT has corrected the Requirement R1 VSL, as you suggest. 2. The SDT believes that missing three components is considered a "significant percentage," and is in accordance with the VSL guidelines.		
Midwest ISO, Inc.	Negative	In the VSL for Table 4 it seems that the phrase "5% or less" should be "not more than 5%". With the original language it seems like an entity could be found to have an R4 lower VSL violation for "failure" of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive.
Response: Thank you for your comments. The VSL Guidelines, developed in accordance with FERC's VSL Order, establish the Lower VSL for stepped VSLs as "5% or less," the Medium VSL as "more than 5% but less than (or equal to) 10%," the High VSL as "more than 10% up to (and including) 15%," and the Severe VSL as "more than 15%."

Dairyland Power Coop.	Negative	See MRO NSRF comments.
U.S. Army Corps of Engineers	Negative	See MRO/NSRF comments
Dairyland Power Coop.	Negative	See NSRF comments.
Beaches Energy Services	Negative	The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The

Organization	Yes or No	Question 4 Comment
		interpretation states: The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)” Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.

Response: Thank you for your comments.

The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection **System**,” and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.

To address your concern, the distribution protective devices and functions cited in this comment are not “installed for the purpose of detecting Faults on BES Elements,” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse

Organization	Yes or No	Question 4 Comment
power relay application described is also not “installed for the purpose of detecting Faults on BES Elements” (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system. Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue.		
U.S. Bureau of Reclamation	Negative	1. The definition for PSMP is incongruous with the use of the PSMP in Requirement R1. Requirement R1, including the Measure and VSL focus on the identification of maintenance method of the Component types and not that the PSMP is in fact being used for maintenance of the component. 2. The requirement R5 indicates the entity has to "demonstrate" efforts to correct identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP. 3. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 4. Re The definition of Components: The standard defined what constitutes a

Organization	Yes or No	Question 4 Comment
		control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: Thank you for your comments. 1. The SDT believes that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program and is the foundation for the standard. Requirements R3-R4 address implementation of the entity's PSMP. 2. The term within Requirement R5, "… demonstrate efforts …" is intended for both – that the entities are acting to correct the deficiency and also (to prove compliance) maintaining documentation of the activities underway to correct the deficiency. The SDT elected to not require a "Corrective Action Plan," as defined in the NERC Glossary of Terms, to avoid much of the systemic, ongoing documentation attendant to that term. However, if an entity wishes to use a Corrective Action Plan as defined, that would be an acceptable method of meeting Requirement R5. 3. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard. 4. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing of these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
Independent Electricity System Operator	Negative	The IESO continues to disagree with the VRF assigned to the new Requirements R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The SDT team disagrees and believes the failure to implement a PSMP should be assigned a VRF of High.		
Illinois Municipal Electric Agency	Negative	The inconsistency between the proposed Protection System language in the Applicability section of PRC-005-2 and the transmission Protection System interpretation recently approved by FERC (PRC-005-1b Appendix 1) needs to be resolved.
Response: The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting Faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference Document for additional discussion.		
Central Lincoln PUD	Negative	The percentage based VSL unreasonably penalizes smaller entities, since one Component can cause them to hit the 10% cutoff for a High VSL while a large entity may miss 100s of components without exceeding the Lower VSL.
Response: Thank you for your comments. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.		
JEA	Negative	This standard greatly expands the scope of work that will be required of JEA without providing a corresponding incremental increase in reliability and may in fact cause reliability issues. Specific concerns are that JEA believes that we do continuous monitoring of a vast majority of our components and our approach has demonstrated its effectiveness but the revised standard will most likely require JEA to have to adopt a new approach with significant increases in manpower hours. Additionally, testing lockouts is of great concern because of its ability to cause reliability issues.
Response: Thank you for your comments. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. If your components are monitored according to the attributes specified in Table 1-1 through 1-5, you may be able to utilize the extended intervals/minimized		

Organization	Yes or No	Question 4 Comment
activities associated with those monitoring attributes within the tables. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same six-year interval required for electromechanical relays. The SDT recognizes the risk of 'human error' trips when testing lockout devices, but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond six years.		
City and County of San Francisco	Negative	VSL's are based upon Failure to Maintain Percentages for "a specific Protection System component type". VSL's should be based upon Failure to Maintain Percentages for total number of Protection System components, and not give greater weight in the VSL determination, to component types with few elements, like station batteries.
Response: Thank you for your comments. The SDT believes that these VSLs should address failures to maintain percentages of each Component Type. Failure to maintain quantities of low-population Component Types, such as station batteries, may have serious consequences for BES reliability, and the SDT believes that these must not be masked by larger populations of other Component Types, such as protective relays.		
Gainesville Regional Utilities	Negative	We support FMPA's position on this matter.
Response: Thank you for your comments. Please see our response to FMPA's comments.

Southwest Transmission Cooperative, Inc.	Affirmative	1. The first part of definition of a Countable Event should be modified as follows: “The failure of a Component such that it requires repair or replacement...”. As it is currently word, it is technically counting the Component as the Countable Event and not the failure of the component. Considering that the other two items that are Countable Events are conditions and misoperations, it seems appropriate to

Organization	Yes or No	Question 4 Comment
		make failure the Countable Event. 2. Application of this standard to UFLS is problematic as worded in Section 4.2.2. The UFLS are only applicable if “installed per ERO underfrequency load-shedding requirements”. Technically, no UFLS fits this description because there are no ERO requirements to have a UFLS. PRC-006-0 was never approved by the Commission and is not enforceable. The Commission considered it a “fill-in-the-blank” standard. While PRC-006-1 corrects the “fill-in-the-blank” issues and was approved by the NERC BOT November 4, 2010, the Commission has yet to act on it. 3. The data retention requirement for the Protection System Maintenance Program documentation seems excessive. The Data Retention section states that all versions since the last compliance audit must be maintained. Since TOs, GOs, and DPs are all on six year audit cycles, this would require maintaining this documentation for six years. Is this really necessary? The length could become even greater once NERC implements registered entity assessments that could shorten or lengthen the periods between compliance audits. The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C - Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of “the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date”. While it may have been intended to apply to both clauses, the “since the previous schedule audit date”

Organization	Yes or No	Question 4 Comment
		only applies to the second clause. Since some of the maintenance activities have intervals of 12 years, this would require the registered entity to retain documentation for 24 years which cannot be audited since it is outside the audit window per the Rules of Procedures. At a minimum, we suggest clarifying that the documentation must not be maintained past the day after the last audit completion date. 4. In the fourth paragraph of the Data Retention section, Component is not used consistently. It is used in both singular and plural form. It seems like it should be one or the other. 5. Requirement R1 VSLs: For the High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. 6. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

Response: Thank you for your comments.

1. The SDT agrees with your comments on Countable Event, and has modified the definition of Countable Event to: "A failure of a Component requiring …"
2. Applicability Clause 4.2.2 applies to whatever ERO-required UFLS that may exist, either today or in the future. NERC Reliability Standard PRC-006-1 has now been approved by FERC.
3. The SDT believes that all versions of the entity's PSMP should be retained for audit purposes. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation.
4. The SDT has corrected the fourth paragraph of the Evidence Retention section as you suggested.
5. The SDT has corrected the Requirement R1- High VSL, as you suggested.
6. The SDT believes that missing three components is considered a "significant percentage," and is in accordance with the VSL

Organization	Yes or No	Question 4 Comment
Guidelines.		
Oncor Electric Delivery	Affirmative	The proposed consolidation of these standards (PRC-005-1, PRC-008-0, PRC-11-0 and PRC-017-0) provides more clarity and less room for varying interpretations for relay maintenance and testing.
Response: The SDT thanks you for your comment and affirmative vote.		
Southern Company Generation		For the 18 month / 6 year activities, it is technically incorrect to allow equivalency between internal ohmic measurements and performance testing. This view is not substantiated by industry experience, documentation, or standards. Additionally, it should be specified to the auditor that the intervals for the battery maintenance are relevant to the component, not the application. This means that if a battery is replaced just before a required 6 year performance test, the 6 year interval for the performance test is reset.
Response: Thank you for your comment. The drafting team agrees with your statement, and those of others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ document will be modified to further elaborate on these concerns. The SDT agrees with your assessment that the maintenance activity is relevant to the component, not the application. Guidance to the auditors of this nature is beyond the ability of the SDT. See Section 4.1 of the Supplementary Reference and FAQ document for additional discussion on this topic.		
Ameren		(a) R3 & R4: Change VRF to “Medium” for the following reasons: (i) Consistency with existing standards that PRC-005-2 replaces. Per the VRF_Standards_Applicability_Matrix_2012-03-01, PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (ii) We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (iii) Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events are extremely rare. (iv) Either change VRF to

Organization	Yes or No	Question 4 Comment
		Medium, or double the percentage ranges applied to each component type across VSLs. We strongly believe that the SDT needs to retune these to match the experienced risk, which has been extremely low. (b) Measure M3 on page 6 should only apply to 99.5% of the components. Please revise to state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." We believe that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance". (c) Measure M5 - add 'internal inventory / parts request, trouble investigation assignment, trouble repair report' as examples of an entity undertaking efforts with internal parts and/or labor resources. (d) Augment R3 and R4 VSL with a 'number based limit for populations up to 100 components' for comparable treatment of small entities. For example, for Lower VSL restate as '...the responsible entity failed to maintain from one to five Components if total Components is less than 100; or 5% or less of the total Components if total exceeds 99 included within a specific Protection System Component Type...'. Otherwise a small entity could unfairly incur a Severe violation for the same number of Components that a larger entity would incur a Lower VSL. (i) Similarly, Moderate numbers should be 6 to 10; High 11 to 15; and Severe 16 or more if the total Components of a certain Component Type that is less than 100. (e) Augment R5 VSL with percentage based limits for comparable treatment of larger entities. For example, for Lower VSL restate as 'The responsible entity failed to undertake efforts to correct 5 or less Unresolved Maintenance Issues if total of such issues in the audit period is less than 100; or 5% or less if total of such issues in the

Organization	Yes or No	Question 4 Comment
		audit period exceeds 99.' (i) Similarly, Moderate numbers should be >5% to 10%; High >10% to 15%; and Severe more than 15% if the total Unresolved Maintenance Issues in the audit period exceeds 99. (f) Please number all pages of the standard. They are missing from pages with tables. (g) Please add a title to the table following Table 3. Is it a continuation of Table 3?

Response: Thank you for your comments.

a) The SDT disagrees, and believes a VRF of High is appropriate for Requirements R3 and R4.

b) NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.

c) The SDT agrees that the examples listed would constitute evidence of undertaking efforts to correct Unresolved Maintenance Issues; however, Measure M5, as written, includes the phrase, "… includes but is not limited to …" to emphasize that entities may use other evidence.

d) The SDT disagrees and believes a smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.

e) The SDT disagrees and believes the VSL's for Unresolved Maintenance Issues should be a numeric quantity and not a percentage.

In response to each of the comments 'a' through 'e', the SDT recommends reviewing the "VRF/VSL Justification" that is posted with the standard. This document provides the SDT's analysis of how the VRFs and VSLs meet FERC and NERC guidelines, as required for the standard to achieve regulatory approval.

f) The SDT numbered all the pages.

g) The SDT corrected the Table 3 header issue.

Organization	Yes or No	Question 4 Comment
Sacramento Municipal Utility District		1) SMUD wishes to comment on the requirement to test the trip paths from relays that do not respond to electrical quantities. In two separate sections of the FAQ, the SDT included this new guidance on the trip paths. In section 2.4.1 of the FAQ, the SDT plainly asserts that the trip path from Sudden Pressure Relays (SPR) will now be covered and implies that the trip paths from non-electrically initiated devices might also be covered. In section 2.4.1, the SDT does not provide any guidance on how to determine which trip paths are included, but does provide guidance on how one might test the trip path. In section 15.3, the SDT finally provides the guidance -

Organization	Yes or No	Question 4 Comment
		control circuits (trip paths) are included if the relay is installed to detect faults on BES Elements. In reviewing the definition of Protection System, SMUD feels the “Control circuitry associated with protective functions...” to be in reference to the “Protective relays which respond to electrical quantities”. The SDT is now applying a new interpretation in which each of the five bullets is considered separately. Furthermore, the SDT appears to be defining “...associated with protective functions...” to mean detecting faults on the BES. What basis can the SDT offer for defining this phrase to mean detecting faults on the BES? Since this same wording is not used in defining the relay, can a relay be covered under the standard, but not its control circuitry? For instance, Out of Step Tripping? Over Excitation? Frequency or Voltage Protection on a generator? These relays respond to electrical quantities, but are not applied to detect faults on BES Elements. SMUD believes this interpretation takes us down a very confusing path. SMUD respectively requests the SDT strike the new wording (as seen on the redlined version) in 2.4.1 and 15.3.

Response: Thank you for your comments.

1. DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the “Control circuitry” portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. The Standards Committee has directed the PSMTSDT to finalize PRC-005-2 and present it to the NERC Board of Trustees for adoption, and concurrent with this posting of PRC_005-2, to post for information a draft SAR for a second phase of Project 2007-17 addressing further modifications to PRC-005-2.

Activities associated with the schedule submitted in the filing will be included in the final SAR to further develop PRC-005. The SDT believes that Protection Systems that trip (or can trip) BES Elements due to a Fault should be included (in the case of a Sudden Pressure Scheme, the control circuitry and DC supply components would apply). The relays mentioned are already covered by the standard, in that they are “Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.”

Organization	Yes or No	Question 4 Comment
Tennessee Valley Authority		1. Regarding the functional test required every 3 months for “unmonitored communication systems” in Table 1-2 of the PRC-005-2 Draft. TVA feels that a Maximum Maintenance Interval for the Functional Test should be every 12 months until auto-checkback has been fully implemented by the utility. 2. The Implementation Plan for PRC-005-2 Step 4 on Page 2 states: “The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.” TVA feels that this is not sufficient time to implement full auto-checkback capability at some utilities. The time schedule of twelve (12) months should be forty-eight (48) months following applicable regulatory approvals. 3. TVA has many excitation transformers directly connected to the generator bus, configured such that a fault on the excitation transformer will cause a generator trip. Is the intent that the revised standard will include these transformers in the applicability? Would they be included by section 4.2.5.1? 4. TVA (Rusty Hardison) has forwarded a slide presentation with six questions to the PRC-005-2 Draft Team requesting consideration as input to the Frequently Asked Questions document accompanying the standard. Thank you for considering.

Response: Thank you for your comments.
1) The SDT believes the four month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status.

2) The Implementation Plan is intended to facilitate implementation of the standard, not to facilitate modifications to meet the requirements of the standard.

3) The SDT revised Applicability Clause 4.2.5.4 to include excitation transformers connected to the generator bus.

Organization	Yes or No	Question 4 Comment
4) The SDT modified the Supplementary Reference and FAQ document to address these questions.		
Tacoma Public Utilities		1. For components that are part of a time-based PSMP, if correction of Unresolved Maintenance Issues takes place before the maximum maintenance interval expires, is it mandatory to demonstrate (document) these efforts to correct identified Unresolved Maintenance Issues? Is the purpose of Requirement R5 only to avoid compliance jeopardy when an entity discovers a problem during maintenance but cannot correct the problem until after the maximum maintenance interval has expired (as discussed in the Supplemental Reference and FAQ document)? Or, is the purpose also to ensure that all Unresolved Maintenance Issues are documented even if they corrected very quickly and within the maximum maintenance intervals and just considered part of routine maintenance (i.e., Unresolved Maintenance Issues not explicitly documented) in a manner similar to recalibrating a relay? 2. Assume that a component under a time-based PSMP is not considered “monitored” per the PSMP, but in actuality it is. If an alarm comes in, indicating a component problem, would the entity have any additional documentation obligations under PRC-005-2 associated with this alarm, provided that all minimum maintenance activities and maximum maintenance intervals associated with the unmonitored component are satisfied? The concern is that, if there are additional documentation obligations; then many entities may disable monitoring in some cases in order to avoid compliance jeopardy. 3. Assume that an entity treats batteries at certain remote communication sites as if they were applicable to PRC-005-2. These sites are not substations or generating facilities but support the broad communication system, including teleprotection functions. Furthermore, these sites have limited access during some times of the year because of heavy snow or ice. It is conceivable that it may not be possible to meet all minimum maintenance activities or all maximum maintenance intervals (4 and 6 calendar months) unless the site is extensively monitored and/or field personnel expose themselves to hazard. Would any allowances be made in these cases? Would

Organization	Yes or No	Question 4 Comment
		these sites even be applicable to PRC-005-2, since they are not part of a "station" DC supply? 4. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. 5. In the Implementation Plan for Requirements R1, R2, and R5, why there is a requirement to "be 100% compliant [with R5] on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals"? The emphasis of this question is on Requirement R5, which pertains to Unresolved Maintenance Issues. 6. In the Implementation Plan for R3 and R4, to be considered "100% compliant with PRC-005-2," is it only necessary to have completed the applicable minimum maintenance activities one time for the applicable component (which is our assumption)? Or, does being considered 100% compliant under this Implementation Plan imply that two instances of the applicable minimum maintenance activities must have been completed for the applicable component?

Response: Thank you for your comments.

1. The definition of Unresolved Maintenance issue has been revised to specify that it applies to deficiencies that "…cannot be corrected during the maintenance interval..."
2. The SDT believes that as long as all minimum maintenance activities and maximum maintenance intervals associated with a component are completed and documented, no additional documentation obligations are necessary.
3. The SDT does not believe that the scope of the standard refers to communication sites. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays

Organization	Yes or No	Question 4 Comment
to alarm at the substation. At this point, the corrective actions can be initiated. 4. The SDT believes that every trip path from relay to trip coil must be verified. If a trip coil has multiple trip paths, verifying DC voltage at the actuating device would not accomplish the maintenance activity identified in Table 1-5 for unmonitored control circuitry. 5. The SDT believes that the entity be 100% compliant with Requirement R5 on the first day of the first calendar quarter because an Unresolved Maintenance Issue could arise during the first calendar quarter. 6. The Implementation Plan addresses the initial performance of the required activity within the required intervals. The entity should expect to comply with PRC-005-1B until they fully implement PRC-005-2.		
Texas Reliability Entity		1. The Implementation Plan is still overly long and complicated. Registered Entities and Regional Entities will have to track and apply multiple versions of this standard for up to 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable at any given time, recognizing that for some Components no action will be required under the standard for a number of years. 2. Referring to R3, R4 and M1 (and other places), it is redundant to add “Protection System” to describe “Components “or “Component Types” based on the “local definitions” provided. Alternatively, the defined term could be changed to “Protection System Component” and used consistently. 3. In Table 1-3, the activity should include verifying that the current and voltage signal values are within tolerances, not just that signal values are present. The minimum activity should include a ratio check and/or burden check of current transformers. Suggest revising to state “Verify that current and/or voltage signal values provided to the protective relays are within the accuracy tolerance of the voltage and current sensing device”. 4. In the VSL for R2, we are assuming that the “4% within three years” is a 4% failure rate based on Attachment A, but that is unclear. We suggest clarifying this language

Organization	Yes or No	Question 4 Comment
		to match Attachment A language. 5. What is the basis for the 4% failure rate limit in Attachment A? It would appear that a 4% failure rate is high for protective relays. Does the SDT have a technical justification supporting the selection of 4% as the applicable limit? 6. In Attachment A, item 4 in the "maintain the technical justification" section needs clarification. It can be assumed that the phrase "for the greater of either the last 30 Components maintained or all Components maintained in the previous year" is referring to Components within a specific Segment, but more specific language may be needed. Also, are the references to "prior year" and "previous year" intended to refer to calendar years or 365 days preceding the analysis? 7. In Attachment A, item 5 in the "maintain the technical justification" section needs clarification. We suggest adding a timeframe for the "experience 4% or more Countable Events" phrase. Does this refer to any 12-month period? Additionally, the determination of a timeframe for "4% of the Segment population" is needed. Example- If there are 100 Components in a performance-based Segment in Year 1 and I add an additional 100 Components in Year 2, is the 4% based on 100 or 200?

Response: Thank you for your comments.

1. The SDT disagrees, and believes that having a shorter implementation plan would not allow entities to complete the requirements. The Implementation Plan is designed to allow an entity to systematically implement PRC-005-2 such that an ongoing program may be facilitated.
2. Strictly speaking, you are correct. However, the SDT has elected to include the emphasis, "Protection System" in these locations to help clarify that such components are only in-scope where they are part of the "Protection System."
3. The SDT disagrees. Verify is defined as, "Determining that the component is functioning correctly." If the signals to the relay are beyond tolerance, the component is not functioning correctly.
4. The SDT agrees and has corrected the Requirement R2 VSL to indicate "…no more than…"

Organization	Yes or No	Question 4 Comment
5. The SDT chose 4% because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation (see Supplemental Reference and FAQ Section 9.1). 6. The SDT affirms that all references to "prior year"and "previous year" refer to "calendar year." 7. The time frame refers to a calendar year. The 4% failure rate is determined from those Component segments tested in the previous calendar year.		
TransAlta Centralia Generation LLC		1.3 Evidence Retention. The standard said: For Requirement R2, R3, R4 and R5, the Transmission Owner, Generator Owner and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance. How to count" the most recent performance ". Is this Standard going forward basis? For some of the protection system component, the maximum maintenance interval is 12 years (such as CT, PT or microprocessor relay) on the standard, how to count the two most recent performance?
Response: Thank you for your comments. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
PacifiCorp		1: The definition of "Protection System" in this version of PRC-005-2 includes "station dc supply associated with protective functions..." as a Protection System component. Page 83 of the FAQ document accompanying the draft standard provides further clarification that the batteries covered under PRC-005-2 are those that "supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System." This statement in the FAQ is much more limiting than the definition of Protection System and may create confusion concerning registered entities' compliance obligations. For example, a registered entity may have one

Organization	Yes or No	Question 4 Comment
		battery / charger system in a station that supplies DC voltage to communication equipment, including that utilized in transfer trip communication, while a separate battery (typically operating at a different DC voltage) is utilized for relay / trip coil operation. In this case, it is unclear whether the battery / charger system utilized for transfer trip communication is subject to the requirements of the standard. PacifiCorp recommends that NERC or the SDT reconcile this apparent inconsistency in the FAQ document. 2: In Tables 1-4(a) thru 1-4(d), the maximum maintenance interval of four calendar months includes inspection “for unintentional grounds.” PacifiCorp seeks clarification on whether this maintenance activity is intended to target the detection of unintentional grounds on the battery bank / rack itself, or a ground located anywhere on the entire DC wiring system. 3: The Violation Severity Level (“VSL”) for R5 - which ranges from a failure to correct 5 or less (“Lower” VSL) to greater than 15 (“Severe” VSL) Unresolved Maintenance Issues - fails to adequately account for the cumulative amount of equipment a registered entity is required to maintain pursuant to PRC-005-2. A better alternative approach may be to base the VSL on the cumulative percentage of Unresolved Maintenance Issues that an entity fails to address and correct. Such an approach would be more consistent with the VSLs for R3 and R4, which are based on a percentage of the total scheduled maintenance. This approach more fairly and reasonably addresses the covered maintenance activities relative to the approach in the VSLs for R5, which are based on a strict count and therefore independent of the cumulative amount of maintenance activities performed by a registered entity. PacifiCorp recommends that the SDT develop an alternative method for determining VSLs for R5 that reflects the scope of an entity’s maintenance activities and the resulting Unresolved Maintenance Issues managed by an entity.

Response: Thank you for your comments.

1. The SDT believes the term “Station dc supply” is clearly defined within the standard, and that the definition should be

Organization	Yes or No	Question 4 Comment
considered when applying the term. Your reference to Page 83 of the Supplemental Reference and FAQ Document clarifies that Table 1-4 of the standard refers to Station Batteries only, and not Communications Site Batteries. 2. The SDT believes the inspection for unintentional grounds applies to the entire DC wiring system. 3. The SDT disagrees and believes the VSL's for Unresolved Maintenance Issues should be a numeric quantity, and not a percentage.		
Essential Power, LLC		1. This DRAFT Standard is written as a prescriptive 'procedure' and not as a 'Standard'. The SDT should revise the Standard to address the goal, or intent, rather prescribing how entities should meet the Standard. 2. Inclusion of non-BES elements within the Standard falls outside of NERC's jurisdiction, as defined in the EPA 2005. The SDT should remove these elements from the Standard. 3. The inclusion of dc circuitry for equipment that is itself not covered under the Standard is not logical and does not contribute to reliability. The SDT should remove this from the Standard.
Response: Thank you for your comments. 1. The SDT believes the standard describes the desired outcomes and is not a 'prescriptive procedure'. The entity is free to determine what maintenance methods are best suited for its program. 2. FPA Section 215(a) Definitions section defines "bulk-power system as … facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Facilities such as those to which you refer are not solely "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if these facilities were not covered by the reliability standards, reliability gaps would exist.		

Organization	Yes or No	Question 4 Comment
3. The SDT believes that Protection Systems that trip (or can trip) for Faults on the BES should be included. This position is consistent with the SAR for Project 2007-17, and with the position of FERC staff.		
MRO NSRF		1. Article 4.2.1 - The NSRF believes that this article should be revised to say "Protection Systems installed for the purpose of protecting BES Elements only and detecting Faults on BES Elements. Protection Systems designed to protect non-BES elements that incidentally open 100 kV and greater breakers are excluded from the scope of PRC-005-2". This makes it very clear what is included in the scope of the Testing and Maintenance program and what is not. 2. Change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to:"Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years "Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).The NSRF believes that as written the testing of "each" trip coil will result in the increased amount of time that the BES is in a less reliable system configuration. The NSRF hopes that the

Organization	Yes or No	Question 4 Comment
		SDT will consider these changes. 3. The NSRF recommends the statement "Excluding distributed UFLS and distributed UVLS (see Table 3)" be added to the top of Table 1-4(f). 4. Table 3. There will be many DP's that have distributed UFLS (or UVLS) solely on the distribution system (less than 100 kV). The only item these DP's will have to verify under Table 3 "Protection System dc supply" is the Protection System dc supply voltage. Yet, the definition of Protection System, as it relates to dc supply is "Station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply)". Our interpretation of Table 3 and Section 15.7 of the Supplementary Reference & FAQ document is that a DP need only check the dc supply voltage at the terminals of the relays. If that is the SDT interpretation as well, we recommend revising Table 3 of the standard to reflect that. Table 3 contains issues that need to be addressed in a similar fashion as discussed for non-UFLS and non-UVLS systems, i.e. Table 1-1. Comparison to independent sources is only one way to check for a reliable AC measuring device. It also appears that monitoring capabilities are not being given any credit in regards to the AC sensing devices, DC supply, or control circuitry themselves. There should be no difference in the way these systems are treated compared to BES Protection Systems. 5. In Section D Compliance, Article 1.3, paragraph 4 the standard requires documentation be kept for the ". . . two most recent performances of each distinct maintenance activity. . .". This needs to clarify that it cannot go back before 06/18/07, as evidenced by the suspension of CAN-0008. Also with some of the testing intervals being 12 years that would dictate a Registered Entity maintain 24 years of records, which is unreasonable. This article should be revised to have documentation for the most current testing interval, if after

Organization	Yes or No	Question 4 Comment
		06/18/07. 6. It is understood that lockout relay testing is important as unexercised lockouts can stick and cause regional outages as experienced at Westwing. However, lockout testing by itself is risky and can lead to local outages. If Registered Entities are required to take on the additional risk of testing lockout relays, dispensation must be granted for outages caused by those tests. The following statement should be included in the standard “No enforcement actions or penalties will result from outages caused by relay testing unless a Registered Entity shows a history of 3 or more test related outages per year for 5 years.” 7. In the VSL for Table 4 it seems that the phrase “5% or less” should be “not more than 5%”. With the original language it seems like an entity could be found to have an R4 lower VSL violation for “failure” of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive. 8. The drafting team needs to clarify “maintenance summaries” as stated in Measure M3. This is an ambiguous term that could be interpreted differently amongst entities. If a term such as ‘summary’ is to be utilized within the standard, a clear definition of what the term is, what it pertains to, where it is located, etc. needs to be included. The NSRF recommends that “maintenance summaries” be defined and included in the “Definition of Terms used in Standard” section. 9. Footnote 1 in the Table sections would be much improved by inserting an example similar to what was provided in Section 8.4 of the Supplemental Reference and FAQ document 10. Additional methods of verification should be allowed for AC measurement monitoring other than simply performing comparison to an independent source. For example, a sudden rate of change in calculated relay MW analog value and/or

Organization	Yes or No	Question 4 Comment
		3Io calculation would give way towards a bad CT and/or path. Loss of potential logic is available in most microprocessor relays today, which is very reliable logic for determining PT/CCVT issues. Consideration should be given to utilities that are capable of performing this type of monitoring in order to allow them to reach that next level of attributes. 11. Please clarify why input/output verification is excluded from the highest level of monitoring related to communications systems (Table 1-2). The way the monitoring attribute is listed does not provide that these will operate when needed. Recommend language be added similar to the monitoring of inputs and outputs described in the relay section (Table 1-1). Table 1-3 should take into account the same concepts mentioned above in regards to AC measurement verification in Table 1-1. There are alternative ways to verify these quantities while still ensuring reliable operation. As such, companies should be given the opportunity to implement them. Additionally, credit should be given to circuit monitoring and alarming in AC circuits with electromechanical relays. If a transducer/alarming relay is placed in the circuit and monitoring is alarmed appropriately, the health of the AC sensing device can be determined. This would essentially provide the same level assurance as mentioned with the microprocessor relays. 12. Clarification is needed on the last row of Table 1-5. Does integrity entail monitoring and alarming of every individual path, if necessary, or is overall integrity sufficient? This statement is once again open to interpretation and leaves the entity at the mercy of the auditor.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.

Organization	Yes or No	Question 4 Comment

2. The SDT sees no appreciable change or improvement in the standard with your proposed change, and respectfully declines to modify the draft.
3. The SDT believes that the suggested change would be redundant to the current text of the Table 1-4(f) header.
4. This is an intentional difference between distributed UFLS/UVLS and the remainder of the Protection Systems addressed within the standard because of the distributed nature of distributed UFLS/UVLS and because these devices are usually tripping distribution System Elements. If an entity were to install monitoring equipment for verification of Station DC supply voltage, or other facets of the reduced maintenance activities regarding distributed UFLS/UFLS, Table 1-3 describes the adjusted activities permitted relative to that monitoring.
5. The SDT believes the Implementation Plan is descriptive in that an entity will be 100% compliant with PRC-005-2 when one maintenance period has elapsed. On a continuing basis, in order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit. The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.
6. The SDT believes it is left to the entity to determine how to align the requirements of the standard with requirements of other regulations and with operational concerns.
7. The VSL Guidelines, developed in accordance with the FERC VSL Order establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.”
8. The SDT believes defining “Maintenance Summaries” is unnecessary. The measure simply lists some types of evidence to demonstrate that an entity has maintained its Protection System in accordance with the standard.
9. The SDT believes that the footnote is adequate, but recognizes that some entities may desire the additional details that are included in Section 8.4 of the Supplementary Reference and FAQ document.
10. The SDT believes that the methods that you suggest would be useful for meeting the 12-calendar-year interval for unmonitored Components. However, for monitored systems with no physical maintenance activities, the SDT is concerned about the quality of some of the methods suggested.

Organization	Yes or No	Question 4 Comment
11. The SDT has modified the last row of Table 1-2 to be similar to the corresponding row of Table 1-1. 12. Section 15.3 of the Supplemental Reference and FAQ provides the following guidance: “Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path.”		
Duke Energy		1. Duke Energy votes “Negative” because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the Successive Ballot but prior to the Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but are not intended to provide protection for the BES. FERC’s September 26, 2011 Order in Docket No. RD11-5 approved NERC’s interpretation of PRC-005-1 R1 and R2, stating: “The interpretation clarifies that the Requirements are “applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES.” This interpretation is consistent with the Commission’s understanding that a “transmission Protection System” is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices.” The SDT’s response to our comment directed us to Section 2.3 of the Supplementary Reference and FAQ document which states “There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard.” We agree with that statement, but question why the SDT insists on changing Section 4.2.1 to include devices that detect Faults on the BES but which do not provide protection for the BES? Duke Energy’s standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate

Organization	Yes or No	Question 4 Comment
		BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following definition: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)". 2. We also note that the Lower VSLs for R3 and R4 include violations for "5% or less," and R5 for "5 or less" which mandates perfection. We believe that the consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability." We suggest that a range of 0.5% to 5% would be more reasonable.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.
2. NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. Much

Organization	Yes or No	Question 4 Comment
of this comment appears to be related to the technical content of the standard, not on the VRFs or VSLs.		
PPL Supply NERC Registered Organizations		Although we have provided some suggested changes in these comments, PPL Generation entities voted in favor of this version. We thank the SDT for the effort on this project and believe that the SDT has developed a revision that improves on many aspects of the existing version of PRC-005.
Response: The SDT thanks you for your affirmative vote.		
ExxonMobil Research and Engineering		As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the Component population below the requirements of Attachment A will result in an unsound program due to Component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
American Transmission Company, LLC		ATC recommends that the SDT change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to:"Verify that a trip coil

Organization	Yes or No	Question 4 Comment
		is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years "Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).ATC continues to recommend a negative ballot since we believe that the testing of "each" trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comment. The SDT sees no appreciable change or improvement in the standard with your proposed change, and respectfully declines to modify the draft.		
Bonneville Power Administration		BPA believes that PRC-005-2 achieves the goal of reducing redundancy and overlap within the PRC standards by consolidating four existing standards into one. BPA's comments are focused on improving the clarity and audit-ability of the proposed standard. 1. Regarding Section D1.3 "Evidence Retention", BPA suggests that the entire first paragraph be removed because for all the instances that follow the first paragraph there is a requirement to keep evidence obtained since the last audit. Therefore, there are no instances where the evidence retention period is shorter

Organization	Yes or No	Question 4 Comment
		than the time since the last audit, and the first paragraph is not necessary. Furthermore, the first paragraph introduces the idea of "other evidence" for which there is no explanation. It is unclear what could be used for evidence other than the items described in the 2. Measures. The idea of "other evidence" should not be introduced without an explanation of what that evidence might be, so this is another reason for removing the first paragraph. 3. Regarding requirements R2 and R4, BPA believes that these two requirements should be combined into a single requirement with two parts. Since both of these requirements deal with performance-based maintenance, it would simplify the standard and improve the flow if they were to be combined. 4. Regarding Table 1-4(f), it is unclear if all of the conditions on the left side need to be met before any of the reduced maintenance activities on the right side are allowed, or if there is a one-on-one relationship between an item on the left and the adjacent item on the right. BPA suggests that the table be reconfigured to clarify the relationship between the conditions on the left and the activities on the right.

Response: Thank you for your comments and support.

1. The SDT has been advised to include this paragraph as the first paragraph in the evidence retention.
2. The list of possible evidence with the measures is not intended to provide a comprehensive list of all type of evidence that may be useful. The entity is provided the flexibility to use other evidence that they deem relevant.
3. Requirements R2 and R4 are separate, as they address two specific requirements; one to establish a performance-based PSMP according to criteria, and the other to implement that PSMP.
4. There is a one-to-one correspondence between the right and left columns, and the SDT believes that further clarification is unnecessary.

Organization	Yes or No	Question 4 Comment
CenterPoint Energy		1. CenterPoint Energy recommends retaining an option to utilize technology for monitoring trip coil continuity as an alternative to the maintenance activity in Table 1-5. The Table 1-5 requirement to "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating devices (regardless of any monitoring of the control circuitry)" appears to address breaker maintenance, instead of Protection System Controls. In the Supplementary Reference and FAQ, monitoring is described as greatly reducing the time between a component failure and discovery of that failure. 2. For the "Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (Excludes non-BES trip coils)", the Table 3 requirement is to "Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)" every 12 calendar years. CenterPoint Energy recommends this requirement be revised to "No periodic maintenance specified". CenterPoint Energy believes this to be a commissioning task, not a preventive maintenance task. A preventive maintenance task, such as the above, is unnecessary for distributed UFLS and UVLS system components. The overriding performance, or "risk-based", NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount. 3. For the "Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays", the Table 1-5 requirement is to "Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices" every 12 calendar years. CenterPoint Energy recommends this requirement be revised to "No periodic maintenance specified". CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. Alternatively,

Organization	Yes or No	Question 4 Comment
		CenterPoint Energy recommends specifically excluding panel wiring and requiring only cabling between panels and interrupting devices be verified. Requiring trip path verification to include panel wiring complicates maintenance while focusing on a component that is not subject to age-related degradation in addition to, historically, not being a source of protection system failures. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping.
Response: Thank you for your comments. 1. While trip coil monitors may demonstrate continuity, they do not fully demonstrate operability. 2. The SDT disagrees regarding UFLS and UFLS-related control circuitry maintenance, and believes that the maintenance specified is appropriate. 3. The SDT disagrees with your proposal regarding Table 1-5 for dc control circuits and auxiliary relays which may be a critical part of a tripping scheme.		
Central Lincoln		Central Lincoln appreciates the good work the SDT has done. We believe this particular team has actually listened to our comments and made changes where needed. Thanks.
Response: The SDT thanks you for your affirmative vote.		
Constellation/Exelon		Constellation/Exelon thanks the drafting team for the hard work on the PRC-005 standard. The standard language made significant progress; however, below are outstanding issues of concern: Table 1-3 1. Table 1-3 should not include current transformers (CTs). The tests mandated by this draft seeks to measure that a signal is "provided to the protective relay" however, for CT's this test merely confirms that a signal is sent, not that it reached the correct protective relay.

Organization	Yes or No	Question 4 Comment
		2. The maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays should be left to the discretion of the Generator Owner. In order to meet the required activity specified in PRC-005-2 draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse affect on the reliability of the BES. Such testing is not recommended by suppliers. Battery Testing 3. The Tables describing battery testing could be consolidated into less granular breakdown and thus alleviate some of the associated compliance burden and avoid potential confusion. 4. Further to battery testing, given the quantity of batteries and the shorter interval cycles, the four calendar month requirement for batteries is too rigid as a firm four months. Similar to how a definition of annual can have a boundary such as within 9 to 16 months; battery testing intervals should allow a boundary such as “three times per year and not more than 6 months between each and average intervals not exceeding four months.” 5. Please confirm that references throughout Standard to battery/batteries relate to the entire battery bank and not to the individual battery cells unless specifically mentioned. Similarly, battery charger maintenance activity should relate to the battery charger in its entirety and not to individual parts or components. Auto Synchronizing Systems and Relays 6. The drafting team should clarify in the language that testing of auto synchronizing

Organization	Yes or No	Question 4 Comment
		systems and relays is excluded. Applicability 7. To make 4.2.5.4 under Facilities more clear, please remove the term "generator-connected". 8. When the SDT changed the original PRC-005 applicability language from "...affecting the reliability of the BES..." to the new 4.2.1 language "...that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)", they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read "...and trips an interrupting device that interrupts current supplied directly from the BES." By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005.Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1

Organization	Yes or No	Question 4 Comment
		language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement:"The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion." Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1:"Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements."This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. Evidence Retention 9. It is not necessary and is undesirable to reiterate the language from the NERC Rules of Procedure (Appendix 4C 3.1.4.2) in the standard. Stating such language in two places is redundant and future changes to this section of the Rules of Procedure language will create compliance conflict. While this language may be recommended for inclusion as new boilerplate-type language for NERC standards

Organization	Yes or No	Question 4 Comment
		and may be used in other recently revised standards, the potential conflict should be taken into account and avoided for PRC-005. The first paragraph in section 1.3 should be removed. 10. Further, the standard language should dictate data retention relevant to the standard activities and not merely default to the time period in between audits. The Rules of Procedure language enables CEAs to confirm compliance for the full audit period, but the Standard retention language allow for a more reasoned obligation for evidence retention. Specific to this standard, two or three years of evidence for certain components, such as battery tests, is sufficient to demonstrate an entity's PSMP program. On a positive note, standardizing the requested evidence information is helpful.

Response: Thank you for your comments.

1. Regarding current transformers, the SDT disagrees, and notes that the table specifies that the entity verify that the signal is provided to the relay.
2. Regarding testing for currents or potentials behind a Generator Operator's electromechanical relay panel, the SDT believes that it is possible during a 12-year interval to find a reasonably low-risk opportunity to perform the required test. Please refer to Section 15.2.1 of the Supplementary Reference and FAQ document for a discussion of this topic.
3. The existing battery tables have evolved such that entities may easily locate the specific table that applies to the technology being used in order to improve clarity and avoid confusion.
4. Regarding battery testing, the SDT believes that sufficient industry expertise supports a four-month interval requirement.
5. The SDT confirms that most of the battery requirements apply to the entire battery bank, and not necessarily to each battery jar or cell; the same is true for battery chargers. Those requirements specific to individual cells are clearly indicated.
6. Automatic synchronizing relays (which generally close circuit breakers, rather than trip them) are not covered by the Applicability.
7. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator, as stated in Applicability 4.2.5.1.
8. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes

Organization	Yes or No	Question 4 Comment
that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference Document for additional discussion. 9. The SDT has been advised to include this paragraph as the first paragraph in the Evidence Retention section. 10. For the Compliance Monitoring Authority to be confident that the corrective action is being implemented, the entity should expect to demonstrate progress toward correcting the Unresolved Maintenance Issue, such as the evidence suggested in Measure M5 (with additional suggested evidence added). The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
DTE Energy		1. DECo does not agree with the 6 year interval for the majority of the Protection System components. There are not sufficient problems found on routine maintenance based on a 10 year interval that would justify that significant of a reduction in the maintenance interval. 2. Also, with respect the station batteries specifically, station batteries, DECo recommends the elimination of the 4 month inspection as annual inspections have been sufficient for early diagnosis of potential issues. Advanced monitoring is not practical at this time as it does not appear that the technology required to forgo the 4 month inspection is readily available.
Response: Thank you for your comments. 1. The SDT believes the intervals and activities specified are technically effective, in a fashion that may be consistently monitored for compliance. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns. If the relevant components are monitored, more lengthy intervals may be utilized. Performance-based maintenance is an option to increase the intervals, if the performance of these devices supports those intervals. 2. Regarding battery testing, the SDT believes that sufficient industry expertise supports a four-month interval requirement.		
FirstEnergy		FE asks that the team clarify the intent of certain aspects of the applicability section:

Organization	Yes or No	Question 4 Comment
		1. Sec. 4.2.5.4 - For transformers supplying unit auxiliaries, protective functions that provide for transferring of auxiliaries without tripping the generating unit should not be included. Also, we believe that the term "station service transformer" is being used inaccurately. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, “Protection Systems for generator-connected station service transformers for generators that are part of the BES.” Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. But since a station service transformer, by definition (IEEE Std. 505), is "a transformer that supplies power from a station high voltage bus to the station auxiliaries and also to the unit auxiliaries during unit startup or shutdown or when the unit auxiliaries transformer is not available, or both." [Ed. note: a.k.a. Start-Up Transformer or Cranker], the terminology "generator-connected station service transformer" is confusing and easily subject to misinterpretation. 2. Also, there needs to be consistency of use of terms between the standard and its Supplementary Reference document. On pages 32 and 33 of the FAQ, the following questions and their respective answers should be consistent with use of terms and replace “station service” with “auxiliary” as follows: FAQ Question - Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected auxiliary transformer to meet the requirements of this Maintenance Standard.FAQ Question - In the case where a plant does not have a generator connected auxiliary transformer such that it is normally fed from a system connected

Organization	Yes or No	Question 4 Comment
		auxiliary transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) auxiliary transformer will result in a trip of a BES generating facility? Therefore, for consistency between the reference FAQ document and the standard, we suggest that "station service" be replaced with "auxiliary" in 4.2.5.4 and read as follows: "Protection Systems for generator-connected auxiliary transformers used on generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."
Response: Thank you for your comments. 1. Applicability Section 4.2.5.4 specifically addresses the Protection Systems that act to trip the generator, and the "station service transformer" term seems to be the most consistently-used term for this application. 2. The SDT modified the Supplementary Reference and FAQ document for consistency with the standard.		
Kansas City Power & Light		1. For clarity, change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to: "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.". Or alternately, "Electrically operate each interrupting device every 6 years". 2. Countable Event as proposed is somewhat unclear. Recommend the following language: Countable Event - A Component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to any other reason are not included in Countable Events.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1. The SDT believes it is important that each individual trip coil be verified. 2. The SDT does not believe that the changes you suggest improve the standard.		
BAE Batteries USA		Major comments have been addressed in Question 3.
Manitoba Hydro		Manitoba Hydro is voting negative for the following reasons: 1 - Battery inspection and verification interval - Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Manitoba Hydro has more than ten years of experience using its existing battery inspection intervals and Manitoba Hydro's reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro's battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro's installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro and may be more than is required for many other utilities. To use a more frequent inspection interval would penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. It would also potentially adversely affect reliability by diverting resources away from projects that are critical to reliability to meet this maintenance interval. In addition, the 4 month time period proposed for basic battery verification and inspection interval is not aligned with the more detailed 18 month battery verification and inspection interval which will result in additional and unnecessary site visits and maintenance activities. As well, Manitoba Hydro does not feel that the SDT has provided sufficient technical basis to support a 4 month battery inspection and verification interval and requests

Organization	Yes or No	Question 4 Comment
		that further justification and external reference be provided. 2 - PBM not permitted for batteries - Manitoba Hydro disagrees with the SDT's basis for not permitting the use of PBM for batteries. The reasons provided by the SDT for disallowing them are that batteries are perishable and involve chemical reactions. However, it is our understanding that many other industries rely on performance based maintenance programs when dealing with similar equipment. We would appreciate an external reference or source which supports the claim that equipment with these characteristics cannot have a performance based maintenance system applied to them. 3 - Phased Implementation Plan - Manitoba Hydro maintains its position that prescribing how an entity must reach full compliance with PRC-005-2 will provide a negligible improvement in reliability while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets and proving compliance for the prescribed percentages of assets during the transition period creates unnecessary overhead with no added value. We suggest that the requirement to demonstrate the percentage of assets currently under PRC-005-1 vs. PRC-005-2 be removed, that entities should be given a single compliance date for each of the maintenance intervals and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-005-2, and that NERC measures progress on reaching PRC-005-2 intervals using means other than Compliance measures such as industry surveys. 4 - Data Retention Requirements - The data retention requirements are too uncertain for two reasons. First, the requirement to "provide other evidence" if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what 'other evidence', besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comments. 1. The SDT believes that sufficient industry expertise supports a four-month interval. 2. The SDT believes that batteries cannot be a unique population segment of a Performance-based Maintenance (PBM) Program because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. 3. The SDT disagrees with your proposal for a phased implementation plan. 4. The SDT has been advised to include this paragraph as the first paragraph in the evidence retention section.		
Alber Corporation		My comment is in regard to the proposed maintenance tasks associated with ohmic testing and capacity testing of lead-acid batteries affected by PRC-005-2.The option is given to the battery use to perform either inter cell/unit ohmic tests OR battery capacity tests whichever suits the user. The two tests, while related, are not directly interchangeable with one another. Ohmic tests are intended to be used as a tool during battery maintenance inspections to determine the general state of health (condition) of the battery as a whole. Capacity tests are intended to demonstrate the actual capacity of a battery. Ohmic tests cannot be substituted for capacity tests. Alber has pioneered the development of portable and fixed internal resistance test equipment for stationary lead-acid batteries since 1972. Through years of research, testing in real-world applications and development, Alber has conclusively determined that there is a direct relationship between internal cell resistance and capacity. However, because this correlation is not linear, ohmic measurements should not be used to calculate capacity or remaining life. Ohmic measurements should be used as a supplement to capacity testing and not as a replacement. These measurements are very valuable in identifying developing problems between the capacity testing intervals and for determining whether a battery string is going to perform its intended mission. IEEE 1188-2005 for VRLA batteries agrees with this and recommends measurement of this parameter once every three months. While not specifically recommended in IEEE 450-2010 for vented lead-acid batteries, ohmic measurements can provide early warning of potential failure and should be performed at least

Organization	Yes or No	Question 4 Comment
		annually. Again, if readings result in doubt that a battery will perform as intended, follow up capacity testing is recommended. A battery discharge test completely simulates the operating environment and therefore conclusively proves that a battery can perform during an emergency. The results of these tests will help set the priority for capacity testing as the user becomes more familiar with their batteries and may assist in extending capacity test intervals. The intention of the proposed NECR PRC-005-2 standard as it relates to the DC supply, and, in particular, the station battery is to increase reliability of the bulk electric system (BES) in north America. In its current draft form, PRC-005-2 proposes the utility may perform internal ohmic measurements or perform capacity, but both tests are not required. It would appear therefore; that the Standards Drafting Team (SDT) has made the assumption that test results obtained from measuring cell internal ohmic values is the same as performing a capacity test. It is not, and to provide the option to perform one test or the other runs counter to industry recommended practices. Such maintenance practices will, in effect, ultimately reduce the reliability of the BES rather than improve it. Periodic capacity testing on a 5 year interval for VLA batteries, and a 2 year interval for VRLA batteries is consistent with IEEE 450-2010 and IEEE 1188-2005 recommended practices respectively. It should be part of a complete maintenance program designed to maximize the DC supply's availability when needed. Respectfully submitted, Richard Tressler Alber Corp.
Response: Thank you for your comment. The SDT agrees with your statement, and those of others, concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ Document has been modified to further elaborate on these concerns.		
NIPSCO		Per NIPSCO Tech Service Dept : There is a need for NERC to provide a format for maintenance reports. Also, it would help if specific test requirements for relays were provided.
Response: Thank you for your comments. The SDT do not believe it is necessary or appropriate to prescribe a specific format for test results or test requirements.		
PNM Resources		PNM Resources appreciate the outstanding work of the SDT! We offer two comments

Organization	Yes or No	Question 4 Comment
		for consideration by the SDT. 1) We believe that the 6 Calendar Month battery cell/unit internal ohmic value measurement for VRLA Batteries may be more frequent than we believe is necessary to maintain reliability. PNM has witnessed no significant failure patterns with VRLA batteries in our system and we currently do impedance testing of all Transmission Station Batteries on a 2-year basis. 2) We also believe that system constraints could arise that will make it difficult to “verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices” as specified in Table 1-5 for “unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays”. Thank you for your consideration.
Response: Thank you for your comments. 1. The SDT believes that it is necessary to verify that the station battery can perform as manufactured by evaluating the cell/unit parameters to station battery baseline if a performance or modified performance test is not conducted. Please see Section 15.4 of the Supplementary Reference and FAQ Document for a discussion of this topic. 2. The SDT believes the intervals and activities specified are technically effective, in a fashion that may be consistently monitored for compliance. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns.		
American Electric Power		PRC-005-2 is intended to supersede the existing standard PRC-017-0 "Special Protection System Maintenance and Testing". As it is currently written, an Entity with a Special Protection System will be required by R1 to select either a time-based, performance-based or combination maintenance method for the Entity's SPS. Since Special Protection Systems are not frequently installed, it is unlikely that an Entity will be able to meet the requirement of R2 and Attachment A that the Segment population contain 60 components for all components of the SPS. This will require the Entity to utilize the time-based maintenance method for at least some

Organization	Yes or No	Question 4 Comment
		components in the SPS. Under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems by their nature may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are not included in the NERC definition of Protection System.
Response: The SDT thanks you for your comments. The SDT does not perceive the gap in maintenance requirements that you describe for SPSs.		
US Bureau of Reclamation		1. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 2. Re The definition of Components: The standard defined what constitutes a control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 4 Comment
1. The standard specifies that the terms used are intended for this standard only; therefore, there should no conflict with their use in any other PRC standard. 2. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
ReliabilityFirst		1. ReliabilityFirst votes in the negative for this standard primarily due to the language in Requirement R5. The language in Requirement R5 is subjective and non-measurable in its present state. ReliabilityFirst offers the following comments for consideration. 2. Definition of "Component" a. The language stating "discrete piece of equipment" within the first sentence is unclear and open ended. ReliabilityFirst suggests the following modified language for the first sentence in the definition of "Component": "A Component is a piece of equipment that is one of the five specific element included in a Protection System, including but not limited to a protective relay or current sensing device." 3. Definition of "Unresolved Maintenance Issue" a. There may be instances when a deficiency is identified and corrected during the maintenance itself. For further clarity and to address this circumstance, ReliabilityFirst recommends the following modification for consideration: "A deficiency identified during a maintenance activity that could not be corrected and causes the component to not meet the intended performance and requires follow-up corrective action." 4. Facilities Section 4.2.1 a. This is too limited or selective in only including Protection Systems that are installed on BES Elements to strictly detect Faults. There are a number of relays

Organization	Yes or No	Question 4 Comment
		that are installed to detect non-Fault but abnormal conditions such as power swings/out of step and overvoltage that should not be excluded from a maintenance program. ReliabilityFirst recommends the following language for consideration: “Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)” 5. Facilitates Section 4.2.2 a. It is unclear what requirements the phrase “installed per ERO underfrequency load-shedding requirements.” is referring to. Is it NERC UFLS Requirements, Regional UFLS Requirements, etc.? To be consistent with section 4.2.3, ReliabilityFirst recommends the following for consideration: “Protection Systems used for underfrequency load-shedding systems installed to arrest declining frequency, for BES reliability. 6. Requirement R3 a. For time-based maintenance program(s), there is no safeguard if more than 4% Countable Events are experienced during a maintenance interval. ReliabilityFirst recommends adding an new Subpart 3.1 (similar to the language for performance-based in Attachment A): “3.1 If the Components in a Protection System Segment maintained through a time-based PSMP experience 4% or more Countable Events, develop, document, and implement a Corrective Action Plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.” 7. Requirement R5 a. Requirement R5 has language which states “...shall demonstrate efforts to correct...”. ReliabilityFirst believes this language is subjective and non-measurable. It will be difficult in determining what amount of demonstration an entity will need to provide in order to be compliant. There is also no timeframe in which the correction needs to be completed (is it 30 days or 30 years?). ReliabilityFirst believes measurable language such as “shall correct” or “shall

Organization	Yes or No	Question 4 Comment
		have and implement a Corrective Action Plan" should be incorporated within the requirement. 8. Table 1-2 a. For "Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function" ReliabilityFirst believes the maintenance interval is too short. Carrier communication failures are a major cause of Misoperations. Many have automatic checkback and are monitored but continue to fail during Fault conditions. ReliabilityFirst recommends a maintenance interval of 6 years. b. For "Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied" ReliabilityFirst believes a maintenance interval should be required. ReliabilityFirst recommends a maintenance interval of 12 years. 9. Table 1-3 a. For "Any voltage and current sensing devices not having monitoring attributes of the category below." ReliabilityFirst recommends a maintenance interval of 6 years. b. For "Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value..." ReliabilityFirst believes the concept of never having to do any testing just because you have continuous monitoring is fundamentally flawed in this table as well as 1-5 and 2. Continuous monitoring and measurement comparison cannot test everything, such as loss of ground, multiple grounds and turn-to-turn failures, and monitoring itself can fail. ReliabilityFirst recommends a maintenance interval of 12 years. 10. Table 1-5 a. ReliabilityFirst recommends adding "auxiliary tripping devices" to

Organization	Yes or No	Question 4 Comment
		Electromechanical lockout devices in row 2 of Table 1-5. If lockout relays are maintained every six years auxiliary tripping devices should be as well. ReliabilityFirst recommends the following language for considerations: “Electromechanical lockout devices and auxiliary tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).”

Response: The SDT thanks you for your comments.

1. Requirement R5 is expressly focused on allowing entities to resolve deficiencies in an effective manner, rather than performing “band-aid” fixes. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “Unresolved Maintenance Issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”
2. The SDT believes it important to distinguish between component “types” (of which there are 5) and individual components (of which there are numerous examples), and believes that you are confusing the two concepts.
3. The definition of “Unresolved Maintenance Issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”
4. The SDT believes your proposed language for Applicability Section 4.2.1 is overly broad and could lead to unintentional application of PRC-005-2 to other as-of-yet unidentified systems.
5. The SDT intends that this refers to either NERC UFLS requirements or regional UFLS requirements.
6. Countable Events apply only to entities that utilize a performance-based PSMP (Requirements R2 and R4). For entities that use a time-based program, the establishment of maximum intervals within the standard relieves the entity from having to have any

Organization	Yes or No	Question 4 Comment
basis, etc., that the intervals used are appropriate, as long as those intervals conform to the tables. 7. Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." 8. a) The SDT believes that sufficient emphasis is placed on communication system checks and maintenance. The SDT also believes that more frequent hands-on testing will be no more effective in finding problems than the automated monitoring of these functions. b). The SDT believes that continuous monitoring requirements, as already drafted, will drastically reduce risk to the BES. 9. a) The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Entities are empowered to develop PSMPs that exceed these requirements, if they determine such a PSMP to be necessary. b). The SDT believes that continuous monitoring is equivalent to actually conducting the maintenance activities otherwise specified at a far more frequent interval than would be possible with physical hands-on maintenance; and, therefore, improves reliability. The SDT has also identified throughout the tables specific activities that they believe to not be effectively conducted via monitoring. 10. The SDT believes the intervals and activities specified for auxiliary relays are technically effective, and believes sufficient emphasis is placed on auxiliary tripping relay maintenance.		
ATCO Electric Ltd		1. Table 1-4(a) Vented Lead-Acid (VLA) Batteries: ATCO Electric has a number of

Organization	Yes or No	Question 4 Comment
		remote substations that are difficult to access frequently. The requirement for a 4 calendar month inspection for electrolyte level is too frequent. (i) Does alarm/monitor technology exist for electrolyte level in battery design today? For in-service battery systems, if battery alarm/monitor technology exists, a capital project is required to retrofit each battery system and this kind of retrofit work could be detrimental to both the battery design life as well as the battery reliability. (ii) The electrolyte level requirement would become achievable if electrolyte level inspection was moved to the 18 calendar months category, or if the 4 calendar months frequency was increased to 8 calendar months. 2. Table 1-4(b) Valve Regulated Lead Acid (VRLA) Batteries: ATCO Electric has a number of remote substations that are difficult to access frequently. The requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category. 3. Table 1-5 Control Circuitry When a breaker is opened, there is no indication on which trip coil is actually operated. How do market participants demonstrate compliance for "verify that each trip coil is able to operate..."? The verification of trip coil health is done during breaker maintenance with various maintenance durations that maybe longer than 6 years depending on breaker types. 4. The requirement of "verify electrical operation of electromechanical lockout

Organization	Yes or No	Question 4 Comment
		devices" introduces high risk of human error outages to the BES system and diminishes the reliability gain from performing this activity. The drafting team should consider lockout relay failure rates, onerous tasks of blocking each trip contacts in many BES elements' tripping circuits, imposed risk, required resources in the overall reliability benefit gained by performing the lockout relay maintenance.
Response: The SDT thanks you for your comments. 1. Devices to monitor electrolyte levels are available. The SDT believes that the four-month interval for checking electrolyte level (absent monitoring) is appropriate, as low electrolyte level may impair the ability of the battery to function properly. 2. The SDT believes that the six-month interval for evaluation of cell/unit ohmic parameters to baseline is appropriate, as degradation of these parameters may impair the ability of the battery to function properly. 3. Breaker control circuitry is typically designed with facilities, such that individual trip coils can be isolated for observation. Also, it may be possible to distinguish operation of individual trip coils by determining what devices initiate those trip coils. 4. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same six- year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices, but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond six years.		
Florida Municipal Power Agency		The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)”Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue.

Organization	Yes or No	Question 4 Comment
		These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.
Response: Thank you for your comments. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting Faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ Document for additional discussion. Reverse power relays and low-set overcurrent relays, as discussed in your comment, are not installed for detecting Faults on BES elements. The SDT does not understand your concerns regarding PRC-023, but we suggest you provide those concerns to the team working on that standard.		
Ingleside Cogeneration LP		The derivation of the implementation plan apparently incorporates the “requirements” of NERC’s Compliance organization, which has released several CANs on the topic. This is exactly backwards, and has led to at least one CAN which has been withdrawn due to legal overreach. However, the plan as written is very complex. We believe that diagrams of acceptable time frames should be included in the implementation plan so that industry stakeholders can better assess the impact

Organization	Yes or No	Question 4 Comment
		on their maintenance operations.
Response: The SDT thanks you for your comments. The SDT has developed the Implementation Plan such that it is clear, both to entities and to Compliance Enforcement Authorities, as to when the various requirements must be fully implemented. The Implementation Plan has been crafted to allow entities to systematically implement the standard in a manner that facilitates effective ongoing performance of a PSMP. The SDT does not believe it necessary to "diagram" the PSMP.		
EPRI		The drafting time should see the opinion of the IEEE Stationary Battery Committee before this standard is rolled out for implementation.
Response: The SDT thanks you for your comments. Several members of the NERC Task Force of the IEEE Stationary Battery Committee participated in developing modifications to the sections of Table 1-4 to be more effective and technically accurate.		
ACES Power Marketing Standards Collaborators		1. The first part of definition of a Countable Event should be modified as follows: "The failure of a Component such that it requires repair or replacement...". As it is currently worded, it is technically counting the Component as the Countable Event and not the failure of the component. Considering that the other two items that are Countable Events are conditions and misoperations, it seems appropriate to make failure the Countable Event. 2. Application of this standard to UFLS is problematic as worded in Section 4.2.2. The UFLS are only applicable if "installed per ERO underfrequency load-shedding requirements". Technically, no UFLS fits this description because there are no ERO requirements to have a UFLS. PRC-006-0 was never approved by the Commission and is not enforceable. The Commission considered it a "fill-in-the-blank" standard. While PRC-006-1 corrects the "fill-in-the-blank" issues and was approved by the NERC BOT November 4, 2010, the Commission has yet to act on it. 3. The data retention requirement for the Protection System Maintenance Program documentation seems excessive. The Data Retention section states that all versions since the last compliance audit must be maintained. Since TOs, GOs,

Organization	Yes or No	Question 4 Comment
		and DPs are all on six year audit cycles, this would require maintaining this documentation for six years. Is this really necessary? The length could become even greater once NERC implements registered entity assessments that could shorten or lengthen the periods between compliance audits. The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C - Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of "the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date". While it may have been intended to apply to both clauses, the "since the previous scheduled audit date" only applies to the second clause. Since some of the maintenance activities have intervals of 12 years, this would require the registered entity to retain documentation for 24 years which cannot be audited since it is outside the audit window per the Rules of Procedures. At a minimum, we suggest clarifying that the documentation must not be maintained past the day after the last audit completion date. In the fourth paragraph of the Data Retention section, Component is not used consistently. It is used in both singular and plural form. It seems like it should be one or the other. 4. Requirement R1 VSLs: For the High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. 5. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1. The SDT agrees with your comments on Countable Event, and has modified the definition of Countable Event to: "A failure of a Component requiring …" 2. Applicability Clause 4.2.2 applies to whatever ERO-required UFLS that may exist, either today or in the future. NERC Reliability Standard PRC-006-1 has now been approved by FERC. 3. The SDT believes that all versions of the entity's PSMP should be retained for audit purposes. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities. 4. The SDT corrected the Requirement R1- High VSL, as you suggested. 5. The SDT believes that missing three components is a "significant percentage," and is in accordance with the VSL Guidelines.		
Independent Electricity System Operator		The IESO continues to disagree with the VRF assigned to the new R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.
Response: Thank you for your comments. The SDT disagrees, and believes the failure to implement a PSMP should be assigned a VRF of High.		
BAE Batteries USA		The NERC Standard should incorporate suggestions made in a letter provided to the NERC Drafting Team along w/ a specific Task Force Report commissioned by the IEEE Stationary Battery Committee.
Response: The SDT thanks you for your comments. Several members of the NERC Task Force of the IEEE Stationary Battery		

Organization	Yes or No	Question 4 Comment
Committee participated in developing modifications to the sections of Table 1-4 to be more effective and technically accurate.		
Nebraska Public Power District		The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES 1. Please provide the basis for the requirement of functional trip checks? 2. Are there recorded instances that an "event" would have been avoided if functional trip checks had been performed? 3. Suggest for monitored microprocessor relays in Table 1-1 and 3 to verify "settings are as specified that are essential to the proper functioning of the protection system". Many settings are not essential. 4. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. All functional tests should be moved to the minimum frequency of 12 years to minimize this unknown but present risk.
Response: The SDT thanks you for your comments. 1. Please see Section 15.3 of the Supplementary Reference and FAQ document. 2. While the SDT cannot comment on any specific events that would have been avoided explicitly by performing functional trip checks, there is no doubt that the number of Misoperations will be reduced if more comprehensive maintenance is performed. It is also likely that mal-performance of control circuitry has been a factor in a number of disturbances. 3. In many microprocessor relays, various settings impact other settings, making it difficult to explicitly determine which are essential to proper functioning of the Protection System. Additionally, the SDT anticipates that this activity, for microprocessor relays, may very well be easily performed by downloading the settings from the relay and comparing them to the file of desired settings. 4. The maintenance of the overall control circuitry is already specified for a 12-year interval. Only trip coil verification and lockout		

Organization	Yes or No	Question 4 Comment
relay verification are specified for six years.		
Southwest Power Pool Standards Development Team		Under section 1.3 Evidence Retention we feel like documentation of the last two performances of each distinct maintenance activity should be limited to the last one. This is due to the amount of documentation being recorded as well as for certain a component there is a 12 year maximum interval. Would you have to store this information for 24 years? This could also violate the NERC ruling that was just made on a CAN 008 that stated you do not have to show intervals earlier than June 18th 2007. Suggested alternate language "For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous audit date, whichever is longer, but not prior to June 18th 2007."
Response: The SDT thanks you for your comments. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
NextEra Energy, Inc.		1. Verifying electrolyte levels of vented lead acid (VLA) batteries every four (4) calendar months is excessive and will not promote the reliability of the bulk electric system (BES). The maximum maintenance interval should be twelve (12) calendar months. Today's lead-calcium and lead-selenium-low antimony batteries do not experience rapid water loss as compared to the legacy lead-antimony batteries and if battery cells should crack from positive plate growth, twelve (12) calendar months is more than adequate to detect electrolyte leakage before cell failure.

Organization	Yes or No	Question 4 Comment
		2. Verifying that unmonitored communication systems are functional every four (4) calendar months is excessive and will not promote the reliability of the BES. The maximum maintenance interval should be twelve (12) calendar months. Based on our operating experience, twelve (12) calendar months is sufficient to detect communication failures without affecting the reliability of the BES.
Response: The SDT thanks you for your comments. 1. The SDT believes that the four-month interval for checking electrolyte level (absent monitoring) is appropriate, as low electrolyte level may impair the ability of the battery to function properly. 2. The SDT believes that the four-month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status.		
Flathead Electric Cooperative, Inc.		1. We appreciate the work of the drafting team to fulfill the SAR objectives. Flathead generally does not like some of the new definitions proposed by the revised standard, especially R5, “Unresolved Maintenance Issues” is too vague and will be left up to individual auditors to determine compliance. 2. In addition, it appears the drafting team is creating new definitions for plain English in the definition of Protection System Maintenance Program (PSMP). Surely "test, monitor, inspect, calibrate" don't need NERC definitions. Let's leave the definition as "An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored." Suggest deleting "A maintenance program for a specific component includes one or more of the following activities: o Verify- Determine that the component is functioning correctly. o Monitor - Observe the routine in-service operation of the component. o Test - Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. o Inspect - Detect visible signs of component failure, reduced performance and degradation.

Organization	Yes or No	Question 4 Comment
		o Calibrate-Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement." 3. In addition, it appears the component and component type definitions alter the meaning of the NERC approved definition of a protection system. I would suggest the drafting team not try to redefine the NERC-approved definition of Protection system. 4. "Countable Event" definition seems to conflict with standards related to Misoperation of protection system.

Response: The SDT thanks you for your comments.

1. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances, such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." The SDT believes the definition is sufficiently clear, while also allowing some flexibility for both TOs and auditors.
2. The SDT believes that the descriptions within the PSMP definition are necessary so that the definition will be clearly understood and so that entities consistently apply those terms as they implement the activities within the tables.
3. The definitions, for use within this standard, do not alter the approved definition of "Protection System," but instead provide consistent terms for use within the standard.

Organization	Yes or No	Question 4 Comment
4. The definition, within this standard, of Countable Event has no relationship to the approved definition of Misoperation. It is used solely to describe and evaluate Protection System performance for the purpose of developing and perpetuating a performance-based PSMP.		
Entergy Services		1. We recommend the word "Protection" be deleted from the definition of Component to make the defined term Component be a generic term. If that word is not deleted then we recommend the term used in the standard "Protection System Component" be changed to "Component" since as defined a Component is a Protection System piece of equipment. Component - A Component is any individual discrete piece of equipment included in a System, including but not limited to a protective relay or current sensing device. 2. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed
Response: The SDT thanks you for your comments. 1. The SDT intends that the term not be generic, and that term explicitly apply within this standard. 2. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
PNGC Comment Group		We thank the SDT for their hard work and will be voting "yes" on this project. However, we have 5 specific comments independent of the questions above and we've listed them in order of priority: 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric

Organization	Yes or No	Question 4 Comment
		System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the "NERC Guidance (Below), this seems to be a contradiction given the language of "...more than one". a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Moderate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required performance. We suggest changing the language for "Lower VSL" for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained... OrFor Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained... 2. The PNGC comment group disagrees with the "Evidence Retention" requirements for the standard. In the current version for R2-R5, entities are required to: "...keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer." The PNGC comment group believes that keeping documentation for one previous maintenance activity or since the last audit, whichever is longer, should be sufficient. Keeping the two most recent instances of an activity with a maximum maintenance interval of 12 years could mean planning for up to 35 years or so of evidence retention. With the longer of "since the last audit" or "at least one maintenance interval" as the minimum retention requirement the CEA should have sufficient basis to determine compliance. 3. The PNGC comment group believes R5, "Unresolved Maintenance Issues" is too

Organization	Yes or No	Question 4 Comment
		vague and will be left up to individual auditors to determine compliance. This requirement appears ripe for misapplication and future CANs on the topic. Good utility practice will ensure that maintenance issues are corrected as a primary function of our members is to provide the most reliable service possible. The SDT lists several possible examples of evidence in M5 but we believe that more specificity is needed for evidence requirements or the requirement should be removed. We understand the importance of "maintenance" of protection systems and that when maintenance issues cannot be immediately addressed there needs to be follow up. We believe notation of the maintenance issue during the inspection should be sufficient for compliance. By including the examples in the associated measure for the requirement, we believe the SDT has confused the issue. In our opinion M5 should indicate that evidence of notation of the issue is all that is required (meaning acknowledging of the issue on the inspection form). Further, in your response to entity comments during the last comment period on this topic, you stated, "The SDT believes that an effective PSMP must include correction of deficiencies...". This statement implies that the standard must cover the correction of deficiencies to completion. There could be very long time frames associated with maintenance including management budget decisions, equipment purchase lead times and personnel scheduling for follow up work. Some issues could potentially require years of tracking within this standard creating an unnecessary compliance risk for the entity. We believe the SDT has met the intent of order 693 if a maintenance activity is initiated. The completion of the initiated maintenance activity should be outside the bounds of the standard and the standard should clearly state this. 4. We also find issues with the "Definitions of Terms Used in Standard "Specifically, the definition of "Component" seems to confuse the subject unnecessarily. We suggest simplifying the definition by breaking out the control circuitry and voltage and current sensing device examples. That is a lot of material to cover in what should be a simple definition of "Component". 5. Also we believe the definitions of the 5 behaviors under the PSMP definition are

Organization	Yes or No	Question 4 Comment
		unnecessary. We believe that indicating that the PSMP involves some or all of the 5 activities without trying to define them is fine. For example, your definition of "Inspect" states: Detect visible signs of component failure, reduced performance and degradation. But what if you find no failure, reduced performance or degradation? Have you not inspected the component? Or what about "verify"? If you determine the component is not functioning correctly, have you not verified anything?

Response: The SDT thanks you for your comments.

1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.
2. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.
3. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." The evidence listed in the Measure is intended to be illustrative of the types potentially effective evidence, but is not all-inclusive, as demonstrated by the term, "… not limited to…"
4. The definitions of terms that are specified for use only within this standard are intended to support consistent application of the

Organization	Yes or No	Question 4 Comment
standard. 5. The SDT believes that the descriptions within the PSMP definition are necessary so that the definition will be clearly understood and so that entities consistently apply those terms as they implement the activities within the tables. The term "inspect" was modified to "Examine for …" in consideration of your comment.		
Western Area Power Administration		Western Area Power Administration - Rocky Mountain Region does not agree with changing lockout devices to 6 year intervals for testing.
Response: The SDT thanks you for your comments. The interval for lockout relays has been at six years for several drafts; this is not a change. The SDT believes that electromechanical lockout relays need periodic operation, and that six years is the appropriate interval. Performance-based maintenance is an option, if you want to extend your intervals beyond six years.		

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.
3. Standard passed the initial ballot with the following results: Quorum - 84.32% and Affirmative - 73.93%.

Description of Current Draft:

This is the second draft of the Standard. This standard merges previous standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and successive ballot.	May – June, 2012
2. Drafting Team Responds to Comments	July – August, 2012
3. Conduct recirculation ballot	August, 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for signs of component failure, reduced performance or degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion

on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owner

   4.1.2 Generator Owner

   4.1.3 Distribution Provider

   4.2. Facilities:

   4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

   4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

> ***Component Type** - Any one of the five specific elements of the Protection System definition.*

1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue** - A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented Protection System Maintenance Program in accordance with Requirement R1.

For each Protection System Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System Components included within its time-based program in accordance with Requirement R3. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.3. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System Component Type.

For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Component, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	The responsible entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entity's PSMP failed to include the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to no more than 4% within five years OR 3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				• Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or fewer Unresolved Maintenance	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	Issues.	Unresolved Maintenance Issues.	Unresolved Maintenance Issues.	Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — May 2012.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[1]	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with: • Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System

Table 1-3 **Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays** **Excluding distributed UFLS and distributed UVLS (see Table 3)**		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(b) **Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(c)

Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries

Excluding distributed UFLS and distributed UVLS (see Table 3)

Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as manufactured when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Devices for SPS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used only for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic evaluation relative to baseline of battery cell/unit measurements indicative of battery performance is required to verify the station battery can perform as manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 **Component Type - Control Circuitry Associated With Protective Functions** **Excluding distributed UFLS and distributed UVLS (see Table 3)** **Note:** Table requirements apply to all Control Circuitry Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 calendar years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with SPS.	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **Segment** population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

> **Segment –** *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.*

> **Countable Event** – *A failure of a component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.
5. If the Components in a Protection System Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.
~~2.~~3. Standard passed the initial ballot with the following results: Quorum - 84.32% and Affirmative - 73.93%.

Description of Current Draft:
This is the second draft of the Standard. This standard merges previous standards PRC-005-~~1a~~1b, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and successive ballot.	May~~rch~~ – June~~April~~, 2012
2. Drafting Team Responds to Comments	~~May~~ July – August~~June~~, 2012
3. Conduct recirculation ballot	August~~June~~, 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — ~~Detect visible~~Examine for signs of component failure, reduced performance ~~and~~or degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

Countable Event – A failure of a Component ~~which has failed and requires~~ requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner

4.1.2 Generator Owner

4.1.3 Distribution Provider

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for station service or excitation transformers connected to the generator ~~-connected station service transformers used on~~bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based ~~(~~per PRC-005 Attachment A~~)~~, or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

> ***Component Type*** *- Any one of the five specific elements of the Protection System definition.*

1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented Protection System Maintenance Program in accordance with Requirement R1.

For each Protection System Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System Components included within its time-based program in accordance with Requirement R3. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint~~s~~

1.3. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System Component Type.

For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Component~~s~~, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	The responsible entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible ~~entities'~~ entity's PSMP failed to include the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to ~~less~~ no more than 4% within three years.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to ~~less~~ no more than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to ~~less~~ no more than 4% within five years OR 3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				• Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or ~~less~~ fewer Unresolved Maintenance	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	Issues.	Unresolved Maintenance Issues.	Unresolved Maintenance Issues.	Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — ~~July~~ May ~~2011~~2012.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	~~6~~ 12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with: • ~~continuous~~ Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years~~No periodic maintenance specified~~	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System~~None.~~

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as ~~designed~~ manufactured by evaluating ~~the measured~~ cell/unit ~~internal ohmic values~~measurements indicative of battery performance (e.g. internal ohmic values or float current) ~~to~~ against the station battery baseline. -or- Verify that the station battery can perform as ~~designed~~ manufactured by conducting a performance~~, service,~~ or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack

Table 1-4(b) **Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as ~~designed~~ manufactured by evaluating ~~the measured~~ cell/unit ~~internal ohmic values~~ measurements indicative of battery performance (e.g. internal ohmic values or float current) ~~to~~ against the station battery baseline. -or- Verify that the station battery can perform as ~~designed~~ manufactured by conducting a performance~~, service,~~ or modified performance capacity test of the entire battery bank.

Table 1-4(c) Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as ~~designed~~ manufactured by conducting a performance ~~service,~~ or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as ~~designed~~ manufactured when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Devices for SPS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used only for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic ~~measurement and~~ evaluation relative to baseline of battery cell/unit measurements indicative of battery performance ~~internal ohmic values~~ is required to verify the station battery can perform as ~~designed~~manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3) **Note:** Table requirements apply to all Control Circuitry Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 calendar years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with SPS.	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **Segment** population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

> **Segment –** *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.*

> **Countable Event** – *A failure of a component ~~which has failed and requires~~ requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

5. If the Components in a Protection System Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

RELIABILITY CORPORATION

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing
PRC-005-02

Standards Involved
Approval:

- PRC-005-2 – Protection System Maintenance

Retirements:

- PRC-005-1b – Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
- PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:
Revised definition of "Protection System"

Background:
The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.
5. The Implementation Schedule set forth in this document facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in approximately equally-distributed steps over those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets the requirements of PRC-005-2 in accordance with this implementation plan.

While entities are transitioning to the requirements of PRC-005-2, each entity must be prepared to identify:

- All of its applicable Protection System components.
- Whether each component has last been maintained according to PRC-005-2 or under PRC-005-1b, PRC-008-0, PRC-011-0, or PRC-017-0, or a combination thereof.

For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

The existing Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following applicable regulatory approval of PRC-005-2 in all jurisdictions.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Implementation Plan for Requirements R3 and R4:

1. For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
2. For Protection System component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
3. For Protection System component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

4. For Protection System component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5. For Protection System component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Applicability:
This standard applies to the following functional entities:

- Transmission Owner
- Generator Owner
- Distribution Provider

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02

Standards Involved

Approval:

- PRC-005-2 – Protection System Maintenance ~~and Testing~~

Retirements:

- PRC-005-~~1a~~ 1b – Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
- PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

Revised definition of "Protection System"

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.
5. The Implementation Schedule set forth in this document facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in approximately equally-distributed steps over those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets the requirements of PRC-005-2 in accordance with this implementation plan.

While entities are transitioning to the requirements of PRC-005-2, each entity must be prepared to identify:

- All of its applicable Protection System components.
- Whether each component has last been maintained according to PRC-005-2 or under PRC-005-~~1a~~1b, PRC-008-0, PRC-011-0, or PRC-017-0, or a combination thereof.

For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

The existing Standards PRC-005-~~1a~~1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter following applicable regulatory approval of PRC-005-2 in all jurisdictions.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Implementation Plan for Requirements R3 and R4:

1. For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
2. For Protection System component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
3. For Protection System component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

4. For Protection System component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5. For Protection System component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Applicability:

This standard applies to the following functional entities:

- Transmission Owner
- Generator Owner
- Distribution Provider

The new proposed definition of Protection System reads as follows:

Protection System:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply, and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

IEEE Stationary Battery Committee

NERC Task Force Report

Part of IEEE Power & Energy Society

March 23, 2012

At the most recent meeting of the IEEE Battery Standards Committee Meeting in January of this year concerns were registered over statements contained in the proposed NERC Document PRC-005-2 Protection System Maintenance.

As a result of these concerns, a special task force (herein referred to as ***the task force***) was formed to study the details of PRC-005-2 as it relates to stationary batteries. This task force is composed of a number of members who are recognized representatives of battery manufacturers, battery charger manufacturers, ohmic measurement and battery monitoring equipment manufacturers, battery testing companies and functional entities (nuclear, power generation and substation).

We recognize that the document is intended to address reliability issues for protection and control circuits for the Bulk Electric System [BES], but because of the integral role played by the stationary batteries, they have been included under the expanded scope of the DC power supply section.

If we understand the objective of the PRC document, it is to lay out a baseline standard that ensures that all components identified within the scope of the standard are capable of performing as expected in a worst case condition and verified by periodic maintenance that includes testing and/or measurements as defined for batteries in Tables 1-4(a) through 1-4(f).

A common thread is that the functional entity employing this Protection System Maintenance Program (PSMP) "verifies" that the functional components (in this case, the battery) "can perform as designed." This is confirmed by the wording at the end of the section describing maintenance activities for the VLA wet cell in Table 1-4(a), the VRLA "sealed" cell in Table 1-4(b) and the Nickel Cadmium cell in Table 1-4(c).

If we read the document correctly, there seems to be an implication that ohmic measurements can act as an alternative to capacity testing to determine that the battery will "perform as designed." It appears that support for this position is confirmed in the *Supplementary Reference and FAQ* where on pages 80 and 81 discussion is made with respect to "two acceptable methods for proving that a station lead acid battery can perform as designed."

Reference is made to EPRI technical reports and application guides and certain IEEE battery standards. The IEEE Battery Standard Committee Guidelines of 450 (VLA), 1188 (VRLA) and 1106 (Ni-Cd) are referenced specifically. The specific EPRI technical reports are not referenced in Section 15.4; however, one of the most widely referenced EPRI documents is 1002925 for “Stationary Battery Monitoring by Internal Ohmic Measurements.” It is the foundational basis for a paper given by Eddie Davis and Dan Funk of the Edan Engineering Corporation and Wayne Johnson of EPRI at the Battcon 2002 conference.

In the EPRI document under Section 13.4 on page 13-6 the conclusion is given: *“Internal ohmic measurements have the ability to identify degradation in individual cells. Although the internal ohmic measurements can identify low capacity cells (which is certainly valuable), the technology does not precisely predict overall battery capacity. Important backup power applications should still be confirmed by periodic battery capacity tests.”*

In the concluding remarks of the 2002 Battcon paper, the statement is fortified: *“This does not really imply a shortcoming of internal ohmic measurement technology, but it does mean that we will likely be limited to identifying good or bad cells rather than making claims that a certain internal resistance indicates a particular cell capacity.”*

In addition to the EPRI report and the Battcon paper there are several other papers that have been written on ohmic measurement testing. All draw the same conclusion. Several leading US and European battery manufacturers have weighed in on the subject through white papers and/or operating instructions. Four examples are given below:

> *“Ohmic measurements are not a substitute for capacity testing and should not be used to predict absolute capacity values”* – EnerSys white paper entitled “Ohmic Measurements as a Maintenance Tool for Lead Acid Stationary Cells.”

> *“In summary, internal ohmic testing can be a valuable tool to assist in diagnosing batteries, but it is important to understand what the measurement value represents and know the limitations. . . . . The only surefire way to tell the battery’s true health and whether or not the batteries will provide sufficient capacity to fully support the system load is through a measured capacity discharge test.”* – C&D Technologies white paper entitled *“Impedance (Conductance) Readings,” 2009.*

> *“Responsible ohmic device manufacturers acknowledge that there is no direct relationship between percent ohmic change from baseline and battery capacity”* – GNB Installation and Operating Instructions for ABSOLYTE GP Batteries, 2010.

Right now the current state of technology of ohmic testing has significant value in monitoring the trend of changes within individual cells or continuity in a battery string. But if performance or capacity has to be verified, the only true methodology at this point in time is a capacity or performance test." – Hoppecke in a paper entitled "Ohmic Measurements as a Tool for Determining Capacity of a Stationary Lead-Acid Battery," 2012.

In conclusion, ***the task force*** wishes to make the following points and recommendations:

1. ***The task force*** in no way wants to instruct the NERC PRC 005 Standard Drafting Team (SDT) on how it should write its standard. It would welcome the opportunity of assigning a representative from our membership to participate with the SDT going forward as it relates to appropriate battery testing and maintenance.

2. ***The task force*** recognizes that many functional entities are looking for a way to reduce costs through reduced manual maintenance and testing equipment related expenses. However, economic or risk-management decisions should be based upon just that, i.e. the economic or risk factors; and not justified by the use of unproven or misleading interpretation of data.

3. ***The task force*** believes strongly, and is supported by the vast majority of battery manufacturers and ohmic measurement testers, as well as from papers and the study of the closest correlation testing published to date, that ohmic measurement testing cannot serve as a substitute for capacity testing if the true reliability of the battery is to be measured against the statement that the battery "can perform as designed." Capacity testing is the only way to confirm that the battery will perform as designed.

4. Therefore, to ensure the highest reliability of a stationary battery system, load testing per IEEE guidelines is recommended. We appreciate that there are installations where the economics are such that load testing may not be a viable option. However, the functional entity must recognize that some level of reliability will be sacrificed if other analytical techniques such as ohmic testing are used in lieu of load testing.

5. It is the opinion of ***the task force*** that ohmic testing alone is not sufficient to achieve the required reliability of the BES.

6. We recommend that language to that effect be clearly established in the revised draft of PRC-005-2.

Respectfully,

Stationary Battery Committee

http://www.ewh.ieee.org/cmte/PES-SBC/

March 27, 2012

Dear Mr. McMeekin,

As chair of the IEEE Stationary Battery Committee, I was approached by several committee members concerning the battery testing and maintenance recommendations in the proposed NERC Document PRC-005-2. There was a consensus in the committee that the aforementioned recommendations did not reflect the best practices in the industry.

In the January Stationary Battery Committee meeting, a task force was formed and approved to review the NERC proposed recommendations. The report from this task force is attached to this letter.

Please note that this task force included some of the committee's most knowledgeable members, including present and past committee chairs, working group chairs, battery and ohmic measurement equipment manufacturers, and an EPRI battery expert who was a principal on the EPRI study regarding ohmic measurements and capacity, as well as many long-time contributors to our standards. The report represents the unanimous agreement of the Task Force.

We trust that this communication will receive the important consideration by you and the NERC SDT that we feel it deserves. We plan to have a few representatives attend your upcoming meeting in Ft. Worth in April. Please feel free to contact me in the meantime if I can provide any additional insight or assistance.

Sincerely,

William P. Cantor

William Cantor
Chair, Stationary Battery Committee

Bill Cantor
Chair of IEEE Station Battery Committee

Dear Mr. Cantor:

The NERC Protection System Maintenance and Testing Standard Drafting Team (PSMTSDT) for NERC Project 2007-17 (PRC-005-2) appreciates your remarks and the comments of the IEEE Stationary Battery Committee Task Force regarding its review of the battery maintenance activities described in the latest versions of PRC-005-2 and its supporting Supplementary Reference and FAQ document.

Your comments and those of the IEEE Task Force reflect the valid concerns of industry experts relative to language in the Supplementary Reference and FAQ document that, in their opinion, seems to imply that periodically reviewing and trending the results of inter cell/unit ohmic tests is equivalent to periodic performance of capacity tests. Based on this valuable feedback, the PSMTDT has modified the Supplementary Reference document to eliminate this misconception by stating that capacity testing is the only industry approved method of determining the true capacity of lead acid and nickel–cadmium station batteries. In the revised language, the Supplementary Reference further expresses that, while it has been stated in the EPRI reports (EPRI TR-108826 and 1002925) cited by the IEEE task force's report that there is a definite relationship between internal ohmic measurements and cell capacity of lead acid batteries, the PSMTSDT believes that an accurate determination of a battery's exact capacity cannot be attained by measuring its cell's internal ohmic values alone.

However, the PSMTSDT feels that both Maintenance Activities listed in tables 1-4(a) and 1-4(b) for lead acid batteries are appropriate for verifying "that the station battery can perform as designed." The PSMTSDT defines this as the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced.

In the mid 1990's, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

As noted by a major manufacturer of lead acid batteries that conducted aging tests on various, similar battery products, some of the trending of ohmic readings from testing conducted on some manufacturers batteries "clearly would have resulted in the rejection/replacement of cells well before the end of their useful life…" This battery manufacturer sums up the methodology most experienced users of periodic trending of ohmic measurements apply when determining that the station battery can perform as designed by saying, "users and manufacturers need to use judgment and experience to analyze the data, and then supplement the data with additional measurements – including capacity testing – when deciding whether to replace product in the field."

Since 2006, when NERC standard PRC-005-1 was adopted by the NERC Board of Trustees, those large and small utilities who put into practice the ohmic measurement condition based maintenance and testing programs for Protection System station batteries, have become NERC-registered Transmission Owners, Generation Owners and Distribution Providers subject to the requirements of PRC-005-1. This mandatory and enforceable standard requires those owners to have “a Protection System maintenance and testing program” that “shall include maintenance and testing intervals and their basis” along with “a summary of their maintenance and testing procedures.” Through the successful performance of ohmic trending that began in the mid 1990’s and over 6 years of applying this method in their maintenance programs required by PRC-005-1, the PSMSDT believes Protection System equipment owners have, effectively, established an acceptable maintenance practice (supported by EPRI technical references) and maximum maintenance interval, for verifying that a station battery can perform as designed.

Historically, Transmission Owners, Generator Owners, and Distribution Providers have not considered the insignificant power requirements of their Protection Systems (several hundred amperes for duration of less than 0.5 seconds and for not more than 10 amperes of continuous protective relay load when the station battery charger is out of service) when sizing batteries used for station dc supply. Instead, these entities have sized their station batteries for other significantly larger dc loads and duty cycles such as those for inverters, heaters, telecommunication equipment, emergency lighting, load profile of emergency bearing oil and seal oil pumps etc. Considering this factor, it would take a loss of battery capacity of well below 50% (which can be easily detected by ohmic trending) for a battery emergency to significantly affect the functioning of Protection System equipment powered from the station battery.

If the primary purpose of the station battery is to provide the instantaneous stored energy of several hundred amperes for extremely short durations (close to the short circuit duration for a station battery) and provide the minimal protective relay power supply load of not greater than 10 amperes whenever the dc station charger is out of service (which is the case for many Transmission Owners), then the minimum activity of evaluating the measured cell/unit internal ohmic values to station battery baseline to verify that the station battery can perform as designed will achieve the reliability purpose of PRC-005-2 and satisfy the risk-management requirements of the Protection System owner.

In contrast to the Transmission Owner battery design function, a Generator Owner's battery likely feeds other critical loads such as DC powered oil pumps, seal oil pumps, and other DC control power loads necessary to safely shutdown a power plant following a loss of AC power. In the case of nuclear plants, these DC loads could include motor operated valves and other loads related to nuclear safety. For the Generator Owner, the design load profile for the battery is a long duration, deep discharge of the battery. While a cell ohmic value trending program might be adequate to prove that the Generator Owners battery could fulfill its Protection System function, the Generator Owner might want to validate the deep discharge capability of the battery by routine periodic capacity testing to prove the battery's adequacy at providing power to those long duration loads critical for plant shutdown. The PSMTSDT believes that this deep discharge battery capacity test approach will prove the battery can meet its function relative to the plant Protection System without also having a trending program for cell ohmic values.

It is the intent of the PSMTSDT to provide Transmission Owners, Generator Owners, and Distribution Providers flexibility to employ testing methods already utilized in their program, and as appropriate for their facility type, in order to prove their battery's "ability to function as designed." The PSMTSDT agrees with the task force suggestion that entities should implement this flexibility with due consideration of the economic or risk-management decisions associated with choosing which minimum maintenance activity is appropriate for battery systems at their facilities. However, the PSMTSDT also believes entities can achieve the reliability purpose of PRC-005-2 (“to document and implement programs for the maintenance of all Protection Systems affecting the reliability of the BES so that these Protection Systems are kept in working order.”) and thereby enhance the reliability of the BES, by using an ohmic value trending program, as described in Tables 1-4(a) and 1-4(b) of the standard, to provide an adequate indicator of battery health.

Again, the PSMTSDT is grateful to the IEEE Stationary Battery Committee’s task force for its review of the draft of the NERC standard PRC-005-2 and the accompanying draft Supplementary Reference and FAQ document. The insights of the task force’s experts have assisted the Drafting Team in revising statements in the Supplementary Reference. Furthermore, please accept the team’s apology for our oversight of leaving the IEEE Stationary Battery Committee off the list of references in our supplemental document. Our goal is to have the proper references attributed within the document that will go to the NERC Board of Trustees for approval.

Please bear in mind that PSMTSDT meetings, as all NERC Drafting Team meetings, are posted on the NERC web site and are always open to guests and observers. The PSMTSDT solicits the active participation of its guests in its meetings. In fact, significant contributions to the development of PRC-005-2 have been made by those who have attended the Drafting Team meetings as guests and observers. In that regard, should you or someone from your membership be interested in coming to any of the PSMTSDT meetings, we would welcome your attendance and participation.

Sincerely

Charles Rogers

Standard Authorization Request Form

Request Date	May 10, 2012

SAR Requester Information	**SAR Type** (*Check a box for each one that applies.*)	
Individual, Group, or Committee Name Protection System Maintenance Standard Drafting Team	☐	New Standard
Primary Contact (if Group or Committee) Charles Rogers	☒	Revision to existing Standard PRC-005-2 – Protection System Maintenance
Company or Group Name Chairman, Protection System Maintenance Standard Drafting Team	☐	Withdrawal of existing Standard
E-mail Charles.Rogers@cmsenergy.com	☐	Project Identified in Reliability Standards Development Plan Project Number and Name: Project 2007-17 Protection System Maintenance and Testing
Telephone 517-788-0027	☒	Modification to NERC Glossary term or addition of new term Protection System

Brief Description of Proposed Standard Modifications/Actions (In three sentences or less, summarize the proposed actions a drafting team will be responsible for implementing.) The Standard Drafting Team shall modify NERC Standard PRC-005-2 to add reclosing relays to the standard. In order to do so, the definition of Protection System shall be revised to include reclosing relays, the Facilities portion of the Applicability of the Standard shall be revised to describe those reclosing relays that are included within the standard, and appropriate minimum maintenance intervals (with maximum allowable intervals) shall be added to the standard. The Standard Drafting Team shall also make any other changes that are necessary to explicitly address reclosing relays, but shall not make general revisions to the standard, either in content or arrangement.
Need (Explain why the Standard is being developed or modified. Clearly indicate why the actions being proposed are needed for maintaining or improving bulk power system reliability, including an assessment of the reliability and market interface impacts. This is similar to the Purpose statement in a Reliability Standard.) Reclosing relays are applied to facilitate automatic restoration of system components following a power system fault. While reclosing relays are often applied to benefit customer service, they are also applied to benefit reliability of the Bulk Electric System. The Federal Energy Regulatory Commission, in paragraphs 16-27 of Order No. 758, directed that NERC include reclosing relays that “can affect the reliable operation of the Bulk-Power System” within NERC Standard PRC-005. Modifying the standard in this fashion will impact Bulk Electric System (BES) reliability by assuring that the reclosing relays that are installed to meet performance goals of approved NERC Standards, as well as those whose improper operation would adversely affect BES reliability, are properly maintained so that they may be expected to perform properly. No market interface impacts are anticipated.
Goals (Describe what must be accomplished in order to meet the above need. This section would become the Requirements in a Reliability Standard.) The revision to PRC-005-2 will require that the definition of Protection System be revised to add reclosing relays to the components of this definition. The Facilities portion of the Applicability of the Standard must be modified to describe explicitly those reclosing relays that entities are to maintain in accordance with the revised standard. The Tables of minimum maintenance activities and maximum maintenance intervals will require modification to include intervals and activities appropriate for reclosing relays. Finally, the informative Supplementary Reference Document (provided as a technical reference for PRC-005-2) should be modified to provide the rationale for the maintenance activities and intervals within the modified standard, as well as to provide application guidance to industry.
Objectives and/or Potential Future Metrics (Describe what the potential measure or criteria for success may be for determining the successful implementation of this request. Provide ideas for potential metrics to be developed and monitored in the future relative to this request, if any.) Successful implementation of the modified standard will assure that reclosing relays, when installed to meet performance requirements of other approved NERC standard, will perform as needed for the conditions anticipated by those performance requirements, and that reclosing relays will not mal-perform in a fashion that would cause adverse BES impacts. Future performance metrics could address successful automatic system restoration as anticipated by approved NERC standards, and also address improper attempted automatic system restoration that adversely impacts the BES.

Detailed Description (In three paragraphs or more, provide a detailed description of the proposed actions a drafting team will be responsible for executing so that the team can efficiently implement this request. While you will check applicability boxes on the following page, this description must include proportional identification of to whom the standard should apply among industry participants.) The drafting team shall: 1. Modify the definition of Protection System to add reclosing relays. 2. Modify the Facilities portion of the Applicability of PRC-005-2 to describe explicitly those reclosing relays that entities are to maintain in accordance with the revised standard. 3. Modify the Tables within PRC-005-2 to include intervals and activities appropriate for reclosing relays, with consideration for the technology of the reclosing relays and for any condition monitoring that may be in place on the relays 4. Modify Table 1-5 of PRC-005-2 to include the control circuitry associated with reclosing relays being addressed. 5. Modify the Measures and Violation Severity Levels as necessary to address the modified requirements. 6. Modify the informative Supplementary Reference Document (provided as a technical reference for PRC-005-2) to provide the rationale for the maintenance activities and intervals within the modified standard, as well as to provide application guidance to industry
OPTIONAL: Technical Analysis Performed to Support Justification (Provide the results of any technical study or analysis performed to justify this request. Alternatively, if deemed necessary, propose a technical study or analysis that should be performed prior to a related standard development project being initiated in response to this request.) No technical analysis has been performed, nor is any being proposed.

Reliability Functions

The Standard(s) May Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Regional Entity	Conducts the regional activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the Bulk Electric System within the region and adjacent regions.
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource	Develops a >one year plan for the resource adequacy of its

	Planner	specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☒	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard(s) comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A reliability standard shall not give any market participant an unfair competitive advantage. Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure. Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard. Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

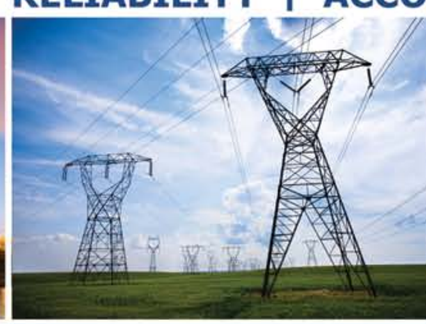
PRC-005-2 Protection System Maintenance

May, 2012

RELIABILITY | ACCOUNTABILITY



3353 Peachtree Road NE
Suite 600, North Tower
Atlanta, GA 30326
404-446-2560 | www.nerc.com

Table of Contents

1. Introduction and Summary

Note: This supplementary reference for PRC-005-2 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control Systems.

These standards are:

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a Fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking Faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A Misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide-area Disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System Components, such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries, which are an important part of the station dc supply, are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear Faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications Systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications Systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"...*affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the Element is a BES Element, then the Protection System protecting that Element should then be included within this standard. If there is regional variation to the definition, then there will be a corresponding regional variation to the Protection Systems that fall under this standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the standard language should simply be applicable to Protection Systems for BES Elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC Glossary of Terms for the present, in-force definition. See the applicable Regional Reliability Organization for any applicable allowed variations.

While this standard will undergo revisions in the future, this standard will not attempt to keep up with revisions to the NERC definition of BES, but, rather, simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GOs and TOs have equipment that is BES equipment. The standard brings in Distribution Providers (DP) because, depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution

Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is Underfrequency Load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example, the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as stipulated in any requirement in this standard.

Additionally, since this standard will now replace PRC-011, it will be important to make the distinction between under-voltage Protection Systems that protect individual Loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load-Shedding scheme that is not applicable to this standard is one in which the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission System that was intact except for the line that was out of service, as opposed to preventing a Cascading outage or Transmission System collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus, a standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems, and replace some other standards at the same time.

2.3.1 Frequently Asked Questions:

What exactly is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, Interconnections with neighboring Systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only Load with one transmission source are generally not included in this definition.

The BES definition is presently undergoing the process of revision.

Each regional entity implements a definition of the Bulk Electric System that is based on this NERC definition; in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is Underfrequency Load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load-Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation, as stated, indicates that the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission System that was intact, except for the line that was out of service, as opposed to preventing Cascading outage or Transmission System collapse.

This standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary Load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

We have a UFLS scheme that, in some locales, sheds the necessary Load through non-BES circuit breakers and, occasionally, even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements, and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as, for example, a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE Device No. 86 (lockout relay) and IEEE Device No. 94 (tripping or trip-free relay), as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage-sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. This standard covers protective relays that use electrical quantity measurements to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close, as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC standards. There is one notable exception: Since PRC-017 will be superseded by PRC-005-2, then if a Special Protection System (previously covered by PRC-017) incorporates automatic closing of breakers, then the SPS-related closing devices must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.). Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the Device No.# 94 to auxiliary tripping relays. Sudden pressure relays are assigned Device No.# 63. Sudden pressure relays are presently excluded from the standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing Element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing Elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1a, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of any trip circuit that is a part of a Protection System. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not presently cover testing of devices, such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters, rather than electrical parameters. There is an expectation that Fault pressure relays and other non-electrically initiated devices may become part of some maintenance standard. This standard presently covers trip paths. It might seem incongruous to test a trip path without a present requirement to test the device; and, thus, be arguably more work for nothing. But one simple test to verify the integrity of such a trip path could be (but is not limited to) a voltage presence test, as a dc voltage monitor might do if it were installed monitoring that same circuit.

The standard specifically mentions auxiliary and lock-out relays. What is an auxiliary tripping relay?

An auxiliary relay, IEEE Device No.# 94, is described in IEEE Standard C37.2-2008 as: "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device No.# 86, is described in IEEE Standard C37.2 as: "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System both depends on the technological generation of the relays, as well as how long they have been in service. Unlike many other transmission asset groups, protection and control Systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices, such as primary measuring relays, monitoring devices, control Systems, and telecommunications equipment.

Modern microprocessor-based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs, such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every Element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture Fault records showing how the Protection System responded to a Fault in its zone of protection, or to a nearby Fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-Fault times. The relays can compute values, such as MW and MVAR line flows, that are sometimes used for operational purposes, such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages, or from relay front panel button requests.
- Construction from electronic components, some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other Components of Protection Systems. Microprocessors are now a part of battery chargers, associated communications equipment, voltage and current-measuring devices, and even the control circuitry (in the form of software-latches replacing lock-out relays, etc.).

Any Protection System Component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all Components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a “lock-out.” Thus, the software-latch 86 that replaces an electro-

mechanical 86 does not require routine trip testing. Any trip circuitry associated with the "soft 86" would still need applicable verification activities performed, but the actual "86" does not have to be "electrically operated" or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System Components are kept in working order and proper operation of malfunctioning Components is restored. A maintenance program for a specific Component includes one or more of the following activities:

- Verify — Determine that the Component is functioning correctly.
- Monitor — Observe the routine in-service operation of the Component.
- Test — Apply signals to a Component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of Component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures, as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the Tables 1-1 through 1-5, Table 2 and Table 3 (collectively the "Tables"), and the various Components of the definition established for a "Protection System Maintenance Program," PRC-005-2 establishes the activities and time basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by "restore" in the definition of maintenance.

The description of "restore" in the definition of a Protection System Maintenance Program addresses corrective activities necessary to assure that the Component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the standard does require that the entity "shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." Some examples of restoration (or correction of Unresolved Maintenance Issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System Components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to microprocessor-based relays following the discovery of failed Components. Restoration, as used in this context, is not to be confused with restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices, and keeps them in working order. If an equipment item is repaired or replaced, then the entity can restart the maintenance-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

Please clarify what is meant by "…demonstrate efforts to correct an Unresolved Maintenance Issue…"; why not measure the completion of the corrective action?

Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requiring battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System Components. However, some Components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System Components can have the ability to remotely conduct tests, either on-command or routinely; the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for Components or groups of Components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme Components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those Components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar Components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of Components demonstrate operational status as those Components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the standard itself, it is important to note that the concepts of CBM are a part of the standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the standard, the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

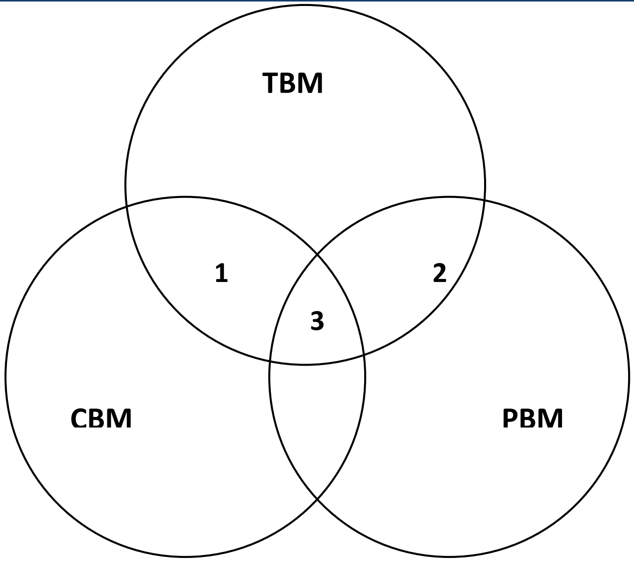
Microprocessor-based Protection System Components that perform continuous self-monitoring verify correct operation of most Components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal Components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours, or even milliseconds between non-disruptive self-monitoring checks within or around Components as they remain in service.

TBM, PBM, and CBM can be combined for individual Components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram, the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual Components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



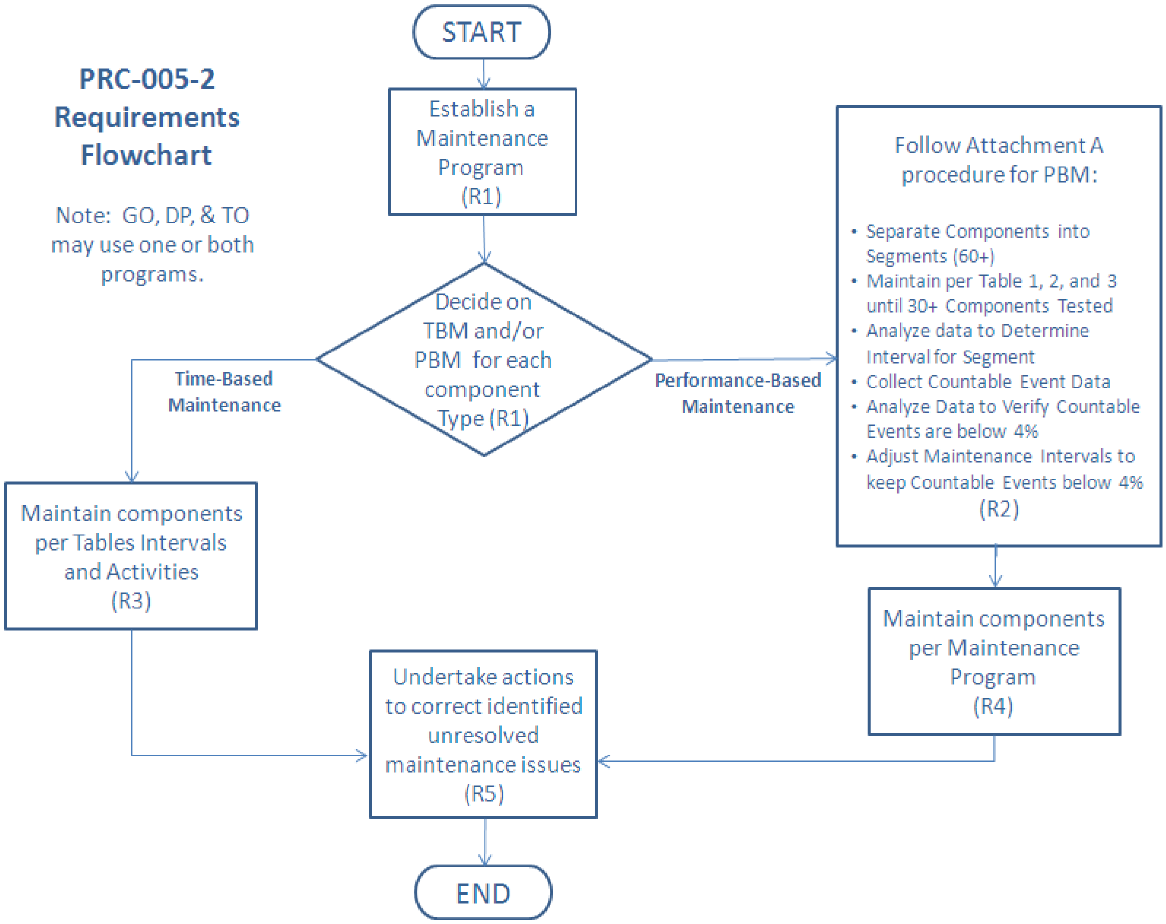
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2), in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System Components and its available lengthened time intervals, then it may, as long as the Component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System Components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of Components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each Component must be maintained per the most frequent hands-on activities listed in the Tables.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each Component of the Protection System, when data on the reliability of the Components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a Component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the Components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every Component within a microprocessor.

- Previous maintenance history for a group of Components of a common type may indicate that the maintenance intervals can be extended, while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance, or PBM. It is also sometimes referred to as reliability-centered maintenance, or RCM; but PBM is used in this document.
- Observed proper operation of a Component may be regarded as a maintenance verification of the respective Component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a Fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the Component or system. It is not unusual to cause failure of a Component by removing it from service and restoring it. The improper application of test signals may cause failure of a Component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the Component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Questions:

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System Elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for Faults and Disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of Fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. **Non-invasive Maintenance:** The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. **Virtually Continuous Monitoring:** CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

To use the extended time intervals available through Condition Based Maintenance, simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of Components into the appropriate levels of monitoring, as per Requirement R1 (Part 1.4) of the standard, is it necessary to provide this documentation about the device by listing of every Component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a Component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device-level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements, as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of Component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure, but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule, dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained Component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system Components.

The result is that:

This NERC standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of Components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a “One Calendar Year Interval,” the next event would have to occur on or before December 31, 2010.

Please provide an example of “4 Calendar Months”.

If a maintenance activity is described as being needed every four Calendar Months then it is performed in a (given) month and due again four months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a four-month inspection was performed in January is due in May, but if performed in March (instead of May)

would still be due four months later therefore the activity is due again July. Basically every "four Calendar Months" means to add four months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System Components. A Protection System Component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored Component of a Protection System has monitoring and alarm circuits on the Protection System Components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but is not limited to, an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored Components within any given Protection System.

Example #1: A combination of monitored and unmonitored Components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, and the trip circuit is not monitored. (unmonitored)

Given the particular Components and conditions, and using Table 1 and Table 2, the particular Components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power System input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System Component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored Control Circuitry Associated with Protective Functions" section'
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #2: A combination of monitored and unmonitored Components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular Components and conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular Components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System Component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions" section
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #3: A combination of monitored and unmonitored Components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)

- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular Components, conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular Components shall have maximum activity intervals of:

Every four calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions section

- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked

Why do Components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System Components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all Components in a Protection System be monitored?

No. For some Components in a Protection System, monitoring will not be relevant. For example, a battery will always need some kind of inspection.

We have a 30-year-old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the Components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years, or when an Unresolved Maintenance Issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every six years.

8. Maximum Allowable Verification Intervals

The maximum allowable testing intervals and maintenance activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System Components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no Fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual Components are still operating within acceptable performance parameters - this type of test is needed for Components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying Fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2 and Table 3 in the standard specify maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of Components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various sub-Systems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions; and, therefore, have the same maintenance needs.

Distributed UFLS and UVLS Systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the Components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your Component. The tables are arranged in the order of mention in the definition of Protection System;

- Table 1-1 is for protective relays,
- Table 1-2 is for the associated communications Systems,
- Table 1-3 is for current and voltage sensing devices,
- Table 1-4 is for station dc supply and
- Table 1-5 is for control circuits.
- Table 2, is for alarms; this was broken out to simplify the other tables.
- Table 3 is for Components which make-up distributed UFLS and UVLS Systems.

- Next look within that table for your device and its degree of monitoring. The Tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance-Based Maintenance (PBM) plan requires <u>more activities,</u> then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the maximum maintenance interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this Component.
- If your Performance-Based Maintenance plan requires activities <u>more often</u> than the Tables maximum, then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given Component of a Protection System can be determined to have a degree of monitoring that may be different from another Component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every four months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the five Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System Component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the

minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. If an entity has a Performance-Based Maintenance program, then that plan must be followed, even if the plan proves to be more stringent than the minimums laid out in the Tables.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a Component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System Components, physical inspection of station batteries for signs of Component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS Systems, and large entities will usually maintain a portion of these Systems in any given year. Additionally, if relatively small quantities of such Systems do not perform properly, it will not affect the integrity of the overall program. Thus, these distributed Systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected (phase value and phase relationships are both equally important to verify).

7. "End-to-end test," as used in this Supplementary Reference, is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test, it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc control circuitry. A documented Real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a Real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities, but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology- and method-neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor- based relays. For relay maintenance departments that choose to test microprocessor-based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled, but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the standard states "…settings are as specified."

Many of the microprocessor- based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement, a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the Component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection; and, thus, the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable, as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system Disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known Fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?

As in all of the Protection System requirements, SPS segments can be tested individually, thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a Component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?

Since Components of the SPS, UFLS and UVLS are the same types of Components as those in Protection Systems, then these Components should be maintained like similar Components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the

exception that distributed Systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example, an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the Real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance, as required, due to a major natural disaster (hurricane, earthquake, etc.), how will this affect my compliance with this standard?

The Sanction Guidelines of the North American Electric Reliability Corporation, effective January 15, 2008, provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays; or, even worse, I am experiencing numerous relay Misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But any entity can choose to test some or all of their Protection System Components more frequently (or to express it differently, exceed the minimum requirements of the standard). Particularly if you find that the maximum intervals in the standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one’s best interest.

We believe that the four-month interval between inspections is unneccessary. Why can we not perform these inspections twice per year?

The Standard Drafting Team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections, the four-month interval was chosen. In lieu of station visits, many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years. If we are unable to achieve this schedule, but we are able to complete the procedures in less than the maximum time interval ,then are we in or out of compliance?

According to R3, if you have a time-based maintenance program, then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables.

According to R4, if your device in question is part of a Performance-Based Maintenance program, then you will be in violation of the standard if you fail to meet your PSMP, even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in the Tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or Systems that must be verified in a generator, generator step-up transformer, generator connected station service or generator connected excitation transformer to meet the requirements of this maintenance standard.

Examples of typical devices and Systems that may directly trip the generator, or trip through a lockout relay, may include, but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip Systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step-up, generator-connected station service transformers, or generator connected excitation transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit; and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary Loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program, even if the loss of the those Loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program, even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the Protection Systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating Facility?

The SDT does not intend that the system-connected station service transformers be included in the Applicability. The generator-connected station service transformers and generator connected excitation transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping," one needs to realize that sometimes there are more inputs and outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every six years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent Load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and Load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three-year retention cycle, the records of verification for a Protection

System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System Components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electromechanical protective relays be tested every three calendar years, with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus, its test records would have a latest routine test, as well as its previous routine test. The interval between tests is, therefore, provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements, while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance-Based Maintenance, then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced, then the entity can restart the maintenance-time-interval-clock if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a Facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-Fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation, and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of Components, such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content; and, therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System Component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the Components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing, as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates, then the testing date should be followed because it is the degradation of Components that is the concern. While accuracy fluctuations may decrease when Components are not energized, there are cases when degradation can take place, even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System Components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its 100 Protection System Components, which would equate to two percent for application to the VSL Table for Requirement R3. This VSL is written to compare missed Components to total Components. In this case two Components out of 100 were missed, or two percent.

How do I achieve a "grace period" without being out of compliance?

The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of six calendar years. Your plan must ensure that your unmonitored relays are tested at least once every six calendar years. You could, within your PSMP, require that your unmonitored relays be tested every four calendar years, with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders, but still has the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of four years; it also has a built-in time extension allowed within the PSMP, and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System Components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. T he survey represented 470 GW of peak Load, or four percent of the NERC peak Load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak Load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of five years for electromechanical or solid state relays, and seven years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond seven years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1], as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1, only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay, as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system Element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a Fault occurs, leading to failure to operate for the Fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal Fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup Fault clearing time of 50 cycles)

Rc, Protected Component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for relay unavailability and abnormal unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay mean time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally, it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods." To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension, while still following FERC Order 693, the Standard Drafting Team arrived at a six-year interval for the electromechanical relay, instead of the five-year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10-year interval was chosen, even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any Component of the Protection System; thus, the maximum allowed interval for these Components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval." The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year number one need not be revisited until six years later (year number seven). For example, a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity’s use of terms like annual, calendar year, etc. Then, once this is within the PSMP, the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals, other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major System outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality Systems (such as ***ISO 9001-2000, Quality management Systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program, the asset owner must first sort the various Protection System Components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM, but does not own 60 units to comprise a population, then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or Components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment, and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries, but can be applied to all other Components of a Protection System, including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003.)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005.)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968.)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of Components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason, the following assumptions are made:

B = five percent

z = 1.96 (This equates to a ninety-five percent confidence level)

π = four percent

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of Components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = five percent

z = 1.44 (eighty-five percent confidence level)

π = four percent

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined, then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of Components tested (or the last 30 units maintained, whichever is more) had fewer than four percent Countable Events. It is notable that four percent is specifically chosen because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one Countable Event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is five percent of the population. Note that this five percent threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of Countable Events equals or exceeds four percent of the last year's tested Components (or the last 30 units maintained, whichever is more), then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the Countable Events is less than four percent; this must be attained within three years.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System Components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System Components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No, you must use actual in-service test data for the Components in the segment.

What types of Misoperations or events are not considered Countable Events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable Events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the Component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered Countable Events. Examples of excluded human errors include relay setting errors, design

errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System Components. Examples of misapplication of Protection System Components include wrong CT or PT tap position, protective relay function misapplication, and Components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES Element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused Misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the four percent tolerance level).

Certain types of Protection System Component errors that cause Misoperations are not considered Countable Events. Examples of excluded Component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of Components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other Components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a Unresolved Maintenance Issue as a result of a Misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System Component for any reason (including as part of a PRC-004 required Misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, “reset the clock” on everything you’ve done. In a Performance-Based Maintenance program, you also need to record the Unresolved Maintenance Issue as a Countable Event within the relevant Component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that Component group. Note that “resetting the clock” should not be construed as interfering with an entity’s routine testing schedule because the “clock-reset” would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of four relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a Misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that “replaced relay” will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of four years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only Element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System Element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system Disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the Components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate. This entity is now allowed to extend the maintenance interval if they choose. The entity chooses to extend the maintenance interval of this population segment out to 10 years. This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year. After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures. This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than four percent per year; the entity has three years to get this failure rate down to four percent or less (per year). In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year, they again find six failures out of the 125 units tested. 6/125= five percent failures. In response to the five percent failure rate, the entity decreases the testing interval to seven years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected. After a year, they again find six failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried five years and they were under the four percent limit and they tried seven years and they were over the four percent limit. They must be back at four percent failures or less in the next year so they might simply elect to go back to five years.)

Instead, in response to the five percent failure rate, the entity decreases the testing interval to six years. This means that they will now test 167 units per year (1000/6). After a year, they again find six failures out of the 167 units tested. 6/167= 3.6% failures. Entity found that they could maintain the failure rate at no more than four percent failures by maintaining the testing interval at six years or less. Entity chose six-year interval and effectively extended their TBM (five years) program by 20 percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than two percent. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "five percent of Components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific Element. Under the included definition of "Component":

The designation of what constitutes a control circuit Component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common Elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual Components.*

Example:

Entity has 1,000 circuit breakers, all of which have two trip coils, for a total of 2,000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard, then this is greater than the minimum sample requirement of 60.

For the sake of further example, the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring, and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago, the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their control circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device

that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the operations control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2,000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored; therefore, the trip paths are continuously tested and the circuit will alarm when there is a failure. These alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification, and is taking care of this activity through other documentation of Real-time Fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12-year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= three percent failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= six percent failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than four percent per year; the entity has three years to get this failure rate down to four percent or less (per year).

In response to the six percent failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >four percent failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the four percent limit; and they tried 14 years, and they were over the four percent limit. They must be back at four percent failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than four percent failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval, and effectively extended their TBM (10 years) program by 20 percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than two percent. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "five percent of Components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures “voltage and current inputs to the protective relays” as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a “Relay Scheme.” Thus, this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT’s or specific PT’s. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages, whereas a transmission maintenance group might create a process that utilizes Real-time system values measured at the relays. Under the included definition of “Component”:

The designation of what constitutes a control circuit Component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common Elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual Components.*

Example:

Entity has 2000 “Relay Schemes,” all of which have three current signals supplied from bushing CTs, and three voltage signals supplied from substation bus PT’s. All cabling and circuitry was designed and built with a consistent (internal entity) standard, and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1,000) are supplied with current signals from ANSI STD C800 bushing CTs and voltage signals from PTs built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards, and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity’s relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs), as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their “Voltage and Current Sensing” population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity’s population.

The entity is tracking many thousands of voltage and current signals within 2,000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored; therefore, the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay, all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PTs). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level; thus, any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show thre failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= three percent failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= six percent failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than four percent per year; the entity has three years to get this failure rate down to four percent or less (per year).

In response to the six percent failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >four percent failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the four percent limit; and they tried 14 years, and they were over the four percent limit. They must be back at four percent failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1,000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than four percent failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval and effectively extended their TBM (10 years) program by 20 percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than two percent. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of Components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System Component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment, as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above, or Attachment A of the standard;
- Opportunistic verification using analysis of Fault records, as described in Section 11

10.1 Frequently Asked Questions:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the Unresolved Maintenance Issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve Fault event records and oscillographic records by data communications after a Fault. They analyze the data closely if there has been an apparent Misoperation, as NERC standards require. Some advanced users have commissioned automatic Fault record processing Systems that gather and archive the data. They search for evidence of Component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured Digital Fault Recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of Faults in the vicinity of the relay that produce relay response records and the specific data captured.

A typical Fault record will verify particular parts of certain Protection Systems in the vicinity of the Fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external Fault records that completely verify the Protection System.

For example, Fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that Fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a Fault just outside their respective zones of protection. The ensemble of internal Fault and nearby external Fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified Components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using Fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple Faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various Components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If Fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the Fault records used, and the maintenance-related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Questions:

I use my protective relays for Fault and Disturbance recording, collecting oscillographic records and event records via communications for Fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as Disturbance Monitoring Equipment, NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements and is being addressed by a standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring Element settings. Analysis of Fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them; for background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple: With legacy relays (non-microprocessor protective relays), it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays, it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process, there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade, then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its

regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays, then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced, then the entity can restart the maintenance-activity-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan, and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment, then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System Components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards, then the requirements of PRC-005-2 are simple – if the Protection System Component performs a Protection System function, then it must be maintained. If the Component no longer performs Protection System functions, then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a Component that is no longer needed, there is no requirement in PRC-005-2 to remove such Component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System Components not used.

While performing relay testing of a protective device on our Bulk Electric System, it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement, even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement, although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states:

"R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified Unresolved Maintenance Issues."

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC standards.

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues..." The type of corrective activity is not stated; however, it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed Systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring, the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring Components in the Protection System should publish for the user a document or map that shows:

- How all internal Elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every Component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an Unresolved Maintenance Issue, so that failures of monitoring or alarming Systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored Components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Questions:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular Component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring, the standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator’s decisions on acceptable Loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a Component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance, but if its battery maintenance program is lacking, then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific Components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore, *manual intervention* to perform certain activities on these type Components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a Faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas, or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor-based equipment in the following ways; the relays should meet the asset owners' tolerances:

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Questions:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System Components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the Component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these Components. The important thing about these signals is to know that the expected output from these Components actually reaches the

protective relay. Therefore, the proof of the proper operation of these Components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device, all the way to the protective relay. The following observations apply:

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; including, but not limited to, the following: By calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this, therefore, tests the CT, as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during Load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the Real-time Loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay, then the verification activity has been satisfied. Thus, event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars, thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current-sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current-sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds.
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay) to another protective relay monitoring the same line, with currents supplied by different CTs.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc.) and verified by calculations and known ratios to be the values expected. For example, a single PT on a 100KV bus will have a specific secondary value that, when multiplied by the PT ratio, arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual Components are functioning properly; and that an ongoing proactive procedure is in place to re-check the various Components of the protective relay measuring Systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay

and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions, as do microprocessor- based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment, like voltmeters and clamp on ammeters, to measure the input signals to the relays. This practice seems very risky, and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays, but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests, such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This Component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path, then the manual-intervention testing of those parallel trip paths can be eliminated; however, the actual operation of the circuit breaker must still occur at least once every six years. This six-year tripping requirement can be completed as easily as tracking the Real-time Fault-clearing operations on the circuit breaker, or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment, and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device, if this ground switch is utilized in a Protection System and forces a ground Fault to occur that then results in an expected Protection System operation to clear the forced ground Fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System Component. The control circuitry would have to be tested within 12 years, and any electromechanically operated device will have to be tested every six years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit, then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type Components, then they must be trip tested. The PSMT SDT considers these Components to share some similarities in failure modes as electromechanical protective relays; as such, there is a six-year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

While relays that do not respond to electrical quantities are presently excluded from this standard, their control circuits are included if the relay is installed to detect Faults on BES Elements. Thus, the control circuit of a BES transformer sudden pressure relay should be verified every 12 years, assuming its integrity is not monitored. While a sudden pressure relay control circuit is included within the scope of PRC-005-2, other alarming relay control circuits, (i.e., SF-6 low gas) are not included, even though they may trip the breaker being monitored.

New technology is also accommodated here; there are some tripping Systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these Systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control Systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual Component's maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as Fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection Component, have to be tested per Table 1.5? (Refer to Table 3)

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection Component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

The NERC definition of a Protection System is:

- Protective relays which respond to electrical quantities,
- Communications Systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The station battery is not the only Component that provides dc power to a Protection System. In the new definition for Protection System, "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery Systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply, as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers, as well as dc Systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two Components: the battery charger and the station battery itself. There are also emerging

technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc Load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies besides the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new, the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity (no open circuits) of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity – lack of an open circuit. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal (no open circuit). Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path, the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc Loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor-based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these

harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, in most battery chargers, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional one- to two-second delay to switch from a low substation dc Load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed, which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery, unless the battery charger is taken out of service. At that time, a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the standard prescribes what must be accomplished during the maintenance activity, it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged, there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- Manufacturers of microprocessor-controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc Load can be measured to confirm continuity.
- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of lead-acid batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string; and when used in conjunction with resistance measurements of the battery's external connections, can prove continuity. Also some methods of taking internal ohmic measurements, by their very nature, can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific gravity tests can infer continuity because, without continuity, there could be no charging occurring; and if there is no charging, then specific gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified, it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as manufactured?

The answer to this question depends on the type of battery (valve-regulated lead-acid, vented lead-acid, or nickel-cadmium) and the maintenance activity chosen.

For example, if you have a valve-regulated lead-acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the six-month interval is important for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is incapable of performing as manufactured.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every three calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead-acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station battery's ability to perform as manufactured, they should be made at some point in time after the installation to allow the cell chemistry to stabilize after the initial freshening charge. An accepted industry practice for establishing baseline values is after six-months of installation, with the battery fully charged and in service. However, it is recommended that each owner, when establishing a baseline, should consult the battery manufacturer for specific instructions on establishing an ohmic baseline for their product, if available.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment, even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of valve-regulated lead-acid (VRLA) batteries and vented lead-acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as manufactured, the establishment of the baseline, as described above, should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries, the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also, several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However, it is important that when using battery manufacturer-supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Although many manufacturers may have provided baseline values, which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For vented lead-acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges, the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This, in turn, reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can, therefore, be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely, if taken shortly after adding water to the cell, the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and valve-regulated lead-acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity

readings. For these two types of batteries, and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully-charged condition, which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery, a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings, or a combination of the two. There are test methods presently that can read post termination resistances and resistance values between external posts. There are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show if the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen, not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other Component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections, such as the bus bar connection to each plate, and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell, or cells, must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery, nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why is it necessary to verify the battery string can perform as manufactured? I only care that the battery can trip the breaker, which means that the battery can perform as designed. I oversize my batteries so that even if the battery cannot perform as manufactured, it can still trip my breakers.

The fundamental answer to this question revolves around the concept of battery performance "as designed" vs. battery performance "as manufactured." The purpose of the various sections of Table 1-4 of this standard is to establish requirements for the Protection System owner to maintain the batteries, to ensure they will operate the equipment when there is an incident that requires dc power, and ensure the batteries will continue to provide adequate service until at least the next maintenance interval. To meet these goals, the correct battery has to be properly selected to meet the design parameters, and the battery has to deliver the power it was manufactured to provide.

When testing batteries, it may be difficult to determine the original design (i.e., Load profile) of the dc system. This standard is not intended as a design document, and requirements relating to design are, therefore, not included.

Where the dc load profile is known, the best way to determine if the system will operate as designed is to conduct a service test on the battery. However, a service test alone might not fully determine if the battery is healthy. A battery with 50 percent capacity may be able to pass a service test, but the battery would be in a serious state of deterioration and could fail at some point in the near future.

To ensure that the battery will meet the required Load profile and continue to meet the Load profile until the next maintenance interval, the installed battery must be sized correctly (i.e., a correct design), and it must be in a good state of health. Since the design of the dc system is not within the scope of the standard, the only consistent and reliable method to ensure that the battery is in a good state of health is to confirm that it can perform as manufactured. If the battery can perform as manufactured and it has been designed properly, the system should operate properly until the next maintenance interval.

How do I verify the battery string can perform as manufactured?

Optimally, actual battery performance should be verified against the manufacturer's rating curves. The best practice for evaluating battery performance is via a performance test. However, due to both logistical and system reliability concerns, some Protection System owners prefer other methods to determine if a battery can perform as manufactured. There are several battery parameters that can be evaluated to determine if a battery can perform as manufactured. Ohmic measurements and float current are two examples of parameters that have been reported to assist in determining if a battery string can perform as manufactured.

The evaluation of battery parameters in determining battery health is a complex issue, and is not an exact science. This standard gives the user an opportunity to utilize other measured parameters to determine if the battery can perform as manufactured. It is the responsibility of the Protection System owner, however, to maintain a documented process that demonstrates the chosen parameter(s) and associated methodology used to determine if the battery string can perform as manufactured.

Whichever parameter is evaluated (ohmic measurements, float current, float voltages, temperature, specific gravity, etc.), the goal is to determine the value of the measurement (or the percentage change) at which the battery fails to perform as manufactured, or the point where the battery is deteriorating so rapidly that it will not perform as manufactured before the next maintenance interval.

This necessitates the need for establishing and documenting a baseline. A baseline may be required of every individual cell, a particular battery installation, or a specific make, model, or size of a cell. Given a consistent cell manufacturing process, it may be possible to establish a baseline number for the cell (make/model/type) and, therefore, a subsequent baseline for every installation would not be necessary. However, future installations of the same battery types should be spot-checked to ensure that your baseline remains applicable.

Consistency is the key when measuring and evaluating ohmic readings. Consistent testing methods by trained personnel are essential. Moreover, it is absolutely critical that personnel use the same make/model of test instrument every time readings are taken if the values are going to be compared. The type of probe, the location of the reading (post, connector, etc.) and the room temperature during the test needs to be carefully recorded when the readings are taken. For every subsequent time the readings are taken, the same make/model of the test instrument must be used, the same type of probes must be used, and the location of the reading must be the same.

A detailed understanding of the characteristic of a battery is also necessary if attempting to use float current as a measure of the ability of a battery to perform as manufactured. For example, trending of float current is a very effective way to determine the rate of antimony poisoning; and, thus, track the positive plate aging process in high antimony lead acid batteries (batteries with greater than 10 percent antimony in their grid lead alloys). The increased float current with age in these high lead antimony batteries can increase the positive plate aging process which gives an excellent indication of battery aging. Trending and evaluation of the measurements of float current on these high antimony lead acid batteries is an acceptable maintenance activity of Tables 1-4(a) and 1-4(b) for verifying the station battery can perform as manufactured. However, lead-calcium acid batteries do not have this property of being able to determine the aging of their grids by trending their float current, because their float current is constant over the life of the battery. Also the lower lead antimony (antimony two percent or lower) batteries do not exhibit this increase in float current as their plate structures age. When attempting to establish a trending program for lead-calcium or low lead antimony (such as lead-selenium) batteries, the Protection System owner should contact the manufacturer of the station battery to see if a trending process is recommended for determining aging of these products.

The establishment of a baseline may be different for various types of cells and for different types of installations. In some cases, it may be possible to obtain a baseline number from the battery manufacturer, although it is much more likely that the baseline will have to be established after the installation is complete. To some degree, the battery may still be “forming” after installation; consequently, determining a stable baseline may not be possible until several months after the battery has been in service.

The most important part of this process is to determine the point where the ohmic reading (or other measured parameter(s)) indicates that the battery cannot perform as manufactured. That point could be an absolute number, an absolute change, or a percentage change of an established baseline.

Since there are no universally-accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured (heretofore referred to as a failed cell). This is the most difficult and important part of the entire process.

To determine the point where the battery fails to perform as manufactured, it is helpful to have a history of a battery type, if the data includes the parameter(s) used to evaluate the battery's ability to perform as manufactured against the actual demonstrated performance/capacity of a battery/cell.

For example, when an ohmic reading has been recorded that the user suspects is indicating a failed cell, a performance test of that cell (or string) should be conducted in order to prove/quantify that the cell has failed. Through this process, the user needs to determine the ohmic value at which the performance of the cell has dropped below 80 percent of the manufactured, rated performance. It is likely that there may be a variation in ohmic readings that indicates a failed cell (possibly significant). It is prudent to use the most conservative values to determine the point at which the cell should be marked for replacement. Periodically, the user should demonstrate that an “adequate” ohmic reading equates to an adequate battery performance (>80% of capacity).

Similarly, acceptance criteria for "good" and "failed" cells should be established for other parameters such as float current, specific gravity, etc., if used to determine the ability of a battery to function as designed.

What are some of the differences between lead-acid and nickel-cadmium batteries?

There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of these two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. In contrast, the primary failure of nickel-cadmium batteries is due to the gradual linear aging of the active materials in the plates. The electrolyte of a nickel-cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel-cadmium battery does not.

Changes to the properties of a lead acid battery when periodically measured and trended to a baseline, can indicate aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate.

Because of the clear differences in the aging process of lead acid and nickel-cadmium batteries, there are no significantly measurable properties of the nickel-cadmium battery that can be measured at a periodic interval and trended to determine aging. For this reason, Table 1-4(c) (Protection System Station dc supply Using nickel-cadmium [NiCad] Batteries) only specifies one minimum maintenance activity and associated maximum maintenance interval necessary to verify that the station battery can perform as manufactured. This maintenance activity is to conduct a performance or modified performance capacity test of the entire battery bank.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.
Because the battery rack is specifically manufactured for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many Systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously, a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the standard refers to "all cells," is it sufficient to have a documentation method that refers to "all cells," or do we need to have separate documentation for every cell? For example, do I need 60 individual documented check-offs for good electrolyte level, or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this standard refer to Station batteries or all batteries; for example, Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications Systems at a remote site would cause the communications Systems associated with protective relays to alarm at the substation. At this point, the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry, these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example, in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand, dc resistance of a cell is measured by a third manufacturer's equipment by applying a dc Load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices, there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a baseline and trending it over time says, "…depending on the degree of change a performance test, cell replacement or other corrective action may be necessary…" (IEEE std 1188-2005, C.4 page 18).

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century, EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity, but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity," they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as manufactured. By evaluation of the trending of the ohmic measurements over time, the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this condition based approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as manufactured.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and, if not corrected, the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the

Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In vented lead-acid (VLA) and nickel-cadmium (NiCad) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in valve-regulated lead-acid (VRLA) batteries cannot be observed, there is no maintenance activity listed in Table 1-4 of the standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCad station battery is a condition requiring correction. Typically, the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCad) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries, the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery, or other unforeseen events can cause rapid loss of electrolyte; the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

What are the parameters that can be evaluated in Tables 1-4(a) and 1-4(b)?

The most common parameter that is periodically trended and evaluated by industry today to verify that the station battery can perform as manufactured is internal ohmic cell/unit measurements.

In the mid 1990s, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

Other examples of measurable parameters that can be periodically trended and evaluated for lead acid batteries are cell voltage, float current, connection resistance. However, periodically trending and evaluating cell/unit Ohmic measurements are the most common battery/cell parameters that are evaluated by industry to verify a lead acid battery string can perform as manufactured.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for valve-regulated lead-acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for vented lead-acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "…verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values to station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as manufactured by conducting a performance, service, or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as manufactured." This is the intent of the "perform as manufactured six-month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25 percent increase over baseline. Rather, it will stick out like a sore thumb when compared to the other cells in a string at a given point in time, regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25 percent increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the six-month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a six-month basis.

It is possible to accomplish both tasks listed (trend testing for capability and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications-assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested. Besides the trip output and wiring to the trip coil(s), there is also a communications medium that must be maintained. Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology. For example, older technologies may have included Frequency Shift Key methods. This technology requires that guard and trip levels be maintained. The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests. Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals. The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore, this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be performed on any communications-assisted trip scheme, regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications Systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier Systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier Systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications Systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications Systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier Systems can be shown to be operational by automated periodic power-line carrier check-back tests with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications Systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications Systems signal quality measurements, including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the four-month inspection of communications-assisted trip scheme equipment?

The four-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms; check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier Systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry, rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria." What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally, an alarm will be indicated. For unmonitored systems, this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a Fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full

power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay Systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the Fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria, depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system, then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the Components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot, and, thus, make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system; the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours, then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System Component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the standard technology neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center, then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and Distributed UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current-sensing devices have the same maintenance activity and interval as Table 1-3. DC Systems need only have their voltage read at the relay every 12 years. Control circuits have the following maintenance activities every 12 years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication Systems for distributed UFLS and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however, the part of the trip path control circuitry between the Load-Shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure, such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just Fault clearing duty; and, therefore, these circuit breakers are operated at least as frequently as any requirements that appear in this standard.

There are times when a Protection System Component will be used on a BES device, as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System Component) will be subject to the Tables of the standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines bulk power system as: "(A) facilities and control Systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition, then, is limited by a later statement which adds the term bulk power system "…does not include facilities used in the local distribution of electric energy." Also, Section 215 also covers users, owners, and operators of bulk power Facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the reliability standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that Load would have to be shed at the Transmission bus to ensure the Load-generation balance and voltage stability is maintained on the BES.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this standard, an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC standards that could, at times, fulfill evidence requirements of this Standard.

15.8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the requirement being documented include, but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms

- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System Component with another Component, what testing do I need to perform on the new Component?

In order to reset the Table 1 maintenance interval for the replacement Component, all relevant Table 1 activities for the Component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus, the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain Disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications, to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my Protection System Components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

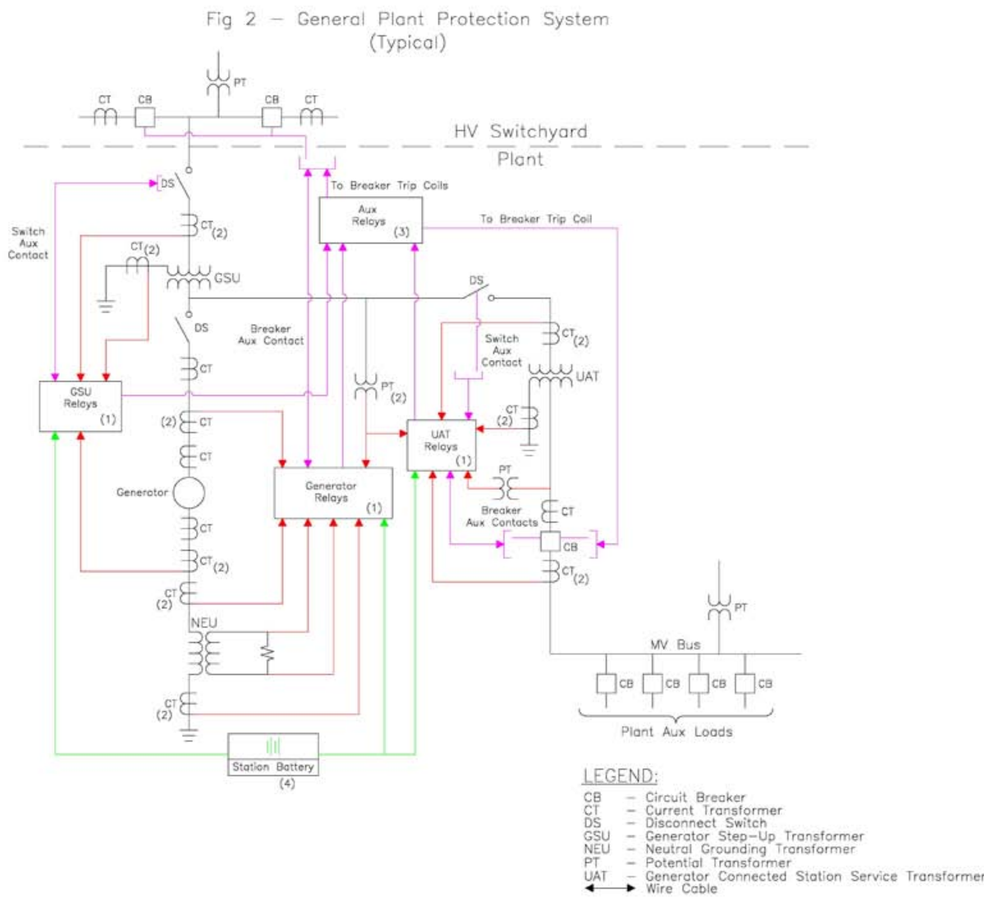
Figure 2: Typical Generation System



For information on Components, see [***Figure 1 & 2 Legend – Components of Protection Systems***]

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check Systems, metering Systems and data acquisition Systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic Systems that carry a trip signal as well as hard-wired Systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications Systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

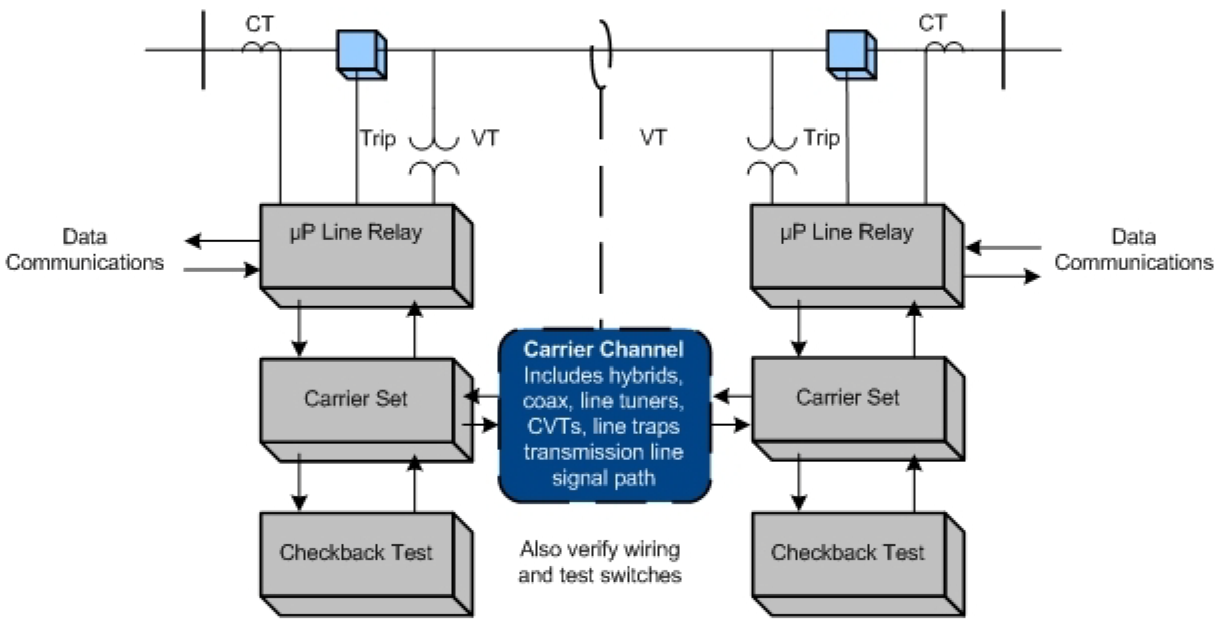
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line Faults, and to avoid over-tripping for Faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

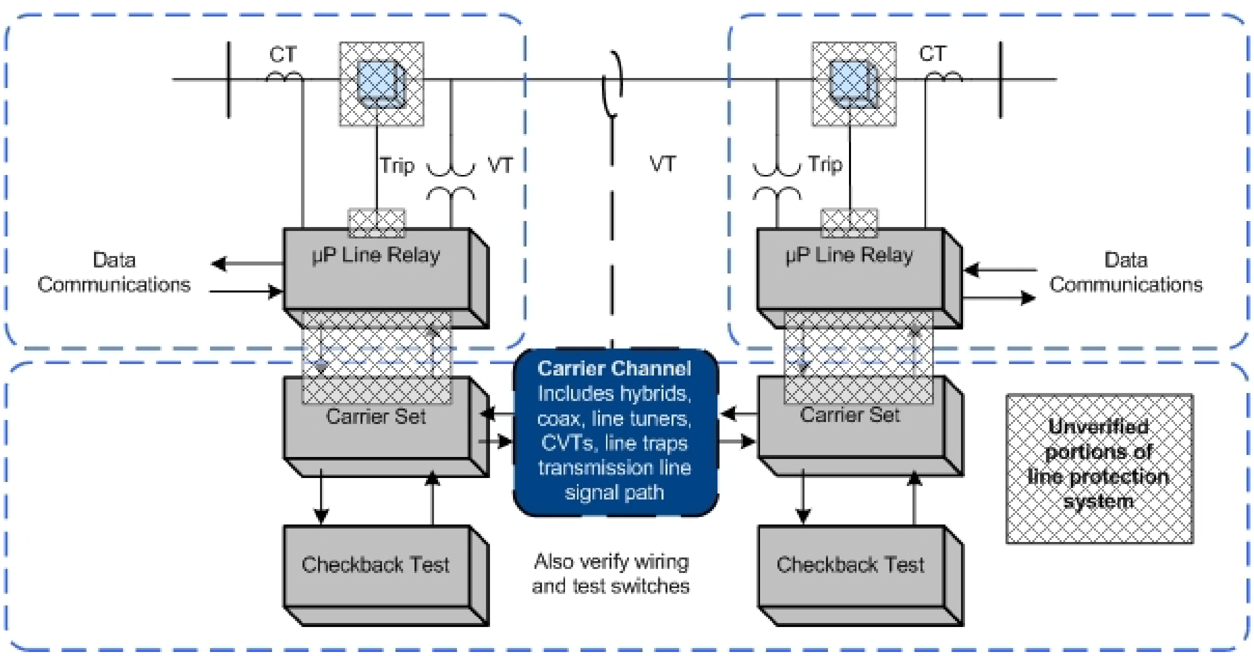
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement Systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One

effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System Elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show Elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These Components are critical for tripping the circuit breaker for a Fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring Faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If Faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated Fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring Faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Table of Contents

1. Introduction and Summary

Note: This supplementary reference ~~to~~for PRC-005-2 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control ~~systems.~~Systems.

These standards are:

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a ~~fault~~Fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking ~~faults~~Faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A ~~misoperation~~Misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide-area ~~disturbances~~Disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System ~~components~~Components, such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries, which are an important part of the station dc supply, are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear ~~faults~~Faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC ~~Standards~~standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications ~~systems~~Systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications ~~systems~~Systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting ~~faults~~Faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this ~~Standard~~standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the ~~element~~Element is a BES ~~element~~Element, then the Protection System protecting that ~~element~~Element should then be included within this ~~Standard.~~standard. If there is regional variation to the definition, then there will be a corresponding regional variation to the Protection Systems that fall under this ~~Standard~~standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the ~~Standard~~standard language should simply be applicable to Protection Systems for BES ~~elements~~Elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC ~~glossary~~Glossary of ~~terms~~Terms for the present, in-force~~,~~ definition. See the applicable ~~regional reliability organization~~Regional Reliability Organization for any applicable allowed variations.

While this ~~Standard~~standard will undergo revisions in the future, this ~~Standard~~standard will not attempt to keep up with revisions to the NERC definition of BES, but, rather, simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because ~~GO's~~GOs and ~~TO's~~TOs have equipment that is BES equipment. The ~~Standard~~standard brings in Distribution Providers (DP) because, depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is ~~underfrequency load~~Underfrequency Load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this ~~Standard~~standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those ~~Standards~~standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those ~~Standards~~standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example, the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just ~~fault~~Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as stipulated in any ~~requirements that might have appeared~~requirement in this ~~Standard~~standard.

Additionally, since this ~~Standard~~standard will now replace PRC-011, it will be important to make the distinction between under-voltage Protection Systems that protect individual ~~loads~~Loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load-Shedding scheme that is not applicable to this ~~Standard~~standard is one in which the tripping action was intended to prevent low distribution voltage to a specific ~~load~~Load from a ~~transmission system~~Transmission System that was intact except for the line that was out of service, as opposed to preventing a ~~cascading~~Cascading outage or ~~transmission system~~Transmission System collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus, a ~~Standard~~standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems, and replace some other ~~Standards~~standards at the same time.

2.3.1 Frequently Asked Questions:

What~~,~~ exactly~~,~~ is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft ~~Standard~~standard.

NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, ~~interconnections~~Interconnections with neighboring ~~systems~~Systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only ~~load~~Load with one transmission source are generally not included in this definition.

The BES definition is presently undergoing the process of revision.

Each ~~Regional Entity~~regional entity implements a definition of the Bulk Electric System that is based on this NERC definition~~,~~; in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is ~~underfrequency load~~Underfrequency Load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load-Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this ~~Standard~~standard?

The situation, as stated, indicates that the tripping action was intended to prevent low distribution voltage to a specific ~~load~~Load from a ~~transmission system~~Transmission System that was intact, except for the line that was out of service, as opposed to preventing ~~cascading~~Cascading outage or ~~transmission system~~Transmission System collapse.
This ~~Standard~~standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary ~~load~~Load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just ~~fault~~Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this ~~Standard~~standard.

We have a UFLS scheme that, in some locales, sheds the necessary ~~load~~Load through non-BES circuit breakers and, occasionally, even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements, and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as~~ (~~, for example~~)~~, a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this ~~Standard~~standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE ~~device #~~Device No. 86 (lockout relay) and IEEE ~~device #~~Device No. 94 (tripping or trip-free relay~~)~~), as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage-sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. This ~~Standard~~standard covers protective relays that use electrical quantity measurements to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close, as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC ~~Standards.~~standards. There is one notable exception: ~~since~~Since PRC-017 will be superseded by PRC-005-2, then if a Special Protection System (previously covered by PRC-017) incorporates automatic closing of breakers, then the SPS-related closing devices must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This ~~Standard~~standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.~~)~~.). Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the ~~device number~~Device No.# 94 to auxiliary tripping relays. Sudden pressure relays are assigned ~~device number~~Device No.# 63. Sudden pressure relays are presently excluded from the ~~Standard~~standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing ~~element~~Element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing ~~elements~~Elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1a, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of any trip circuit that is a part of a Protection System. This ~~Standard~~standard does not cover circuit breaker maintenance or transformer maintenance. The ~~Standard~~standard also does not presently cover testing of devices, such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters, rather than electrical parameters. There is an expectation that ~~fault~~Fault pressure relays and other non-electrically initiated devices may become part of some maintenance standard. This ~~Standard~~standard presently covers trip paths. It might seem incongruous to test a trip path without a present requirement to test the device; and, thus, be arguably more work for nothing. But~~,~~ one simple test to verify the integrity of such a trip path could be (but is not limited to) a voltage presence test, as a dc voltage monitor might do if it were installed monitoring that same circuit.

The ~~Standard~~standard specifically mentions auxiliary and lock-out relays~~; what~~. What is an auxiliary tripping relay?

An auxiliary relay, IEEE Device ~~Number~~No.# 94, is described in IEEE Standard C37.2-2008 as: “A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed.”

What is a lock-out relay?

A lock-out relay, IEEE Device ~~Number~~No.# 86, is described in IEEE Standard C37.2 as: “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System~~,~~ both depends on the technological generation of the relays, as well as how long they have been in service. Unlike many other transmission asset groups, protection and control ~~systems~~Systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices, such as primary measuring relays, monitoring devices, control ~~systems~~Systems, and telecommunications equipment.

Modern microprocessor-based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs, such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every ~~element~~Element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture ~~fault~~Fault records showing how the Protection System responded to a ~~fault~~Fault in its zone of protection, or to a nearby ~~fault~~Fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-~~fault~~Fault times. The relays can compute values, such as MW and MVAR line flows, that are sometimes used for operational purposes, such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording~~,~~ and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages, or from relay front panel button requests.
- Construction from electronic components, some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other ~~components~~Components of Protection Systems. Microprocessors are now a part of ~~Battery Chargers, Associated Communications Equipment, Voltage~~battery chargers, associated communications equipment, voltage and ~~Current Measuring Devices~~current-measuring devices, and even the control circuitry (in the form of software-latches replacing lock-out relays, etc~~).~~.).

Any Protection System ~~component~~Component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all ~~components~~Components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a “lock-out~~”.~~.” Thus, the software-latch 86 that replaces an electro-mechanical 86 does not require routine trip testing. Any trip circuitry associated with the “soft 86” would still need applicable verification activities performed, but the actual “86” does not have to be “electrically operated” or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System ~~components~~Components are kept in working order and proper operation of malfunctioning ~~components~~Components is restored. A maintenance program for a specific ~~component~~Component includes one or more of the following activities:

- Verify — Determine that the ~~component~~Component is functioning correctly.
- Monitor — Observe the routine in-service operation of the ~~component~~Component.
- Test — Apply signals to a ~~component~~Component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of ~~component~~Component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures, as reflected in the previous ~~Standard~~standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the ~~tables~~Tables 1-1 through 1-5, Table 2 and Table 3 (collectively the “Tables”), and the various ~~components~~Components of the definition established for a “Protection System Maintenance Program~~”,~~,” PRC-005-2 establishes the activities and time ~~-~~basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by “restore” in the definition of maintenance.

The description of “~~Restore~~restore” in the definition of a Protection System Maintenance Program~~,~~ addresses corrective activities necessary to assure that the ~~component~~Component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the ~~Standard~~standard does require that the entity “shall demonstrate efforts to correct any identified ~~unresolved maintenance issues”.~~Unresolved Maintenance Issues.” Some examples of restoration (or correction of ~~maintenance-correctable issues~~Unresolved Maintenance Issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System ~~components~~Components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to ~~micro-processor-~~microprocessor-based relays following the discovery of failed ~~components~~Components. Restoration, as used in this context, is not to be confused with ~~Restoration~~restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This ~~Standard~~standard does not identify all of the

Protection System problems that must be detected and eliminated, rather it is the intent of this ~~Standard~~standard that an entity determines the necessary working order for their various devices, and keeps them in working order. If an equipment item is repaired or replaced, then the entity can restart the maintenance-time-interval-clock, if desired~~,~~; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements~~; in~~. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the ~~Standard~~standard.

Please clarify what is meant by "…demonstrate efforts to correct an ~~unresolved maintenance issue~~Unresolved Maintenance Issue…"; why not measure the completion of the corrective action?

Management of completion of the identified ~~unresolved maintenance issue~~Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex ~~unresolved maintenance issues~~Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a ~~6~~ six-month check. In instances such as one that requiring battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the ~~6~~ six-calendar-month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible ~~unresolved maintenance issues~~Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (~~TMB~~TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System ~~components.~~Components. However, some ~~components~~Components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System ~~components~~Components can have the ability to remotely conduct tests, either on-command or routinely~~,~~; the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for ~~components~~Components or groups of ~~components~~Components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed~~,~~ and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme ~~components~~Components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those ~~components~~Components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar ~~components~~Components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of ~~components~~Components demonstrate operational status as those ~~components~~Components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the ~~Standard~~standard itself, it is important to note that the concepts of CBM are a part of the ~~Standard~~standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals” existing within the ~~Standard~~standard, the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

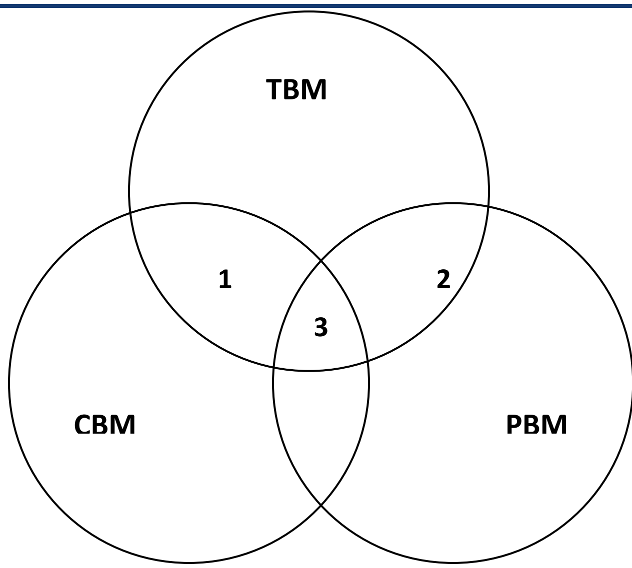
Microprocessor-based Protection System ~~components~~Components that perform continuous self-monitoring verify correct operation of most ~~components~~Components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal ~~components~~Components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours, or even milliseconds between non-disruptive self-monitoring checks within or around ~~components~~Components as they remain in service.

TBM, PBM, and CBM can be combined for individual ~~components~~Components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram, the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual ~~components~~Components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



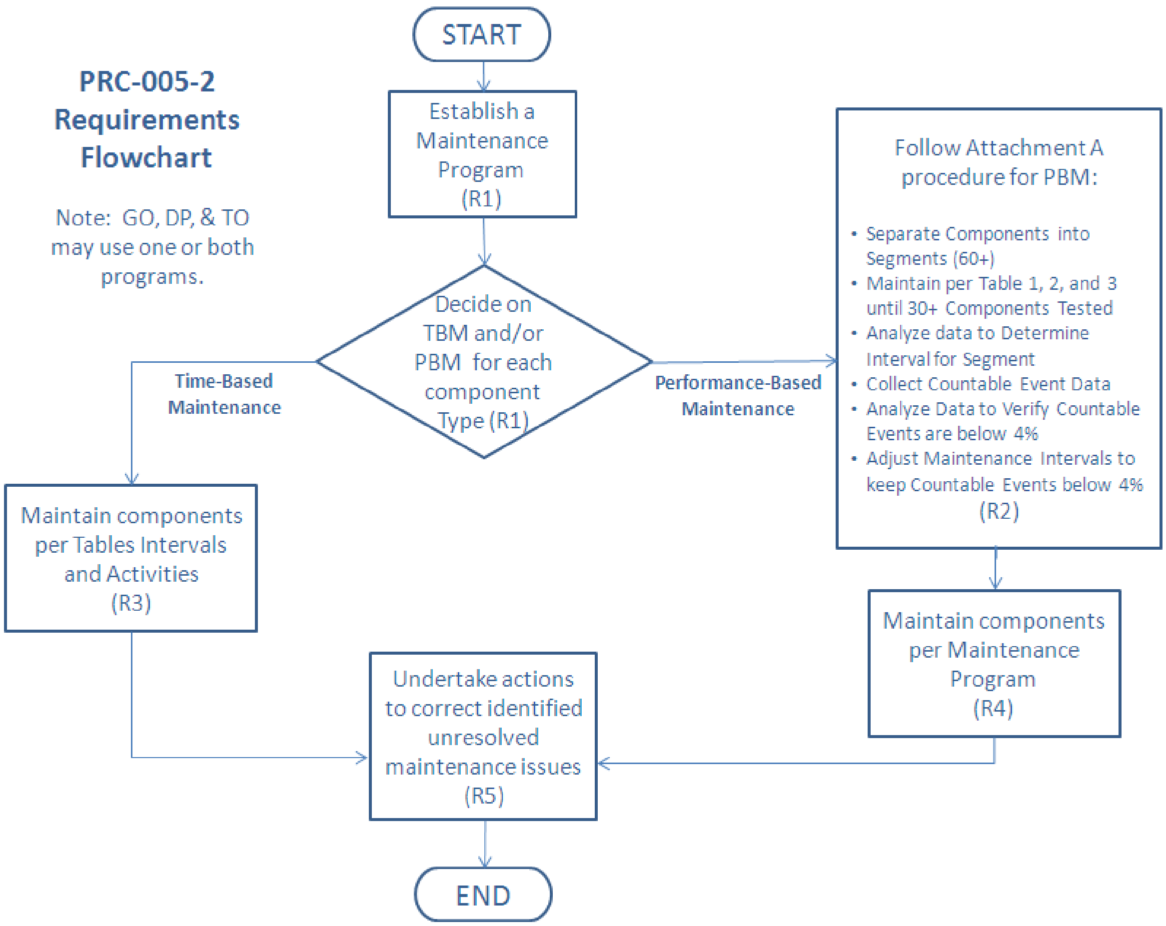
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The ~~Standard~~standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the ~~Standard~~standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2~~)~~), in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System ~~components~~Components and its available lengthened time intervals, then it may, as long as the ~~component~~Component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System ~~components~~Components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the ~~Standard~~standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of ~~components~~Components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each ~~component~~Component must be maintained per the most frequent hands-on activities listed in the Tables.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each ~~component~~Component of the Protection System, when data on the reliability of the ~~components~~Components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a ~~component~~Component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the ~~components~~Components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every ~~component~~Component within a microprocessor.

- Previous maintenance history for a group of ~~components~~Components of a common type may indicate that the maintenance intervals can be extended, while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance, or PBM. It is also sometimes referred to as reliability-centered maintenance, or RCM~~,~~; but PBM is used in this document.

- Observed proper operation of a ~~component~~Component may be regarded as a maintenance verification of the respective ~~component~~Component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a ~~fault~~Fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the ~~component~~Component or system. It is not unusual to cause failure of a ~~component~~Component by removing it from service and restoring it. The improper application of test signals may cause failure of a ~~component~~Component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the ~~component~~Component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked ~~Question~~Questions:

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct any identified ~~unresolved maintenance issues.~~Unresolved Maintenance Issues." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System ~~elements~~Elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for ~~faults~~Faults and ~~disturbances~~Disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of ~~fault~~Fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. **Non-invasive Maintenance:** The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. **Virtually Continuous Monitoring:** CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

To use the extended time intervals available through Condition Based Maintenance~~,~~ simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of ~~components~~Components into the appropriate levels of monitoring, as per Requirement R1 (Part 1.4) of the ~~Standard~~standard, is it necessary to provide this documentation about the device by listing of every ~~component~~Component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a ~~component~~Component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are ~~Monitored~~monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered ~~Monitored~~monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device-level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered ~~Monitored~~monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered ~~Unmonitored~~unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements, as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of ~~component~~Component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure, but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The ~~Standard~~standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule, dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained ~~component~~Component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system ~~components~~Components.

The result is that:

This NERC ~~Standard~~standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of ~~components~~Components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a “One Calendar Year Interval~~”,~~,” the next event would have to occur on or before December 31, 2010.

Please provide an example of “4 Calendar Months”.

If a maintenance activity is described as being needed every ~~4~~four Calendar Months then it is performed in a (given) month and due again ~~4~~four months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a ~~4~~four-month inspection was performed in January is due in May, but if performed in March (instead of May) would still be due four months later therefore the activity is due again July. Basically every "~~4Calendar~~four Calendar Months" means to add ~~4~~four months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System ~~components.~~Components. A Protection System ~~component~~Component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored ~~component~~Component of a Protection System has monitoring and alarm circuits on the Protection System ~~components.~~Components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but is not limited to, an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored ~~components~~Components within any given Protection System.

Example #1: A combination of monitored and unmonitored ~~components~~Components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A ~~Vented~~vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, and the trip circuit is not monitored. (unmonitored)

Given the particular ~~components~~Components and conditions, and using Table 1 and Table 2, the particular ~~components~~Components have maximum activity intervals of:

Every ~~4~~four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity

- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

__Every ~~6~~six calendar years__, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

__Every 12 calendar years__, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power ~~system~~System input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System ~~component~~Component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored ~~control circuitry associated with protective functions~~Control Circuitry Associated with Protective Functions" section'
- Auxiliary outputs not in a trip path (i.e~~.~~., annunciation or DME input) are not required, by this ~~Standard~~standard, to be checked~~.~~

Example #2: A combination of monitored and unmonitored ~~components~~Components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A ~~Vented Lead-Acid~~vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular ~~components~~Components and conditions, and using the Table 1 ~~("~~(Maximum Allowable Testing Intervals and Maintenance Activities~~")~~) and Table 2

~~(“~~(Alarming Paths and Monitoring~~”),~~), the particular ~~components~~Components have maximum activity intervals of:

Every ~~4~~four calendar months, inspect:

- Electrolyte level (~~Station~~station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every ~~6~~six calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System ~~component~~Component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the ~~‘~~Unmonitored ~~control circuitry associated~~Control Circuitry Associated with ~~protective functions" section’~~Protective Functions" section
- Auxiliary outputs not in a trip path (i.e~~.~~., annunciation or DME input) are not required, by this ~~Standard~~standard, to be checked

Example #3: A combination of monitored and unmonitored ~~components~~Components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)

- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular ~~components~~Components, conditions, and using the Table 1 ~~("~~(Maximum Allowable Testing Intervals and Maintenance Activities~~")~~) and Table 2 ~~("~~(Alarming Paths and Monitoring~~"),~~), the particular ~~components~~Components shall have maximum activity intervals of:

Every ~~4~~four calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every ~~6~~six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay

- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the ~~'~~Unmonitored ~~control circuitry associated~~Control Circuitry Associated with ~~protective functions" section'~~Protective Functions section
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this ~~Standard~~standard, to be checked

Why do ~~components~~Components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System ~~components.~~Components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all ~~components~~Components in a Protection System be monitored?

No. For some ~~components~~Components in a Protection System, monitoring will not be relevant. For example, a battery will always need some kind of inspection.

We have a 30-year-old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the ~~components~~Components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years, or when an ~~unresolved maintenance issue~~Unresolved Maintenance Issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every ~~6~~six years.

8. Maximum Allowable Verification Intervals

The ~~Maximum Allowable Testing Intervals~~maximum allowable testing intervals and ~~Maintenance Activities~~maintenance activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System ~~components~~Components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no ~~fault~~Fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual ~~components~~Components are still operating within acceptable performance parameters - this type of test is needed for ~~components~~Components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying ~~fault~~Fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2 and Table 3 in the ~~Standard,~~standard specify maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of ~~components~~Components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various ~~subsystems~~sub-Systems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions; and, therefore, have the same maintenance needs.

Distributed UFLS and UVLS ~~systems~~Systems, which use local sensing on the distribution system and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the ~~components~~Components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your ~~component.~~Component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications ~~systems~~Systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits.
    - Table 2, is for alarms; this was broken out to simplify the other tables.
    - Table 3 is for ~~components~~Components which make-up distributed UFLS and UVLS ~~systems~~Systems.
- Next look within that ~~Table~~table for your device and its degree of monitoring. The ~~tables~~Tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance-Based Maintenance (PBM) plan requires more activities, then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the ~~Maximum Maintenance Interval~~maximum maintenance interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this ~~component~~Component.
- If your Performance-Based Maintenance plan requires activities more often than the Tables maximum, then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given ~~component~~Component of a Protection System can be determined to have a degree of monitoring that may be different from another ~~component~~Component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every ~~4~~four months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the ~~5~~five Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System ~~component~~Component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. If an entity has a Performance-Based Maintenance program, then that plan must be followed, even if the plan proves to be more stringent than the minimums laid out in the Tables.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a ~~component~~Component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System ~~components~~Components, physical inspection of station batteries for signs of ~~component~~Component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for ~~Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium~~vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS ~~systems~~Systems, and large entities will usually maintain a portion of these ~~systems~~Systems in any given year. Additionally, if relatively small quantities of such ~~systems~~Systems do not perform properly, it will not affect the integrity of the overall program. Thus, these distributed ~~systems~~Systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected~~,~~ (phase value and phase relationships are both equally important to verify).

7. “End-to-end test~~”~~,” as used in this Supplementary Reference, is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test, it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc ~~Control Circuitry.~~control circuitry. A documented ~~real~~Real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or~~,~~ another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a ~~real~~Real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities, but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the ~~Standard~~standard is technology- and method-neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by “Verify that settings are as specified” maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor- based relays. For relay maintenance departments that choose to test microprocessor~~-~~-based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled, but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the ~~Standard~~standard states “…settings are as specified.”

Many of the microprocessor- based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement, a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require “…that the relay settings be correct…” because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the ~~component~~Component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection~~,~~; and, thus, the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable, as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system ~~disturbances.~~Disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known ~~fault~~Fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this ~~Standard~~standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?

As in all of the Protection System requirements, SPS segments can be tested individually, thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a ~~component~~Component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?

Since ~~components~~Components of the SPS, UFLS~~,~~ and UVLS are the same types of ~~components~~Components as those in Protection Systems, then these ~~components~~Components should be maintained like similar ~~components~~Components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed ~~systems~~Systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example, an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the ~~real~~Real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance, as required, due to a major natural disaster (hurricane, earthquake, etc~~),~~.), how will this affect my compliance with this ~~Standard.~~standard?

The Sanction Guidelines of the North American Electric Reliability Corporation, effective January 15, 2008, provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays~~,~~; or, even worse, I am experiencing numerous relay ~~misoperations~~Misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But~~,~~ any entity can choose to test some or all of their Protection System ~~components~~Components more frequently (or~~,~~ to express it differently, exceed the minimum requirements of the ~~Standard~~standard). Particularly~~,~~ if you find that the maximum intervals in the ~~Standard~~standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest.

We believe that the ~~4~~four-month interval between inspections is unneccessary~~, why~~. Why can we not perform these inspections twice per year?

The ~~standard drafting team~~Standard Drafting Team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections, the ~~4~~four-month interval was chosen. In lieu of station visits, many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years~~; if~~. If we are unable to achieve this schedule, but we are able to complete the procedures in less than the ~~Maximum Time Interval~~ maximum time interval ,then are we in or out of compliance?

According to R3, if you have a time-based maintenance program, then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables. According to R4, if your device in question is part of a Performance-Based Maintenance program, then you will be in violation of the standard if you fail to meet your PSMP, even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in ~~tables~~the Tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or ~~systems~~Systems that must be verified in a generator, generator step-up transformer, ~~and~~ generator connected station ~~auxiliary~~ service or generator connected excitation transformer to meet the requirements of this ~~Maintenance Standard~~maintenance standard.

Examples of typical devices and ~~systems~~Systems that may directly trip the generator, or trip through a lockout relay, may include, but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip ~~systems~~Systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step-up ~~or~~, generator-connected station ~~auxiliary~~service transformers, or generator connected excitation transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit; and, as such, would be included in the program:

- Transformer differential relays

- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary ~~loads~~Loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program, even if the loss of the those ~~loads~~Loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program, even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the ~~protection systems~~Protection Systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating ~~facility?~~ Facility?

The SDT does not intend that the system-connected station ~~auxiliary~~service transformers be included in the Applicability. The generator-connected station service transformers and generator connected excitation transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping~~"~~," one needs to realize that sometimes there are more ~~Inputs~~inputs and ~~Outputs~~outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every ~~6~~six years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every ~~twelve~~12 years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent ~~load~~Load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and ~~load~~Load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three-year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System ~~components~~Components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: “Company A” has a maintenance plan that requires its electromechanical protective relays be tested every ~~3~~three calendar years, with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus, its test records would have a latest routine test, as well as its previous routine test. The interval between tests is, therefore, provable to an auditor as being within “Company A’s” stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements, while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance-Based Maintenance, then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced, then the entity can restart the maintenance-time-interval-clock if desired~~;~~, however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements~~; in~~. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the ~~Standard~~standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This ~~Standard~~standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a ~~facility~~Facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-~~fault~~Fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation, and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of ~~components~~Components, such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the ~~Standard~~standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content; and, therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System ~~component~~Component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the ~~components~~Components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing, as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates, then the testing date should be followed because it is the degradation of ~~components~~Components that is the concern. While accuracy fluctuations may decrease when ~~components~~Components are not energized, there are cases when degradation can take place, even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System ~~components~~Components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its ~~one hundred~~100 Protection System ~~components~~Components, which would equate to two percent for application to the VSL Table for Requirement R3. This VSL is written to compare missed ~~components~~Components to total ~~components~~Components. In this case ~~2 components~~two Components out of 100 were missed, or ~~2 %.~~two percent.

How do I achieve a "grace period" without being out of compliance?

~~According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded.~~ The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays,~~ –~~ – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of ~~6~~six calendar years. Your plan must ensure that your unmonitored relays are tested at least once every ~~6~~six calendar years. You could, within your PSMP, require that your unmonitored relays be tested every ~~4~~four calendar years, with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders, but still ~~have~~has the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of ~~4~~four years; it also has a built-in time extension allowed within the PSMP, and yet does not exceed the maximum time interval allowed by the ~~Standard~~standard. So while there are no time extensions allowed beyond the ~~Standard~~standard, an entity can still have substantial flexibility to maintain their Protection System ~~components~~Components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. ~~The~~T he survey represented 470 GW of peak ~~load~~Load, or ~~64%~~four percent of the NERC peak ~~load.~~Load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak ~~load~~Load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of ~~5~~five years for electromechanical or solid state relays, and ~~7~~seven years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond ~~7~~seven years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1~~]~~], as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1, only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay, as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system ~~element~~Element to be protected is in service.

- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a ~~fault~~Fault occurs, leading to failure to operate for the ~~fault~~Fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal ~~fault~~Fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup ~~fault~~Fault clearing time of 50 cycles)

Rc, Protected ~~component~~Component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for ~~Relay Unavailability and Abnormal Unavailability~~relay unavailability and abnormal unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay ~~Mean Time~~mean time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally, it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods~~"~~." To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension, while still following FERC Order 693, the Standard Drafting Team arrived at a ~~6~~ six-year interval for the electromechanical relay, instead of the ~~5~~ five-year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10-year interval was chosen, even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any ~~component~~Component of the Protection System; thus, the maximum allowed interval for these ~~components~~Components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval~~".~~." The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year ~~#1~~number one need not be revisited until ~~6~~six years later (year ~~#7).~~number seven). For example~~:~~, a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this ~~Standard~~standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP, the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals, other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major ~~system~~System outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality ~~systems~~Systems (such as ***ISO 9001-2000, Quality management ~~systems~~Systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program, the asset owner must first sort the various Protection System ~~components~~Components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM, but does not own 60 units to comprise a population, then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or ~~components~~Components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment, and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries, but can be applied to all other ~~components~~Components of a Protection System, including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003~~)~~.)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003~~)~~.)

> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003~~)~~.)

> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005~~)~~.)

> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968~~)~~.)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of ~~components~~Components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason, the following assumptions are made:

B = ~~5%~~five percent

z = 1.96 (This equates to a ~~95%~~ninety-five percent confidence level)

π = ~~4%~~four percent

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of ~~components~~Components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = ~~5%~~five percent

z = 1.44 (~~85%~~eighty-five percent confidence level)

π = ~~4%~~four percent

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the ~~Standard~~standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined, then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of ~~components~~Components tested (or the last 30 units maintained, whichever is more) had fewer than ~~4% countable events.~~four percent Countable Events. It is notable that ~~4%~~four percent is specifically chosen because an entity with a small population (~~60~~30 units) would have to adjust its time intervals between maintenance if more than ~~1 countable event~~one Countable Event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is ~~5%~~five percent of the population. Note that this ~~5%~~five percent threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of ~~countable events~~Countable Events equals or exceeds ~~4%~~four percent of the last year's tested ~~components~~Components (or the last 30 units maintained, whichever is more~~)~~), then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the ~~countable events~~Countable Events is less than ~~4%;~~four percent; this must be attained within three years.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System ~~components~~Components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System ~~components~~Components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No~~. You~~, you must use actual in-service test data for the ~~components~~Components in the segment~~.~~.

What types of ~~misoperations~~Misoperations or events are not considered ~~countable events~~Countable Events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable ~~events~~Events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the ~~component~~Component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System ~~misoperations~~Misoperations during system installation or maintenance activities are not considered ~~countable events~~Countable Events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System ~~components~~Components. Examples of misapplication of Protection System ~~components~~Components include wrong CT or PT tap position, protective relay function misapplication, and ~~components~~Components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES ~~element~~Element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused ~~misoperations~~Misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the ~~4%~~four percent tolerance level).

Certain types of Protection System ~~component~~Component errors that cause ~~misoperations~~Misoperations are not considered ~~countable events~~Countable Events. Examples of excluded ~~component~~Component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of ~~components~~Components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.

- Components within the mal-performing segment can be replaced with other ~~components~~Components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a ~~maintenance-correctable issue~~Unresolved Maintenance Issue as a result of a ~~misoperation~~Misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System ~~component~~Component for any reason (including as part of a PRC-004 required ~~misoperation~~Misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, “reset the clock” on everything you’ve done. In a Performance-Based Maintenance program, you also need to record the ~~maintenance-correctable issue~~Unresolved Maintenance Issue as a ~~countable event~~Countable Event within the relevant ~~component~~Component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that ~~component~~Component group. Note that “resetting the clock” should not be construed as interfering with an entity’s routine testing schedule because the “clock-reset” would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of ~~4~~four relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a ~~misoperation~~Misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that “replaced relay” will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of ~~4~~four years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only ~~element~~Element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System ~~element~~Element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system ~~disturbances~~Disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the ~~components~~Components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate. This entity is now allowed to extend the maintenance interval if they choose. The entity chooses to extend the maintenance interval of this population segment out to 10 years. This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year. After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures. This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than ~~4%~~four percent per year; the entity has three years to get this failure rate down to ~~4%~~four percent or less (per year). In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year, they again find ~~6~~six failures out of the 125 units tested. 6/125= ~~5%~~five percent failures. In response to the ~~5%~~five percent failure rate, the entity decreases the testing interval to ~~7~~seven years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected. After a year, they again find ~~6~~six failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried ~~5~~five years and they were under the ~~4%~~four percent limit and they tried ~~7~~seven years and they were over the ~~4%~~four percent limit. They must be back at ~~4%~~four percent failures or less in the next year so they might simply elect to go back to ~~5~~five years.)

Instead, in response to the ~~5%~~five percent failure rate, the entity decreases the testing interval to ~~6~~six years. This means that they will now test 167 units per year (1000/6). After a year, they again find ~~6~~six failures out of the 167 units tested. 6/167= 3.6% failures. Entity found that they could maintain the failure rate at no more than ~~4%~~four percent failures by maintaining the testing interval at ~~6~~six years or less. Entity chose ~~6-~~six-year interval and effectively extended their TBM (~~5~~five years) program by 20~~%.~~ percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than ~~2%.~~two percent. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested~~/~~/year) may be un-workable.

Note that the "~~5%~~five percent of ~~components~~Components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from ~~6~~six years to 20 years. In the event that an entity finds a failure rate greater than ~~4%~~four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to ~~4%~~four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific ~~element.~~Element. Under the included definition of "Component":

The designation of what constitutes a control circuit ~~component~~Component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit ~~components~~Components. Another example of where the entity has some discretion on determining what constitutes a single ~~component~~Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single ~~component~~Component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or ~~components~~Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common ~~elements~~Elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual ~~components~~Components.*

Example:

Entity has ~~1000~~1,000 circuit breakers, all of which have two trip coils, for a total of ~~2000~~2,000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard, then this is greater than the minimum sample requirement of 60.

For the sake of further example, the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring, and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago, the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their ~~Control Circuitry~~control circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population~~,~~ (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the ~~Operations Control~~operations control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking ~~2000~~2,000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored~~,~~; therefore, the trip paths are continuously tested and the circuit will alarm when there is a failure~~; these~~. These alarms have to be verified every 12 years for correct operation.

The entity now has ~~1000~~1,000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification, and is taking care of this activity through other documentation of ~~real~~Real-time ~~fault~~Fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12-year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= three percent failure rate.

~~For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.~~

~~After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.~~

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds ~~3~~three failed units. 3/50= ~~6%~~six percent failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than ~~4%~~four percent per year; the entity has three years to get this failure rate down to ~~4%~~four percent or less (per year).

In response to the ~~6%~~six percent failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

~~After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.~~

In response to the >~~4%~~four percent failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find ~~3~~three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the ~~4%~~four percent limit; and they tried 14 years, and they were over the ~~4%~~four percent limit. They must be back at ~~4%~~four percent failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

~~After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.~~

Entity found that they could maintain the failure rate at no more than ~~4%~~four percent failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval, and effectively extended their TBM (10 years) program by 20~~%.~~ percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than ~~2%.~~two percent. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "~~5%~~five percent of ~~components~~Components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from ~~6~~six years to 20 years. In the event that an entity finds a failure rate greater than ~~4%~~four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to ~~4%~~four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme~~".~~." Thus, this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages, whereas a transmission maintenance group might create a process that utilizes ~~real~~Real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit ~~component~~Component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit ~~components~~Components. Another example of where the entity has some discretion on determining what constitutes a single ~~component~~Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single ~~component~~Component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or ~~components~~Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common ~~elements~~Elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual ~~components~~Components.*

Example:

Entity has 2000 "Relay Schemes~~",~~," all of which have three current signals supplied from bushing ~~CT's~~CTs, and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard, and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (~~1000~~1,000) are supplied with current signals from ANSI STD C800 bushing ~~CT's~~CTs and voltage signals from ~~PT's~~PTs built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards, and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs~~)~~), as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within ~~2000~~2,000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored~~,~~; therefore, the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has ~~1000~~1,000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay, all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just ~~PT's).~~PTs). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level; thus, any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay~~.)~~).

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show ~~3~~thre failures per year~~,~~; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds ~~3~~three failures in the 100 units tested. 3/100= ~~3%~~three percent failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.~~This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.~~ After that year of testing these 50 units, the entity again finds ~~3~~three failed units. 3/50= ~~6%~~six percent failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than ~~4%~~four percent per year; the entity has three years to get this failure rate down to ~~4%~~four percent or less (per year).

In response to the ~~6%~~six percent failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

~~After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.~~

In response to the >~~4%~~four percent failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find ~~3~~three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the ~~4%~~four percent limit; and they tried 14 years, and they were over the ~~4%~~four percent limit. They must be back at ~~4%~~four percent failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (~~1000~~1,000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

~~After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.~~

Entity found that they could maintain the failure rate at no more than ~~4%~~four percent failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval and effectively extended their TBM (10 years) program by 20~~%.~~ percent.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than ~~2%.~~two percent. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested~~/~~/year) may be un-workable.

Note that the "5% of ~~components~~Components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from ~~6~~six years to 20 years. In the event that an entity finds a failure rate greater than ~~4%~~four percent, then the test rate must be accelerated such that within three years the failure rate must be brought back down to ~~4%~~four percent or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System ~~component~~Component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment, as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above, or Attachment A of the ~~Standard~~standard;
- Opportunistic verification using analysis of ~~fault~~Fault records, as described in Section 11

10.1 Frequently Asked ~~Question~~Questions:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the ~~issue.~~Unresolved Maintenance Issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve ~~fault~~Fault event records and oscillographic records by data communications after a ~~fault.~~Fault. They analyze the data closely if there has been an apparent ~~misoperation~~Misoperation, as NERC ~~Standards~~standards require. Some advanced users have commissioned automatic ~~fault~~Fault record processing ~~systems~~Systems that gather and archive the data. They search for evidence of ~~component~~Component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured ~~digital fault recorder~~Digital Fault Recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of ~~faults~~Faults in the vicinity of the relay that produce relay response records~~,~~ and the specific data captured.

A typical ~~fault~~Fault record will verify particular parts of certain Protection Systems in the vicinity of the ~~fault.~~Fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external ~~fault~~Fault records that completely verify the Protection System.

For example, ~~fault~~Fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that ~~fault.~~Fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a ~~fault~~Fault just outside their respective zones of protection. The ensemble of internal ~~fault~~Fault and nearby external ~~fault~~Fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified ~~components~~Components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using ~~fault~~Fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple ~~faults~~Faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various ~~components~~Components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If ~~fault~~Fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the ~~fault~~Fault records used, and the maintenance-related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked ~~Question~~Questions:

I use my protective relays for ~~fault~~Fault and ~~disturbance~~Disturbance recording, collecting oscillographic records and event records via communications for ~~fault~~Fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as ~~disturbance monitoring equipment, the~~Disturbance Monitoring Equipment, NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements~~,~~ and is being addressed by a ~~Standards~~standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this ~~Standard~~standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring ~~element~~Element settings. Analysis of ~~fault~~Fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them~~. For~~; for background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple~~.~~: With legacy relays (non-microprocessor protective relays~~)~~), it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays, it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process, there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade, then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its

regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays, then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced, then the entity can restart the maintenance-activity-time-interval-clock, if desired~~,~~; however, the replacement of equipment does not remove any documentation requirements. The requirements in the ~~Standard~~standard are intended to ensure that an entity has a maintenance plan, and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment, then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System ~~components.~~Components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards, then the requirements of PRC-005-2 are simple – if the Protection System ~~component~~Component performs a Protection System function, then it must be maintained. If the ~~component~~Component no longer performs Protection System functions, then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a ~~component~~Component that is no longer needed, there is no requirement in PRC-005-2 to remove such ~~component~~Component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System ~~components~~Components not used.

While performing relay testing of a protective device on our Bulk Electric System, it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement, even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement, although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states:

"R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified ~~unresolved maintenance issues.~~Unresolved Maintenance Issues."

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC ~~Standards~~standards.

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified ~~unresolved maintenance issues…"~~Unresolved Maintenance Issues…" The type of corrective activity is not stated; however, it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed ~~systems~~Systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring~~,~~ the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring ~~components~~Components in the Protection System should publish for the user a document or map that shows:

- How all internal ~~elements~~Elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every ~~component~~Component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an ~~unresolved maintenance issue~~Unresolved Maintenance Issue, so that failures of monitoring or alarming ~~systems~~Systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored ~~components~~Components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked ~~Question~~Questions:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular ~~component~~Component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This ~~Standard~~standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring~~;~~, the ~~Standard~~standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the ~~Standard~~standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the ~~Standard~~standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC ~~Standard~~standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable ~~loading~~Loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a ~~component~~Component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance, but if its battery maintenance program is lacking, then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific ~~components.~~Components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore, *manual intervention* to perform certain activities on these type ~~components~~Components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a ~~faulted~~Faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas, or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor-based equipment in the following ways~~,~~; the relays should meet the asset owners' tolerances~~.~~:

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.1.1 Frequently Asked ~~Question~~Questions:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System ~~components~~Components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the ~~component.~~Component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this ~~Standard~~standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these ~~components.~~Components. The important thing about these signals is to know that the expected output from these ~~components~~Components actually reaches the protective relay. Therefore, the proof of the proper operation of these ~~components~~Components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device, all the way to the protective relay. The following observations apply~~.~~:

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; ~~(~~including, but not limited to, the following~~) by~~: By calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this, therefore, tests the CT, as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during ~~load~~Load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the ~~real~~Real-time ~~loading~~Loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay, then the verification activity has been satisfied. Thus, event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars, thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current-sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current-sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds.
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay~~),~~) to another protective relay monitoring the same line, with currents supplied by different ~~CT's~~CTs.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc~~).~~.) and verified by calculations and known ratios to be the values expected. For example, a single PT on a 100KV bus will have a specific secondary value that, when multiplied by the PT ratio, arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual ~~components~~Components are functioning properly; and that~~,~~ an ongoing proactive procedure is in place to re-check the various ~~components~~Components of the protective relay measuring ~~systems~~Systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions, as do microprocessor- based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment, like voltmeters and clamp on ammeters, to measure the input signals to the relays. This practice seems very risky, and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays, but is not required by the ~~Standard~~standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests, such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This ~~component~~Component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path, then the manual-intervention testing of those parallel trip paths can be eliminated~~,~~; however, the actual operation of the circuit breaker must still occur at least once every six years. This ~~6~~six-year tripping requirement can be completed as easily as tracking the ~~real~~Real-time

~~fault~~Fault-clearing operations on the circuit breaker, or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this ~~Standard~~standard is to require maintenance intervals and activities on Protection Systems equipment, and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device, if this ground switch is utilized in a Protection System and forces a ground ~~fault~~Fault to occur that then results in an expected Protection System operation to clear the forced ground ~~fault.~~Fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System ~~component.~~Component. The control circuitry would have to be tested within 12 years, and any electromechanically operated device will have to be tested every ~~6~~six years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit, then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type ~~components~~Components, then they must be trip tested. The PSMT SDT considers these ~~components~~Components to share some similarities in failure modes as electromechanical protective relays; as such, there is a six-year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

While relays that do not respond to electrical quantities are presently excluded from this standard, their control circuits are included if the relay is installed to detect ~~faults~~Faults on BES Elements. Thus, the control circuit of a BES transformer sudden pressure relay should be verified every 12 years, assuming its integrity is not monitored. While a sudden pressure relay control circuit is included within the scope of PRC-005-2, other alarming relay control circuits, (i.e~~.~~., SF-6 low gas~~,~~) are not included, even though they may trip the breaker being monitored.

New technology is also accommodated here; there are some tripping ~~systems~~Systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these ~~systems~~Systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control ~~systems~~Systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual ~~components'~~Component's maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as ~~fault~~Fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection ~~component~~Component, have to be tested per Table 1.5? (Refer to Table 3)

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection ~~component~~Component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial ~~loads~~Loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.

- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

~~IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).~~

~~The currently proposed~~The NERC definition of a Protection System is:

- Protective relays which respond to electrical quantities,
- Communications ~~systems~~Systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices~~."~~.

The station battery is not the only ~~component~~Component that provides dc power to a Protection System. In the new definition for Protection System, "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the ~~Standard~~standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to ~~the two~~other conventional methods ~~recommended in the IEEE standards.~~of showing continuity. Continuity, as used in Table 1-4 of the ~~Standard~~standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery ~~systems.~~Systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply, as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers, as well as dc ~~systems~~Systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two ~~components~~Components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc ~~load~~Load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies ~~beside~~besides the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new, the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the ~~Standard~~standard to allow the owner to choose how to verify continuity (no open circuits) of a battery set by various methods, and not to limit the owner to ~~the two~~other conventional methods ~~recommended in the IEEE standards.~~of showing continuity – lack of an open circuit. Continuity, as used in Table 1-4 of the ~~Standard~~standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal~~.~~ (no open circuit). Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path, the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc ~~loads~~Loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor-based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, in most battery chargers, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional ~~1~~one- to ~~2~~ two-second delay to switch from a low substation dc ~~load~~Load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed, which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery, unless the battery charger is taken out of service. At that time, a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the ~~Standard~~standard prescribes what must be accomplished during the maintenance activity, it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged, there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor-controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc ~~load~~Load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of ~~Lead Acid Batteries~~lead-acid batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string; and when used in conjunction with resistance measurements of the battery's external connections, can prove continuity. Also some methods of taking internal ohmic measurements, by their very nature, can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific ~~Gravity~~gravity tests can infer continuity because, without continuity, there could be no charging occurring; and if there is no charging, then ~~Specific Gravity~~specific gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified, it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as ~~designed~~manufactured?

The answer to this question depends on the type of battery (~~Valve-Regulated Lead-Acid, Vented Lead-Acid~~valve-regulated lead-acid, vented lead-acid, or ~~Nickel-Cadmium),~~nickel-cadmium) and the maintenance activity chosen.

For example, if you have a ~~Valve-Regulated Lead-Acid~~valve-regulated lead-acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the ~~6-~~six-month interval is ~~consistent with IEEE guidelines~~important for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is ~~no longer capable of its design capacity~~incapable of performing as manufactured.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every ~~3~~three calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead-acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station ~~batteries ability to perform as designed they should be made upon installation of the station battery and the completion of a performance test of the battery's capacity.~~ battery's ability to perform as manufactured, they should be made at some point in time after the installation to allow the cell chemistry to stabilize after the initial freshening charge. An accepted industry practice for establishing baseline values is after six-months of installation, with the battery fully charged and in service. However, it is recommended that each owner, when establishing a baseline, should consult the battery manufacturer for specific instructions on establishing an ohmic baseline for their product, if available.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment, even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of ~~Valve-Regulated Lead-Acid~~valve-regulated lead-acid (VRLA) batteries and ~~Vented Lead-Acid~~vented lead-acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as ~~designed~~manufactured, the establishment of the baseline, as described above, should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries, the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also, several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However, it is important that when using battery manufacturer-supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). ~~Of course, a measurement of "Conductance" from one manufacturer in a given year could be trended against a measurement of "Conductance" from a different manufacturer's device. This would be true for any unit measurements whether it is conductance, impedance, resistance, voltage, amperage, etc.~~

Although many manufacturers may have provided ~~base line~~baseline values, which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

~~IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.~~

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For ~~Vented Lead-Acid~~vented lead-acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges, the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This, in turn, reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can, therefore, be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely, if taken shortly after adding water to the cell, the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-~~Cadmium~~cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and ~~Valve-Regulated Lead-Acid~~valve-regulated lead-acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries, and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully-charged condition, which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery, a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings, or a combination of the two. There are test methods~~,~~ presently~~,~~ that can read post termination resistances and resistance values between external posts~~, there~~. There are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show if the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen, not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

~~IEEE Standard 450 for Vented Lead-Acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.~~

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other ~~component~~Component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections, such as the bus bar connection to each plate, and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell, or cells, must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery, nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

~~*Why consider the ability of the station battery to perform as designed?*~~

~~Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.~~

~~The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests~~

~~and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.~~

~~The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.~~

~~It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.~~

~~This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).~~

~~The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.~~

~~The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.~~

~~IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed or needs to be replaced soon.~~

Why is it necessary to verify the battery string can perform as manufactured? I only care that the battery can trip the breaker, which means that the battery can perform as designed. I oversize my batteries so that even if the battery cannot perform as manufactured, it can still trip my breakers.

The fundamental answer to this question revolves around the concept of battery performance "as designed" vs. battery performance "as manufactured." The purpose of the various sections of Table 1-4 of this standard is to establish requirements for the Protection System owner to maintain the batteries, to ensure they will operate the equipment when there is an incident that requires dc power, and ensure the batteries will continue to provide adequate service until at least the next maintenance interval. To meet these goals, the correct battery has to be properly selected to meet the design parameters, and the battery has to deliver the power it was manufactured to provide.

When testing batteries, it may be difficult to determine the original design (i.e., Load profile) of the dc system. This standard is not intended as a design document, and requirements relating to design are, therefore, not included.

Where the dc load profile is known, the best way to determine if the system will operate as designed is to conduct a service test on the battery. However, a service test alone might not fully determine if the battery is healthy. A battery with 50 percent capacity may be able to pass a service test, but the battery would be in a serious state of deterioration and could fail at some point in the near future.

To ensure that the battery will meet the required Load profile and continue to meet the Load profile until the next maintenance interval, the installed battery must be sized correctly (i.e., a correct design), and it must be in a good state of health. Since the design of the dc system is not within the scope of the standard, the only consistent and reliable method to ensure that the battery is in a good state of health is to confirm that it can perform as manufactured. If the battery can perform as manufactured and it has been designed properly, the system should operate properly until the next maintenance interval.

How do I verify the battery string can perform as manufactured?

Optimally, actual battery performance should be verified against the manufacturer's rating curves. The best practice for evaluating battery performance is via a performance test. However, due to both logistical and system reliability concerns, some Protection System owners prefer other methods to determine if a battery can perform as manufactured. There are several battery parameters that can be evaluated to determine if a battery can perform as manufactured. Ohmic measurements and float current are two examples of parameters that have been reported to assist in determining if a battery string can perform as manufactured.

The evaluation of battery parameters in determining battery health is a complex issue, and is not an exact science. This standard gives the user an opportunity to utilize other measured parameters to determine if the battery can perform as manufactured. It is the responsibility of the Protection System owner, however, to maintain a documented process that demonstrates the chosen parameter(s) and associated methodology used to determine if the battery string can perform as manufactured.

Whichever parameter is evaluated (ohmic measurements, float current, float voltages, temperature, specific gravity, etc.), the goal is to determine the value of the measurement (or the percentage change) at which the battery fails to perform as manufactured, or the point where the battery is deteriorating so rapidly that it will not perform as manufactured before the next maintenance interval.

This necessitates the need for establishing and documenting a baseline. A baseline may be required of every individual cell, a particular battery installation, or a specific make, model, or size of a cell. Given a consistent cell manufacturing process, it may be possible to establish a baseline number for the cell (make/model/type) and, therefore, a subsequent baseline for every installation would not be necessary. However, future installations of the same battery types should be spot-checked to ensure that your baseline remains applicable.

Consistency is the key when measuring and evaluating ohmic readings. Consistent testing methods by trained personnel are essential. Moreover, it is absolutely critical that personnel use the same make/model of test instrument every time readings are taken if the values are going to be compared. The type of probe, the location of the reading (post, connector, etc.) and the room temperature during the test needs to be carefully recorded when the readings are taken. For every subsequent time the readings are taken, the same make/model of the test instrument must be used, the same type of probes must be used, and the location of the reading must be the same.

A detailed understanding of the characteristic of a battery is also necessary if attempting to use float current as a measure of the ability of a battery to perform as manufactured. For example, trending of float current is a very effective way to determine the rate of antimony poisoning; and, thus, track the positive plate aging process in high antimony lead acid batteries (batteries with greater than 10 percent antimony in their grid lead alloys). The increased float current with age in these high lead antimony batteries can increase the positive plate aging process which gives an excellent indication of battery aging. Trending and evaluation of the measurements of float current on these high antimony lead acid batteries is an acceptable maintenance activity of Tables 1-4(a) and 1-4(b) for verifying the station battery can perform as manufactured. However, lead-calcium acid batteries do not have this property of being able to determine the aging of their grids by trending their float current, because their float current is constant over the life of the battery. Also the lower lead antimony (antimony two percent or lower) batteries do not exhibit this increase in float current as their plate structures age. When attempting to establish a trending program for lead-calcium or low lead antimony (such as lead-selenium) batteries, the Protection System owner should contact the manufacturer of the station battery to see if a trending process is recommended for determining aging of these products.

The establishment of a baseline may be different for various types of cells and for different types of installations. In some cases, it may be possible to obtain a baseline number from the battery manufacturer, although it is much more likely that the baseline will have to be established after the installation is complete. To some degree, the battery may still be "forming" after installation; consequently, determining a stable baseline may not be possible until several months after the battery has been in service.

The most important part of this process is to determine the point where the ohmic reading (or other measured parameter(s)) indicates that the battery cannot perform as manufactured. That point could be an absolute number, an absolute change, or a percentage change of an established baseline.

Since there are no universally-accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured (heretofore referred to as a failed cell). This is the most difficult and important part of the entire process.

To determine the point where the battery fails to perform as manufactured, it is helpful to have a history of a battery type, if the data includes the parameter(s) used to evaluate the battery's ability to perform as manufactured against the actual demonstrated performance/capacity of a battery/cell.

For example, when an ohmic reading has been recorded that the user suspects is indicating a failed cell, a performance test of that cell (or string) should be conducted in order to prove/quantify that the cell has failed. Through this process, the user needs to determine the ohmic value at which the performance of the cell has dropped below 80 percent of the manufactured, rated performance. It is likely that there may be a variation in ohmic readings that indicates a failed cell (possibly significant). It is prudent to use the most conservative values to determine the point at which the cell should be marked for replacement. Periodically, the user should demonstrate that an "adequate" ohmic reading equates to an adequate battery performance (>80% of capacity).

Similarly, acceptance criteria for "good" and "failed" cells should be established for other parameters such as float current, specific gravity, etc., if used to determine the ability of a battery to function as designed.

What are some of the differences between lead-acid and nickel-cadmium batteries?

There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of these two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. In contrast, the primary failure of nickel-cadmium batteries is due to the gradual linear aging of the active materials in the plates. The electrolyte of a nickel-cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel-cadmium battery does not.

Changes to the properties of a lead acid battery when periodically measured and trended to a baseline, can indicate aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate.

Because of the clear differences in the aging process of lead acid and nickel-cadmium batteries, there are no significantly measurable properties of the nickel-cadmium battery that can be measured at a periodic interval and trended to determine aging. For this reason, Table 1-4(c) (Protection System Station dc supply Using nickel-cadmium [NiCad] Batteries) only specifies one minimum maintenance activity and associated maximum maintenance interval necessary to verify that the station battery can perform as manufactured. This maintenance activity is to conduct a performance or modified performance capacity test of the entire battery bank.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

~~The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected.~~ The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically ~~designed~~manufactured for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many ~~systems~~Systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The ~~Standard~~standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously, a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the ~~Standard~~standard refers to "all cells~~"~~," is it sufficient to have a documentation method that refers to "all cells~~"~~," or do we need to have separate documentation for every cell? For example, do I need 60 individual documented check-offs for good electrolyte level, or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this ~~Standard~~standard refer to Station batteries or all batteries~~,~~; for example, Communications Site Batteries?

This ~~Standard~~standard refers to Station Batteries. The drafting team does not believe that the scope of this ~~Standard~~standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications ~~systems~~Systems at a remote site would cause the communications ~~systems~~Systems associated with protective relays to alarm at the substation. At this point, the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry, these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example, in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand, dc resistance of a cell is measured by a third ~~manfacturer's~~manufacturer's equipment by applying a dc ~~load~~Load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices, there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life. ~~A consistent measurement device should not be confused with a requirement to always stay with the same manufacturer. After all volts are volts, impedance is impedance, etc. It is just important to not expect to get consistent "Impedance" data if you switch to a "Conductance" measuring device in the middle of your trending program.~~

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for “cell/unit internal ohmic measurements (impedance, conductance and resistance)” and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a ~~base line~~baseline and trending it over time says, ~~“~~“…depending on the degree of change a performance test, cell replacement or other corrective action may be necessary~~.~~…” (IEEE std 1188-2005, C.4 page 18).

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century, EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell’s capacity, but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs “an accurate measure of the overall battery capacity~~”~~,” they should “perform a battery capacity test.”

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station’s battery became the maintenance activity for determining if the station battery could perform as ~~designed~~manufactured. By evaluation of the trending of the ohmic measurements over time, the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this condition based approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as ~~designed~~manufactured.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and, if not corrected, the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In ~~Vented Lead-Acid~~vented lead-acid (VLA) and ~~Nickel-Cadmium (NiCd~~nickel-cadmium (NiCad) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in ~~Valve-Regulated Lead-Acid~~valve-regulated lead-acid (VRLA) batteries cannot be observed, there is no maintenance activity listed in Table 1-4 of the ~~Standard~~standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or ~~NiCd~~NiCad station battery is a condition requiring correction. Typically, the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and ~~NiCd~~NiCad) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries, the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery, or other unforeseen events can cause rapid loss of electrolyte; the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

What are the parameters that can be evaluated in Tables 1-4(a) and 1-4(b)?

The most common parameter that is periodically trended and evaluated by industry today to verify that the station battery can perform as manufactured is internal ohmic cell/unit measurements.

In the mid 1990s, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

Other examples of measurable parameters that can be periodically trended and evaluated for lead acid batteries are cell voltage, float current, connection resistance. However, periodically

trending and evaluating cell/unit Ohmic measurements are the most common battery/cell parameters that are evaluated by industry to verify a lead acid battery string can perform as manufactured.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for ~~Valve-Regulated Lead-Acid~~valve-regulated lead-acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for ~~Vented Lead-Acid~~vented lead-acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is ~~"~~"…verify that the station battery can perform as ~~designed~~manufactured by evaluating the measured cell/unit internal ohmic values to station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as ~~designed~~manufactured by conducting a performance, service, or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as ~~designed".~~ manufactured." This is the intent of the "perform as ~~designed 6~~ manufactured six-month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25~~%~~ percent increase over baseline. Rather, it will stick out like a sore thumb when compared to the other cells in a string at a given point in time, regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25~~%~~ percent increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the ~~6~~ six-month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a ~~6-~~six-month basis.

It is possible to accomplish both tasks listed (trend testing for ~~capacity~~capability and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications-assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested. Besides the trip output and wiring to the trip coil(s~~)~~), there is also a communications medium that must be maintained. Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology. For example~~;~~, older technologies may have included Frequency Shift Key methods. This technology requires that guard and trip levels be maintained. The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests. Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals. The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore, this ~~Standard~~standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this ~~Standard~~standard to require that a test be performed on any communications-assisted trip scheme, regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications ~~systems~~Systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier ~~systems~~Systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier ~~systems~~Systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications ~~systems~~Systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications ~~systems~~Systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier ~~systems~~Systems can be shown to be operational by automated periodic power-line carrier check-back tests~~,~~ with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications ~~systems~~Systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications ~~systems~~Systems signal quality measurements, including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously

monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the ~~4~~four-month inspection of communications-assisted trip scheme equipment?

The ~~4~~four-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms~~,~~; check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e~~.~~., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier ~~systems~~Systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry, rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria~~"~~." What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally, an alarm will be indicated. For unmonitored systems, this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a ~~fault~~Fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end

receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay ~~systems~~Systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the ~~fault~~Fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This ~~Standard~~standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria, depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system, then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the ~~components~~Components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot, and, thus, make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a ~~Standard~~standard alarming system or an auto-polling system~~,~~; the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours, then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System ~~component~~Component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the ~~Standard~~standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the ~~Standard~~standard technology ~~-~~neutral. The Standard Drafting Team wants to avoid the need to revise the ~~Standard~~standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center, then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and Distributed UVLS Systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current-sensing devices have the same maintenance activity and interval as Table 1-~~2~~3. DC ~~systems~~Systems need only have their voltage read at the relay every ~~twelve~~12 years. Control circuits have the following maintenance activities every ~~twelve~~12 years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication ~~systems~~Systems for distributed UFLS and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however, the part of the trip path control circuitry between the ~~load shed~~Load-Shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping ~~-~~action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single Transmission Protection System failure, such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just ~~fault~~Fault clearing duty; and, therefore, these circuit breakers are operated at least as frequently as any requirements that appear in this ~~Standard~~standard.

There are times when a Protection System ~~component~~Component will be used on a BES device, as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System ~~component~~Component) will be subject to the Tables of the ~~Standard~~standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS ~~…~~

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines ~~"~~bulk ~~-~~power system as ~~(~~: "(A) facilities and control ~~systems~~Systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition, then, is limited by a later statement which adds the term bulk ~~-~~power system ~~"~~"…does not include facilities used in the local distribution of electric energy." Also, ~~section~~Section 215 also covers users, owners, and operators of bulk ~~-~~power ~~facilities~~Facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy~~"~~," despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the ~~Reliability Standards~~reliability standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that ~~load~~Load would have to be shed at the ~~transmission~~Transmission bus to ensure the ~~load~~Load-generation balance and voltage stability is maintained on the BES.

15.8 Examples of Evidence of Compliance

To comply with the requirements of this ~~Standard~~standard, an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC ~~Standards~~standards that could, at times, fulfill evidence requirements of this Standard.

15.8.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the ~~Requirement~~requirement being documented~~,~~ include, but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System ~~component~~Component with another ~~component~~Component, what testing do I need to perform on the new ~~component~~Component?

In order to reset the Table 1 maintenance interval for the replacement ~~component~~Component, all relevant Table 1 activities for the ~~component~~Component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus, the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain ~~disturbance~~Disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications, to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my ~~components of my~~ Protection System ~~components~~Components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

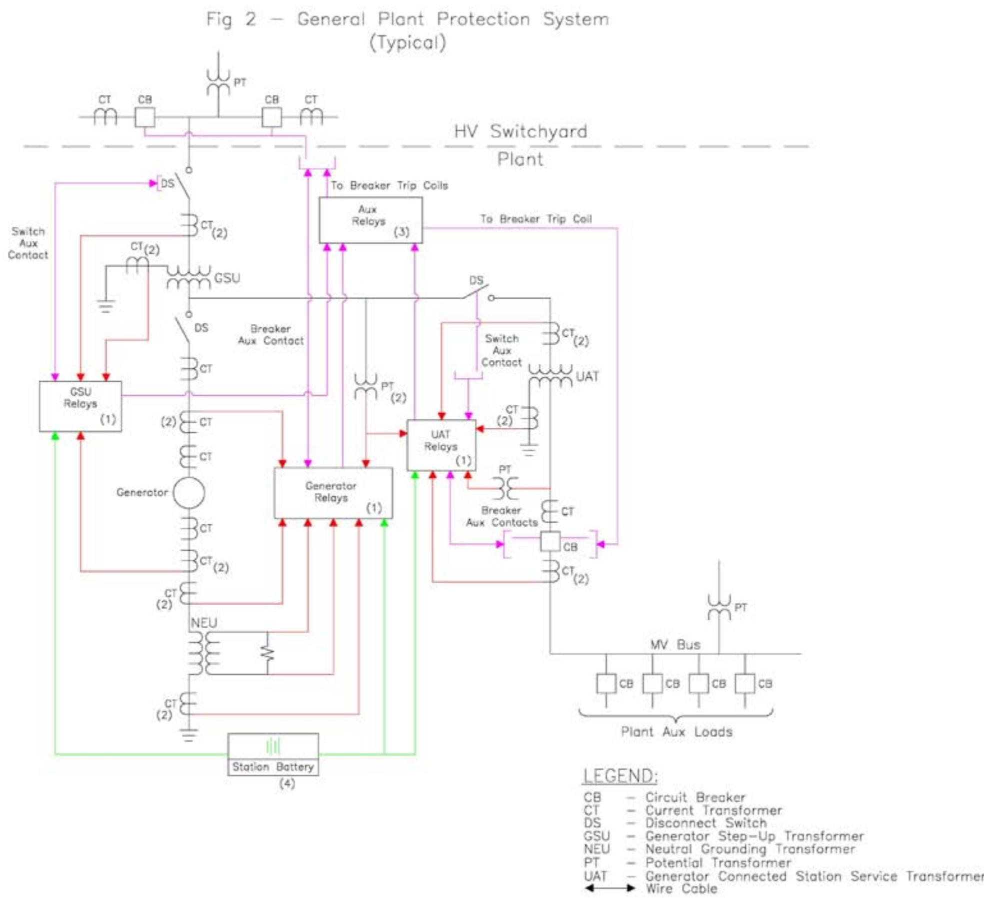
Figure 2: Typical Generation System



For information on ~~components~~Components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check ~~systems~~Systems, metering ~~systems~~Systems and data acquisition ~~systems~~Systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic ~~systems~~Systems that carry a trip signal as well as hard-wired ~~systems~~Systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications ~~systems~~Systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

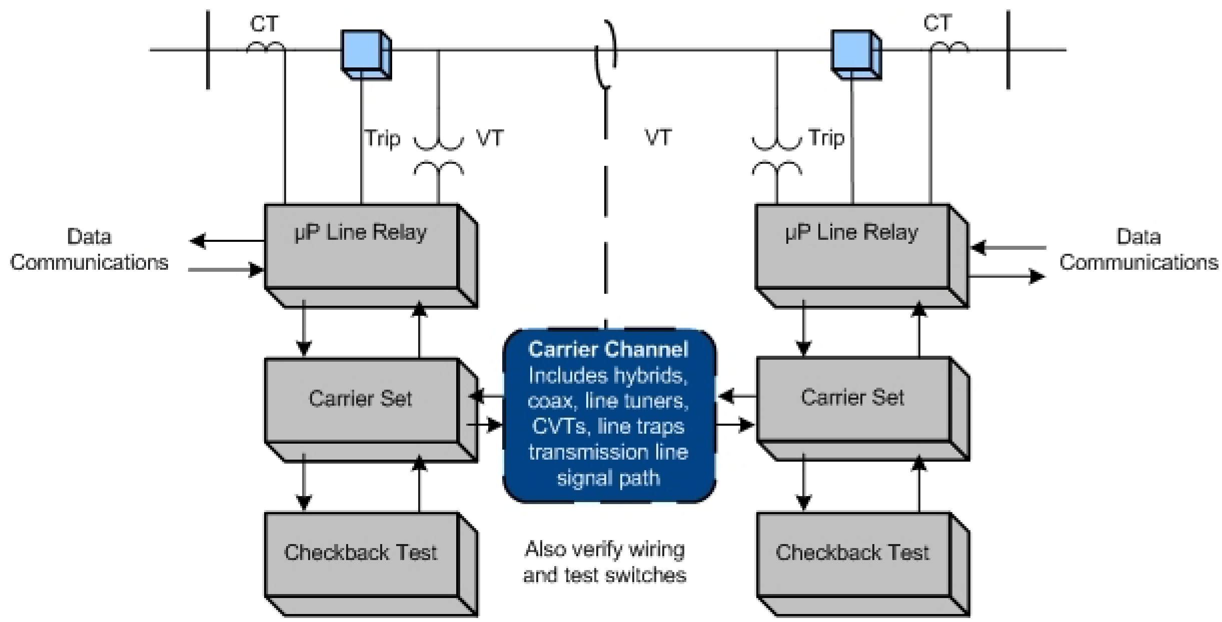
Appendix A

Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line ~~faults~~Faults, and to avoid over-tripping for ~~faults~~Faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement ~~systems~~Systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays.

One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

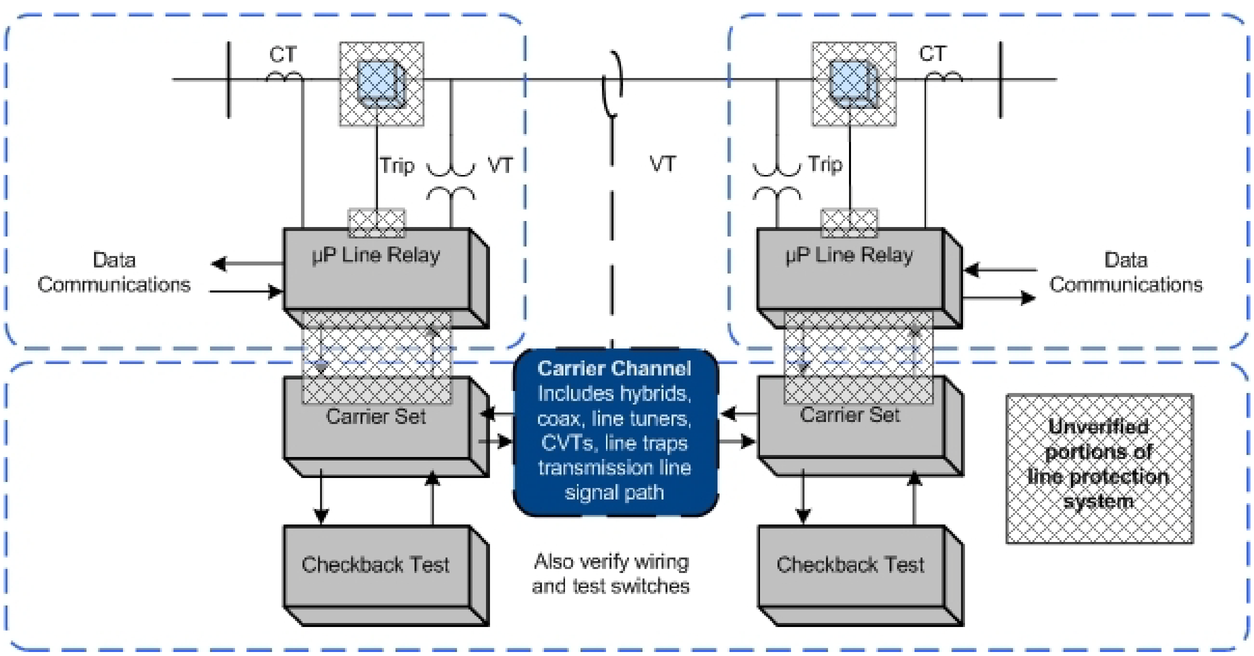
5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.

6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.

7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System ~~elements~~Elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show ~~elements~~Elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These ~~components~~Components are critical for tripping the circuit breaker for a ~~fault~~Fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring ~~faults~~Faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If ~~faults~~Faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated ~~fault~~Fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring ~~faults~~Faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Technical Justification

PRC-005-2 Protection System Maintenance

The purpose of the proposed PRC-005-2 Reliability Standard is to document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. The proposed Reliability Standard further combines the legacy Reliability Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0, as these legacy Reliability Standards have similar reliability goals and requirements. This purpose is consistent with NERC's goal to create and implement reliability standards that enable or support at least one of the eight, defined Reliability Principles. The requirements of the proposed PRC-005-1 Reliability Standard directly support the following Reliability Principles:

> Reliability Principle 1 – Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
>
> Reliability Principle 7 – The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis.

The existing PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 Reliability Standards, as assessed by the NERC System Protection and Control Task Force (SPCTF) in its report of March 8, 2007, contain several fundamental flaws within the requirements. Within this assessment, the SPCTF asserts, for all four standards, that:

"The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.""

And further recommends that:

- *"The standards should clearly state which power system elements are being addressed."*
- *"The requirements should reflect the inherent differences between different technologies of protection systems."*
- *"The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity."*
- *"The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to*

have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor," and

- *The SPCTF recommends that standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 … be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.*

Relative to PRC-005-1, the Federal Energy Regulatory Commission (FERC), in Order 693 further directed in paragraph 1476:

"… the Commission directs the ERO to develop a modification to PRC–005–1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System. We further direct the ERO to consider FirstEnergy's and ISO–NE's suggestion to combine PRC–005–1, PRC–008–0, PRC–011–0, and PRC–017–0 into a single Reliability Standard through the Reliability Standards development process."

FERC offered, in paragraphs 1492, 1517, and 1547, similar directives regarding PRC-008-0, PRC-011-0, and PRC-017-0, respectively.

With the development of the proposed PRC-005-2 Reliability Standard, the Standard Drafting Team (SDT) for Project 2007-17 – Protection System Maintenance, has followed the observations and recommendation of the NERC SPCTF assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. The SDT also addressed FERC's directives from Order 693. The SDT accomplishes this by:

1. Merging the reliability objectives of the four legacy standards.
2. Establishing minimum acceptable maintenance activities and accompanying maximum allowable maintenance intervals, reflecting various technologies of the Components being addressed.
3. Providing entities the flexibility to implement condition-based maintenance by adjusting the minimum acceptable maintenance activities and maximum allowable maintenance intervals to reflect condition monitoring of the various Protection System Components, and
4. Providing requirements for effective implementation of a performance-based maintenance program.

The proposed PRC-005-2 Reliability Standard includes five requirements that:

1. Combine the reliability goals of developing detailed tables of minimum maintenance activities and maximum maintenance intervals for all five Component Types addressed within the NERC definition of Protection System. These tables include adjustments to those activities and intervals to reflect the benefits of any condition monitoring that may be present.

2. Require, within Requirement R1, that entities using a time-based maintenance program (which includes condition-based maintenance) shall establish a Protection System Maintenance Program (PSMP) that conforms to the tables described above.
3. Establish, within Requirement R2, the opportunity and requirements for establishment of a performance-based maintenance program for those entities that have (or wish to develop) sufficient performance observations for their Protection System Components such that they may determine maintenance intervals other than those specified within the tables while maintaining the level of reliability prescribed within the Standard.
4. Require, within Requirements R3 and R4, that entities fully implement their PSMP as determined pursuant to Requirement R1 for time-based maintenance programs and Requirement R2 for performance-based maintenance programs, respectively.
5. Further require, within Requirement R5, that entities demonstrate efforts to correct any deficiency identified during a maintenance interval that causes the Component to not meet the intended performance and requires follow-up corrective action in order to return it to good working order. The SDT elected to not require that entities complete the resolution of these issues, as the time required to effectively resolve the problems may vary widely depending on the scope of that resolution.

The proposed PRC-005-2 Reliability Standard provides a comprehensive set of requirements and associated information (within the tables) that define a strong PSMP. Entities that monitor the actual condition of their Protection System Components are further empowered to utilize the monitoring to improve the efficiency and effectiveness of their PSMP, and those entities that have extensive performance data regarding their Protection System Components can utilize that performance data to further improve the efficiency and effectiveness of their PSMP.

Requirement R1:

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. *Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.*

1.2. *Include the applicable monitoring attributes applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System components.*

Background and Rationale

Establishment of a Protection System Maintenance Program as directed by Requirement R1 is needed to detect and correct plausible age- and service-related degradation of Protection System components. To ensure reliability of the Bulk Electric System, it is important that a Protection System continue to function as designed over its service life.

Requirement R1 establishes that entities develop a comprehensive maintenance program for Protection System components addressing the elements specified in the Protection System Maintenance Program definition:

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

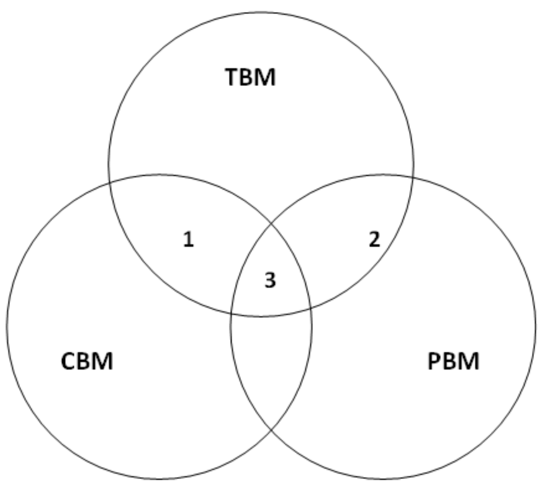
  A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the directives of FERC Order 693 even more effectively than the strictly time-based tests of the same system components.

  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

The PSMP shall:

R1, Part 1.1 Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System component type.

R1, Part 1.1 gives entities the flexibility to choose between the various methods listed above to maintain their Protection System equipment.

All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

R1, Part 1.2 Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

It is necessary for entities to specify the monitoring attributes utilized in their PSMP to demonstrate the existence of the monitoring elements which permit using the extended maintenance intervals established in Tables 1-1 through 1-5, Table 2, and Table 3 of the standard.

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. Making use of the extended intervals by employing component monitoring minimizes human performance errors. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Requirement R2:

Overview

Requirement 2, stated below, deals with Performance Based Maintenance. The requirement refers to Attachment A. Rather than simply list Attachment A, the requirements of Attachment A are listed below with a technical justification discussion for each. The criteria within Attachment A are largely based on application of statistical analysis theory.

Requirement R2

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Background and Rationale

Performance Based Maintenance (PBM) is included in PRC-005-2 to allow utilities to adjust maintenance intervals based on their individual experience with equipment types and manufacture. The utility must create a segment of components with similar manufacture and model characteristics of statistically significant size.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Based on equipment failure(s) and out-of-tolerance(s), called Countable Events, in any given year, the utility then sets its maintenance interval to keep the Countable Events below 4%. Performance Based Maintenance is discussed at length in Section 9.1 of the Supplemental Reference for PRC-005-2. Many of the technical justifications shown below come from of the Supplemental Reference. Each requirement of Attachment A will now be listed and individually discussed.

Countable Event – *A failure of a component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **segment** population of 60 Components.

   A sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a “Pass/Fail” format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:
B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4% (see number 5 below)
Using the equation above, n=59.0. The Standard Drafting Team chose to use the round number of 60 for the requirement.

2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.

   An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

   To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

“… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

“If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation.” (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

“The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

“… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection.” (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.

   This requirement needs little justification. To analyze system performance, the activities and results must be documented.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.

   This requirement states the obvious for a program that is based on the performance results of the Segment.

5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

   The Performance Based Maintenance (PBM) program ensures no more than a 4% failure rate for each segment of a Component Type. The 4% number was developed using the following:
   - General experience of the Standard Drafting Team (SDT) based on open discussions of past performance.

- Test results provided by Consumers Energy for the years 1998-2008 showing a yearly average of 7.5% out-of-tolerance relay test results and a yearly average of 1.5% defective rate.
- Two failure analysis reports from Tennessee Valley Authority (TVA) where TVA identified problematic equipment based on a noticeably higher failure of a certain relay type (failure rate of 2.5%) and voltage transformer type (failure rate of 3.6%).

In addition to the number "30" discussion from number 2 above, the Error of Distribution formula discussed in number 1 above allows the number of Components that should be included in a sample size for evaluation of the appropriate testing interval to be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8. The Standard Drafting Team chose to use the round number of 30.

6. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.

   Annually was chosen as a reasonable time frame to update Component Segments due to Component installation, replacement, and retirement.

7. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.

   Note: this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

   This requirement ensures that a utility keeps a flow of recent data to use in its annual analysis. The Standard Drafting Team felt that 20 years was the maximum time that should be allowed before a Component should be checked or maintained. The minimum number of three allows for the same 20 years interval based on the minimum Segment population of 60 (60/3=20).
8. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

   Annually was chosen as a reasonable time frame to allow for collection of new data to update the program's performance analysis.
9. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the segment experiences Countable Events on no more than 4% of the

Components within the Segment, for the greater of either the last 30 Components maintained or all components maintained in the previous year.

Refer to number 5 above.

10. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

    The 4% number is discussed in number 5 above. Three years was chosen by the Standard Drafting Team because it allows time to modify the program and for the effects of a modified program to be observed.

Requirement R3:

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance programs shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R3 requires the implementation of the minimum maintenance activities and maximum allowable maintenance intervals as elucidated in Requirement R1 and the tables within the standard.

Requirement R4:

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance programs in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R4 requires the implementation of an entity's Protection System Maintenance Program established pursuant to Requirement R2.

Requirement R5:

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

Background and Rationale

The reliability objective of this requirement is to assure that Protection System Components are returned to working order following the discovery of failures or malfunctions during scheduled maintenance. The maintenance activities specified in the Tables 1-1 through 1-5, Table 2, and Table 3 do not present any requirements related to restoration; therefore Requirement R5 of the Standard was developed to require the entity to "demonstrate efforts to correct identified Unresolved Maintenance Issues".

The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action has been initiated. Therefore Requirement R5 requires only the entity demonstrate efforts to correct the Unresolved Maintenance Issues.

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose to require the entity to “demonstrate efforts to correct …” because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity.

During the period of time that the Protection System is operating in a degraded mode, NERC Standard PRC-001-1 requires that operating entities be informed of any Protection System failures that reduce reliability, and several NERC IRO-series and TOP-series standards require that operating entities operate the system in a manner that assures reliability while recognizing any system degradation.

Technical Justification

PRC-005-2 Protection System Maintenance

The purpose of the proposed PRC-005-2 Reliability Standard is to document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. The proposed Reliability Standard further combines the legacy Reliability Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0, as these legacy Reliability Standards have similar reliability goals and requirements. This purpose is consistent with NERC's goal to create and implement reliability standards that enable or support at least one of the eight, defined Reliability Principles. The requirements of the proposed PRC-005-1 Reliability Standard directly support the following Reliability Principles:

> Reliability Principle 1 – Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
>
> Reliability Principle 7 – The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis.

The existing PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 Reliability Standards, as assessed by the NERC System Protection and Control Task Force (SPCTF) in its report of March 8, 2007, contain several fundamental flaws within the requirements. Within this assessment, the SPCTF asserts, for all four standards, that:

"The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.""

And further recommends that:

- *"The standards should clearly state which power system elements are being addressed."*
- *"The requirements should reflect the inherent differences between different technologies of protection systems."*
- *"The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity."*
- *"The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to*

have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor," and

- *The SPCTF recommends that standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 … be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.*

Relative to PRC-005-1, the Federal Energy Regulatory Commission (FERC), in Order 693 further directed in paragraph 1476:

"… the Commission directs the ERO to develop a modification to PRC–005–1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System. We further direct the ERO to consider FirstEnergy's and ISO–NE's suggestion to combine PRC–005–1, PRC–008–0, PRC–011–0, and PRC–017–0 into a single Reliability Standard through the Reliability Standards development process."

FERC offered, in paragraphs 1492, 1517, and 1547, similar directives regarding PRC-008-0, PRC-011-0, and PRC-017-0, respectively.

With the development of the proposed PRC-005-2 Reliability Standard, the Standard Drafting Team (SDT) for Project 2007-17 – Protection System Maintenance, has followed the observations and recommendation of the NERC SPCTF assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. The SDT also addressed FERC's directives from Order 693. The SDT accomplishes this by:

1. Merging the reliability objectives of the four legacy standards.
2. Establishing minimum acceptable maintenance activities and accompanying maximum allowable maintenance intervals, reflecting various technologies of the ~~components~~ Components being addressed.
3. Providing entities the flexibility to implement condition-based maintenance by adjusting the minimum acceptable maintenance activities and maximum allowable maintenance intervals to reflect condition monitoring of the various Protection System ~~components~~Components, and
4. Providing requirements for effective implementation of a performance-based maintenance program.

The proposed PRC-005-2 Reliability Standard includes five requirements that:

1. Combine~~s~~ the reliability goals of developing detailed tables of minimum maintenance activities and maximum maintenance intervals for all five ~~c~~Component ~~t~~Types addressed within the NERC definition of Protection System. These tables include adjustments to those activities and intervals to reflect the benefits of any condition monitoring that may be present.

2. Require~~s~~, within Requirement R1, that entities using a time-based maintenance program (which includes condition-based maintenance) shall establish a Protection System Maintenance Program (PSMP) that conforms to the tables described above.
3. Establish~~es~~, within Requirement R2, the opportunity and requirements for establishment of a performance-based maintenance program for those entities that have (or wish to develop) sufficient performance observations for their Protection System ~~c~~Components such that they may determine maintenance intervals other than those specified within the tables while maintaining the level of reliability prescribed within the Standard.
4. Require~~s~~, within Requirements R3 and R4, that entities fully implement their PSMP as determined pursuant to Requirement R1 for time-based maintenance programs and Requirement R2 for performance-based maintenance programs, respectively.
5. Further require~~s~~, within Requirement R5, that entities ~~initiate resolution~~demonstrate efforts to correct ~~of~~ any ~~issues~~ deficiency identified ~~discovered~~ during a maintenance interval that causes the ~~entities to be~~Component to not meet the intended performance and requires follow-up corrective action in order ~~unable~~ to return ~~the associated components~~ it to good working order. The SDT elected to not require that entities complete the resolution of these issues, as the time required to effectively resolve the problems may vary widely depending on the scope of that resolution.

The proposed PRC-005-2 Reliability Standard provides a comprehensive set of requirements and associated information (within the tables) that define a strong PSMP. Entities that monitor the actual condition of their Protection System ~~c~~Components are further empowered to utilize the monitoring to improve the efficiency and effectiveness of their PSMP, and those entities that have extensive performance data regarding their Protection System ~~c~~Components ~~to~~ can utilize that performance data to further improve the efficiency and effectiveness of their PSMP.

Requirement R1:

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. *Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.*

1.2. *Include the applicable monitoring attributes applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System components.*

Background and Rationale

Establishment of a Protection System Maintenance Program as directed by Requirement R1 is needed to detect and correct plausible age- and service-related degradation of Protection System components. To ensure reliability of the Bulk Electric System, it is important that a Protection System continue to function as designed over its service life.

Requirement R1 establishes that entities develop a comprehensive maintenance program for Protection System components addressing the elements specified in the Protection System Maintenance Program definition:

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for~~Detect visible~~ signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

  A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the directives of FERC Order 693 even more effectively than the strictly time-based tests of the same system components.

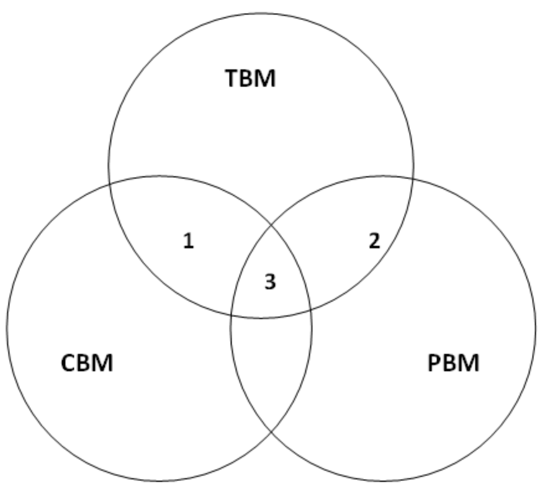
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a

relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

The PSMP shall:

R1, Part 1.1 **Identify which maintenance method (time-based, performance-based ~~(~~per PRC-005 Attachment A~~)~~, or a combination) is used to address each Protection System component type.**

R1, Part 1.1 gives entities the flexibility to choose between the various methods listed above to maintain their Protection System equipment.

All batteries associated with the station dc supply ~~component~~ Component ~~type~~ Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

R1, Part 1.2 **Include the applicable monitor~~ing~~ed Component attributes applied to each Protection System ~~component~~ Component ~~type~~ Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System ~~components~~Components.**

It is necessary for entities to specify the monitoring attributes utilized in their PSMP to demonstrate the existence of the monitoring elements which permit using the extended maintenance intervals established in Tables 1-1 through 1-5, Table 2, and Table 3 of the standard.

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. Making use of the extended intervals by employing component monitoring minimizes human performance errors. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Requirement R2:

Overview

Requirement 2, stated below, deals with Performance Based Maintenance. The requirement refers to Attachment A. Rather than simply list Attachment A, the requirements of Attachment A are listed below with a technical justification discussion for each. The criteria within Attachment A are largely based on application of statistical analysis theory.

Requirement R2

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Background and Rationale

Performance Based Maintenance (PBM) is included in PRC-005-2 to allow utilities to adjust maintenance intervals based on their individual experience with equipment types and manufacture. The utility must create a segment of components with similar manufacture and model characteristics of statistically significant size.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Based on equipment failure(s) and out-of-tolerance(s), called ~~countable~~ Countable ~~events~~Events, in any given year, the utility then sets its maintenance interval to keep the ~~countable~~ Countable ~~events~~ Events below 4%. Performance Based Maintenance is discussed at length in Section 9.1 of the Supplemental Reference for PRC-005-2. Many of the technical justifications shown below come from of the Supplemental Reference. Each requirement of Attachment A will now be listed and individually discussed.

Countable Event – *A failure of a component ~~which has failed and requires~~requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

1. Develop a list with a description of ~~components~~ Components included in each designated ~~segment~~ Segment of the Protection System ~~component~~ Component population, with a minimum **segment** population of 60 ~~components~~Components.

   A sample size requirement can be

estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:
B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4% (see number 5 below)
Using the equation above, n=59.0. The Standard Drafting Team chose to use the round number of 60 for the requirement.

2. Maintain the ~~components~~ Components in each ~~segment~~ Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the ~~segment~~ Segment are available for a minimum of 30 individual ~~components~~ Components of the ~~segment~~Segment.

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

3. Document the maintenance program activities and results for each ~~segment~~Segment, including maintenance dates and ~~countable~~ Countable ~~events~~ Events for each included ~~component~~Component.

   This requirement needs little justification. To analyze system performance, the activities and results must be documented.
4. Analyze the maintenance program activities and results for each ~~segment~~ Segment to determine the overall performance of the ~~segment~~ Segment and develop maintenance intervals.

   This requirement states the obvious for a program that is based on the performance results of the ~~segment~~Segment.

5. Determine the maximum allowable maintenance interval for each ~~segment~~ Segment such that the ~~segment~~ Segment experiences **~~countable~~ Countable ~~events~~ Events** on no more than 4% of the ~~components~~ Components within the segment, for the greater of either the last 30 ~~components~~ Components maintained or all ~~components~~ Components maintained in the previous year.

The Performance Based Maintenance (PBM) program ensures no more than a 4% failure rate for each segment of a ~~component~~ Component ~~type~~Type. The 4% number was developed using the following:

- General experience of the Standard Drafting Team (SDT) based on open discussions of past performance.
- Test results provided by Consumers Energy for the years 1998-2008 showing a yearly average of 7.5% out-of-tolerance relay test results and a yearly average of 1.5% defective rate.
- Two failure analysis reports from Tennessee Valley Authority (TVA) where TVA identified problematic equipment based on a noticeably higher failure of a certain relay type (failure rate of 2.5%) and voltage transformer type (failure rate of 3.6%).

In addition to the number "30" discussion from number 2 above, the Error of Distribution formula discussed in number 1 above allows the number of ~~c~~Components that should be included in a sample size for evaluation of the appropriate testing interval to be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8. The Standard Drafting Team chose to use the round number of 30.

6. At least annually, update the list of Protection System ~~components~~ Components and ~~segments~~ Segments and/or description if any changes occur within the ~~segment~~Segment.

   Annually was chosen as a reasonable time frame to update ~~component~~ Component ~~segments~~ Segments due to ~~component~~ Component installation, replacement, and retirement.

7. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each ~~segment~~ Segment or 3 individual ~~components~~ Components within the ~~segment~~ Segment in each year.

   Note: this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

   This requirement ensures that a utility keeps a flow of recent data to use in its annual analysis. The Standard Drafting Team felt that 20 years was the maximum time that should be allowed before a ~~component~~ Component should be checked or maintained. The minimum number of three allows for the same 20 years interval based on the minimum ~~segment~~ Segment population of 60 (60/3=20).

8. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

   Annually was chosen as a reasonable time frame to allow for collection of new data to update the program's performance analysis.
9. Using the prior year's data, determine the maximum allowable maintenance interval for each ~~segment~~ Segment such that the segment experiences ~~countable~~ Countable ~~events~~ Events on no more than 4% of the ~~components~~ Components within the ~~segment~~Segment, for the greater of either the last 30 ~~components~~ Components maintained or all components maintained in the previous year.

   Refer to number 5 above.

10. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more ~~countable~~ Countable ~~events~~Events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

    The 4% number is discussed in number 5 above. Three years was chosen by the Standard Drafting Team because it allows time to modify the program and for the effects of a modified program to be observed.

Requirement R3:

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance programs shall maintain its Protection System ~~components~~ Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R3 requires the implementation of the minimum maintenance activities and maximum allowable maintenance intervals as elucidated in Requirement R1 and the tables within the standard.

Requirement R4:

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance programs in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System ~~components~~ Components that are included within the performance-based program. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

Background and Rationale

NERC Reliability Principle 1 establishes that "Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards."

NERC Reliability Principle 7 establishes that "The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis."

The proper performance of Protection Systems is fundamental to the reliability of the Bulk Electric System (BES) as embodied in Reliability Principles 1 and 7, and proper performance of Protection Systems cannot be assured without periodic maintenance of those systems.

Therefore, Requirement R4 requires the implementation of an entity's Protection System Maintenance Program established pursuant to Requirement R2.

Requirement R5:

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue*** - *A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

Background and Rationale

The reliability objective of this requirement is to assure that Protection System ~~c~~Components are returned to working order following the discovery of failures or malfunctions during scheduled maintenance. The maintenance activities specified in the Tables 1-1 through 1-5, Table 2, and Table 3 do not present any requirements related to restoration; therefore Requirement R5 of the Standard was developed to require the entity to "demonstrate efforts to correct identified ~~unresolved~~ Unresolved ~~maintenance~~ Maintenance ~~issues~~Issues".

The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action has been initiated. Therefore Requirement R5 requires only the entity demonstrate efforts to correct the ~~unresolved~~ Unresolved ~~maintenance~~ Maintenance ~~issues~~Issues.

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose to require the entity to "demonstrate efforts to correct …" because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity.

During the period of time that the Protection System is operating in a degraded mode, NERC Standard PRC-001-1 requires that operating entities be informed of any Protection System failures that reduce reliability, and several NERC IRO-series and TOP-series standards require that operating entities operate the system in a manner that assures reliability while recognizing any system degradation.

Project 2007-17 Protection System Maintenance and Testing Mapping Document

Mapping Document Showing Translation of PRC-005-1b – Transmission and Generation Protection System Maintenance and Testing, PRC-008-0- Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing, and PRC-017-0 - Special Protection System Maintenance and Testing into PRC-005-2 – Protection System Maintenance.

Standard: PRC-005-1b - Transmission and Generation Protection System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in PRC-005-2 – Protection System Maintenance Or Comment**
R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include: R1.1. Maintenance and testing intervals and their basis. R1.2. Summary of maintenance and testing procedures.	PRC-005-2, R1 and PRC-005-2, R2 PRC-005-2, Tables 1-1 through 1-5, Table 2, and Table 3.	R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. The PSMP shall: 1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3. 1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond

Standard: PRC-005-1b - Transmission and Generation Protection System Maintenance and Testing		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Proposed Language in PRC-005-2 – Protection System Maintenance Or Comment**
		those specified for unmonitored Protection System Components. R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. See PRC-005-2 Tables 1-1 through 1-5, Table 2, and Table 3. The Tables establish prescribed maximum intervals and minimum maintenance activities, and, as such, the entity no longer needs to establish the basis for their intervals.
R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include: R2.1. Evidence Protection System devices were maintained and tested within	PRC-005-2, R3 PRC-005-2, R4, PRC-005-2, M3, PRC-005-2, M4 NERC Compliance Monitoring Enforcement Program Data Retention 1.3	R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance programs shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance programs in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program. The legacy requirement that the entity provide the program results to the RRO and NERC on

Internal Project Report

Project 2007-17

Protection System Maintenance and Testing

Issues -

Fill in the Blank Team

ISSUE: Okay if PRC-006 is fixed

"Okay if PRC-006 is fixed"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Applicability section of PRC-005-2 (4.2.2) establishes applicability to UFLS established in accordance with ERO requirements.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Applicability section of PRC-005-2 (4.2.2) establishes applicability to UFLS established in accordance with ERO requirements.

NERC Audit Observation Team

ISSUE: As applicable, each TO,DP and GOP shall have a protection system maintenance and testing program for protection systems that affect the reliability of the BES. Does this include major equipment like circuit breakers and transformers?

"As applicable, each TO,DP and GOP shall have a protection system maintenance and testing program for protection systems that affect the reliability of the BES. Does this include major equipment like circuit breakers and transformers?"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Maintenance of Protection Systems on all BES equipment is included within this standard. See definition of Protection System.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Maintenance of Protection Systems on all BES equipment is included within this standard. Circuit breakers and power transformers are not included in the definition of Protection System; instrument transformers are included within the definition. See definition of Protection System.

ISSUE: Determine what on schedule means. Is an entity who maintained/tested 95% of their relays at the same level of non-compliance as an entity who maintained/tested 10% of their relays?

"Determine what on schedule means. Is an entity who maintained/tested 95% of their relays at the same level of non-compliance as an entity who maintained/tested 10% of their relays?"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The VSLs for maintenance program implementations (Requirements R3 and R4) establish different VSLs depending on the degree to which the program is implemented.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The VSLs for maintenance program implementations (Requirements R3 and R4) have been phased such that an entity that misses only a few required activities will be at a lower VSL than entities that miss many such activities.

ISSUE: How do you verify compliance for for cts/pts? How do you audit these within a scheduled maintenance program. As part of the procedure, most have accepted visual inspection. Some entities state that testing of the relays verify functionality of the ct/pts

"How do you verify compliance for for cts/pts? How do you audit these within a scheduled maintenance program. As part of the procedure, most have accepted visual inspection. Some entities state that testing of the relays verify functionality of the ct/pts"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific activities for current and voltage transformers have been defined within Table 1-3.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Verification activities in Table 1-3 establish the activities required for the voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices.

ISSUE: How do you verify DC control power? All regions require functional testing of the breaker. This should include functional relay & station battery checks, including breaker tripping, not just a visual inspection.

"How do you verify DC control power? All regions require functional testing of the breaker. This should include functional relay & station battery checks, including breaker tripping, not just a visual inspection."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific verification activities are established in Table 1-4.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Specific activities for maintenance of dc control circuitry have been defined within Table 1-4. These activities include periodic verification of proper functioning of the dc control circuitry

Phase III/IV Team

ISSUE: All generation protection systems whose misoperations impact the bulk electric system

"All generation protection systems whose misoperations impact the bulk electric system"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specificity is provided in Applicability 4.2.5 addressing maintenance of Protection Systems for generator facilities.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Specificity is provided in Applicability 4.2.5 addressing maintenance of Protection Systems for generator facilities.

ISSUE: All protection systems on the bulk electric system.

"All protection systems on the bulk electric system."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The Applicabilty section of the standard defines the facilities to which the standard applies.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The Applicabilty section of the standard defines the facilities to which the standard applies.

ISSUE: Modify applicability to clarfify that the requirements are applicable to the following:

"Modify applicability to clarfify that the requirements are applicable to the following:"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The applicability section has been modified.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The applicability section has been modified.

ISSUE: Need to add language to ensure the Regional Requirements focus on the most impactive scenarios

"Need to add language to ensure the Regional Requirements focus on the most impactive scenarios"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The draft standard establishes minimim ERO-wide requirements; any Regional requirements would have to exceed the ERO requirements.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The draft standard establishes minimim ERO-wide requirements; any Regional requirements would have to exceed the ERO requirements.

ISSUE: PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term.

"PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The applicability section addresses Protection Systems designed to provide protection for BES Element(s), and provides additional specificity regarding applicable generator Protection Systems.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The applicability section addresses Protection Systems designed to provide protection for BES Element(s), and provides additional specificity regarding applicable generator Protection Systems.

ISSUE: There is no performance requirement or measure of effectiveness of a maintenance program required by the standard

"There is no performance requirement or measure of effectiveness of a maintenance program required by the standard"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

For Time-Based (or Condition-Based) maintenance, minimum activities and maximum intervals are specified; for performance-based maintenance, performance (or effectiveness) goals are established.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: For Time-Based (or Condition-Based) maintenance, minimum activities and maximum intervals are specified; for performance-based maintenance, performance (or effectiveness) goals are established.

Version 0 Team

ISSUE: Consistent wording from standard to standard required

"Consistent wording from standard to standard required"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The SDT is combining the four legacy standards into one.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: The SDT is combining the four legacy standards into one.

ISSUE: Define evidence

"Define evidence"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

ISSUE: Define evidence

"Define evidence"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

ISSUE: Define evidence

"Define evidence"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

ISSUE: Definition of evidence required

"Definition of evidence required"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

Status: In Drafting Delivery: 11/7/2012

Solution Details: Requirements R3 and R4 state that the programs must be implemented. Evidence that the program is implemented is included in the Measures M3 and M4.

ISSUE: Exemptions for those with shunt reactors

"Exemptions for those with shunt reactors"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

UV Relays on shunt reactors is not UVLS; these relays would be included as pertinent to relays ""applied on or to protect the BES"".

Status: In Drafting Delivery: 11/7/2012

Solution Details: UV Relays on shunt reactors is not UVLS; these relays would be included as pertinent to relays "applied on or to protect the BES".

ISSUE: Include breakers/switches in list

"Include breakers/switches in list"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Breakers/switches are specifically NOT included in the Protection System definition, and therefore NOT addressed in the draft standard.

Status: In Drafting Delivery: 11/7/2012

Solution Details: Breakers/switches are specifically NOT included in the Protection System definition, and therefore NOT addressed in the draft standard.

ISSUE: Need to retain two dates

"Need to retain two dates"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

The Standard requires that data be retained for the last two maintenance intervals or to the last audit, whichever is longer.

Status: In Drafting Delivery: 11/7/2012

Solution Details: The Standard requires that data be retained for the last two maintenance intervals or to the last audit, whichever is longer.

FERC Staff

ISSUE: Definition of Protection System Maintenance Program (PSMP)

"Draft PRC-005-2 R3 does not address what maintenance means in the context of the standard itself. The standard only requires documentation of protection system maintenance and testing program with supporting documentation that devices were maintained and tested within the intervals defined in the process document and the date that each device was last tested and/or maintained. The ambiguity that arose was with a program that defines scheduled maintenance and testing, as opposed to just stating maintenance in general, but not unscheduled, leaving a gap in the plan"

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Definition of PSMP addresses key concerns

Status: In Drafting   Delivery: 11/7/2012

Solution Details: Protection System Maintenance Program (PSMP) is defined within PRC-005-2 as "An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored." Further details are included, and this term is intended to be placed into the NERC Glossary of Terms when approved. <#CR><#LF>These concerns are otherwise beyond the scope of this standard, as reflected by the directives of FERC Order 693.<#CR><#LF>

Directives -

Mandatory Reliability Standards for the Bulk-Power System (Order 693)

DIRECTIVE: S- Ref 10351 - Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.   1

Due 4/10/2012

Para 1475

"1475. In addition, for the reasons discussed in the NOPR, the Commission directs the ERO to develop a modification to PRC-005-1 through the Reliability Standards
development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is
appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 2 for time-based programs.

Status: In Drafting   Delivery: 2012

Solution Details: Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 2 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.

DIRECTIVE: S- Ref 10352 - Consider FirstEnergys and ISO-NEs suggestions to combine PRC-005, PRC-008, PRC-011, and PRC-017 into a single standard.

Para 1475

"Consider FirstEnergys and ISO-NEs suggestions to combine PRC-005, PRC-008, PRC-011, and PRC-017 into a single standard."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

These suggestions were adopted. The SDT is combining the four legacy standards into one.

Status: In Drafting   Delivery: 2012

Solution Details: These suggestions were adopted. The SDT is combining the four legacy standards into one.

DIRECTIVE: S- Ref 10355 - Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.

Due 4/10/2012

Para 1492

"1492. In addition, the Commission directs the ERO to develop a modification to PRC-008-0 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 3 for time-based programs.

Status: In Drafting   Delivery: 2012

Solution Details: Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 3 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.

DIRECTIVE: S- Ref 10358 - Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.

Due 4/10/2012

Para 1516

"1516. The Commission believes that the proposal is presently part of the process. The Commission approves Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, the Commission directs the ERO to submit a modification to PRC-011-0 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, Table 2, and Table 3 for time-based programs.

Status: In Drafting   Delivery: 2012

Solution Details: Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, Table 2, and Table 3 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.

DIRECTIVE: S- Ref 10362 - Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.

Para 1546

"Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system."

Assigned: Project 2007-17 - Protection System Maintenance and Testing

Addressed

Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 2 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.

Status: In Drafting   Delivery: 2012

Solution Details: Specific maximum allowable intervals are included in the draft standard within Tables 1-1 through 1-5, and Table 2 for time-based programs. Also adding a requirement allowing performance-based maintenance intervals.

Project 2007-17 – PRC-005-2 Protection System Maintenance

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-2 — Protection System Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria - Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC Violation Risk Factor Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report
The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.
In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard
The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005-2 Protection System Maintenance is a revision of PRC-005-1a Transmission and Generation Protection System Maintenance and Testing with the stated purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. PRC-008-0 Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 Undervoltage Load Shedding System Maintenance and Testing and PRC-017-0 Special Protection System Maintenance and Testing are also being replaced by merging them into PRC-005-2 in accordance with suggestions from FERC Order 693. PRC-005-2 also establishes maximum allowable maintenance intervals as directed by FERC in Order 693 in their discussion of the legacy standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

PRC-005-2 has five (5) requirements that incorporate and enhance the intent of the requirements of PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. Several Tables of minimum maintenance activities and maximum maintenance intervals are also included to addresses FERC's directives from Order 693. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Protection System Components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement-to-requirement comparison of VRFs is irrelevant. When developing VRFs for the

requirements of PRC-005-2, the Standard Drafting Team carefully considered the NERC criteria for developing VRFs, as well as the FERC VRF guidelines. Therefore, PRC-005-2 Requirements R3 and R4 are assigned a VRF of High, while Requirements R1, R2, and R5 are assigned VRFs of Medium.

PRC-005-2 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-2 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-2 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a Component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - Violation Severity Levels

Violation Severity Levels (VSLs) define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

Violation severity levels should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on Violation Severity Levels

In its June 19, 2008 Order on Violation Severity Levels, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-2 Requirement R1.

VRF and VSL Justifications – PRC-005-2, R1			
Proposed VRF	**Medium**		
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF..		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Project 2007-17 – PRC-005-2 Protection System Maintenance

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-2 — Protection System Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria - Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC Violation Risk Factor Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards
The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005-2 Protection System Maintenance is a revision of PRC-005-1a Transmission and Generation Protection System Maintenance and Testing with the stated purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. PRC-008-0 Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 Undervoltage Load Shedding System Maintenance and Testing and PRC-017-0 Special Protection System Maintenance and Testing are also being replaced by merging them into PRC-005-2 in accordance with suggestions from FERC Order 693. PRC-005-2 also establishes maximum allowable maintenance intervals as directed by FERC in Order 693 in their discussion of the legacy standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

PRC-005-2 has five (5) requirements that incorporate and enhance the intent of the requirements of PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. Several Tables of minimum maintenance activities and maximum maintenance intervals are also included to addresses FERC's directives from Order 693. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Protection System ~~components~~Components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement-to-requirement comparison of VRFs is irrelevant. When developing VRFs for the requirements of PRC-005-2, the Standard Drafting Team carefully considered the NERC criteria for developing VRFs, as well as the FERC VRF guidelines. Therefore, PRC-005-2 Requirements R3 and R4 are assigned a VRF of High, while Requirements R1, R2, and R5 are assigned VRFs of Medium.

PRC-005-2 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-2 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-2 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a ~~component~~Component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - Violation Severity Levels

Violation Severity Levels (VSLs) define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

Violation severity levels should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital ~~component~~Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on Violation Severity Levels

In its June 19, 2008 Order on Violation Severity Levels, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-2 Requirement R1.

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF..
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL – PRC-005-2, R1			
Lower	**Moderate**	**High**	**Severe**
The responsible entity's PSMP failed to specify whether one ~~component type~~Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entity's PSMP failed to specify whether two ~~component types~~Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible ~~entities'~~entity's PSMP failed to include the applicable monitoring attributes applied to each Protection System ~~component type~~Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more ~~component types~~Component Types are being

Unofficial Comment Form for 3rd Draft of PRC-005-2: Protection System Maintenance

Project 2007-17

Please **DO NOT** use this form to submit comments on the 3rd draft of the standard for Protection System Maintenance. Please submit comments using the electronic comment form. Comments must be submitted by **June 27, 2012**. If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:

The standard recently passed ballot with a quorum of 84.32% and weighted segment approval of 73.93%; for the VRF/VSL Non-binding poll the quorum was 80.72% with 64.88% casting a supporting opinion. The drafting team appreciates the affirmative votes and the constructive feedback provided by the commenters. The team modified the standard based on stakeholder comments and has posted the standard, implementation plan, and other supporting documents for a parallel 30-day formal comment period and 10-day successive ballot through June 27, 2012.

The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) made several changes to PRC-005-2, including the associated definitions, based on comments received from industry. The changes include:

- **Definition of Protection System Maintenance Program (PSMP)**: Revised the "Inspect" element of the definition to "Examine for signs of component failure, reduced performance or degradation."
- **Definition of Unresolved Maintenance Issues:** Revised the definition for additional clarity. The definition now reads: "A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action."
- **Definition of Countable Event**: Revised the definition to "A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events."

- **Applicability**: Clarified Applicability clause 4.2.5.4 to "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."
- **Table 1-2 Component Type – Communication Systems:** The interval for the second portion of the first row of the Table was changed from 6 years to 12 years, and extensive changes were made to the last row of the Table.
- Several activities within Table 1-4a, Table 1-4b, Table 1-4c, Table 1-4d, and Table 1-4f, relating to verification that the station battery can perform properly, were modified with the assistance of representatives of the IEEE Stationary Battery Committee. **Note: Please see the Section 15.4 of the Supplementary Reference for background information on these changes**.
- The VSLs for Requirement R2 were modified from "reduce Countable Events to less than 4%" to "reduce Countable Events to no more than 4%."
- The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised within comments.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

For questions 1 and 2, please provide specific comments related to the individual question. Please reserve question 3 for general comments not related to questions 1 and 2. Comments not related to the specific question will not be addressed.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. In response to stakeholder input, the SDT made several changes to the standard and associated definitions as detailed below:

   - Revised the "Inspect" element of the definition of Protection System Maintenance Program (PSMP), the definition of the term Unresolved Maintenance Issues, and the definition of the term Countable Event.
   - Revised Clause 4.2.5.4 of the Applicability section of the standard.
   - Revised Table 1-2 "Component Type - Communications Systems."
   - Revised Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f "Component Type - Protection System Station dc Supply…."

   Do you agree with these changes? If not, please indicate which changes you do not agree with and provide specific suggestions in the comment area for improvements that would allow you to support the standard.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT made complementary changes in the "Supplementary Reference and FAQ Document" to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for further improvements?

   ☐ Yes

   ☐ No

   Comments:

3. If you have any other comments **<u>that you have NOT provided in response to the above questions</u>**, please provide them here. (Please do not repeat comments that you provided elsewhere.)

   Comments:

A. Introduction

1. **Title:** **Transmission and Generation Protection System Maintenance and Testing**

2. **Number:** PRC-005-1

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

4. **Applicability**

   4.1. Transmission Owner.

   4.2. Generator Owner.

   4.3. Distribution Provider that owns a transmission Protection System.

5. **Effective Date:** May 1, 2006

B. Requirements

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained.

C. Measures

M1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have an associated Protection System maintenance and testing program as defined in Requirement 1.

M2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have evidence it provided documentation of its associated Protection System maintenance and testing program and the implementation of its program as defined in Requirement 2.

D. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Monitoring Responsibility

   Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for three years.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and the Generator Owner that owns a generation Protection System, shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program provided was incomplete as required in R1, but records indicate maintenance and testing did occur within the identified intervals for the portions of the program that were documented.

2.2. Level 2: Documentation of the maintenance and testing program provided was complete as required in R1, but records indicate that maintenance and testing did not occur within the defined intervals.

2.3. Level 3: Documentation of the maintenance and testing program provided was incomplete, and records indicate implementation of the documented portions of the maintenance and testing program did not occur within the identified intervals.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
1	December 1, 2005	1. Changed incorrect use of certain hyphens (-) to "en dash" (–) and "em dash (—)." 2. Added "periods" to items where appropriate. 3. Changed "Timeframe" to "Time Frame" in item D, 1.2.	01/20/05

A. Introduction

1. Title: Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program

2. Number: PRC-008-0

3. Purpose: Provide last resort system preservation measures by implementing an Under Frequency Load Shedding (UFLS) program.

4. Applicability:

4.1. Transmission Owner required by its Regional Reliability Organization to have a UFLS program

4.2. Distribution Provider required by its Regional Reliability Organization to have a UFLS program

5. Effective Date: April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.

R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner’s and Distribution Provider’s UFLS equipment maintenance and testing program contains the elements specified in Reliability Standard PRC-007-0_R1.

M2. Each Transmission Owner and Distribution Provider shall have evidence that it provided the results of its UFLS equipment maintenance and testing program’s implementation to its Regional Reliability Organization and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (within 30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Undervoltage Load Shedding System Maintenance and Testing**

2. **Number:** PRC-011-0

3. **Purpose:** Provide system preservation measures in an attempt to prevent system voltage collapse or voltage instability by implementing an Undervoltage Load Shedding (UVLS) program.

4. **Applicability:**

   4.1. Transmission Owner that owns a UVLS system

   4.2. Distribution Provider that owns a UVLS system

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include:

R1.1. The UVLS system identification which shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have documentation that its UVLS equipment maintenance and testing program conforms with Reliability Standard PRC-011-0_R1.

M2. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have evidence it provided documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program as specified in Reliability Standard PRC-011-0_R2.

D. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. Title: **Special Protection System Maintenance and Testing**

2. Number: PRC-017-0

3. Purpose: To ensure that all Special Protection Systems (SPS) are properly designed, meet performance requirements, and are coordinated with other protection systems. To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected.

4. Applicability:

4.1. Transmission Owner that owns an SPS

4.2. Generator Owner that owns an SPS

4.3. Distribution Provider that owns an SPS

5. Effective Date: April 1, 2005

B. Requirements

R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include:

R1.1. SPS identification shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

C. Measures

M1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place that includes all items in Reliability Standard PRC-017-0_R1.

M2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have evidence it provided documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization. Each Region shall report compliance and violations to NERC via the NERC Compliance Reporting process.

Timeframe:
On request (30 calendar days.)

1.2. Compliance Monitoring Period and Reset Timeframe

Compliance Monitor: Regional Reliability Organization.

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

Standards Announcement

Project 2007-17 – Protection System Maintenance & Testing

Successive Ballot Window Open through 8 p.m. Wednesday, June 27, 2012

Now Available

A successive ballot for PRC-005-2 – Protection System Maintenance is open through **8 p.m. Eastern on Wednesday, June 27, 2012**.

Instructions
Members of the ballot pool associated with this project may log in and submit their vote for the Standard by clicking here.

Due to modifications to NERC's balloting software, voters will no longer be able to submit commits via the balloting software.

Next Steps
The drafting team will consider all comments received during the formal comment period and successive ballot and, if needed, make revisions to the standard. If the comments do not show the need for significant revisions, the standard will proceed to a recirculation ballot.

Background
The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Documents for this project are posted on the project's webpage.

Standards Development Process
The Standards Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend out thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 – Protection System Maintenance & Testing

Formal Comment Period Open: May 29 – June 27, 2012

Upcoming:
Successive Ballot June 18 – 27, 2012

Now Available

A formal comment period for PRC-005-2 – Protection System Maintenance is open through **8 p.m. Eastern on Wednesday, June 27, 2012**. Documents for this project are posted on the project's webpage.

The drafting team has made clarifying changes to definitions and the Applicability section of the standard, minor revisions to the VSLs, and changes to several Tables. Several activities within Table 1-4a, Table 1-4b, Table 1-4c, Table 1-4d, and Table 1-4f, relating to verification that the station battery can perform properly, were modified with the assistance of representatives of the IEEE Stationary Battery Committee. A copy of the letter and report these representatives sent to the team, and the drafting team's response have been posted on the project page. In addition, adjustments were made to *Table 1-2 Component Type: Communications Systems* in response to stakeholder comments.

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a redline of proposed PRC-005-2 that shows the changes to the last approved version of the standard:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference.

The drafting team has also posted a draft SAR to address modifications to PRC-005-2 required by FERC in Order No. 758. In this order, FERC approved an interpretation of PRC-005-1 but directed further revisions to PRC-005 to address ""…maintenance and testing of reclosing relays that can affect the reliable operation of the Bulk-Power System, as discussed above, within these reinitiated efforts to revise Reliability Standard PRC-005." The team has proposed that this directive be addressed in a second phase of Project 2007-17, and the Standards Committee directed the drafting team to post the draft SAR for information and defer activity in modifying PRC-005-2 to address the Order 758 directive until the current modifications to PRC-005-2 have completed recirculation ballot.

Instructions for Commenting

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page.

Commenters and voters must submit comments through the electronic comment form. Due to modifications to NERC's balloting software, voters are no longer able to submit comments via the balloting software.

Next Steps

A successive ballot of the standard will be conducted beginning on Monday, June 18, 2012 through 8 p.m. Eastern on Wednesday, June 27, 2012.

Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Announcement

Project 2007-17 – Protection System Maintenance & Testing

Successive Ballot Results

Now Available

A successive ballot of PRC-005-2 – Protection System Maintenance concluded Wednesday, June 27, 2012.

Voting statistics for each ballot are listed below, and the Ballots Results page provides a link to the detailed results.

Approval	Non-binding Poll Results
Quorum: 79.46% Approval: 79.00%	Quorum: 75.00% Supportive Opinions: 70.21%

Next Steps

The drafting team is considering all comments submitted, and based on the comments will determine whether to make additional changes. If the drafting team determines that no substantive changes to the standard are required, the team will submit the standard and implementation plan for a recirculation ballot. If the drafting team makes substantive changes to the standard, the team will submit it consideration of comments, along with the revised standard and implementation plan, for a quality review prior to posting for another successive ballot.

Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Additional information is available on the project page.

BPA believes the term communications system and channel needs to be clarified as to whether the intent is the communications system, a channel on the telecommunication channel, the teleprotection channel, or the teleprotection function. Minimum battery maintenance interval is to assure that the battery plant will perform as needed, and obtain a reasonable confidence that it will continue acceptable performance until the next maintenance evaluation. Typically, any utility VLA battery application, steady state float charge/long duration discharge, a Monthly or Quarterly maintenance is excessive given a proper design/maintenance program (IEEE 450, 484, 485). There is a 60 year proven history of this. BPA recognizes that there will be specific VLA battery installations that will be required beyond this minimum. BPA recommends to roll the 4 month maintenance into the 18 month maintenance schedule. The scientific vetted method of determining a VLA batteries current performance, and projected performance, is a capacity test. This has been scientifically verified at least 10 times since 1919, with consistent results. This approach is consistent with the IEEE 450, as well as many other standards, and is supported by the industry. If an alternate approach using measured parameters to predict current and future battery performance is to be allowed, then it must assure the same result. Battery monitoring does enable measurements to be made automatically with greater frequency. Additionally it provides the ability to collect, store, report, and analyze data from the battery even during an outage. It does not mitigate the necessity to perform battery maintenance. If battery monitoring is performed mandatory maintenance should also be required on the monitor.
Yes
BPA requests the drafting team to provide more detailed examples of the following for both monitoring and testing: • That addresses the multiple routes, and automated switching between the routes, in a typical large Telecommunications Network Cloud. This applies only if testing of the ‘cloud’, or a teleprotection channel through the ‘cloud’, is the intent of the standard. • That addresses the fact that many older teleprotection technologies, not only used separate test inputs/outputs, but the internal path through the equipment is unverified until the particular function is activated. I.E.: In certain technologies, a functioning ‘guard’ signal does not have any correlation to a functioning ‘trip’ signal.
Table 1-2: Communication Systems: BPA believes that the entire section of Table 1-2 needs clarity. A channel, channel performance criteria, & communication system all have very precise definitions in

the communications world. (Please refer to Supplemental Frequency AQ – Figure 1 – Typical Transmission System Diagram,Telecommunications Network Cloud) When referring to the terms in Table 1-2, if the drafting team is referring to the 'telecommunications cloud', this section is unclear. BPA believes it is more clear if the drafting team is referring to the two telecommunications equipment panels and requests documented clarification. The traditional term for this would be teleprotection channel or teleprotection function. BPA assumes the intention was teleprotection channel. BPA recognizes that the teleprotection equipment panels, in many modern cases, are built into the relay. For background information, the Telecommunications Network is composed of multiple Communication Systems (40 to 50 is not uncommon) that contain multiple thousand (5-6K) pieces of equipment. These systems and equipment are tied together with hundreds of thousands of Communication Channels and Tributaries. Most of the Channels and Tributaires have, at least a primary and backup (WECC Guideline: Design of Critical Communications Circuits), and some have multiple primary's and backups. All of these are needed to create the circuit connections, as indicated on the diagram from one teleprotection panel to another teleprotection panel. Given the above scenario - the confusion is possible.; As an example, for the component attribute: 'Any unmonitored communication system necessary for the correct operation of the protective functions, and not having all the monitoring attributes of a category below.' The 4 calendar month maintenance activity is to: 'Verify that the communications system is functional' The questions that arise are which systems, the drop system or the transport system? The whole system, or just the part carrying the protective signals? What about the channels interconnecting the various systems and so on? BPA suggests clarifying : Any unmonitored teleprotection function necessary for the correct operation of the protective functions, and not having all the monitoring attributes of a category below. The 4 calendar month maintenance activity is to: 'Verify that the teleprotection function is functional' BPA believes this is a much better approach as it identifies only that the teleprotection panels must get inputs and outputs to the relays between them. BPA believes more clarity is still needed. A simple example of an old tone based FSK transfer Trip System over a single point to point analog MW radio channel; the teleprotection panel will normally transmit a guard tone in a particular spectrum over a single radio channel to the teleprotection panel at the far end. BPA understands that one way to verify that the teleprotection function is serviceable in a 4 month maintenance activity is if the guard signal arrives a the opposing end, correct? BPA infers that this is efficient as entities can now monitor loss of guard and have a continuously monitored system which will result in performing just a 12 year maintenance. Is this correct? This raises the question of the trip function. Until the the trip function is energized from the relay, the circuitry sending the trip by initiating a FSK in not functioning. Does this function needs to be check in addition to the guard function? This raises the question of the MW radio channel. BPA recognizes that the FSK trip signal travels over different spectrum in the analog MW radio. Even if the radio will transmit a Guard FSK signal to the far end, it will not necessarily transmit a Trip FSK signal to the far end (a common hidden failure mode in many MW system). Do entities need to check for guard at the far end and test that a FSK Trip signal propagates through the radio system and is received at the teleprotection panel? BPA requests clarification in the followings scenario: Using testing inputs as opposed to operating inputs that trips and guards may be initiated from a different set of inputs of the teleprotection panel, and monitored from a different set of outputs on the teleprotection panel (very common on teleprotection equipment). The test might work, but an actual Trip signal would not work (a common hidden failure mode on current available equipment). If one were to say 'good enough' for a 4 month test (and hope any auditors agree if there is ever a false operation). How about the 12 calendar year test? For a point to point analog MW radio, there is only a single channel that can be tested for passage of guard and trip tones. If the radio is redundant, which it most likely is (WECC Guideline: Design of Critical Communications Circuits) then this has to be done twice, once for each path. Can the drafting team clarify this scenario? In a more typical real-world case, the circuit connection, between the two teleprotection panels, will transverse multiple redundant communications systems. If it crosses 4 redundant systems in the communications cloud, then there are a total of 4^2 or 16 possible communication channels, each with different test criteria, that need to be tested. Additionally, the channels are rerouted manually and automatically much faster than a 12 year cycle (daily is not uncommon). Do all these combinations need to be tested? This discussion illustrates the confusion of the current wording. BPA recommends that: If the intention is to test in the 'cloud' or the performance of the 'cloud', BPA believes there needs to be a new standard, or set of standards created to deal with the intricacies of the telecommunication cloud. If the intention was to test the teleprotection channel, BPA believes additional clarity needs to be provided to address the dynamic redundancies and rerouting of the

communications system. If the intention was to test the teleprotection function BPA believes additional clarity needs to be provided to test/monitor the functions (inputs and outputs) between the teleprotection panels. Table 1-4(a): VLA Battery: 4 Months/Inspect/Electrolyte Level BPA believes that for a properly designed and installed steady state float charge/long duration discharge type battery plant this is not needed. The inspection at 4 Month intervals will unearth catastrophic failures (Split cells, Severe overcharging, etc…). These types of failures can happen anytime, and need to be designed around. Unless the battery plant is under high cyclic load, water usage can be handled in a 12/18 month maintenance cycle. Severe overcharging needs to be dealt with by design/maintenance practices (for example: an Appropriate high voltage alarmed with an immediate call out) since 4 months is too long to wait to detect the condition. Minor overcharging will not be detectable in a 4 month interval (and one wants to very slightly overcharge a battery verse any individual cell being undercharged, but that is a whole different technical discussion). IEEE484 specifies ventilation should be provided for the worst-case hydrogen generation due to overcharging. Other than an inherent manufactures defect that can happen anytime 24/7, splitting cells due to sulfation build up is a slow know process that can be handled in a 12/18 month maintenance cycle with a good visual inspection. Although this is in line with IEEE450, given the specific type of battery configuration in the utility world, this is excessive. Should there be a unique battery plant design, then it is incumbent on that utility to have appropriate shorter intervals. BPA is in support of “For unintentional grounds” and recognizes that it does not apply to intentionally grounded battery systems (teleprotection systems run off of communication batteries in sites where there is no station battery { i.e.: Grand Coulee/Lower Snake }). In general there are two types of batteries used by utilities, outside of their control centers, which will be supplying protective systems. The vast majority is the station battery, which is described very well in the IEEE standards: Switchgear control battery applications typically require output current levels that vary over a relatively long period of time. The battery operates on a float charge during steady state conditions. The battery charger powers relays, indicating lights, and peripheral devices during normal conditions. Instantaneous operation of the circuit breaker and switches require battery output current. Initially, this current may be relatively high for a short duration and then reduce for an extended period of time, followed by another high operating current demand. If the charger output is lost, these low-level currents are supplied by the battery for a specified period. The second is a telecommunications battery supplying the teleprotection equipment (excluding the telecommunications batteries supplying only the communication cloud), which are described very well in the IEEE standards: Telecommunication systems are typically of high reliability, with a minimum uptime of 99.99% is often required. Although the batteries are sized for long duration discharge, short duration discharges are usually the case. Excess charging capacity is often available because of redundant charger configurations and engineered overcapacity. The reserve battery time is usually of long duration.

Nick Wehner
Yes
Yes
Several capitalized terms in the supplementary reference document are used inconsistently with their definition or the reference to their definition is not clear. For example, “communications Systems” in the second bullet in section 2.2 uses “Systems” inconsistently with its definition. The use of “sensing Element” on page 6 is another example. We believe this is inconsistent with the definition of Element which could be a generator, transformer, circuit breaker, bus section, etc. but does not appear to be a Protection System Component. The “localized” definition of Component that is contained in the standard should also be included in the reference document since it is not in the NERC Glossary. Use of “dc Load” on page 82 is not consistent with the definition of Load. Load is an end use customer. There are many other places in the document where there are inconsistencies with these definitions. Thus, the document needs to be further reviewed to ensure the use of the terms is consistent with their definitions.
-1- The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C – Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance

audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of “the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date”. Given that many of the maximum maintenance intervals exceed audit periods for responsible entities, an entity could be required to retain data previous to its last audit, which is not consistent with the Rules of Procedure. We suggest changing this such that the data only needs to be maintained since the last audit. -2- Under the “Definitions” section, for the definition of “Protection System” it is unclear whether the bullets constitute items that are considered to be Protection Systems, elements that may be included within a Protection System, or elements which all must be included to constitute a Protection System. A statement preceding the bullets that explains their relationship to the term “Protection System” would be helpful. This clarification should at least be made within the supplementary reference document, if it cannot be made to the actual definition. -3- Requirement R1 VSLs: It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

Ingleside Cogeneration LP
Yes
Ingleside Cogeneration LP agrees that the changes described above make PRC-005-2 clearer and less ambiguous. We believe that this will result in far fewer violations related to administrative or documentation errors – and focus on those cases which actually may impair BES reliability.
No
Although Ingleside Cogeneration LP does not want to derail the improvements that the SDT has obviously made to PRC-005-1, we remain concerned that expansions in scope of a BES Protection System will automatically roll over to other standards. For example, if the loss of a low voltage auxiliary transformer can trip a generator, its Protection System will be in-scope for PRC-005-2. It is not a big leap in logic to assume that the auxiliary transformer itself should be a BES Element – and subject to the whole body of CIP, MOD, IRO, and TOP standards. Our experience has been that Compliance authorities will make these assumptions, even if that was never the intent of the SDT. The effort to develop and maintain procedures, test results, and communications concerning every BES Element is not trivial – and a single instance of a missed requirement may lead to fines in the thousands of dollars. Ingleside Cogeneration is committed to take any action required to assure BES reliability, but NERC and the project teams must have evidence of its own that it is worth the cost.
Group
Duke Energy
Greg Rowland
Yes
No
Duke Energy votes “Negative” because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the previous Successive Ballot

but prior to the associated Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but which are not intended to provide protection for the BES. The SDT's response to our comment directs us to Section 2.3 of the Supplementary Reference And FAQ Document which states "There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard." We agree with that statement, but point out that Section 4.2.1 is inconsistent with that statement, and has a much broader reach because it includes devices that detect Faults on the BES but which do NOT provide protection for the BES. Compliance audits will be driven by the words in the standard, not the explanations in the Supplementary Reference And FAQ Document. We would appreciate a response to our concern that explains the reliability benefit associated with this expansion of scope, and which specifically addresses the following Duke Energy situation: Duke Energy's standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following wording for Section 4.2.1: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)". FERC's September 26, 2011 Order in Docket No. RD11-5 approved NERC's interpretation of PRC-005-1 R1 and R2, stating: "The interpretation clarifies that the Requirements are "applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES." This interpretation is consistent with the Commission's understanding that a "transmission Protection System" is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices."
Group
Progress Energy
Jim Eckelkamp
R3 and the VSL for R3 seem to imply that an entity would not be in violation of this standard if they exceed their PSMP intervals (including any program grace) as long as the maintenance is performed within the maximum intervals prescribed within the tables. This interpretation was further supported in the previous draft of the Supplemental Reference (Section 8.2.1, page 35), which stated: "According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded." However, this statement has been removed from the supplemental document under the latest draft revision. Would the entity be noncompliant if they exceed their PSMP interval but not the maximum table interval? 2. Table 1-4(e): Typo. "Any Protection System dc supply used only for tripping only…." 3. Page 51, 4th paragraph, 5th line: Typo "thre" should be "three."
Individual
Michael Falvo
Independent Electricity System Operator
Yes
No
The IESO continues to disagree with the VRF assigned to the new Requirements R3 and R4. R3 and

R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our request to change R3's VRF to Medium.

Jennifer Wright
San Diego Gas & Electric
Yes
TABLE 1-5: Similar to the distributed under-frequency load-shedding relays, SPS control circuitry should only be regulated to verify the integrity of the control circuits from the relay to the lockout or auxiliary relay that is used to trip the circuit breakers, but not to the circuit breakers themselves. Owners of SPS control circuitry should have the option of testing these schemes using test procedures that will confirm the control circuitry through the completed trip circuit is continuous and that the circuit breaker will operate when required. Often times the operation of the circuit breaker is confirmed by operation through other protection systems and the SPS function is a parallel path that can be verified without operating the circuit breaker. This change would allow the Transmission Owner to eliminate equipment outages required to test this scheme or the risk caused by removing the SPS for energized testing.
No
R5/M5: M5 should add “The evidence may include but is not limited to…tracking of the unresolved maintenance issue in accordance with the TO's corrective maintenance process.” This alleviates the Transmission Owner from setting up a separate corrective maintenance tracking process intended solely for this regulation.

In tables 1-4 with regards to station batties. 1. DC Supply voltage. Is this reading taken off the batteries or out of the charger? Which read needs to be documented? 2. Unintentional grounds. If the charger has the ability to detect and alarm on unintentional grounds, do we need to manually check this as well? 3. In the 18 month section there is a reference to Float voltage of charger. How do we document in our procedure? Can we use SCADA? 4. In the NICAD batery section. Why can't we do impedance testing? Why only load testing? 5. In table 1-5 there is mention of "Lockout Devices" does this mean that 86 relays are being brought into scope? 6. In table 2 there is discussion with regard to Alarm paths and alarm path monitoring. Table 1-5 itme 4 discusses Auxiliary Relays in the control circuit path. Typically, Auxiliary relays in this scenario are closed contacts and open when in an alarmed state. For example, a low SF6 alarm contacts on a breaker interrupts the trip circuit and prevents the breaker from operating. Does this type of auxiliary relay need to be tested every 12 years? 7. For monitoring transmission PTs- Can we measure low side voltage (13kv) PTs multiplied by the power transformer ratio to verify transmission PT accuracy? 8. Table 1-3 describes independent "measurements continuously verified by comparison" Does separte AC measurement need to be connected to same relay? or can it be connected to separte relay with comparison done in SCADA?

While we agree with the changes made, we believe that table 1-4 should include in the 18 calendar month maintenance activities: 1) Setting the battery charger to equalize, and 2) Inspect battery charger components for leakage and or damage. These additional steps would verify the ability of the battery charger to operate as needed.
Yes

Kenneth A Goldsmith
Alliant Energy
Yes
While we agree with the changes made, we believe that Table 1-4 should include in the 18 month maintenance activities more checks on Battery Chargers. Based on EPRI data and vendor recommendation we believe that 1) Setting the Battery Charger to equalize, and 2) Inspect battery charger components for leakage and/or damage should be added. These additional steps would better verify the ability of the battery charger to operate as needed.
Yes
Section 15.4 of the FAQ document does an excellent job of describing the details of battery maintenance and testing, but there is essentially no description of battery charger maintenance and testing activities. We believe this section needs to be expanded to include a good description of battery charger maintenance activities as well.
We appreciate the work done by the SDT and believe it is an excellent product.

The first column, third row of Table 1-2 should be clarified to indicate whether the bulleted items are related by an “or” clause or an “and” clause. For example, must the communication system have either or both of those attributes for it to be considered?
Yes
Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might also help prevent the need for future CANs and interpretation requests. Though the guidance provided in these documents may appear to be beneficial, we are troubled that the SDT feels it is necessary to provide such a volume of material outside the standard itself, and yet still consider such “references” as enforceable.
As stated in our previous comments for R3, Table 1-5 notes a “mitigating device” as part of component attributes. The meaning of this phrase is open to interpretation and needs to be clearly defined. Is it a discrete device? A protection scheme? Either? The team’s response, by stating its intentions regarding this phrase, actually illustrates the need to provide clarity for this term within the standard. As stated previously, under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems, by their nature, may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish both

minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are *not* included in the NERC definition of Protection System. For example, consider a Special Protection System that is comprised of the following elements: Generating Unit Distributed Control System (DCS) - Qty 1 Protective Relays - Qty 4 - Provide digital inputs to DCS Boiler Pressure Transmitters - Qty 2 - Provide analog inputs to DCS For a predetermined set of system events, the protective relays operate, indicating to the DCS that the event has occurred. If the pressure transmitters indicate that the boiler pressure exceeds a predefined threshold, the DCS responds by adjusting the analog output signals to the turbine valves. For compliance with the existing version of PRC-017-0, the owner of the above system has written a Maintenance and Testing Program that thoroughly tests the protective relays, DCS logic and analog inputs and outputs. However, under PRC-005-2, the owner of the system would not be able to use the proposed performance based method because the system does not have the required Segment population of 60 components. This leaves the owner no other option than the time based method. However, only the protective relays meet the NERC definition of Protection System and they are the only elements of this hypothetical SPS described in Tables 1-1 through 1-5. The existing PRC-005-2 draft does not contain time based activities that would be applicable to the DCS logic, analog inputs and analog outputs. Therefore, whereas the existing NERC standards demand the testing of these devices, NERC standards would no longer require their testing upon the implementation of PRC-005-2.

We recommend removing requirement 5. This is adding the requirement for a corrective action program to the standard. Performance metrics should be utilized to measure if a registered entity is correcting maintenance deficiencies in a timely manner. Examples of performance metrics include: • A Countable event has already been defined in the definition of terms, which would cover the need to replace equipment. • The quantity and causes of Misoperations are a direct correlation to good or poor maintenance practices and corrective actions by a utility. • TADS records events which are initiated by failed protection system equipment and would identify utilities with poor corrective action processes. Can you show us a study or references justifying why records need to be kept for longer

than the end of the current audit period. We are concerned that the complexities and costs of tracking and maintaining records, along with the corresponding maintenance program and PRC-005 revision that old tests would fall under will be an undue cost to small utilities. We suggest requiring entities to retain the last maintenance record or any records created during the current audit period. The comment from the previous consideration of comments, “The SDT believes that Protection Systems that trip (or can trip) the BES should be included” seems to include any device that can affect the BES. This sets a precedence to include any device that can trigger trip coils into the maintenance system. These devices are meant to protect equipment and not the BES. Based on the IEEE device numbers, please indicate which devices are part of the BES protection system and should be included in a maintenance program. Why do functional trip checks need to be done on any interval if checks are done upon commissioning, maintenance and modification? We suggest eliminating any interval and making the requirement to check upon commissioning, maintenance and modification. Comments on SAR for 2007-17 Very few reclosing relays protect the BES. Most reclosing relays actually would have a negative impact on the reliability of the bulk electric system . It is imperative that the SDT clearly define what types of reclosing relays are referred to here, and if it pertains to ANY reclosing relay that can affect the BES. There is a difference between components designed to protect the BES and components which can affect the BES. For R5 if the maintenance interval is 6 years does the maintenance issue become an “unresovled” item immediatley or does the next maintenance interval 6 years later need to be reached before it takes on an unresoved status to be auditable under R5? Comments: Suggest for monitored microprocessor relays in Table 1-1 and 3 to change wording to verify “settings are as specified that are essential to the proper functioning of the protection system”. Many settings are not essential. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. I suggest there be consideration that the interval for functional tests be moved to the minimum frequency of 12 years to minimize this unknown but present risk.

ReliabilityFirst
No
ReliabilityFirst offers the following comments related to the bullet points in Question 1: a. Bullet 1 - Agree with definition revisions b. Bullet 2 - Agree with clause 4.2.5.4 c. Bullet 3 - Disagree with revised Table 1-2 “Component Type - Communications Systems.” The revision increased the maximum time for unmonitored systems to 12 years. However, communication failures correspond to one of the top three causes of Misoperations. The revised last row of the Table 1-2 still permits continuous monitoring to be substituted for testing. It is not clear that the available monitoring can actually identify the health of many of the components that can fail in a power line carrier communication system. RFC believes more research is needed to substantiate the 12 calendar year maintenance interval for unmonitored communications systems. d. Bullet 4 - Disagree with revised tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f “Component Type - Protection System Station dc Supply….” The changes appear to largely ignore the recommendations of the IEEE Stationary Battery Committee.
ReliabilityFirst offers the following comments for considerations: 1. General Comment a. ReliabilityFirst believes not only should there be testing required for individual components (as required Protection System Maintenance Program), ReliabilityFirst believes that the entire Protection System (consisting of all Protective relays, communications systems, Voltage and current sensing devices, etc.) should be tested as a whole. Individually each component may test successfully but while tested as a complete Protection System (through interaction between all the interdependent components), deficiencies in settings along with logic and wiring errors could be discovered. 2. Requirement R5 a. ReliabilityFirst believes the language in Requirement R5 (“…shall demonstrate efforts to correct…”) is subjective and non-measurable. It will be difficult in determining what amount of “demonstration” an entity will need to provide in order to be compliant along with lack of timeframe in which the correction needs to be completed. While RFC understands it is hard to prescribe a specific timeframe/deadline (it can depend on various number of supply, process and management problems), RFC believes at a minimum, the applicable entity should be required to develop a Corrective Action Plan to address the Unresolved Maintenance Issue. ReliabilityFirst offers

the following modification for consideration: “Each Transmission Owner, Generator Owner, and Distribution Provider shall put in place a corrective action plan to remedy all identified Unresolved Maintenance Issues.”

Maggy Powell
Exelon Corporation and its affiliates
1. In the response to Exelon’s previous comment regarding current transformers, the SDT disagreed that test mandated by the current Standard draft seeks to measure a signal is “provided to the protective relay”; however, the test referenced in Table 1-3 merely confirms that the signal is sent and not that it reached the correct protective relay. Generation sites are built in phases, and these requirements do not ensure that the wiring of the protection system matches the prints and the intent of the engineers who designed it. Please provide a technical explanation of how this type of test for a CT will verify that the signal reaches the relay. 2. In the response to Exelon’s previous comment related to the maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays the SDT disagreed that the maintenance program should be left to the discretion of the Generator Owner. Exelon further explained that In order to meet the required activity specified in PRC-005-2 draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse affect on the reliability of the BES. In its response the SDT has not provided the justification as to why performing such a high risk activity increases the reliability of the BES and justification for testing that refutes existing manufacturers recommendations. 3. In the last round of comments, the SDT did not specifically address Exelon’s comments regarding the omission of “...and trips an interrupting device that interrupts current supplied directly from the BES” from the revised applicability language in Section 4.2.1. We are concerned that the SDT may not fully appreciate our concern. Without the qualification that comes from the “and…” phrase above, Exelon feels that section 4.2.1 will bring reverse-looking relays on radial transformers into scope, which are not interpreted as BES Protection Systems. By doing so, it creates a perverse incentive to disable these protection functions, even though they provide a reliability benefit, for the sake of limiting compliance exposure. Please offer a direct response to why the phrase, “...and trips an interrupting device that interrupts current supplied directly from the BES” is no longer included in 4.2.1 and clarify that non-BES relays are not considered within scope. Comments and SDT Response from last comment period (for reference): Exelon Comment: When the SDT changed the original PRC-005 applicability language from “...affecting the reliability of the BES...” to the new 4.2.1 language “...that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)”, they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read “...and trips an interrupting device that interrupts current supplied directly from the BES.” By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005. Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1 language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement:”The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT

observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.” Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1:”Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements.”This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. SDT Response: The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting Faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference Document for additional discussion. Thank you for the opportunity to comment.

We agree with the purpose in section 3 of the Standard. However, section 4.2.1 expands the scope from "affecting the reliability of the Bulk Electric System" to "detecting Faults on BES Elements". In our opinion, the Applicability should be limited to the stated Purpose. Expanding the scope as is done in 4.2.1 greatly increases the number of Protection Systems covered without an increase in reliability of the BES. We prefer the applicability as expressed in Appendix 1 of PRC-005-1b. We suggest changing "Component Type" in R1.2 to something similar to "Segment" as defined within the Standard. A "Component Type" limits to one of five categories, whereas a "Segment" must share similar attributes. In item 2 of the second section of Attachment A, it is only necessary to use 5%, as 5% of a Segment (minimum of 60) is always 3 or more.

I agree with the basic changes, but recommend that a slight modification be made to Tables 1-4(a) and 1-4(b). In the box defining the 18 calendar Months or 6 Calendar Years, the portion in parentheses (e.g. internal ohmic values or float current) should be changed to (e.g. internal ohmic values or float current in concert with other accepted measurements).
Yes
1. On page 21 of 97,Question 7.1, "Please provide an example of the unmonitored versus other levels of monitoring available," "Every six calendar years, perform/verify the following: Battery performance test (if ohmic tests are not opted)" - add after ohmic tests "or other accepted battery measurement parameters." 2. pg 22 of 97, Example 2 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to

station battery baseline . . ." 3. pg 23 of 97, Example 3 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to station battery baseline . . ." 4. pg 23 of 97, Example 3 "Every six calendar years": Add the same verbiage so that the first bullet reads: "(if internal ohmic test or other accepted battery measurement parameters to station battery baseline are not opted)" 5. pg 27 of 97, Question 8.1.2, item #4: Change the last sentence to read: "However, the methods prescribed in these recommendations cannot be specifically required because they are offered as best practice guidelines and not set as standards." 6. pg 71 of 97, Question 15.4.1, Frequently asked Questions: "How is a baseline established for cell/unit internal ohmic measurements?" 2nd paragraph, 1st sentence, replace the word "consistent test equipment" with "the same type of test equipment." In addition, should add a final sentence at the end of this paragraph that states,"Also, in many cases, one manufacturer's 'conductance' test may not produce the same measurement results as another 'conductance' test manufacuter's equipment. Therefore, for meaningful results to an established baseline, the same instrument should always be used." 7. Page 73 of 97, Question 15.4.1, Frequently asked questions: "What conditinos should be inspected for visible battery cells?" Approximately in the 7th line modify the sentence to read . . .abnomral color(which is an indicator of sulfation or possible copper contamination) . . . 8. Page 75 of 97, Question 15.4.1, Frequently asked questions:"How do I verify the battery string can perform as manufactured?" 2nd paragraph that reads "Whichever parameter is evalutated . . ." should be revised to say "Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, specific gravity, performance test, or combination thereof), the goal is to determine . . . 9. Page 75 of 97, Question 15.4.1, Frequently asked questions:"How do I verify the battery string can perform as manufactured?" 5th paragraph starts, "A detailed understanding of the characteristic of a battery is also attempting to use float current as a measure of the abitlity of a battery . . . and ends with "to see if a trending process is reommended for determining aging of these products." The Stationary Battery Task Force recommends deleting this whole paragraph due to inaccuracies or statements that are not relevant. If a paragraph that alludes to float current is considered critically essential, then a short paragraph could be substituted which might say," Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement devices is to establish a trending line against baseline so that a documented process establishes the validity of the judgement used to determine that the battery may perform or not perform as manufactured." 10. Page 81 of 97, Question 15.4.1, Frequently asked questions: "Why does it appear that there are two maintenance activities in Table 1-4(b) for VRLA batteries . . . .?" 3rd paragraph: "A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to 'perform as manufactured.'" This might better be restated as follows: "Trending against the baseline of VRLA cells in a battery string is essential to determine approximate state of health of the battery. For example, using ohmic measurement testing as the mechanism for measuring the battery cells, then, if all the cells in the string show to be in a consistent trend line and that trend line has not risen above say a 25-30% deviation over baseline, then a judgement can be made that the battery is still in a reasonably good state of health. This judgement can assume that the battery is still able to 'perform as manufactured.' It would be wise to confirm the accepted deviation range with the manufacuter of the battery in question to assure good judgement in deciding on the state of health to perform as manufactured.' This is the intent of the "perform as manufactured six-month test' at Row 4 on Table 1-4(b)." 11. Page 81 of 97, Question 15.4.1, Frequently asked questions: [same as Item #10 above], following paragraph: Recommend using a range of 25-30% with the statement that "It would be wise to confirm the accepted deviation range with the manufacuter of the battery in question to assure good judgement' in deciding on the state of health to perform as manufactured.
This revision is a major improvement over the previous draft. Hopefully, the comments above are seen in the light of ensuring basic accuracy of the revised statements. They are not intended to materially change the intent of the position agreed upon at the last drafting team meeting.

Recommend adding further comments on data retention. We prefer the interpretation for the maintenance cycles equaling 12 calendar years, example microprocessor protective relays. This proves the extreme of data retention. We interpret the retention period to be 24 years. Previous test record to current test record equals 12 years, and 12 more years (next maintenance cycle) before removing previous records from storage (24 years).
We cast our ballot as an affirmative vote and agree with the nature of the standard. We raise concerns on the measures that are very prescriptive on documentation. We prefer a standard based on the program and measures that track the application and performance of the groups program. Maintaining the documentation for individual elements becomes a group's prime directive along with maintaining the equipment; this develops a process more controlled by documentation than results. This also adds a level of complexity for data retention, the drafting team tried to resolve by reducing the load of data. We contend the retention levels to be extreme considering some of the 12 calendar year cycles, interpret the data for compliance to be 24 years. One cannot remove previous documents until new maintenance performed 12 years after the current recorded date. We recommend reducing the data retention to list or check sheets and not the extreme of each individual component. Another important factor in managing the data is the capability of retrieval after 12 or 24 years. Some systems and formats are not available for 12 or 24 years and add a burden on companies to maintain legacy systems or convert massive amounts of data.

The term 'Underfrequency' is capitalized in the Supplementary Reference document yet it is not included in NERC's Glossary of terms. We suggest a return to lower case. In fact, given this document is meant to be used for reference only, we question the need to capitalize any term.
On the Redline version of the standard, page 11 Version History; Version 2 Action, should PRC-005-1a be listed as PRC-005-1b and PRC-017 listed as PRC-017-0. Additionally, it does not appear that the Version History has captured a complete record of all revisions to this standard.

The SDT has provided ONE Protection System Component with two differing maintenance periods, the lockout (86) device. Six years is used for the lockout operation and twelve years is used for contact testing of the lockouts. Earlier the SDT had a similar arrangement with microprocessor relays, the microprocessor relay would be tested on a twelve year cycle but the microprocessor's electro-mechanical trip outputs were to be tested on a six year cycle. The SDT then made a decision that the single microprocessor asset would have a common testing cycle of twelve years, reasonably considering it a single asset with a single maintenance cycle of 12 years. To eliminate confusion with lockout relays, it is recommended that a similar decision be made by the SDT to make a single lockout relay asset have a common maintenance cycle of twelve years. The lockout relay twelve year cycle would include both the lockout operational test and the lockout relay tripping contact tests. This twelve year cycle would also be in direct maintenance alignment with other microprocessor relays and auxiliary relay testing cycles. In addition, the sudden pressure relays and their integral control circuit, should either be included or excluded. This is a compliance trap and will lead to many findings of non-compliance, based on sudden pressure relays not being included in many prior versions and currently not included in this version, except for their DC control circuit.

Pawel Krupa
SCL supports the position of WECC PNGC with regard to the position paper VRF/VSL recommendation. Specifically it is the contention of PMGC and members that small entities with maybe 2 or 3 components within a Component Type that sustain a violation will unnecessarily be subjected to a “severe” or “high” VSL assignment due to the % based parameter. We feel the SDT did not adequately address our concerns during the last ballot/comment period. While this is a non-issue for larger entities with hundreds or thousands of individual components, we believe this exposes smaller entities to unnecessary compliance risk. 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given NERC Guidance (following), this seems to be a contradiction given the language of “…more than one” [NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance. ii. MODERATE: Missing at least one significant element (or a moderate percentage) of the required performance. iii. HIGH: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. SEVERE: Missing most or all of the significant elements (or a significant percentage) of the required performance.] Thus we support the WECC PNGC suggestion to change the language for “Lower VSL” for R3 to: 'For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained…' OR 'For Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained…'

We believe that the SDT has improved the definitions with these changes and we fully support them. In addition, we also support the Table 1-2 Communication Systems changes based on our experience, and the Station dc Supply changes in the five Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f because they are realistic and consistent with our experience.
Yes
(1) Capitalizing in some cases is inappropriate (e.g., Systems; Glossary defines System as ‘A combination of generation, transmission, and distribution components.’ So ‘communication System’

incorrectly capitalizes 'system'). (2) Page 15, we disagree with retention of maintenance records for replaced equipment as this can cause confusion. We believe that at the most the last maintenance date could be retained to prove interval between it and the test date of the replacement equipment that provides like-kind protection. (3) We request the SDT to provide a few examples of 'non-battery-based dc supply'. The SDT has previously responded that this does not include 'capacitor trip devices'. Does the SDT mean to include M-G sets, flywheels, and / or rectifiers? Also, Emerging Technologies on page 73 is vague please clarify.
(1) Remove Table 1-4 batteries from the Countable Event definition. (2) Please change Table 1-4(d) title to "Component Type – Protection System Non Battery Based Station dc Supply" [delete: Using Non Battery Based Energy Storage] to be consistent with the definition. (3) R3 & R4: Change VRF to "Medium" for the following reasons: (a) Guideline (3) - Consistency among Reliability Standards is not satisfied. The VRF_Standards_Applicability_Matrix_2012-03-01 clearly shows that comparable requirements in the standards that PRC-005-2 replaces are Medium or Lower, specifically PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (b) The High Risk Requirement is not met. We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (c) Guideline (4) Consistency with NERC's Definition of the Violation Risk Factor Level is not met. Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events continues to be extremely rare. (4) Measure M3 on page 6 should only apply to 99.5% of the components. We strongly advocate the SDT to revise and state: "Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated…." We believe I that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. Note that we are not suggesting for the VSL to be changed. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance".

1. PNM seeks clarification on the revised Clause 4.2.5.4 of the Applicability section of the standard. - "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays." Will Auxiliary Transformers that are directly connected to the generator bus of generators which are part of the BES and that step down to distribution level voltage & perform similar functions as that of station service transformer fall under this clause?
Yes
The Supplementary Reference and FAQ Document has served as a valuable resource and PNM commends the drafting team's efforts in writing a comprehensive document. Section 13. Self Monitoring Capabilities and Limitations – Last but one bullet on Page 59 of the Supplementary Reference and FAQ Document is confusing and needs possible rewording and clarification. "With this information in hand, the user can document monitoring for some or all sections by extending the monitoring to include…" appears confusing.
Table 1-1 Component Type – Protective Relay and Table 1-2 Component Type – Communications Systems refer to Table 2 Alarm Paths and Monitoring for monitoring related attributes. However, the maximum maintenance interval in rows referring to Table 2 in both Tables 1-1 and 1-2 is 12 calendar years whereas there is a row in Table 2 that if there is an Alarm Path with monitoring (row 2 of Table 2), no periodic maintenance is required. Does this mean that even if there is an Alarm Path with monitoring for which no periodic maintenance is required, the component type – Protective Relay or Communications Systems will still be required to be maintained within the maximum 12 calendar years interval? This appears to be contradictory especially since rows in Tables 1-3, 1-4(f), and 1-5 that refer to Table 2 have "no periodic maintenance specified" under maximum maintenance interval. This also appears to be contradictory to the text provided under bullet 1 of Section 5.2 Extending

Time-Based Maintenance which states that – If continuous indication of the functional condition of the Component is available (from relays or chargers or any self monitoring device), then the intervals may be extended, or manual testing may be eliminated.” Rows referring to Table 2 in Tables 1-1 and 1-2 do not suggest that manual testing will be eliminated as it is requiring a 12 calendar year maintenance time interval even if it meets the requirements under table 2 for alarm path with monitoring. PNM recommends adding the following under Maximum Maintenance Interval to be consistent with other tables 1-3, 1-4(f), and 1-5 – “12 calendar years OR no periodic maintenance specified”.

Steve Alexanderson P.E.
Central Lincoln
No
Central Lincoln agrees with most of the changes except for the change from “as designed” to “as manufactured” in the Station DC supply table. The concern is not high enough to warrant a negative ballot, and we appreciate the difficulty the SDT has had on this issue with IEEE. The “as manufactured” performance may be interpreted as the battery’s capacity when new and fully charged. Of course a properly engineered system will be based on a future aged battery capacity, reduced from the brand new capacity. We prefer “as designed,” but this might lead a CEA to ask for design documentation an entity may have not retained. In the end, it is not the manufactured or design capacity that matters, it is the battery’s ability to power the protection systems and trip the breakers. We suggest “as manufactured” be changed to “as needed.”
Yes
Group
Southern Company
Antonio Grayson
Yes
Related to the changes identified in the Battery Tables: • We do not see that the change from “as designed” to “as manufactured” really changed the meaning of the battery capability to delivery its rated capacity. We would like the SDT to consider the following language: “verify that the station battery can provide adequate power to the Protection System by conducting…..” • For Generating Plant Batteries, we feel as though that the only way to prove that a generation battery can deliver what it is supposed to be able to deliver for “All” of its functions is by conducting a capacity test”. We would like the SDT to consider adding such a Note to the battery tables and/or make the statement in the FAQ document.
Yes
See comment on Generating Plant Batteries in Question #1.
• We would like the SDT to consider rewording M5 as follows: The evidence may include any form of evidence indicating an entity is demonstrating efforts to correct identified Unresolved Maintenance Issues. Additionally: All of the examples of evidence should be moved to the Supp Ref doc and be there only for reference. • Page numbers should be visible on all pages.

Table 1-4a Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell. -and- Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank. Table 1-4b Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell. -or- Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank. Table 1-4c Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell. -and- Verify that

the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank.
Yes
Why consider the ability of the station battery to perform as manufactured? The reason the term “perform as manufactured” was used is because there is not much data available to verify actual sizing of the cells for their application. The only battery values for typical Protection systems that have a verifiable basis are the battery manufacturer’s data. The only way to know when a battery needs to be replaced is to compare measured values against manufacturer’s data or other established values. To verify that the station battery can perform as manufactured is the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. Inspections alone do not provide trending information that indicates the state of aging of a station battery. The maintenance activities listed in Table 1-4 to “verify that a station battery can perform as manufactured” are intended to provide information about the aging process of a station battery. A Transmission Owner, Generator Owner or Distribution Provider can then use the information provided by the maintenance activity to determine if testing of a station battery is required or if timely replacement or removal of the station battery or its components (cell/unit) should be accomplished. Capacity discharge testing is the only industry approved method of determining the true capacity of lead acid and nickel–cadmium station batteries. The performance capacity test of the entire battery bank listed as maintenance activities of table 1-4 provides a mechanism for trending battery discharge characteristics based on manufacturers published data. Trending discharge test results is the basis for determining the aging of a station battery serving a Protection System. Based on these results, decisions concerning replacement of a battery serving a Protection System and its components can be made by the Transmission Owner, Generator Owner or Distribution Provider. There is a marked difference in the aging process of lead acid and nickel–cadmium station batteries. The difference in the aging process of the two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. However, the primary failure of nickel – cadmium batteries is because of the gradual linear aging of the active materials in the plates. The electrolyte of a nickel – cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel – cadmium battery does not. Changes to the periodic measured properties of a lead acid battery when trended to a baseline can provide an indication of aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate. Since aging in nickel-cadmium cells is linear, periodic measured properties of nickel-cadmium cells when trended to a baseline can provide an indication of aging of the active material in the positive plates. By trending periodic measured properties of a station battery serving its Protection System the Transmission Owner, Generator Owner or Distribution Provider can develop a condition based method to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test. There is a clear differences in the aging process of lead acid and nickel–cadmium batteries. The measurable properties of a nickel – cadmium battery will change more gradually than VRLA cells; therefore, periodic interval and trending to determine aging has very little industry experience, but the user should work with the battery manufacturer to determine if internal ohmic measurements can be applied to their product. While it has been proven that there is a relationship between internal ohmic measurements and cell capacity of lead acid batteries, an accurate determination of a battery’s exact capacity cannot be attained by measuring its cell’s internal ohmic values. However, trending internal ohmic measurement of VRLA battery cells to establish a base line is a method of trending measured properties by Transmission Owners, Generator Owners and Distribution Providers to evaluate their station battery cells for health and aging. Evaluating internal ohmic cell/unit measurements against the battery cell baseline values is an acceptable Maintenance Activity listed in tables 4-1(a) and 4-1(b) 4-1(c) to verify that the station battery can perform as manufactured as long as it is measured and trended to the baseline values at an interval less than or equal to the published Maximum Maintenance Interval of tables. Why was the term “manufactured” used instead of “designed” in the maintenance activities of tables 1-4(a), 1-4(b), 1-

4(c), 1-4(d) and 1-4(f)? The phrase “as designed” always raises the question of “who made the design requirements that are being tested to or evaluated, the manufacturer of the battery or the engineer sizing the battery? The use of the term designed when discussing a battery’s ability to perform was incorrect because we did not differentiate between a performance test and a service test. The phrase “meets the design requirements” is used when discussing a service test which is a discharge test that measures a battery’s capability to meet a duty cycle which was designed by the person sizing the battery. However, when talking about a performance capacity test, the test is a measure of the currents or amp-hour discharge rates based on the battery manufacturer data for the station battery being tested. The term “manufactured” used in the tables avoids the confusion caused by the term “designed” and its application to service testing. Also, when discussing internal ohmic measurement trending, “manufactured” applies to establishing a set of base line values when compared to a battery of known capacity based on the manufacturer’s published data. When trending other measurable properties that assist in establishing aging, the battery manufacturer’s data are used as a basis for establishment of baseline values and therefore the use of “manufactured” avoids any ambiguity that might be caused by use of the term “designed”.

Yes
Yes
The PNGC Small Entity Comment Group appreciates the hard work of the Standards Development Team on this difficult and complex project. However we are disappointed with the response to our concerns over the VSL matrix and although we believe on balance this should not be the sole reason for voting "no", we find it difficult to re-cast a "yes" vote and will therefore vote "abstain" to maintain the integrity of the quorum and reflect our position. Your response to our comment;"1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate." reflects a position that indicates are cursory and dismissive review of our concern. We would counter that because a smaller entity has less to maintain, a solely percentage violation measure is therefore inappropriate. We've appended our original comment below in addition to the SDT response. PNGC Comment: 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the “NERC Guidance (Below), this seems to be a contradiction given the language of “…more than one”. a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Modedrate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required

performance. We suggest changing the language for “Lower VSL” for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained... Or For Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained... SDT response: 1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.

This comment is regarding the Implementation Plan for Requirements R3 and R4, 1. (page 3 of 5) of The Implementation Plan for Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02. Number 1. states: For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5: • The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities. TVA Comment: Even though TVA has already started a plan to address this issue, it will take several years to implement automatic checkback on 541 carrier blocking sets on the TVA system. TVA performed quarterly testing from 2000 through 2007, then after data showed failures not attributed to signal margin, the test was changed to twice a year in 2008. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 test/year. We suggest a graduated implementation plan for this effort similar to number 3 (being compliant 30% in 24 months, 60% in 36 months, and 100% in 48 months) on Pages 3 and 4 of 5.

This is a follow-up question/comment from the previous round of balloting; please see the part in all capitals. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions IF DC VOLTAGE IS VERIFIED AT EACH APPLICABLE SET OF ACTUATING DEVICE TRIP TERMINALS SO THAT EVERY TRIP PATH IS ADDRESSED. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. In Table 1-2, does the ‘channel’ include the communication interface/driver that is part of the end device?

No
See Question 3 Comments
PPL Generation, LLC thanks the SDT for there effort on this latest version of the standard and has voted affirmatively. We offer the following comments/suggestions: 1.) PPL Generation, LLC would like more direction on how the Tables 1-3 are to be interpreted. Under the left column “Component Attributes,” it is not completely clear as to which situation is applicable in order to know what “Maintenance Activity” applies. Either the table's "Component attributes" or the statement “Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components” could be more prescriptive on the specific component attributes to provide entities direction as to when exactly each table is to be followed. 2.) In regards to Unresolved Maintenance Issues, PPL Generation, LLC is concerned with the use of the word “efforts” in regards to the use in “shall demonstrate efforts” in Requirement 5. We suggest that either a formal definition of “effort” is provided or more clarity is added in the Requirement 5, shown below, that gives a quantitative scale of what constitutes an effort. “Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.” In its current form, “efforts” can be broadly interpreted by auditors as any number of different required actions of an entity and could potentially lead to inconsistencies in applying the term throughout the regions.

Luminant
Brenda Hampton
Yes
Yes
The testing of non-BES breakers for plants should be discussed in the FAQ using the similar application for Distribution Providers. Luminant recommends a section for Generation Owners that describes what Elements (circuit breakers) should be tested. Luminant strongly believes that there is no additional benefit to the BES by requiring the GO to test the non-BES breakers (UAT low side and generator field breakers). These circuits are radial fed.
In addition to the revised Supplemental Reference and FAQ guide revision requested in question 2, Luminant recommends that Table 1-5; Line 1 and 4 be revised to specifically state that only BES elements (circuit breakers/interrupting devices) are to be tested. There is no benefit to the BES system for testing the non-BES breakers and some locations, trip testing of the breakers would cause a unit black-out due to unit design. Some units do not have start-up transformers. By performing these tests, there is a risk of causing unit damage while the unit is off-line. Therefore Luminant recommends that Table 1-5 be revised to only require BES breakers be tested for compliance purposes. This would be consistent with the requirements covered in Table 3 for UFLS Systems.

Western Area Power Administration
Brandy A. Dunn
No
The Standard Drafting Team has made changes to the battery maintenance tables 1-4 (a-f) that does not reflect the extensive re-wording of the Supplemental Reference/FAQ document or address the posted recommendations of IEEE Battery Task Force. The industry needs clear, concise maintenance tasks, intervals and standards for their maintenance programs that are developed and tested by industry experts such as IEEE and EPRI.
Yes
Western Area Power Administration is appreciative of the hard work done by the SDT and NERC. We respectfully submit that the Supplementary Reference and FAQ Document should: 1. Offer guidance

on establishing baselines for older battery banks 2. Be in agreement with IEEE standards for battery maintenance 3. Replace the existing CANS
Western Area Power Administration is appreciative of the hard work done by the SDT and NERC. We respectfully submit our professional opinion that the increased relay testing required by the PRC-005-2 will result in a net degradation to the reliability of the BES due to human hands disturbing working systems. We propose that auxiliary relays be tested at commissioning and anytime the circuits are rewired or redesigned. If there is evidence that the relay has functioned properly in its current configuration then the best practice for insuring reliability is to leave it alone. The maintenance interval of 6 years for lock-out relay testing is not consistent with 12 year interval of auxiliary relay testing or control circuit testing. No justification is provided for this increased testing interval of lock-out relays versus other electro-mechanical devices. These inconsistent testing intervals, within the same protection control schemes and protective devices, will complicate the industry's Protection System Maintenance Program and cause an increase in maintenance costs. Condition Based Monitoring or Performance Based Monitoring are not allowed on trip coil circuits or lock-out relays. This is inconsistent with current or future technology. Deviation from the 6 year testing interval should be allowed, using CBM or PBM. The Standard should not present a barrier to technology advancements or industry initiatives. The continuous, frequent testing of these devices is detrimental to system reliability. Disagree with testing of the dc control portion of the sudden pressure device as defined by the FAQ. We feel that this device and its wiring were deemed out of scope previously.

ATC recommends that the SDT change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 24, Row 1, Column 3 to: “Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years” Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. In addition, many utilities purchase breakers with dual redundant trip coils to mitigate the possibility of a failure. It is well recognized that the most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice to mitigate the most prevalent cause of breaker failure. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). ATC continues to recommend a negative ballot since we believe that the testing of “each” trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

The FAQ should clarify why a the requirement for a "Summary of maintenance and testing procedures" developed by an entity is concidered prescribing a methodology to meet those requirements. The entity is developing the methodology for meeting the requirements that the elements be maintained.

The reliability level for protection systems has been lowered by elimintating the requirement for entity defined maintenance and testing procedures. Currently the draft only prescribes that the elements are indentified as to when they will be maintained. The FAQ suggested that the PRC-005 did not have sufficient specificity with regard to the PSMP requirement. The entity no longer must be able to document that they were maintained in accordance with any prescribed method, jus tthat they were maintained in accordnace within an acceptable interval. Second, the measure for R1 does not specificy what evidence is considered acceptable. This makes the standard hard to enforce.
Group
Florida Municipal Power Agency
Frank Gaffney
The SDT is still not agreeing with the applicability as interpreted and approved by FERC PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: In these two standards, use of the phrase transmission Protection System indicates that the requirements using this phrase are applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES. The SDT continues to ignore this FERC approved interpretation, and this omission causes us to vote Negative again. The basic issue is that some distribution protection will be swept in with the applicability of the standard, which states: 4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.) Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should have adopted the FERC approved interpretation. We have made this recommendation several times before.

Oncor Electric Delivery
Yes
Yes
On Page 81 of the Supplementary reference and FAQ Draft it appears that the drafting team changed the term “designed” to “manufactured” and then used the quotation from the previous standard’s Table 1-4(b). Oncor recommends that the two statements on page 81 of the Supplementary Reference and FAQ – Draft be changed from the present version “…verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values to station battery baseline.” “Verify that the station battery can perform as manufactured by conducting a performance, service, or modified performance capacity test of the entire battery bank.” to a new version of the quotes based on the new version of Table 1-4(b). The new quotes should be stated as follows: “…verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline.” “Verify that the station battery can perform as manufactured by

conducting a performance or modified performance capacity test of the entire battery bank.”
On Page 89 of the Supplementary reference and FAQ Draft document on the References page (reference #12) the correct number of the standard should read “Std 450-2010” instead of “Std 45-2010.”

VSL should not be a function of "specific Protection System Component Type". VSL should look at percentage of TOTAL Protection System Components that were not tested within scheduled test date. Consider the entity with 400 Protection System Components, including 2 station battery systems. If that entity completed 399 of 400 tests within schedule and missed 1 battery test, the VSL would be high or severe. Alternatively, if the entity completed 399 of 400 tests , but the missed test was one of 200 protective relays, the VSL would be low. There is no assurance though that the missed battery test resulted in higher risk for the BES than the missed protective relay test. As a result the relationship between VSL and the degree of violation severity lacks predictability.

The following paragraph from the top of page 71 in the FAQ should be retained. When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment. Keep in mind that one manufacturer’s “Conductance” test equipment does not produce similar results as another manufacturer’s “Impedance” test equipment, even though both manufacturers have produced “Ohmic” test equipment. This paragraph from page 78 (second full paragraph) should be stricken or re written. Consistency is the key when measuring and evaluating ohmic readings. Consistent testing methods by trained personnel are essential. Moreover, it is absolutely critical that personnel use the same make/model of test instrument every time readings are taken if the values are going to be compared. The type of probe, the location of the reading (post, connector, etc.) and the room temperature during the test needs to be carefully recorded when the readings are taken. For every subsequent time the readings are taken, the same make/model of the test instrument must be used, the same type of probes must be used, and the location of the reading must be the same. The first paragraph explain the consistency issue and the second then removes the ability to use consistent equipment and rather demands that identical equipment be used. This is not a feasible position as manufacturers can and do leave the testing space and therefore the entity should be cognizant of using the appropriate compatible test equipment but to spell out that particular make/models be maintained is not acceptable and brushes against anti-trust complications by inhibiting new players in this testing space.

Colorado Springs Utilities
Jennifer Eckels
Yes
No
Colorado Springs Utilities votes "negative" based on the document "Draft SAR for Phase 2 of Project 2007-17" under the section titled Brief Description of Proposed Standard Modifications/Actions, which states " The Standard Drafting Team shall modify NERC Standard PRC-005-2 to add reclosing relays to the standard. In order to do so, the definition of Protection System shall be revised to include reclosing relays, the Facilities portion of the Applicability of the Standard shall be revised to describe those reclosing relays that are included within the standard, and appropriate minimum maintenance intervals (with maximum allowable intervals) shall be added to the standard. The Standard Drafting Team shall also make any other changes that are necessary to explicitly address reclosing relays, but shall not make general revisions to the standard, either in content or arrangement." Colorado Springs Utilities position is reclosing relays are used as part of the system restoration process, and should not be associated with the protection or reliability of the system. Reclosing relays should be grouped with SCADA controls of breakers and manual controls of breakers, and should be tested with the same frequency. Breaker reclosing is not used on many lines, and is disabled on many lines. Automatic Breaker Reclosing is a system enhancement, not a system requirement.

Protection System Maintenance and Testing - Project 2007-17

The Protection System Maintenance and Testing Drafting team thanks all commenters who submitted comments on the 3rd draft of the standard for Protection System Maintenance. These standards were posted for a 30-day public comment period from June 18, 2012 through June 27, 2012. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 51 sets of comments, including comments from approximately 170 different people from approximately 110 companies representing all 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Definitions:

No changes were made to the Definitions.

Applicability:

No changes were made to the Applicability.

Requirements:

No changes were made to the Requirements.

Tables

In Table 1-2, the interval for the second portion of the first row of the table was changed from 12 years to 6 years. Also, in Table 1-2, "channels" was modified to "communications systems" in two locations,

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_StandardsProcessesManual_20120131.pdf

and the Component Attributes in the last row were modified to clarify that all attributes must be present to use the associated intervals and activities.

Editorial changes were made to Tables 1-4c, 1-4d., and 1-4e. The words "Protection System" were added to the headers of Tables 1-4c and 1-4d; in Table 1-4e, a redundant "only" was removed.

No additional changes were made to the Tables.

Measures

No changes were made to the Measures.

VRFs and VSLs

No changes were made to the VRFs and VSLs.

Version History

The Version History was updated to reflect the latest approved version of PRC-005.

Implementation Plan

The Implementation Plan was revised to retire the four legacy standards upon full implementation of PRC-005-2 rather than upon the Effective Date. Clarifying language was added to address this change.

Supplementary Reference and FAQ Document

Numerous changes, both technical and editorial, were made throughout the Supplementary Reference and FAQ.

Mapping Document

Minor clarifying changes were made to the Mapping Document.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. **In response to stakeholder input, the SDT made several changes to the standard and associated definitions as detailed below:**
   - **Revised the "Inspect" element of the definition of Protection System Maintenance Program (PSMP), the definition of the term Unresolved Maintenance Issues, and the definition of the term Countable Event.**
   - **Revised Clause 4.2.5.4 of the Applicability section of the standard.**
   - **Revised Table 1-2 "Component Type - Communications Systems."**
   - **Revised Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f "Component Type - Protection System Station dc Supply…."**

   Do you agree with these changes? If not, please indicate which changes you do not agree with and provide specific suggestions in the comment area for improvements that would allow you to support the standard.

Summary Consideration:

Some commenters continued to object to various activities and/or intervals within the tables. The drafting team made several changes detailed below in response to these comments.

1. One interval was changed – the interval for the activity in Table 1-2 for unmonitored communications systems was changed from 12 years back to 6 years as it had been in all previous postings. This change promotes consistency with similar activities within Table 1-1 (Protective Relays).
2. The language in two activities in Table 1-2 was changed from "channels" to "communications systems".
3. The language in the Component Attributes in the last row of Table 1-2 was modified to read: "Any communications system with all of the following:" to clarify that all must be present to use the related intervals and activities.
4. In Table 1-4e, a redundant "only" was removed from the Component Attributes in the last row.

A few commenters continued to contrast the Applicability (4.2.1) with the Interpretation represented in PRC-005-1b. The drafting team responded, but no changes were made.

Several comments were offered on the informational posting of the draft SAR to revise PRC-005-2 to add reclosing relays. The drafting team responded, but no changes were made.

Organization	Yes or No	Question 1 Comment

Organization	Yes or No	Question 1 Comment
Bonneville Power Administration	No	1. BPA believes the term communications system and channel needs to be clarified as to whether the intent is the communications system, a channel on the telecommunication channel, the teleprotection channel, or the teleprotection function. 2. A. Minimum battery maintenance interval is to assure that the battery plant will perform as needed, and obtain a reasonable confidence that it will continue acceptable performance until the next maintenance evaluation. Typically, any utility VLA battery application, steady state float charge/long duration discharge, a Monthly or Quarterly maintenance is excessive given a proper design/maintenance program (IEEE 450, 484, 485). There is a 60 year proven history of this. BPA recognizes that there will be specific VLA battery installations that will be required beyond this minimum. BPA recommends rolling the 4 month maintenance into the 18 month maintenance schedule. B. The scientific vetted method of determining a VLA batteries current performance, and projected performance, is a capacity test. This has been scientifically verified at least 10 times since 1919, with consistent results. This approach is consistent with the IEEE 450, as well as many other standards, and is supported by the industry. If an alternate approach using measured parameters to predict current and future battery performance is to be allowed, then it must assure the same result. C. Battery monitoring does enable measurements to be made automatically with greater frequency. Additionally it provides the ability to collect, store, report, and analyze data from the battery even during an outage. It does not mitigate the necessity to perform battery maintenance. If battery monitoring is performed mandatory maintenance should also be required on the monitor.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT has modified "channel" to "communications system" in Table 1-2 in response to your comment. Discussion was also added to Section 15.5.1 of the Supplementary Reference and FAQ Document to explain "channel". 2. See below: A. The drafting team disagrees with your assertion that the 4 month interval should be extended to the 18 month maintenance schedule for performance of maintenance activities. The 18 month maximum maintenance interval for the unmonitored VLA battery used in a Protection System station dc supply is too long for verification that there is any voltage on the dc supply, that each cell of the unmonitored station battery is inspected to see that it has electrolyte in it, or that the unmonitored dc supply is inspected for unintentional dc grounds. B. The drafting team agrees with you that the performance capacity test is a well proven method to determine the capacity of a station battery and provides an indication of the health of the battery. However, there are other measurements that are indicative of battery health and performance that when trended to the station battery baseline and examined along with the other maintenance activities required in Table 1-4 of the standard can indicate that station battery can perform as manufactured. By trending periodically measured properties indicative of battery performance while serving its Protection System, the Transmission Owner, Generator Owner or Distribution Provider can develop a condition based method to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) if the station battery should be replaced without performing a capacity test, based on the analysis of the trended data. C. The drafting team agrees that, "battery monitoring does enable measurements to be made automatically with greater frequency. Additionally it provides the ability to collect, store, report, and analyze data from the battery even during an outage." Besides these positive qualities it alleviates the necessity to physically perform - in the station - most of the battery maintenance activities listed in Table 1-4 (see Table1-4 (f)). However, the inspection of the battery, its cells and the physical condition of the battery rack are mandatory maintenance activities that must be performed by the maintenance workforce at the station or via remote control. Concerning the maintenance of the monitoring system, please refer to Table 2 (Alarming Paths and Monitoring) of the standard for the mandatory maintenance that is required on the monitor.		
Imperial Irrigation District (IID)	No	IID does not agree with the proposed changes to the definition of Inspect using the word Examine and suggests using Visual Examination instead.
Response: Thank you for your comments. The SDT believes the word 'Examine' is correct.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td>Western Area Power Administration</td><td>No</td><td>The Standard Drafting team has made changes to the battery maintenance tables 1-4 (a-f) that does not reflect the extensive re-wording of the Supplemental Reference/FAQ document or address the posted recommendations of IEEE Battery Task Force. The industry needs clear, concise maintenance tasks, intervals and standards for their maintenance programs that are developed and tested by industry experts such as IEEE and EPRI.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
The changes to maintenance tables 1-4 (a-f) were made as a result of conversations with members of the IEEE Battery Task Force and their recommendations to the drafting team. The drafting team disagrees with the assertion that the changes to the tables do “not reflect the extensive re-wording of the Supplementary Reference and FAQ document.” The drafting team considered the IEEE Battery Task Force Recommendations and revised the Standard with the assistance of several of their members (see the drafting team response posted on the NERC site).
The drafting team believes that the Component Attributes, Maximum Maintenance Intervals and Maintenance Activities of Table 1-4 are clear and concise. If an owner has a question concerning how to perform any maintenance activity listed in the table, the Supplementary reference and FAQ document along with IEEE and EPRI documents provide unambiguous and succinct examples of how to perform the activity. This standard is not intended to instruct the Transmission Owners, Generator Owners or Distribution Providers on how to perform the minimum maintenance activates listed in the tables. PRC-005-2 must plainly and tersely tell the owners what they must do - not how to do it.</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>The first column, third row of Table 1-2 should be clarified to indicate whether the bulleted items are related by an “or” clause or an “and” clause. For example, must the communication system have either or both of those attributes for it to be considered?</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. We are requiring both bullets to be applicable and have changed the wording to better reflect our intention.</td></tr>
<tr><td>ReliabilityFirst</td><td>No</td><td>ReliabilityFirst offers the following comments related to the bullet points in Question 1:</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
		a. Bullet 1 - Agree with definition revisions b. Bullet 2 - Agree with clause 4.2.5.4 c. Bullet 3 - Disagree with revised Table 1-2 “Component Type - Communications Systems.” The revision increased the maximum time for unmonitored systems to 12 years. However, communication failures correspond to one of the top three causes of Misoperations. The revised last row of the Table 1-2 still permits continuous monitoring to be substituted for testing. It is not clear that the available monitoring can actually identify the health of many of the components that can fail in a power line carrier communication system. RFC believes more research is needed to substantiate the 12 calendar year maintenance interval for unmonitored communications systems. d. Bullet 4 - Disagree with revised tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f “Component Type - Protection System Station dc Supply....” The changes appear to largely ignore the recommendations of the IEEE Stationary Battery Committee.
Response: Thank you for your comments. A. Thank you. B. Thank you. C. The SDT agrees with your comment and has changed the maximum interval for this activity back to 6 calendar years. D. The changes to maintenance tables 1-4 (a-f) were made as a result of conversations with members of the IEEE Battery Task Force and their recommendations to the drafting team. The drafting team considered the IEEE Battery Task Force Recommendations and revised the standard with the assistance of several of their members (see the drafting team response posted on the NERC site).		
BAE Batteries USA	No	I agree with the basic changes, but recommend that a slight modification be made to Tables 1-4(a) and 1-4(b). In the box defining the 18 calendar Months or 6 Calendar Years, the portion in parentheses (e.g. internal ohmic values or float current) should be changed to (e.g. internal ohmic values or

Organization	Yes or No	Question 1 Comment
		float current in concert with other accepted measurements).
Response: Thank you for your comments. The drafting team disagrees and believes that examination of other accepted measurements and inspection results (indicative of battery performance) are a part of trending to the station battery baseline. This same inference applies to the interpretation of the results of a performance or modified performance capacity test for determining whether a station battery should be replaced or cells removed. Please see section 15.4 of the Supplementary Reference and FAQ document for a further discussion of this topic.		
Central Lincoln	No	Central Lincoln agrees with most of the changes except for the change from “as designed” to “as manufactured” in the Station DC supply table. The concern is not high enough to warrant a negative ballot, and we appreciate the difficulty the SDT has had on this issue with IEEE. The “as manufactured” performance may be interpreted as the battery’s capacity when new and fully charged. Of course a properly engineered system will be based on a future aged battery capacity, reduced from the brand new capacity. We prefer “as designed,” but this might lead a CEA to ask for design documentation an entity may have not retained. In the end, it is not the manufactured or design capacity that matters, it is the battery’s ability to power the protection systems and trip the breakers. We suggest “as manufactured” be changed to “as needed.”
Response: Thank you for your comment. One of the reasons that “as designed” was changed to “as manufactured” is as you discussed. If “as designed” is used it will be difficult for the owner to determine the original design for the dc system, making it difficult for an owner during an audit. Just like the term “as designed” is difficult to document, “as needed” will also be harder for the owner to document than “as manufactured.” See question “Why is it necessary to verify the battery string can perform as manufactured?” in Section 15.4 of the Supplementary Reference and FAQ document for a further explanation of this change.		
EPRI	No	1. Table 1-4a - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-and-Verify that the station battery can perform as manufactured by conducting a performance capacity test of

Organization	Yes or No	Question 1 Comment
		the entire battery bank. 2. Table 1-4b - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-or-Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank. 3. Table 1-4c - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-and-Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank.
Response: Thank you for your comments: 1. The standard drafting team believes the “or” of table 1-4(a) should not be replaced with the “- and -” as stated in your comment. The station battery owner of a VLA battery should be allowed to perform either of the two maintenance activities listed in table 1-4(a) to be compliant with the standard, and that “cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current)” should remain in the standard. 2. The standard drafting team agrees that the “-or-”should remain as you suggested in your comment. This will allow the owner of a VLRA battery to choose compliance by performing either of the two maintenance activities at their maximum maintenance intervals listed in table 1-4(b). 3. Because of the marked difference in the aging process of lead acid and nickel-cadmium station batteries the drafting team does not believe that trending ohmic values against the baseline values of each cell, and conducting a performance capacity test of the entire battery bank is the appropriate maintenance activity for NiCad Batteries to ‘Verify’ that the station battery can perform as manufactured. The only appropriate maintenance activity in Table 1-4(c) at the maximum maintenance interval of 6 calendar years is to “Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.”		
Illinois Municipal Electric Agency	No	Illinois Municipal Electric Agency supports comments submitted by Florida Municipal Power Agency. IMEA appreciates SDT efforts, and supports the overall refinements in PRC-005-2; however, the inconsistency between 4.2.1 and the FERC-approved interpretation of PRC-005-1b needs to be resolved

Organization	Yes or No	Question 1 Comment
		to avoid confusion. This issue has implications for smaller entities in particular.
Response: Thank you for your comments. The SDT believes that the Applicability 4.2.1 as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT believes all Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the Interpretation does not apply to PRC-005-2. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.		
PPL Generation, LLC on behalf of its Supply NERC Registered Entities	No	See Question 3 Comments
Response: Thank you for your comments. Please see the response to your Question 3 comments.		
TPI	No	See IEEE Stationary Battery Committee Letter dated 23 March 2012
Response: Thank you for your comments. The drafting team considered the IEEE Battery Task Force Recommendations and revised the standard with the assistance of several of their members (see the drafting team response posted on this project’s page of the NERC website).		
Tennessee Valley Authority	No	
MRO NSRF	Yes	While we agree with the changes made, we believe that table 1-4 should include in the 18 calendar month maintenance activities: 1) Setting the battery charger to equalize, and 2) Inspect battery charger components for leakage and or damage. These additional steps would verify the ability of the battery charger to operate as needed.
Response: Thank you for your comments. Because all battery chargers used in Protection Systems do not have equalize settings or have components that leak, the drafting		

Organization	Yes or No	Question 1 Comment
team does not believe your recommendation is appropriate for this standard.		
Southern Company	Yes	Related to the changes identified in the Battery Tables: 1. We do not see that the change from "as designed" to "as manufactured" really changed the meaning of the battery capability to delivery its rated capacity. We would like the SDT to consider the following language: "verify that the station battery can provide adequate power to the Protection System by conducting....." 2. For Generating Plant Batteries, we feel as though that the only way to prove that a generation battery can deliver what it is supposed to be able to deliver for "All" of its functions is by conducting a capacity test". We would like the SDT to consider adding such a Note to the battery tables and/or make the statement in the FAQ document.
Response: Thank you for your comments: 1. To "verify that the station battery can provide adequate power" for a battery serving a generating station dc supply or a station dc supply that has dc loads considerably greater than the Protection System requirements may appear to be a good choice; however, the use of "adequate power" makes it difficult for the Generator Owner to determine the original design of the dc system and show an auditor that "adequate power" can be delivered to the dc system by the battery. For this reason and others explained in the Supplementary Reference and FAQ document under the question "why is it necessary to verify the battery string can perform as manufactured?" The drafting team believes that perform as "manufactured" is the best wording for the standard. 2. Your concerns about large amp-hour batteries used in generating stations and transmission stations with large auxiliary loads was addressed in the drafting team's response to the Chair of the IEEE Stationary Battery Committee, which stated: "In contrast to the Transmission Owner battery design function, a Generator Owner's battery likely feeds other critical loads such as DC powered oil pumps, seal oil pumps, and other DC control power loads necessary to safely shutdown a power plant following a loss of AC power. In the case of nuclear plants, these DC loads could include motor operated valves and other loads related to nuclear safety. For the Generator Owner, the design load profile for the battery is a long duration, deep discharge of the battery. While a cell ohmic value trending program might be adequate to prove that the Generator Owners battery could fulfill its Protection System function, the Generator Owner might want to		

Organization	Yes or No	Question 1 Comment
validate the deep discharge capability of the battery by routine periodic capacity testing to prove the battery's adequacy at providing power to those long duration loads critical for plant shutdown. The PSMTSDT believes that this deep discharge battery capacity test approach will prove the battery can meet its function relative to the plant Protection System without also having a trending program for cell ohmic values.”		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP agrees that the changes described above make PRC-005-2 clearer and less ambiguous. We believe that this will result in far fewer violations related to administrative or documentation errors - and focus on those cases which actually may impair BES reliability.
Response: Thanks for your support.		
San Diego Gas & Electric	Yes	TABLE 1-5: Similar to the distributed under-frequency load-shedding relays, SPS control circuitry should only be regulated to verify the integrity of the control circuits from the relay to the lockout or auxiliary relay that is used to trip the circuit breakers, but not to the circuit breakers themselves. Owners of SPS control circuitry should have the option of testing these schemes using test procedures that will confirm the control circuitry through the completed trip circuit is continuous and that the circuit breaker will operate when required. Often times the operation of the circuit breaker is confirmed by operation through other protection systems and the SPS function is a parallel path that can be verified without operating the circuit breaker. This change would allow the Transmission Owner to eliminate equipment outages required to test this scheme or the risk caused by removing the SPS for energized testing.
Response: Thank you for your comments. The table only requires that the SPS control circuit path including the trip coil of the breaker be verified with a 12 year maximum interval. The testing does not have to be done all at once; the maintenance activities in the table can be performed in segments and are complete as long as the entire circuit is tested within the interval. Section 10 of the Supplementary Reference and FAQ document provides additional discussion on this.		
Alliant Energy	Yes	While we agree with the changes made, we believe that Table 1-4 should

Organization	Yes or No	Question 1 Comment
		include in the 18 month maintenance activities more checks on Battery Chargers. Based on EPRI data and vendor recommendation we believe that 1) Setting the Battery Charger to equalize, and 2) Inspect battery charger components for leakage and/or damage should be added. These additional steps would better verify the ability of the battery charger to operate as needed.
Response: Thank you for your comments. Because all battery chargers used in Protection Systems do not have equalize settings or have components that leak, the drafting team does not believe your recommendation is appropriate for this standard.		
Ameren	Yes	We believe that the SDT has improved the definitions with these changes and we fully support them. In addition, we also support the Table 1-2 Communication Systems changes based on our experience, and the Station dc Supply changes in the five Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f because they are realistic and consistent with our experience.
Response: Thank you for your support.		
Public Service Company of New Mexico	Yes	1. PNM seeks clarification on the revised Clause 4.2.5.4 of the Applicability section of the standard. - “Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.” Will Auxiliary Transformers that are directly connected to the generator bus of generators which are part of the BES and that step down to distribution level voltage & perform similar functions as that of station service transformer fall under this clause?
Response: Thank you for your comments. If the cited Protection Systems trip the generator, they are applicable to the requirements of PRC-005-2 and maintained accordingly.

2. The SDT made complementary changes in the "Supplementary Reference and FAQ Document" to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for further improvements?

Summary Consideration:

Commenters suggested a variety changes to the Supplementary Reference and FAQ document. The SDT appreciated the feedback and made numerous modifications to the document ranging from correcting typographical errors to including some additional FAQ and corresponding answers, as well as presenting new and revised technical content.

Organization	Yes or No	Question 2 Comment
San Diego Gas & Electric	No	R5/M5: M5 should add "The evidence may include but is not limited to...tracking of the unresolved maintenance issue in accordance with the TO's corrective maintenance process." This alleviates the Transmission Owner from setting up a separate corrective maintenance tracking process intended solely for this regulation.
Response: Thank you for your comments. This comment is related to the standard itself and not to the Supplementary Reference and FAQ document. The Measures are intended to provide examples of evidence, and are not meant to be all-inclusive.

Bonneville Power Administration	Yes	BPA requests the drafting team to provide more detailed examples of the following for both monitoring and testing: 1. That addresses the multiple routes, and automated switching between the routes, in a typical large Telecommunications Network Cloud. This applies only if testing of the 'cloud', or a teleprotection channel through the 'cloud', is the intent of the standard. 2. That addresses the fact that many older teleprotection technologies, not only used separate test inputs/outputs, but the internal path through the equipment is unverified until the particular function is activated. I.E.: In certain technologies, a functioning 'guard' signal does not have any correlation to a functioning 'trip' signal.
Response: Thank you for your comments. 1. The intent of the standard is to verify the teleprotection channel is functional, regardless of what constitutes the channel. 2. The SDT believes that the maintenance activity in Table 1-2, "Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System" allows the entity flexibility to maintain the various technologies that they may own. The Supplementary Reference and FAQ document addresses some of the options available, but obviously cannot provide detail on all types of equipment.		
ACES Power Marketing Standards Collaborators	Yes	Several capitalized terms in the supplementary reference document are used inconsistently with their definition or the reference to their definition is not clear. For example, "communications Systems" in the second bullet in section 2.2 uses "Systems" inconsistently with its definition. The use of "sensing Element" on page 6 is another example. We believe this is inconsistent with the definition of Element which could be a generator, transformer, circuit breaker, bus section, etc. but does not appear to be a Protection System Component. The "localized" definition of Component that is contained in the standard should also

Organization	Yes or No	Question 2 Comment
		be included in the reference document since it is not in the NERC Glossary. Use of “dc Load” on page 82 is not consistent with the definition of Load. Load is an end use customer. There are many other places in the document where there are inconsistencies with these definitions. Thus, the document needs to be further reviewed to ensure the use of the terms is consistent with their definitions.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document as you suggested.		
Dominion	Yes	The term ‘Underfrequency' is capitalized in the Supplementary Reference document yet it is not included in NERC’s Glossary of terms. We suggest a return to lower case. In fact, given this document is meant to be used for reference only, we question the need to capitalize any term.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document as you suggested. For consistency with the standard, the SDT will continue to capitalize terms when they are used in the context defined in the NERC Glossary of Terms.		
Luminant	Yes	The testing of non-BES breakers for plants should be discussed in the FAQ using the similar application for Distribution Providers. Luminant recommends a section for Generation Owners that describes what Elements (circuit breakers) should be tested. Luminant strongly believes that there is no additional benefit to the BES by requiring the GO to test the non-BES breakers (UAT low side and generator field breakers). These circuits are radial fed.
Response: Thank you for your comments. The FAQ discussion on testing of non-BES breakers for Distribution Providers pertains to those devices used as part of UFLS or UVLS schemes. Section 15.3.1 of the Supplementary Reference and FAQ document has been augmented to address this topic for Generator Owners.		
Southern Company	Yes	See comment on Generating Plant Batteries in Question #1.
Response: Thank you for your comments. Please see the response to your comments in Question 1.		
Western Area Power	Yes	Western Area Power Administration is appreciative of the hard work done by the SDT

Organization	Yes or No	Question 2 Comment
Administration		and NERC. We respectfully submit that the Supplementary Reference and FAQ Document should: 1. Offer guidance on establishing baselines for older battery banks 2. Be in agreement with IEEE standards for battery maintenance 3. Replace the existing CANS
Response: Thank you for your comments. 1. Please see Section 15.4.1 of the Supplementary Reference and FAQ document, specifically the question, "How is baseline established for cell/unit internal ohmic measurements?" which offers guidance on establishing baselines for older battery banks. 2. The IEEE documents to which you refer are "Recommended Practices" as explicitly stated in their titles and not mandatory standards. The SDT considered the IEEE Recommended Practices, as well as other documents, in developing the minimum requirements and maximum intervals within PRC-005-2. 3. The CANs are developed by NERC Compliance Staff to address specific currently-approved NERC Standards, and will be retired when the related standards are retired. The SDT has no control or influence regarding CANs.		
Alliant Energy	Yes	Section 15.4 of the FAQ document does an excellent job of describing the details of battery maintenance and testing, but there is essentially no description of battery charger maintenance and testing activities. We believe this section needs to be expanded to include a good description of battery charger maintenance activities as well.
Response: Thank you for your comments. While manufacturers' recommendations for maintenance of their equipment are quite diverse, the required maintenance activities within PRC-005-2 for battery chargers are: verification of the station dc supply voltage (maximum unmonitored maintenance interval 4 calendar months); and, verification of the battery charger float voltage (maximum unmonitored maintenance interval of 18 calendar months). If anomalies regarding the battery charger are found by performing these activities, relevant corrective actions should be taken.		
American Electric Power	Yes	Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might also help prevent

Organization	Yes or No	Question 2 Comment
		the need for future CANs and interpretation requests. Though the guidance provided in these documents may appear to be beneficial, we are troubled that the SDT feels it is necessary to provide such a volume of material outside the standard itself, and yet still consider such “references” as enforceable.
Response: Thank you for your comments. This document provides supporting discussion, but is not part of the standard and not enforceable. The SDT intends that it be posted as a reference document accompanying the standard. As established in the SDT Guidelines, the standard is to be a terse statement of requirements, and is not to include explanatory information like that included in the Supplementary Reference and FAQ document. The Supplementary Reference and FAQ document will be revised in conjunction with any revisions of PRC-005.		
BAE Batteries USA	Yes	1. On page 21 of 97,Question 7.1, "Please provide an example of the unmonitored versus other levels of monitoring available," "Every six calendar years, perform/verify the following: Battery performance test (if ohmic tests are not opted)" - add after ohmic tests "or other accepted battery measurement parameters." 2. pg 22 of 97, Example 2 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to station battery baseline . . ." 3. pg 23 of 97, Example 3 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to station battery baseline . . ." 4. pg 23 of 97, Example 3 "Every six calendar years": Add the same verbiage so that the first bullet reads: "(if internal ohmic test or other accepted battery measurement parameters to station battery baseline are not opted)" 5. pg 27 of 97, Question 8.1.2, item #4: Change the last sentence to read: "However, the methods prescribed in these recommendations cannot be specifically required because they are offered as best practice guidelines and not set as standards." 6. pg 71 of 97, Question 15.4.1, Frequently asked Questions: "How is a baseline

Organization	Yes or No	Question 2 Comment
		established for cell/unit internal ohmic measurements?" 2nd paragraph - 1st sentence, replace the word "consistent test equipment" with "the same type of test equipment." In addition, should add a final sentence at the end of this paragraph that states, "Also, in many cases, one manufacturer's 'conductance' test may not produce the same measurement results as another 'conductance' test manufacturer's equipment. Therefore, for meaningful results to an established baseline, the same instrument should always be used." 7. Page 73 of 97, Question 15.4.1, Frequently asked questions: "What conditions should be inspected for visible battery cells?" Approximately in the 7th line modify the sentence to read . . .abnormal color(which is an indicator of sulfation or possible copper contamination) . . . 8. Page 75 of 97, Question 15.4.1, Frequently asked questions: "How do I verify the battery string can perform as manufactured?" 2nd paragraph that reads "Whichever parameter is evaluated . . ." should be revised to say "Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, specific gravity, performance test, or combination thereof), the goal is to determine . . . 9. Page 75 of 97, Question 15.4.1, Frequently asked questions: "How do I verify the battery string can perform as manufactured?" 5th paragraph starts, "A detailed understanding of the characteristic of a battery is also attempting to use float current as a measure of the ability of a battery . . . and ends with "to see if a trending process is recommended for determining aging of these products." The Stationary Battery Task Force recommends deleting this whole paragraph due to inaccuracies or statements that are not relevant. If a paragraph that alludes to float current is considered critically essential, then a short paragraph could be substituted which might say," Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement devices is to establish a trending line against baseline so that a documented process establishes the validity of the judgment used to determine that the battery may

Organization	Yes or No	Question 2 Comment
		perform or not perform as manufactured." 10. Page 81 of 97, Question 15.4.1, Frequently asked questions: "Why does it appear that there are two maintenance activities in Table 1-4(b) for VRLA batteries . . . .?" 3rd paragraph: "A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to 'perform as manufactured.'" This might better be restated as follows: "Trending against the baseline of VRLA cells in a battery string is essential to determine approximate state of health of the battery. For example, using ohmic measurement testing as the mechanism for measuring the battery cells, then, if all the cells in the string show to be in a consistent trend line and that trend line has not risen above say a 25-30% deviation over baseline, then a judgment can be made that the battery is still in a reasonably good state of health. This judgment can assume that the battery is still able to 'perform as manufactured.' It would be wise to confirm the accepted deviation range with the manufacturer of the battery in question to assure good judgment in deciding on the state of health to perform as manufactured.' This is the intent of the "perform as manufactured six-month test' at Row 4 on Table 1-4(b)." 11. Page 81 of 97, Question 15.4.1, Frequently asked questions: [same as Item #10 above], following paragraph: Recommend using a range of 25-30% with the statement that "It would be wise to confirm the accepted deviation range with the manufacturer of the battery in question to assure good judgment' in deciding on the state of health to perform as manufactured.

Response: Thank you for your comments.

1. The SDT modified the Supplementary Reference and FAQ document on page 21 as you suggested.
2. The SDT modified the Supplementary Reference and FAQ document on page 22 as you suggested.
3. The SDT modified the Supplementary Reference and FAQ document on page 23 as you suggested.
4. The SDT modified the Supplementary Reference and FAQ document on page 23 as you suggested.
5. The drafting team agrees with your comment concerning all of the best practices of the IEEE guidelines not being requirements of the standard and incorporated your comments into the Supplementary Reference and FAQ document on page 27.

Organization	Yes or No	Question 2 Comment
6. The drafting team incorporated your comments concerning same type test equipment replacing consistent type test equipment on pages 71 & 72 of the Supplementary Reference and FAQ document. 7. The drafting team added a comment regarding color observation on page 74 of the Supplementary Reference and FAQ document. 8. The SDT modified the Supplementary Reference and FAQ document on page 75 as you suggested. 9. The SDT modified the paragraph on float current on page 75 of the Supplementary Reference and FAQ document as you suggested. 10. The SDT modified the Supplementary Reference and FAQ document based on your comment. 11. The SDT revised the Supplementary Reference and FAQ document as you suggested.		
Georgia Transmission Corporation	Yes	Recommend adding further comments on data retention. We prefer the interpretation for the maintenance cycles equaling 12 calendar years, example microprocessor protective relays. This proves the extreme of data retention. We interpret the retention period to be 24 years. Previous test record to current test record equals 12 years, and 12 more years (next maintenance cycle) before removing previous records from storage (24 years).
Response: Thank you for your comments. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05.		
Ameren	Yes	(1) Capitalizing in some cases is inappropriate (e.g., Systems; Glossary defines System as 'A combination of generation, transmission, and distribution components.' So 'communication System' incorrectly capitalizes 'system'). (2) Page 15, we disagree with retention of maintenance records for replaced equipment as this can cause confusion. We believe that at the most the last maintenance date could be retained to prove interval between it and the test date of the replacement equipment that provides like-kind protection. (3) We request the SDT to provide a few examples of 'non-battery-based dc supply'. The SDT has previously responded that this does not include 'capacitor trip devices'.

Organization	Yes or No	Question 2 Comment
		Does the SDT mean to include M-G sets, flywheels, and / or rectifiers? Also, Emerging Technologies on page 73 is vague please clarify.
Response: Thank you for your comments. 1. The SDT revised the Supplementary Reference and FAQ document to address your comment. 2. The records for removed/replaced equipment need to be retained to provide documented evidence that the entity was in compliance for the entire compliance monitoring period. This documentation includes maintenance activities as well as maintenance intervals. 3. As noted, the drafting team previously stated that the “capacitor trip devices” on circuit breakers and reclosers are not examples of station dc supply devices using emerging technology. Some of the non-battery based energy storage devices with demonstrated prototypes for use in Protection System dc supplies are the flywheel and the fuel cell. One non-battery based dc supply commercially available in the United States and Canada uses compressed air and a capacitor to replace the electrochemical process of a station battery for supplying the dc power required for operating Protection System elements and for supplying normal dc power to the station in the event of loss of ac power.		
Public Service Company of New Mexico	Yes	The Supplementary Reference and FAQ Document has served as a valuable resource and PNM commends the drafting team’s efforts in writing a comprehensive document. Section 13. Self Monitoring Capabilities and Limitations - Last but one bullet on Page 59 of the Supplementary Reference and FAQ Document is confusing and needs possible rewording and clarification. “With this information in hand, the user can document monitoring for some or all sections by extending the monitoring to include...” appears confusing.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document to address your comment.		
EPRI	Yes	Why consider the ability of the station battery to perform as manufactured? The reason the term “perform as manufactured” was used is because there is not much data available to verify actual sizing of the cells for their application. The only battery values for typical Protection systems that have a verifiable basis are the battery manufacturer’s data. The only way to know when a battery needs to be replaced is to

Organization	Yes or No	Question 2 Comment
		compare measured values against manufacturer’s data or other established values. To verify that the station battery can perform as manufactured is the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. Inspections alone do not provide trending information that indicates the state of aging of a station battery. The maintenance activities listed in Table 1-4 to “verify that a station battery can perform as manufactured” are intended to provide information about the aging process of a station battery. A Transmission Owner, Generator Owner or Distribution Provider can then use the information provided by the maintenance activity to determine if testing of a station battery is required or if timely replacement or removal of the station battery or its components (cell/unit) should be accomplished. Capacity discharge testing is the only industry approved method of determining the true capacity of lead acid and nickel-cadmium station batteries. The performance capacity test of the entire battery bank listed as maintenance activities of table 1-4 provides a mechanism for trending battery discharge characteristics based on manufacturers published data. Trending discharge test results is the basis for determining the aging of a station battery serving a Protection System. Based on these results, decisions concerning replacement of a battery serving a Protection System and its components can be made by the Transmission Owner, Generator Owner or Distribution Provider. There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of the two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. However, the primary failure of nickel - cadmium batteries is because of the gradual linear aging of the active materials in the plates. The electrolyte of a nickel - cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued

Organization	Yes or No	Question 2 Comment
		corrosion of the positive plate and grid structure throughout its operational life while a nickel - cadmium battery does not. Changes to the periodic measured properties of a lead acid battery when trended to a baseline can provide an indication of aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate. Since aging in nickel-cadmium cells is linear, periodic measured properties of nickel-cadmium cells when trended to a baseline can provide an indication of aging of the active material in the positive plates. By trending periodic measured properties of a station battery serving its Protection System the Transmission Owner, Generator Owner or Distribution Provider can develop a condition based method to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test. There is a clear difference in the aging process of lead acid and nickel-cadmium batteries. The measurable properties of a nickel - cadmium battery will change more gradually than VRLA cells; therefore, periodic interval and trending to determine aging has very little industry experience, but the user should work with the battery manufacturer to determine if internal ohmic measurements can be applied to their product. While it has been proven that there is a relationship between internal ohmic measurements and cell capacity of lead acid batteries, an accurate determination of a battery's exact capacity cannot be attained by measuring its cell's internal ohmic values. However, trending internal ohmic measurement of VRLA battery cells to establish a base line is a method of trending measured properties by Transmission Owners, Generator Owners and Distribution Providers to evaluate their station battery cells for health and aging. Evaluating internal ohmic cell/unit measurements against the battery cell baseline values is an acceptable Maintenance Activity listed in tables 4-1(a) and 4-1(b) 4-1(c) to verify that the station battery can perform as manufactured as long as it is measured and trended to the baseline values at an interval less than or equal to the published Maximum Maintenance Interval of tables. Why was the term "manufactured" used instead of "designed" in the maintenance activities of tables 1-

Organization	Yes or No	Question 2 Comment
		4(a), 1-4(b), 1-4(c), 1-4(d) and 1-4(f)?The phrase “as designed” always raises the question of “who made the design requirements that are being tested to or evaluated, the manufacturer of the battery or the engineer sizing the battery? The use of the term designed when discussing a battery’s ability to perform was incorrect because we did not differentiate between a performance test and a service test. The phrase “meets the design requirements” is used when discussing a service test which is a discharge test that measures a battery’s capability to meet a duty cycle which was designed by the person sizing the battery. However, when talking about a performance capacity test, the test is a measure of the currents or amp-hour discharge rates based on the battery manufacturer data for the station battery being tested. The term “manufactured” used in the tables avoids the confusion caused by the term “designed” and its application to service testing. Also, when discussing internal ohmic measurement trending, “manufactured” applies to establishing a set of base line values when compared to a battery of known capacity based on the manufacturer’s published data. When trending other measurable properties that assist in establishing aging, the battery manufacturer’s data are used as a basis for establishment of baseline values and therefore the use of “manufactured” avoids any ambiguity that might be caused by use of the term “designed”.

Response: Thank you for your comments.

The drafting team recognizes that the majority of your comments support and amplify the information contained in the Supplementary Reference and FAQ document. However, the drafting team does not agree with some of the information contained in your comments.

1. While the drafting team agrees that part of the process of determining when to replace a battery should be “to compare measured values against manufacturer’s data or other established values,” we disagree with the statement “the only way to know when a battery needs to be replaced is by using this maintenance activity” because it does not give credit to the role visual inspections play in the replacement process.
2. The drafting team has a broader interpretation of the term “manufactured” than that implied in your comment concerning ohmic measurement trending (“manufacturer’s published data”). We believe the term “manufactured” as used in the maintenance activities of the standard also includes as you stated earlier in your comment “other established values.” Just as

Organization	Yes or No	Question 2 Comment
battery manufacturers establish tolerances that when exceeded constitute further examination of the battery for replacement, test equipment manufacturers, battery owners and others have established tolerances for specific batteries that are considered valid to determine if the particular battery can perform as "manufactured." 3. As implied in your comment and by over a decade of industry experience, it has been proven that there is a relationship between internal ohmic measurements and the aging process of lead-acid batteries. No such relationship has been established for nickel-cadmium batteries. Also at this time - with the exception of the results of a capacity test - the drafting team is unaware of any published data for nickel-cadmium battery properties that can be measured and trended against the station battery baseline. The drafting team believes that either of the two maintenance activities listed in table 1-4(a) and 1-4(b) for lead-acid batteries are acceptable to verify that the station battery can perform as manufactured when conducted at the maximum maintenance intervals of the tables. However, the drafting team disagrees with your inference that table 1-4(c) for Nickel Cadmium batteries should have any other maintenance activity besides the performance or modified performance capacity test of the entire bank to verify that the station battery can perform as manufactured.		
US Bureau of Reclamation	Yes	The FAQ should clarify why the requirement for a "Summary of maintenance and testing procedures" developed by an entity is considered prescribing a methodology to meet those requirements. The entity is developing the methodology for meeting the requirements that the elements be maintained.
Response: Thank you for your comment. "Summary of maintenance and testing procedures" is terminology used in Requirement R1.2 of the existing standard PRC-005-1.1b and is not applicable to version PRC-005-2.		
Oncor Electric Delivery	Yes	On Page 81 of the Supplementary reference and FAQ Draft it appears that the drafting team changed the term "designed" to "manufactured" and then used the quotation from the previous standard's Table 1-4(b). Oncor recommends that the two statements on page 81 of the Supplementary Reference and FAQ - Draft be changed from the present version "...verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values to station battery baseline." "Verify that the station battery can perform as manufactured by conducting a performance, service, or modified performance capacity test of the entire battery bank." to a new version of the quotes based on the new version of Table 1-4(b). The new quotes should be stated as follows:"...verify that the station

Organization	Yes or No	Question 2 Comment
		battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline.” ”Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.”
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document based on your comments.		
Brazos Electric Power Cooperative	Yes	Please see the formal comments submitted by ACES Power Marketing.
Response: Thank you for your comment. Please see the responses to the ACES Power Marketing comments.		
Xcel Energy	Yes	The following paragraph from the top of page 71 in the FAQ should be retained. When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment. Keep in mind that one manufacturer’s “Conductance” test equipment does not produce similar results as another manufacturer’s “Impedance” test equipment, even though both manufacturers have produced “Ohmic” test equipment. This paragraph from page 78 (second full paragraph) should be stricken or re written. Consistency is the key when measuring and evaluating ohmic readings. Consistent testing methods by trained personnel are essential. Moreover, it is absolutely critical that personnel use the same make/model of test instrument every time readings are taken if the values are going to be compared. The type of probe, the location of the reading (post, connector, etc.) and the room temperature during the test needs to be carefully recorded when the readings are taken. For every subsequent time the readings are taken, the same make/model of the test instrument must be used, the same type of probes must be used, and the location of the reading must be the same. The first paragraph explain the consistency issue and the second then removes the ability to

Organization	Yes or No	Question 2 Comment
		use consistent equipment and rather demands that identical equipment be used. This is not a feasible position as manufacturers can and do leave the testing space and therefore the entity should be cognizant of using the appropriate compatible test equipment but to spell out that particular make/models be maintained is not acceptable and brushes against anti-trust complications by inhibiting new players in this testing space.
Response: Thank you for your comments. The SDT revised the Supplementary Reference and FAQ document to address your concerns.		
TPI	Yes	Page 81...this statement is incorrect and should be changed: "A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life." "can be used" has to be changed to "may be used". This should refer to the other FAQ to fully explain how to use ohmic measurements. Page 81...25% is not a universally accepted value. This value has to be determined by experience for a particular type/model of battery. This part of the FAQ contradicts other FAQs.
Response: Thank you for your comments. 1. The SDT revised the Supplementary Reference and FAQ document based on your comment. 2. The SDT used 25% as an example, and revised the Supplementary Reference and FAQ document for clarity. Since there are no universally accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured. This is the most difficult and important part of the entire process. The paragraph on page 81 of the Supplementary Reference and FAQ document has been modified based on your comments.

3. **If you have any other comments that you have NOT provided in response to the above questions, please provide them here. (Please do not repeat comments that you provided elsewhere.)**

Summary Consideration:

Some commenters continued to object to various activities and/or intervals within the tables. The drafting team made several changes detailed below in response to these comments.

1. One interval was changed – the interval for the activity in Table 1-2 for unmonitored communications systems was changed from 12 years back to 6 years as it had been in all previous postings. This change promotes consistency with similar activities within Table 1-1 (Protective Relays).
2. The language in two activities in Table 1-2 was changed from "channels" to "communications systems".
3. The language in the Component Attributes in the last row of Table 1-2 was modified to read: "Any communications system with all of the following:" to clarify that all must be present to use the related intervals and activities.
4. In Table 1-4e, a redundant "only" was removed from the Component Attributes in the last row.

A few commenters objected to the prescribed VRFs and/or VSLs. The SDT responded that these VRFs and VSLs are in accordance with guidance from FERC and NERC.

A few comments were offered regarding Data Retention, generally objecting to retaining the maintenance records for two complete maintenance intervals. The SDT responded that the data retention specifications are consistent with auditors' expectations and with Compliance Process Bulletins 2011-001 and 2009-05.

Several comments were made (some expressed as the reason for a Negative Ballot) in response to the informational posting of the draft SAR to modify PRC-005-2 to add reclosing relays. No changes were made as a result of these comments.

Organization	Yes or No	Question 3 Comment
Ameren		(1) Remove Table 1-4 batteries from the Countable Event definition. (2) Please change Table 1-4(d) title to "Component Type - Protection System Non Battery Based Station dc Supply" [delete: Using Non Battery Based Energy Storage] to be consistent with the definition.

Organization	Yes or No	Question 3 Comment
		(3) R3 & R4: Change VRF to "Medium" for the following reasons: (a) Guideline (3) - Consistency among Reliability Standards is not satisfied. The VRF_Standards_Applicability_Matrix_2012-03-01 clearly shows that comparable requirements in the standards that PRC-005-2 replaces are Medium or Lower, specifically PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (b) The High Risk Requirement is not met. We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (c) Guideline (4) Consistency with NERC's Definition of the Violation Risk Factor Level is not met. Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events continues to be extremely rare. (4) Measure M3 on page 6 should only apply to 99.5% of the components. We strongly advocate the SDT to revise and state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." We believe l that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. Note that we are not suggesting for the VSL to be changed. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance".

Response: Thank you for your comments.

1. The SDT believes that R1.1 is very explicit (All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program) and has precedence over the Countable Event definition. However, the

Organization	Yes or No	Question 3 Comment
drafting team does not agree that Table 1-4 should be removed from the Countable Event definition; Table 1-4(d) addresses non-battery-based energy storage devices, which can use a performance based program. 2. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard. The drafting team believes the words "Energy Storage" in the title of Table 1-4(d) better conveys the role or circumstance of not having a battery in the dc supply, more so than using the wording from the latest version of the definition of Protection System (non-battery-based dc supply). 3. The SDT believes that the assigned VRFs are correct, as explained below: a. The SDT believes the requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement – to – requirement comparison of VRFs is irrelevant. b. The SDT believes that failure to implement and follow its PSMP could cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures. c. The SDT believes that failure to implement and follow its PSMP could cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures. **4.** VSLs define the degree to which compliance with a requirement was not achieved. Anything less than 100% constitutes a violation.		
ACES Power Marketing Standards Collaborators		-1- The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C – Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of "the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date". Given that many of the maximum maintenance intervals exceed audit periods for responsible entities, an entity could be required to retain data previous to its last audit, which is not consistent with the Rules of Procedure. We suggest changing this such that the data only needs to be maintained since the last audit. -2- Under the "Definitions" section, for the definition of "Protection System" it is

Organization	Yes or No	Question 3 Comment
		unclear whether the bullets constitute items that are considered to be Protection Systems, elements that may be included within a Protection System, or elements which all must be included to constitute a Protection System. A statement preceding the bullets that explains their relationship to the term “Protection System” would be helpful. This clarification should at least be made within the supplementary reference document, if it cannot be made to the actual definition. -3- Requirement R1 VSLs: It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.
Response: Thank you for your comments. 1. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT’s experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. 2. The definition of Protection System is expressed in the manner that FERC approved on February 3, 2012. 3. The SDT believes that missing three component types is a “significant percentage” and is in accordance with the VSL Guidelines.		
Exelon Corporation and its affiliates		1. In the response to Exelon’s previous comment regarding current transformers, the SDT disagreed that test mandated by the current Standard draft seeks to measure a signal is “provided to the protective relay”; however, the test referenced in Table 1-3 merely confirms that the signal is sent and not that it reached the correct protective relay. Generation sites are built in phases, and these requirements do not ensure that the wiring of the protection system matches the prints and the intent of the engineers who designed it. Please provide a technical explanation of how this type of test for a CT will verify that the signal reaches the relay. 2. In the response to Exelon’s previous comment related to the maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays the SDT disagreed that the maintenance program should be left to the discretion of the Generator Owner. Exelon further explained that In order to meet the required activity specified in PRC-005-2 draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice

Organization	Yes or No	Question 3 Comment
		introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse effect on the reliability of the BES. In its response the SDT has not provided the justification as to why performing such a high risk activity increases the reliability of the BES and justification for testing that refutes existing manufacturers recommendations. 3. In the last round of comments, the SDT did not specifically address Exelon's comments regarding the omission of "...and trips an interrupting device that interrupts current supplied directly from the BES" from the revised applicability language in Section 4.2.1. We are concerned that the SDT may not fully appreciate our concern. Without the qualification that comes from the "and..." phrase above, Exelon feels that section 4.2.1 will bring reverse-looking relays on radial transformers into scope, which are not interpreted as BES Protection Systems. By doing so, it creates a perverse incentive to disable these protection functions, even though they provide a reliability benefit, for the sake of limiting compliance exposure. Please offer a direct response to why the phrase, "...and trips an interrupting device that interrupts current supplied directly from the BES" is no longer included in 4.2.1 and clarify that non-BES relays are not considered within scope. Comments and SDT Response from last comment period (for reference):Exelon Comment: When the SDT changed the original PRC-005 applicability language from "...affecting the reliability of the BES..." to the new 4.2.1 language "...that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)", they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read "...and trips an interrupting device that interrupts current supplied directly from the BES." By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005.Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such

Organization	Yes or No	Question 3 Comment
		relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1 language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement: ” The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.” Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1:”Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements.” This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. SDT Response: The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the

Organization	Yes or No	Question 3 Comment
		interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting Faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference Document for additional discussion. Thank you for the opportunity to comment.
Response: Thank you for your comments. 1. Section 15.2 of the Supplementary Reference and FAQ document provides a technical explanation of how this type of test for a CT will verify the signal reaches the relay. 2. The SDT believes it is possible during a 12-year interval to find a reasonably low-risk opportunity to perform the required test and that performing the test satisfies FERC Order 693 “…that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System.” Please see Section 15.2.1 of the Supplementary Reference and FAQ document for examples of off-line tests that can minimize the risk you describe. **3.** Reverse-looking relays (in the cited application) are not installed for the purpose of detecting faults on the BES and would not be subject to this standard. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES.		
Southern Company		1. We would like the SDT to consider rewording M5 as follows: The evidence may include any form of evidence indicating an entity is demonstrating efforts to correct identified Unresolved Maintenance Issues. Additionally: All of the examples of evidence should be moved to the Supp Ref doc and be there only for reference. 2. Page numbers should be visible on all pages.
Response: Thank you for your comments. 1. The SDT does not believe that the changes you suggest improve the standard. Regarding “demonstrate efforts to correct…,” the SDT’s intent is to allow an entity to furnish a way of addressing Unresolved Maintenance Issues without the formality and burden of a full-fledged Corrective Action Plan. 2. The SDT agrees and has referred the concern to NERC Staff for their consideration when preparing the documents for posting.		
Ingleside Cogeneration LP		Although Ingleside Cogeneration LP does not want to derail the improvements that the SDT has obviously made to PRC-005-1, we remain concerned that expansions in

Organization	Yes or No	Question 3 Comment
		scope of a BES Protection System will automatically roll over to other standards. For example, if the loss of a low voltage auxiliary transformer can trip a generator, its Protection System will be in-scope for PRC-005-2. It is not a big leap in logic to assume that the auxiliary transformer itself should be a BES Element - and subject to the whole body of CIP, MOD, IRO, and TOP standards. Our experience has been that Compliance authorities will make these assumptions, even if that was never the intent of the SDT. The effort to develop and maintain procedures, test results, and communications concerning every BES Element is not trivial - and a single instance of a missed requirement may lead to fines in the thousands of dollars. Ingleside Cogeneration is committed to take any action required to assure BES reliability, but NERC and the project teams must have evidence of its own that it is worth the cost.
Response: Thank you for your comments. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
American Electric Power		1. As stated in our previous comments for R3, Table 1-5 notes a “mitigating device” as part of component attributes. The meaning of this phrase is open to interpretation and needs to be clearly defined. Is it a discrete device? A protection scheme? Either? The team’s response, by stating its intentions regarding this phrase, actually illustrates the need to provide clarity for this term within the standard. 2. As stated previously, under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems, by their nature, may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish both minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are *not* included in the NERC definition of Protection System. For example, consider a Special Protection

Organization	Yes or No	Question 3 Comment
		System that is comprised of the following elements: Generating Unit Distributed Control System (DCS) - Qty 1Protective Relays - Qty 4 - Provide digital inputs to DCS Boiler Pressure Transmitters - Qty 2 - Provide analog inputs to DCS For a predetermined set of system events, the protective relays operate, indicating to the DCS that the event has occurred. If the pressure transmitters indicate that the boiler pressure exceeds a predefined threshold, the DCS responds by adjusting the analog output signals to the turbine valves. For compliance with the existing version of PRC-017-0, the owner of the above system has written a Maintenance and Testing Program that thoroughly tests the protective relays, DCS logic and analog inputs and outputs. However, under PRC-005-2, the owner of the system would not be able to use the proposed performance based method because the system does not have the required Segment population of 60 components. This leaves the owner no other option than the time based method. However, only the protective relays meet the NERC definition of Protection System and they are the only elements of this hypothetical SPS described in Tables 1-1 through 1-5. The existing PRC-005-2 draft does not contain time based activities that would be applicable to the DCS logic, analog inputs and analog outputs. Therefore, whereas the existing NERC standards demand the testing of these devices, NERC standards would no longer require their testing upon the implementation of PRC-005-2.
Response: Thank you for your comments. 1. A mitigating device is one that acts to respond as directed by a Special Protection System (SPS). It may be a breaker, valve, distributed control system, or any variety of other devices. 2. The SDT notes that the definition of a Special Protection System states "An automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability." If the SPS you described meets this definition and contains Protection System components, then PRC-005-2 applies to those Protection System components.		
American Transmission Company, LLC		ATC recommends that the SDT change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 24, Row 1, Column 3" to: "Verify that a trip

Organization	Yes or No	Question 3 Comment
		coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years." Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. In addition, many utilities purchase breakers with dual redundant trip coils to mitigate the possibility of a failure. It is well recognized that the most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice to mitigate the most prevalent cause of breaker failure. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).ATC continues to recommend a negative ballot since we believe that the testing of "each" trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comments. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to make the modification.		
Colorado Springs Utilities		Colorado Springs Utilities votes "negative" based on the document "Draft SAR for Phase 2 of Project 2007-17" under the section titled Brief Description of Proposed Standard Modifications/Actions, which states " The Standard Drafting team shall modify NERC Standard PRC-005-2 to add reclosing relays to the standard. In order to do so, the definition of Protection System shall be revised to include reclosing relays, the Facilities portion of the Applicability of the Standard shall be revised to describe

Organization	Yes or No	Question 3 Comment
		those reclosing relays that are included within the standard, and appropriate minimum maintenance intervals (with maximum allowable intervals) shall be added to the standard. The Standard Drafting team shall also make any other changes that are necessary to explicitly address reclosing relays, but shall not make general revisions to the standard, either in content or arrangement." Colorado Springs Utilities position is reclosing relays are used as part of the system restoration process, and should not be associated with the protection or reliability of the system. Reclosing relays should be grouped with SCADA controls of breakers and manual controls of breakers, and should be tested with the same frequency. Breaker reclosing is not used on many lines, and is disabled on many lines. Automatic Breaker Reclosing is a system enhancement, not a system requirement.
Response: Thank you for your comments. The SDT notes that the draft SAR for Phase 2 of Project 2007-17 is not applicable to the current successive ballot and was posted for informational purposes only. In Order 758, FERC directed NERC to include reclosing relays in a future version of PRC-005; the SDT developed this draft SAR to address FERC's directive.		
Duke Energy		Duke Energy votes "Negative" because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the previous Successive Ballot but prior to the associated Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but which are not intended to provide protection for the BES. The SDT's response to our comment directs us to Section 2.3 of the Supplementary Reference And FAQ Document which states "There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard." We agree with that statement, but point out that Section 4.2.1 is inconsistent with that statement, and has a much broader reach because it includes devices that detect Faults on the BES but which do NOT provide protection for the BES. Compliance audits will be driven by the words in the standard, not the explanations in the Supplementary Reference And FAQ Document. We would appreciate a response to our concern that explains the reliability benefit associated

Organization	Yes or No	Question 3 Comment
		with this expansion of scope, and which specifically addresses the following Duke Energy situation: Duke Energy's standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following wording for Section 4.2.1: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)".FERC's September 26, 2011 Order in Docket No. RD11-5 approved NERC's interpretation of PRC-005-1 R1 and R2, stating: "The interpretation clarifies that the Requirements are "applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES." This interpretation is consistent with the Commission's understanding that a "transmission Protection System" is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices."

Response: Thank you for your comments.

The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. All Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within

Organization	Yes or No	Question 3 Comment
PRC-005-2; thus the Interpretation does not apply to PRC-005-2. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.		
Entergy Services		Entergy provides the following comments to achieve consistency in the written standards: • Numbers indicating measurable quantities should be numbers: 95%, 5%, etc. and not spelled out. • Words indicating a specific document or entity should be capitalized: this Standard • Words indicating generic devices should not be capitalized: components, faults, monitors, misoperation • 4. If two words go together with a singular meaning they should both be either capitalized or not: Communication Systems
Response: Thank you for your comments. The SDT followed NERC's style guide for the various issues you point out.		
FirstEnergy		FirstEnergy supports the standard and thanks the drafting team for all their hard work.
Response: Thank you for your comments.		
Luminant		In addition to the revised Supplemental Reference and FAQ guide revision requested in question 2, Luminant recommends that Table 1-5; Line 1 and 4 be revised to specifically state that only BES elements (circuit breakers/interrupting devices) are to be tested. There is no benefit to the BES system for testing the non-BES breakers and some locations, trip testing of the breakers would cause a unit black-out due to unit design. Some units do not have start-up transformers. By performing these tests, there is a risk of causing unit damage while the unit is off-line. Therefore Luminant recommends that Table 1-5 be revised to only require BES breakers be tested for compliance purposes. This would be consistent with the requirements covered in Table 3 for UFLS Systems.
Response: Thank you for your comments.		

Organization	Yes or No	Question 3 Comment
The SDT revised Section 15.3.1 of the Supplementary Reference and FAQ document to address this concern, and does not believe that further revision of the standard is necessary.		
Public Utility District No. 1 of Okanogan County		In tables 1-4 with regards to station batteries. 1. DC Supply voltage. Is this reading taken off the batteries or out of the charger? Which read needs to be documented? 2. Unintentional grounds. If the charger has the ability to detect and alarm on unintentional grounds, do we need to manually check this as well? 3. In the 18 month section there is a reference to Float voltage of charger. How do we document in our procedure? Can we use SCADA? 4. In the NICAD battery section. Why can't we do impedance testing? Why only load testing? 5. In table 1-5 there is mention of "Lockout Devices" does this mean that 86 relays are being brought into scope? 6. In table 2 there is discussion with regard to Alarm paths and alarm path monitoring. Table 1-5 item 4 discusses Auxiliary Relays in the control circuit path. Typically, Auxiliary relays in this scenario are closed contacts and open when in an alarmed state. For example, a low SF6 alarm contacts on a breaker interrupts the trip circuit and prevents the breaker from operating. Does this type of auxiliary relay need to be tested every 12 years? 7. For monitoring transmission PTs- Can we measure low side voltage (13kv) PTs multiplied by the power transformer ratio to verify transmission PT accuracy? 8. Table 1-3 describes independent "measurements continuously verified by comparison" Does separate AC measurement need to be connected to same relay? or can it be connected to separate relay with comparison done in SCADA?
Response: Thank you for your comments. 1. The verification of dc voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not		

Organization	Yes or No	Question 3 Comment
malfunctioning, and the standard is indifferent as to where the voltage is actually measured. However, Section 15.4.1 of the Supplementary Reference and FAQ document suggests that this voltage be optimally measured at the battery's main terminals. 2. Per Table 1-4(f) and Table 2, if your charger has the ability to detect and alarm on unintentional grounds and meets the Table 2 requirements, no periodic inspection of unintentional dc grounds is required. 3. As explained in Section 15.4.1 of the Supplementary Reference and FAQ document, the maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltage on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. Per Table 1-4(f) and Table 2, if your charger has the ability to monitor and alarm to ensure correct float voltage is being applied on the station dc supply and meets the Table 2 requirements, no periodic verification of float voltage of battery charger is required. The standard is proscribed from describing "how". It is left to the entity to determine what methods best address their program. 4. At this time - with the exception of the results of a capacity test - the drafting team is unaware of any published data for nickel-cadmium battery properties that can be measured and trended against the station battery baseline. 5. As explained in Section 15.3 of the Supplementary Reference and FAQ document, if the lock-out relays (86) are electromechanical type components, then they must be trip tested per Table 1-5. 6. As explained in Section 15.3 of the Supplementary Reference and FAQ document, contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 6 or 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. 7. There are multiple methods to verify the current and voltage signal values as explained in Section 15.2 of the Supplementary Reference and FAQ document. 8. It is left to the entity to determine what methods best address their program. Section 15.2 of the Supplementary Reference and FAQ document discusses various methods of conducting this comparison.		
Manitoba Hydro		Manitoba Hydro is maintaining our negative vote based on our previously submitted comments (see comments submitted in the comment period ending on March 28th, 2012).
Response: Thank you for your comment. The SDT has also not changed its position from that expressed in response to the earlier comments.		
Oncor Electric Delivery		On Page 89 of the Supplementary reference and FAQ Draft document on the References page (reference #12) the correct number of the standard should read "Std

Organization	Yes or No	Question 3 Comment
		450-2010" instead of "Std 45-2010."
Response: Thank you for comment. The Supplementary Reference and FAQ document has been corrected.		
Dominion		On the Redline version of the standard, page 11 Version History; Version 2 Action, should PRC-005-1a be listed as PRC-005-1b and PRC-017 listed as PRC-017-0. Additionally, it does not appear that the Version History has captured a complete record of all revisions to this standard.
Response: Thank you for your comments. The references to the approved standards and the Version History have been corrected.		
Brazos Electric Power Cooperative		Please see the formal comments submitted by ACES Power Marketing.
Response: Thank you for your comment. Please see our responses to the comments submitted by ACES Power Marketing.		
PPL Generation, LLC on behalf of its Supply NERC Registered Entities		PPL Generation, LLC thanks the SDT for their effort on this latest version of the standard and has voted affirmatively. We offer the following comments/suggestions: 1.) PPL Generation, LLC would like more direction on how the Tables 1-3 are to be interpreted. Under the left column "Component Attributes," it is not completely clear as to which situation is applicable in order to know what "Maintenance Activity" applies. Either the table's "Component attributes" or the statement "Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components" could be more prescriptive on the specific component attributes to provide entities direction as to when exactly each table is to be followed. 2.) In regards to Unresolved Maintenance Issues, PPL Generation, LLC is concerned with the use of the word "efforts" in regards to the use in "shall demonstrate efforts" in Requirement 5. We suggest that either a formal definition of "effort" is provided or more clarity is added in the Requirement 5, shown below, that gives a quantitative

Organization	Yes or No	Question 3 Comment
		scale of what constitutes an effort. “Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.” In its current form, “efforts” can be broadly interpreted by auditors as any number of different required actions of an entity and could potentially lead to inconsistencies in applying the term throughout the regions.
Response: Thank you for your comments. 1. The left column of the Tables describes the monitoring attributes (if any) that are available on the particular components. The center and right columns describe the related maximum maintenance intervals and minimum maintenance activities. **2.** The SDT believes there is sufficient understanding in the industry for the term “efforts” and the risk of compliance jeopardy is minimal.		
Progress Energy		1. R3 and the VSL for R3 seem to imply that an entity would not be in violation of this standard if they exceed their PSMP intervals (including any program grace) as long as the maintenance is performed within the maximum intervals prescribed within the tables. This interpretation was further supported in the previous draft of the Supplemental Reference (Section 8.2.1, page 35), which stated: “According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded.” However, this statement has been removed from the supplemental document under the latest draft revision. Would the entity be noncompliant if they exceed their PSMP interval but not the maximum table interval? 2. Table 1-4(e): Typo. “Any Protection System dc supply used only for tripping only....” 3. Page 51, 4th paragraph, 5th line: Typo “thre” should be “three.”
Response: Thank you for your comments. 1. The standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Requirement R3 was revised recently to establish that entities must maintain their Protection System components, at a minimum, in accordance with the relevant tables. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP is necessary; however, according to Requirement R3, the entity will not be held to their more-aggressive (than the tables) PSMP for compliance monitoring purposes.		

Organization	Yes or No	Question 3 Comment
2. The SDT made the suggested editorial change to Table 1-4(e). **3.** The Supplementary Reference and FAQ document has been corrected as suggested.		
ReliabilityFirst		ReliabilityFirst offers the following comments for considerations: 1. General Comment a. ReliabilityFirst believes not only should there be testing required for individual components (as required Protection System Maintenance Program), ReliabilityFirst believes that the entire Protection System (consisting of all Protective relays, communications systems, Voltage and current sensing devices, etc.) should be tested as a whole. Individually each component may test successfully but while tested as a complete Protection System (through interaction between all the interdependent components), deficiencies in settings along with logic and wiring errors could be discovered. 2. Requirement R5 a. ReliabilityFirst believes the language in Requirement R5 ("...shall demonstrate efforts to correct...") is subjective and non-measurable. It will be difficult in determining what amount of "demonstration" an entity will need to provide in order to be compliant along with lack of timeframe in which the correction needs to be completed. While RFC understands it is hard to prescribe a specific timeframe/deadline (it can depend on various number of supply, process and management problems), RFC believes at a minimum, the applicable entity should be required to develop a Corrective Action Plan to address the Unresolved Maintenance Issue. ReliabilityFirst offers the following modification for consideration: "Each Transmission Owner, Generator Owner, and Distribution Provider shall put in place a corrective action plan to remedy all identified Unresolved Maintenance Issues."
Response: Thank you for your comments. 1. The SDT does not believe it feasible to craft requirements for testing an entire Protection System as a whole that would simultaneously prove performance of every component and believes such invasive testing would jeopardize BES reliability. 2. The SDT's intent is to furnish a way for an entity to address Unresolved Maintenance Issues without the formality and burden of a		

Organization	Yes or No	Question 3 Comment
full-fledged Corrective Action Plan.		
Seattle City Light Operations		SCL supports the position of WECC PNGC with regard to the position paper VRF/VSL recommendation. Specifically, it is the contention of PMGC and members that small entities with maybe 2 or 3 components within a Component Type that sustain a violation will unnecessarily be subjected to a “severe” or “high” VSL assignment due to the % based parameter. We feel the SDT did not adequately address our concerns during the last ballot/comment period. While this is a non-issue for larger entities with hundreds or thousands of individual components, we believe this exposes smaller entities to unnecessary compliance risk. 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given NERC Guidance (following), this seems to be a contradiction given the language of “...more than one” [NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance. ii. MODERATE: Missing at least one significant element (or a moderate percentage) of the required performance. iii. HIGH: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. SEVERE: Missing most or all of the significant elements (or a significant percentage) of the required performance.] Thus we support the WECC PNGC suggestion to change the language for “Lower VSL” for R3 to: 'For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained...' OR 'For Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained...'

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. The SDT respectfully disagrees and believes that the Standard appropriately incorporates and accounts for the system risks and burdens of maintenance for both large and small entities. The VSLs were developed in accordance with the "FERC VSL Order" and the NERC criteria; for stepped VSLs - Lower VSL is "5% or less", Medium VSL is "more than 5% up to (and including) 10%", High VSL is "more than 10% up to (and including) 15%", and Severe VSL is "more than 15%".		
Public Service Company of New Mexico		Table 1-1 Component Type - Protective Relay and Table 1-2 Component Type - Communications Systems refer to Table 2 Alarm Paths and Monitoring for monitoring related attributes. However, the maximum maintenance interval in rows referring to Table 2 in both Tables 1-1 and 1-2 is 12 calendar years whereas there is a row in Table 2 that if there is an Alarm Path with monitoring (row 2 of Table 2), no periodic maintenance is required. Does this mean that even if there is an Alarm Path with monitoring for which no periodic maintenance is required, the component type - Protective Relay or Communications Systems will still be required to be maintained within the maximum 12 calendar years interval? This appears to be contradictory especially since rows in Tables 1-3, 1-4(f), and 1-5 that refer to Table 2 have "no periodic maintenance specified" under maximum maintenance interval. This also appears to be contradictory to the text provided under bullet 1 of Section 5.2 Extending Time-Based Maintenance which states that - If continuous indication of the functional condition of the Component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated." Rows referring to Table 2 in Tables 1-1 and 1-2 do not suggest that manual testing will be eliminated as it is requiring a 12 calendar year maintenance time interval even if it meets the requirements under table 2 for alarm path with monitoring. PNM recommends adding the following under Maximum Maintenance Interval to be consistent with other tables 1-3, 1-4(f), and 1-5 - "12 calendar years OR no periodic maintenance specified".
Response: Thank you for your comments. For protective relays and communications systems, the only maintenance activity in the last line of the related table is to verify those unmonitored inputs and outputs that are essential to the proper functioning of the Protection System. The SDT sees no appreciable		

Organization	Yes or No	Question 3 Comment
improvement in the standard with your proposed change and respectfully declines to modify the standard.		
Bonneville Power Administration		1. Table 1-2: Communication Systems: BPA believes that the entire section of Table 1-2 needs clarity. A channel, channel performance criteria, & communication system all have very precise definitions in the communications world. (Please refer to Supplemental Frequency AQ - Figure 1 - Typical Transmission System Diagram, Telecommunications Network Cloud)When referring to the terms in Table 1-2, if the drafting team is referring to the 'telecommunications cloud', this section is unclear. BPA believes it is clearer if the drafting team is referring to the two telecommunications equipment panels and requests documented clarification. The traditional term for this would be teleprotection channel or teleprotection function. BPA assumes the intention was teleprotection channel. BPA recognizes that the teleprotection equipment panels, in many modern cases, are built into the relay. For background information, the Telecommunications Network is composed of multiple Communication Systems (40 to 50 is not uncommon) that contain multiple thousand (5-6K) pieces of equipment. These systems and equipment are tied together with hundreds of thousands of Communication Channels and Tributaries. Most of the Channels and Tributaires have, at least a primary and backup (WECC Guideline: Design of Critical Communications Circuits), and some have multiple primary's and backups. All of these are needed to create the circuit connections, as indicated on the diagram from one teleprotection panel to another teleprotection panel. Given the above scenario - the confusion is possible. As an example, for the component attribute: 'Any unmonitored communication system necessary for the correct operation of the protective functions, and not having all the monitoring attributes of a category below.' The 4 calendar month maintenance activity is to: 'Verify that the communications system is functional.' The questions that arise are which systems, the drop system or the transport system? The whole system or just the part carrying the protective signals? What about the channels interconnecting the various systems and so on? BPA suggests clarifying: Any unmonitored teleprotection function necessary for the correct operation of the protective

Organization	Yes or No	Question 3 Comment
		functions, and not having all the monitoring attributes of a category below. The 4 calendar month maintenance activity is to: 'Verify that the teleprotection function is functional' BPA believes this is a much better approach as it identifies only that the teleprotection panels must get inputs and outputs to the relays between them. BPA believes more clarity is still needed. A simple example of an old tone based FSK transfer Trip System over a single point to point analog MW radio channel; the teleprotection panel will normally transmit a guard tone in a particular spectrum over a single radio channel to the teleprotection panel at the far end. BPA understands that one way to verify that the teleprotection function is serviceable in a 4 month maintenance activity is if the guard signal arrives at the opposing end, correct? BPA infers that this is efficient as entities can now monitor loss of guard and have a continuously monitored system which will result in performing just a12 year maintenance. Is this correct? This raises the question of the trip function. Until the trip function is energized from the relay, the circuitry sending the trip by initiating a FSK in not functioning. Does this function needs to be check in addition to the guard function? This raises the question of the MW radio channel. BPA recognizes that the FSK trip signal travels over different spectrum in the analog MW radio. Even if the radio will transmit a Guard FSK signal to the far end, it will not necessarily transmit a Trip FSK signal to the far end (a common hidden failure mode in many MW systems). Do entities need to check for guard at the far end and test that a FSK Trip signal propagates through the radio system and is received at the teleprotection panel? BPA requests clarification in the followings scenario: Using testing inputs as opposed to operating inputs that trips and guards may be initiated from a different set of inputs of the teleprotection panel, and monitored from a different set of outputs on the teleprotection panel (very common on teleprotection equipment). The test might work, but an actual Trip signal would not work (a common hidden failure mode on current available equipment). If one were to say 'good enough' for a 4 month test (and hope any auditors agree if there is ever a false operation). How about the 12 calendar year test? For a point to point analog MW radio,

Organization	Yes or No	Question 3 Comment
		there is only a single channel that can be tested for passage of guard and trip tones. If the radio is redundant, which it most likely is (WECC Guideline: Design of Critical Communications Circuits) then this has to be done twice, once for each path. Can the drafting team clarify this scenario? In a more typical real-world case, the circuit connection, between the two teleprotection panels, will transverse multiple redundant communications systems. If it crosses 4 redundant systems in the communications cloud, then there are a total of 4^2 or 16 possible communication channels, each with different test criteria, that need to be tested. Additionally, the channels are rerouted manually and automatically much faster than a 12 year cycle (daily is not uncommon). Do all these combinations need to be tested? This discussion illustrates the confusion of the current wording. BPA recommends that: If the intention is to test in the 'cloud' or the performance of the 'cloud', BPA believes there needs to be a new standard, or set of standards created to deal with the intricacies of the telecommunication cloud. If the intention was to test the teleprotection channel, BPA believes additional clarity needs to be provided to address the dynamic redundancies and rerouting of the communications system. If the intention was to test the teleprotection function BPA believes additional clarity needs to be provided to test/monitor the functions (inputs and outputs) between the teleprotection panels. 2. Table 1-4(a):VLA Battery: 4 Months/Inspect/Electrolyte Level BPA believes that for a properly designed and installed steady state float charge/long duration discharge type battery plant this is not needed. The inspection at 4 Month intervals will unearth catastrophic failures (Split cells, severe overcharging, etc...). These types of failures can happen anytime, and need to be designed around. Unless the battery plant is under high cyclic load, water usage can be handled in a 12/18 month maintenance cycle. Severe overcharging needs to be dealt with by design/maintenance practices (for example: an Appropriate high voltage alarmed with an immediate call out) since 4 months is too long to wait to detect the condition. Minor overcharging will not be detectable in a 4 month interval (and one wants to very slightly overcharge a battery verse any individual cell being

Organization	Yes or No	Question 3 Comment
		undercharged, but that is a whole different technical discussion). IEEE484 specifies ventilation should be provided for the worst-case hydrogen generation due to overcharging. Other than an inherent manufactures defect that can happen anytime 24/7, splitting cells due to sulfation build up is a slow know process that can be handled in a 12/18 month maintenance cycle with a good visual inspection. Although this is in line with IEEE450, given the specific type of battery configuration in the utility world, this is excessive. Should there be a unique battery plant design, then it is incumbent on that utility to have appropriate shorter intervals. BPA is in support of “For unintentional grounds” and recognizes that it does not apply to intentionally grounded battery systems (teleprotection systems run off of communication batteries in sites where there is no station battery {i.e.: Grand Coulee/Lower Snake}).In general there are two types of batteries used by utilities, outside of their control centers, which will be supplying protective systems. The vast majority is the station battery, which is described very well in the IEEE standards: Switchgear control battery applications typically require output current levels that vary over a relatively long period of time. The battery operates on a float charge during steady state conditions. The battery charger powers relays, indicating lights, and peripheral devices during normal conditions. Instantaneous operation of the circuit breaker and switches require battery output current. Initially, this current may be relatively high for a short duration and then reduce for an extended period of time, followed by another high operating current demand. If the charger output is lost, these low-level currents are supplied by the battery for a specified period. The second is a telecommunications battery supplying the teleprotection equipment (excluding the telecommunications batteries supplying only the communication cloud), which are described very well in the IEEE standards: Telecommunication systems are typically of high reliability, with a minimum uptime of 99.99% is often required. Although the batteries are sized for long duration discharge, short duration discharges are usually the case. Excess charging capacity is often available because of redundant charger configurations and engineered

Organization	Yes or No	Question 3 Comment
		overcapacity. The reserve battery time is usually of long duration.
Response: Thank you for your comments. 1. The SDT does not necessarily agree that the term “teleprotection” is universally used or interpreted consistently in the utility protection industry and believes its use in the standard would not improve the standard. Your comments in the complexity and intricacy of the telecommunications “cloud” are well-taken; however, it was the SDT’s intent to require an overall functional test of the “cloud”-based path, but not an exhaustive test of each and every individual channel that could be involved. Yes, there is some risk in a FSK-based guard/trip scheme that the trip function may not perform even if the guard function does, but the SDT sees this risk as manageable and in line with other risks inherent in interval-based maintenance. **2.** This standard is applicable to station batteries. Please see Section 15.4.1 of the Supplementary Reference and FAQ document for more discussion. The scope of this standard does not include communication site batteries. The SDT believes that PRC-005-2 strikes an appropriate balance between maintenance burden, failure modes, manufacturer recommendations and IEEE battery guidelines.		
Independent Electricity System Operator		The IESO continues to disagree with the VRF assigned to the new Requirements R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our request to change R3’s VRF to Medium.
Response: Thank you for your comments. The SDT respectfully disagrees and contends that the consequences of failing to maintain Protection Systems in the required time frames merit a High VRF.		
PNGC Small Entity Comment Group		The PNGC Small Entity Comment Group appreciates the hard work of the Standards Development Team on this difficult and complex project. However we are disappointed with the response to our concerns over the VSL matrix and although we believe on balance this should not be the sole reason for voting "no", we find it difficult to re-cast a "yes" vote and will therefore vote "abstain" to maintain the integrity of the quorum and reflect our position. Your response to our comment;"1.

Organization	Yes or No	Question 3 Comment
		A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate." reflects a position that indicates are cursory and dismissive review of our concern. We would counter that because a smaller entity has less to maintain, a solely percentage violation measure is therefore inappropriate. We've appended our original comment below in addition to the SDT response. PNGC Comment:1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the "NERC Guidance (Below), this seems to be a contradiction given the language of "...more than one". a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Moderate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required performance. We suggest changing the language for "Lower VSL" for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained... Or for Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained... SDT response: 1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.

Response: Thank you for your comments.

The SDT respectfully disagrees and believes that the Standard appropriately incorporates and accounts for the system risks and burdens of maintenance for both large and small entities. The VSLs were developed in accordance with the "FERC VSL Order" and the NERC criteria; for stepped VSLs - Lower VSL is "5% or less", Medium VSL is "more than 5% up to (and including) 10%", High VSL is

Organization	Yes or No	Question 3 Comment
"more than 10% up to (and including) 15%", and Severe VSL is "more than 15%".		
US Bureau of Reclamation		The reliability level for protection systems has been lowered by eliminating the requirement for entity defined maintenance and testing procedures. Currently the draft only prescribes that the elements are identified as to when they will be maintained. The FAQ suggested that the PRC-005 did not have sufficient specificity with regard to the PSMP requirement. The entity no longer must be able to document that they were maintained in accordance with any prescribed method, jus that they were maintained in accordance within an acceptable interval. Second, the measure for R1 does not specific what evidence is considered acceptable. This makes the standard hard to enforce.
Response: Thank you for your comments. The standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP to be necessary. Measure M1 offers examples of documentation that should ease compliance and enforcement.		
Seminole Electric Cooperative, Inc		1. The SDT has provided ONE Protection System Component with two differing maintenance periods, the lockout (86) device. Six years is used for the lockout operation and twelve years is used for contact testing of the lockouts. Earlier the SDT had a similar arrangement with microprocessor relays, the microprocessor relay would be tested on a twelve year cycle but the microprocessor's electro-mechanical trip outputs were to be tested on a six year cycle. The SDT then made a decision that the single microprocessor asset would have a common testing cycle of twelve years, reasonably considering it a single asset with a single maintenance cycle of 12 years. To eliminate confusion with lockout relays, it is recommended that a similar decision be made by the SDT to make a single lockout relay asset have a common maintenance cycle of twelve years. The lockout relay twelve year cycle would include both the lockout operational test and the lockout relay tripping contact tests. This twelve year cycle would also be in direct maintenance alignment with other microprocessor relays and auxiliary relay testing cycles.

Organization	Yes or No	Question 3 Comment
		2. In addition, the sudden pressure relays and their integral control circuit should either be included or excluded. This is a compliance trap and will lead to many findings of non-compliance, based on sudden pressure relays not being included in many prior versions and currently not included in this version, except for their DC control circuit.
Response: Thank you for your comments. 1. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance based maintenance is an option if you want to extend the intervals beyond 6 years. However, the SDT modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification. **2.** The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently approved PRC-005-1 and with the SAR for Project 2007-17.		
Florida Municipal Power Agency		1. The SDT is still not agreeing with the applicability as interpreted and approved by FERC PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: In these two standards, use of the phrase transmission Protection System indicates that the requirements using this phrase are applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES. The SDT continues to ignore this FERC approved interpretation, and this omission causes us to vote Negative again. The basic issue is that some distribution protection will be swept in with the applicability of the standard, which states: 4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines,

Organization	Yes or No	Question 3 Comment
		buses, transformers, etc.) 2. Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should have adopted the FERC approved interpretation. We have made this recommendation several times before.

Response: Thank you for your comments.

1. The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT observes that the approved interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.
2. In the case you cite, the transformer is likely not a BES element; thus reverse power relays, even if installed to detect a fault in the transformer rather than actually to detect transformer energizing current, would not be included (as they are not installed for the purpose of detecting a fault on the BES). Please note that reverse power relays respond to real power (watts) instead of

Organization	Yes or No	Question 3 Comment
reactive power, and fault current is highly reactive.		
Tennessee Valley Authority		This comment is regarding the Implementation Plan for Requirements R3 and R4, 1. (Page 3 of 5) of The Implementation Plan for Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02. Number 1. states: For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5: o The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities. TVA Comment: Even though TVA has already started a plan to address this issue, it will take several years to implement automatic checkback on 541 carrier blocking sets on the TVA system. TVA performed quarterly testing from 2000 through 2007, then after data showed failures not attributed to signal margin, the test was changed to twice a year in 2008. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We suggest a graduated implementation plan for this effort similar to number 3 (being compliant 30% in 24 months, 60% in 36 months, and 100% in 48 months) on Pages 3 and 4 of 5.
Response: Thank you for your comments. If an entity's experience is that these components require less-frequent maintenance, a performance-based program in accordance with Requirement R2 and Attachment A is an option. Your comments on your failure rates seems to indicate that you are performing a failure rate analysis similar to what is required under Attachment A for performance maintenance. While it is unfortunate that you feel you cannot meet the implementation requirements, the SDT believes that the existing plan is judicious in its time frame relative to the maximum intervals required by the standard.		
Tacoma Power		1. This is a follow-up question/comment from the previous round of balloting; please see the part in all capitals. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an

Organization	Yes or No	Question 3 Comment
		acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions IF DC VOLTAGE IS VERIFIED AT EACH APPLICABLE SET OF ACTUATING DEVICE TRIP TERMINALS SO THAT EVERY TRIP PATH IS ADDRESSED. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. 2. In Table 1-2, does the 'channel' include the communication interface/driver that is part of the end device?
Response: Thank you for your comments. 1. The method chosen for verification is left to the entity. The second to last paragraph of Section 15.3 of the Supplementary Reference and FAQ document states: "Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control Systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker." If your suggested activity verifies each and every individual path to the trip coil, it may be an effective method of addressing this requirement; simply checking for voltage at the trip coil may not verify all individual paths. 2. Please see Section 15.5.1 of the Supplementary Reference and FAQ document. The maintenance activities in Table 1-2 related to "channel" have been revised to "communications systems"		
BAE Batteries USA		This revision is a major improvement over the previous draft. Hopefully, the comments above are seen in the light of ensuring basic accuracy of the revised statements. They are not intended to materially change the intent of the position agreed upon at the last drafting team meeting.
Response: Thank you for your comments.		
HHWP		VSL should not be a function of "specific Protection System Component Type". VSL should look at percentage of TOTAL Protection System Components that were not tested within scheduled test date. Consider the entity with 400 Protection System Components, including 2 station battery systems. If that entity completed 399 of 400 tests within schedule and missed 1 battery test, the VSL would be high or severe.

Organization	Yes or No	Question 3 Comment
		Alternatively, if the entity completed 399 of 400 tests, but the missed test was one of 200 protective relays, the VSL would be low. There is no assurance though that the missed battery test resulted in higher risk for the BES than the missed protective relay test. As a result the relationship between VSL and the degree of violation severity lacks predictability.
Response: Thank you for your comments. The SDT disagrees because a battery supplies control power to numerous protective schemes, failure to ensure that the battery is fit for duty is more egregious than missing one component of numerous schemes.		
Consumers Energy		1. We agree with the purpose in section 3 of the Standard. However, section 4.2.1 expands the scope from "affecting the reliability of the Bulk Electric System" to "detecting Faults on BES Elements". In our opinion, the Applicability should be limited to the stated Purpose. Expanding the scope as is done in 4.2.1 greatly increases the number of Protection Systems covered without an increase in reliability of the BES. We prefer the applicability as expressed in Appendix 1 of PRC-005-1b. 2. We suggest changing "Component Type" in R1.2 to something similar to "Segment" as defined within the Standard. A "Component Type" limits to one of five categories, whereas a "Segment" must share similar attributes. 3. In item 2 of the second section of Attachment A, it is only necessary to use 5%, as 5% of a Segment (minimum of 60) is always 3 or more.
Response: Thank you for your comments. 1. The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT observes that the approved interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. 2. In the documentation to support Requirement R1.2, an entity can list different technologies within a Component Type along with their respective monitoring attributes. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard.		

Organization	Yes or No	Question 3 Comment
3. The SDT agrees with your observation but sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard.		
Alliant Energy		We appreciate the work done by the SDT and believe it is an excellent product.
Response: Thank you for your comments.		
Georgia Transmission Corporation		We cast our ballot as an affirmative vote and agree with the nature of the standard. We raise concerns on the measures that are very prescriptive on documentation. We prefer a standard based on the program and measures that track the application and performance of the groups program. Maintaining the documentation for individual elements becomes a group's prime directive along with maintaining the equipment; this develops a process more controlled by documentation than results. This also adds a level of complexity for data retention, the drafting team tried to resolve by reducing the load of data. We contend the retention levels to be extreme considering some of the 12 calendar year cycles, interpret the data for compliance to be 24 years. One cannot remove previous documents until new maintenance performed 12 years after the current recorded date. We recommend reducing the data retention to list or check sheets and not the extreme of each individual component. Another important factor in managing the data is the capability of retrieval after 12 or 24 years. Some systems and formats are not available for 12 or 24 years and add a burden on companies to maintain legacy systems or convert massive amounts of data.
Response: Thank you for your comments. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The SDT has specified the data retention in the posted standard to establish this level of documentation. The entity is urged to assure that data is retained as specified within the standard.		
Nebraska Public Power District		1. We recommend removing requirement 5. This is adding the requirement for a

Organization	Yes or No	Question 3 Comment
		corrective action program to the standard. Performance metrics should be utilized to measure if a registered entity is correcting maintenance deficiencies in a timely manner. Examples of performance metrics include: o A Countable event has already been defined in the definition of terms, which would cover the need to replace equipment. o The quantity and causes of Misoperations are a direct correlation to good or poor maintenance practices and corrective actions by a utility. o TADS records events which are initiated by failed protection system equipment and would identify utilities with poor corrective action processes. 2. Can you show us a study or references justifying why records need to be kept for longer than the end of the current audit period. We are concerned that the complexities and costs of tracking and maintaining records, along with the corresponding maintenance program and PRC-005 revision that old tests would fall under will be an undue cost to small utilities. We suggest requiring entities to retain the last maintenance record or any records created during the current audit period. 3. The comment from the previous consideration of comments, "The SDT believes that Protection Systems that trip (or can trip) the BES should be included" seems to include any device that can affect the BES. This sets a precedence to include any device that can trigger trip coils into the maintenance system. These devices are meant to protect equipment and not the BES. 4. Based on the IEEE device numbers, please indicate which devices are part of the BES protection system and should be included in a maintenance program. 5. Why do functional trip checks need to be done on any interval if checks are done upon commissioning, maintenance and modification? We suggest eliminating any interval and making the requirement to check upon commissioning, maintenance and modification. 6. Comments on SAR for 2007-17 Very few reclosing relays protect the BES. Most reclosing relays actually would have a negative impact on the reliability of the bulk electric system. It is imperative that the SDT clearly define what types of reclosing relays are referred to here, and if it pertains to ANY reclosing relay that

Organization	Yes or No	Question 3 Comment
		can affect the BES. 7. There is a difference between components designed to protect the BES and components which can affect the BES. 8. For R5 if the maintenance interval is 6 years does the maintenance issue become an “unresolved” item immediately or does the next maintenance interval 6 years later need to be reached before it takes on an unresolved status to be auditable under R5? 9. Comments: Suggest for monitored microprocessor relays in Table 1-1 and 3 to change wording to verify “settings are as specified that are essential to the proper functioning of the protection system”. Many settings are not essential. 10. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. I suggest there be consideration that the interval for functional tests be moved to the minimum frequency of 12 years to minimize this unknown but present risk.

Response: Thank you for your comments.

1. The SDT disagrees:
   NERC has demonstrated its belief that returning Protection System devices to good working order exists currently as a required element of a sound maintenance program subject to the existing Protection System maintenance and testing standard, PRC-005-1. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to “…look for relay test results or field records with annotations such as “as-found” readings or pass/fail results; <u>if failed, then adjustments made. The maintenance record for adjustments may be requested”</u>.
   Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible

Organization	Yes or No	Question 3 Comment
		remediation projects and therefore impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective actions are being undertaken. 2. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The SDT has specified the data retention in the posted standard to establish this level of documentation. The entity is urged to assure that data is retained as specified within the standard. 3. The response cited from a previous consideration of comments was specifically related to sudden pressure relays. The Applicability 4.2.1 of the standard, specifically states, "…installed for the purpose of detecting Faults on BES Elements". 4. It is left to the entity to determine which devices and their complementary IEEE device numbers are installed for the purpose of detecting Faults on BES Elements. 5. The standard does not specify "functional trip tests", but instead requires that various elements of the dc control circuit be verified at various intervals. Also, FERC Order 693 directs NERC to establish maximum allowable maintenance intervals for Protection System components. Please see Section 15.3 of the Supplementary Reference and FAQ Document. 6. Reclosing relays are not covered in PRC-005-2. In Order 758, FERC directed NERC to include reclosing relays in a future version of PRC-005; the SDT developed the draft SAR to address FERC's directive 7. The SDT agrees; the standard explicitly covers "Protection Systems that are installed for the purpose of detecting Faults on BES elements (lines, buses, transformers, etc.)". 8. The item does not become an "Unresolved Maintenance Issue" unless it is not corrected before the current maintenance interval expires. 9. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard. 10. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES. The standard does not specify "functional trip tests", but instead requires that various elements of the dc control circuit be verified at various intervals.
Western Area Power Administration		Western Area Power Administration is appreciative of the hard work done by the SDT and NERC. 1. We respectfully submit our professional opinion that the increased relay testing

Organization	Yes or No	Question 3 Comment
		required by the PRC-005-2 will result in a net degradation to the reliability of the BES due to human hands disturbing working systems. 2. We propose that auxiliary relays be tested at commissioning and anytime the circuits are rewired or redesigned. If there is evidence that the relay has functioned properly in its current configuration then the best practice for insuring reliability is to leave it alone. 3. The maintenance interval of 6 years for lock-out relay testing is not consistent with 12 year interval of auxiliary relay testing or control circuit testing. No justification is provided for this increased testing interval of lock-out relays versus other electro-mechanical devices. These inconsistent testing intervals, within the same protection control schemes and protective devices, will complicate the industry's Protection System Maintenance Program and cause an increase in maintenance costs. 4. Condition Based Monitoring or Performance Based Monitoring are not allowed on trip coil circuits or lock-out relays. This is inconsistent with current or future technology. Deviation from the 6 year testing interval should be allowed, using CBM or PBM. The Standard should not present a barrier to technology advancements or industry initiatives. The continuous, frequent testing of these devices is detrimental to system reliability. 5. Disagree with testing of the dc control portion of the sudden pressure device as defined by the FAQ. We feel that this device and its wiring were deemed out of scope previously.

Response: Thank you for your comments.

1. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES.
2. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES. Also, FERC Order 693 directs NERC to establish maximum allowable maintenance intervals for Protection System components.
3. The SDT believes that electromechanical lockout relays need periodic operation to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. Performance based maintenance is an option if you want to extend the intervals beyond 6 years.
4. Performance-based maintenance per Attachment A of the standard may be applied to both trip coil circuits and lockout relays.

Organization	Yes or No	Question 3 Comment
5. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from the definition of Protection System because the SDT is unaware of industry recognized testing protocol for the sensing elements. This position is consistent with the currently-approved PRC-005-1 and the SAR for Project 2007-17.

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.
3. Standard passed the initial ballot with the following results: Quorum - 84.32% and Affirmative - 73.93%.
4. Draft standard was posted for a 30-day concurrent posting and successive ballot from February 28, 2012 through March 28, 2012.
5. Standard passed the successive ballot with the following results: Quorum – 84.32% and Affirmative – 73.93%.
6. Draft standard was posted for a 30-day concurrent posting and successive ballot from May 29, 2012 through June 27, 2012.
7. Standard passed the successive ballot with the following results: Quorum – 79.46% and Affirmative – 79.00%.

Description of Current Draft:
This is the second draft of the Standard. This standard merges previous standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing*, *PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs*, *PRC-011-0 — UVLS System Maintenance and Testing*, *PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and successive ballot.	July 2012
2. Drafting Team Responds to Comments	September 2012
3. Conduct recirculation ballot	October 2012
4. BOT Adoption	December 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for signs of component failure, reduced performance or degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion

on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**
2. **Number:** PRC-005-2
3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.
4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner

4.1.2 Generator Owner

4.1.3 Distribution Provider

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

> ***Component Type** - Any one of the five specific elements of the Protection System definition.*

1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue** - A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented Protection System Maintenance Program in accordance with Requirement R1.

For each Protection System Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System Components included within its time-based program in accordance with Requirement R3. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.3. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System Component Type.

For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Component, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	The responsible entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entity's PSMP failed to include the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to no more than 4% within five years OR 3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				• Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or fewer Unresolved Maintenance	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	Issues.	Unresolved Maintenance Issues.	Unresolved Maintenance Issues.	Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — July 2012.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1b, PRC-008-0, PRC-011-0, PRC-017-0	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed.
For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the communication system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 calendar years	Verify that the communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with all of the following: • Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack

Table 1-4(a) **Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(b) **Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack

Table 1-4(b) **Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(c) **Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries** **Excluding distributed UFLS and distributed UVLS (see Table 3)** Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as manufactured when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Devices for SPS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic evaluation relative to baseline of battery cell/unit measurements indicative of battery performance is required to verify the station battery can perform as manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3) **Note:** Table requirements apply to all Control Circuitry Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 calendar years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with SPS.	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **Segment** population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

> **Segment** – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.*

> **Countable Event** – *A failure of a component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.
5. If the Components in a Protection System Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approved posting SAR and draft standard on August 11, 2011.
2. SAR and draft standard were posted for a 45-day concurrent posting and initial ballot from August 15, 2011 through September 29, 2011.
3. Standard passed the initial ballot with the following results: Quorum - 84.32% and Affirmative - 73.93%.
4. Draft standard was posted for a 30-day concurrent posting and successive ballot from February 28, 2012 through March 28, 2012.
5. Standard passed the successive ballot with the following results: Quorum – 84.32% and Affirmative – 73.93%.
6. Draft standard was posted for a 30-day concurrent posting and successive ballot from May 29, 2012 through June 27, 2012.
7. ~~3.~~ Standard passed the successive ballot with the following results: Quorum – 79.46% and Affirmative – 79.00%.

Description of Current Draft:
This is the second draft of the Standard. This standard merges previous standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and successive ballot.	~~May – June,~~July 2012
2. Drafting Team Responds to Comments	~~July – August,~~September 2012
3. Conduct recirculation ballot	~~August~~October~~,~~ 2012
4. BOT Adoption	December 2012

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for signs of component failure, reduced performance or degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion

on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owner

4.1.2 Generator Owner

4.1.3 Distribution Provider

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

The PSMP shall:

> ***Component Type*** *- Any one of the five specific elements of the Protection System definition.*

1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System Component Type. All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

1.2. Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented Protection System Maintenance Program in accordance with Requirement R1.

For each Protection System Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station dc supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each protection Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.2)

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include but is not limited to Component lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System Components included within its time-based program in accordance with Requirement R3. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the Protection System Maintenance Program for the Protection System Components included in its performance-based program in accordance with Requirement R4. The evidence may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include but is not limited to work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Investigation

Self-Reporting

Complaint

1.3. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System Component Type.

For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Component, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1) OR The responsible entity's PSMP failed to include applicable station batteries in a time-based program. (Part 1.1)	The responsible entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The responsible entity's PSMP failed to include the applicable monitoring attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components. (Part 1.2).	The responsible entity failed to establish a PSMP. OR The responsible entity failed to specify whether three or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to no more than 4% within five years OR 3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				• Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.
R4	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.
R5	The responsible entity failed to undertake efforts to correct 5 or fewer Unresolved Maintenance	The responsible entity failed to undertake efforts to correct greater than 5, but less than or equal to 10	The responsible entity failed to undertake efforts to correct greater than 10, but less than or equal to 15	The responsible entity failed to undertake efforts to correct greater than 15 Unresolved Maintenance

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	Issues.	Unresolved Maintenance Issues.	Unresolved Maintenance Issues.	Issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — ~~May~~ July 2012.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from ~~PRC-005-1, PRC-005-1a,~~ PRC-005-1b, PRC-008-0, PRC-011-0, PRC-017-0	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed.
For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval[1]**	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	~~12~~ 6 calendar years	Verify that the ~~channel~~ communication system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 calendar years	Verify that the ~~channel~~ communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with all of the following: • Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(c) Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station dc supply used only for non-BES interrupting devices for SPS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as manufactured when ac power is not present.

Table 1-4(e)		
Component Type – Protection System Station dc Supply for non-BES Interrupting Devices for SPS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply used ~~only~~ for tripping only non-BES interrupting devices as part of a SPS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage.

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic evaluation relative to baseline of battery cell/unit measurements indicative of battery performance is required to verify the station battery can perform as manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 **Component Type - Control Circuitry Associated With Protective Functions** **Excluding distributed UFLS and distributed UVLS (see Table 3)** **Note:** Table requirements apply to all Control Circuitry Components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 calendar years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with SPS.	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 calendar years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or SPS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5 and Table 3, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 and Table 3 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment of the Protection System Component population, with a minimum **Segment** population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.

> **Segment** – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.*

3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences **Countable Events** on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

> **Countable Event** – *A failure of a component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.

4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.
5. If the Components in a Protection System Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02

Standards Involved
Approval:

- PRC-005-2 – Protection System Maintenance (PRC-005-2)

Retirements:

- PRC-005-1b – Transmission and Generation Protection System Maintenance and Testing (PRC-005-1b)
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program (PRC-008-0)
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing (PRC-011-0)
- PRC-017-0 – Special Protection System Maintenance and Testing (PRC-017-0)

Prerequisite Approvals:
Revised definition of "Protection System."

Background:
The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.
5. The Implementation Schedule set forth in this document facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in approximately equally-distributed steps over those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets the requirements of PRC-005-2 in accordance with this implementation plan. Each entity shall be responsible for maintaining each of their Protection System components according to their maintenance program already in place for the legacy standards (PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0) or according to their maintenance program for PRC-005-2, but not both. Once an entity has designated PRC-005-2 as its maintenance program for specific Protection System components, they cannot revert to the original program for those components.

While entities are transitioning to the requirements of PRC-005-2, each entity must be prepared to identify:

- All of its applicable Protection System components.
- Whether each component has last been maintained according to PRC-005-2 or under PRC-005-1b, PRC-008-0, PRC-011-0, or PRC-017-0.

For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0, which are being replaced by PRC-005-2, shall remain active throughout the phased implementation period of PRC-005-2 and shall be applicable to an entity's Protection System component maintenance activities not yet transitioned to PRC-005-2. Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is

required, at midnight of the day immediately prior to the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Implementation Plan for Requirements R3 and R4:

1. For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
2. For Protection System component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
3. For Protection System component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

4. For Protection System component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5. For Protection System component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

* The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Applicability:

This standard applies to the following functional entities:

* Transmission Owner
* Generator Owner
* Distribution Provider

Implementation Plan

Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02

Standards Involved

Approval:

- PRC-005-2 – Protection System Maintenance (PRC-005-2)

Retirements:

- PRC-005-1b – Transmission and Generation Protection System Maintenance and Testing (PRC-005-1b)
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program (PRC-008-0)
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing (PRC-011-0)
- PRC-017-0 – Special Protection System Maintenance and Testing (PRC-017-0)

Prerequisite Approvals:

Revised definition of "Protection System."

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish minimum maintenance activities for Protection System component types and the maximum allowable maintenance intervals for these maintenance activities. The maintenance activities established may not be presently performed by some entities and the established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities not presently performing a maintenance activity or using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately compliant with the new activities or intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees.
5. The Implementation Schedule set forth in this document facilitates implementation of the more lengthy maintenance intervals within the revised Protection System Maintenance Program in approximately equally-distributed steps over those intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1b~~a~~, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets the requirements of PRC-005-2 in accordance with this implementation plan. Each entity shall be responsible for maintaining each of their Protection System components according to their maintenance program already in place for the legacy standards (PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0) or according to their maintenance program for PRC-005-2, but not both. Once an entity has designated PRC-005-2 as its maintenance program for specific Protection System components, they cannot revert to the original program for those components.

While entities are transitioning to the requirements of PRC-005-2, each entity must be prepared to identify:

- All of its applicable Protection System components.
- Whether each component has last been maintained according to PRC-005-2 or under PRC-005-1b, PRC-008-0, PRC-011-0, or PRC-017-0~~, or a combination thereof~~.

For activities being added to an entity's program as part of PRC-005-2 implementation, evidence may be available to show only a single performance of the activity until two maintenance intervals have transpired following initial implementation of PRC-005-2.

Retirement of Existing Standards:

~~The existing~~ Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0, which are being replaced by PRC-005-2, shall remain active throughout the phased implementation period of PRC-005-2 and shall be applicable to an entity's Protection System component maintenance activities not yet ~~converted~~transitioned to PRC-005-2. Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, at midnight of the day immediately prior to the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption~~first calendar quarter following applicable regulatory approval of PRC-005-2 in all jurisdictions~~.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 R3, R4 and R5 which use this defined term.

Implementation Plan for Requirements R1, R2 and R5:

Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Implementation Plan for Requirements R3 and R4:

1. For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
2. For Protection System component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
3. For Protection System component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:
   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter twenty-four (24) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty-six (36) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter forty-eight (48) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter sixty (60) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

4. For Protection System component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5. For Protection System component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

   - The entity shall be at least 30% compliant with PRC-005-2 on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant with PRC-005-2 on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Applicability:

This standard applies to the following functional entities:

- Transmission Owner
- Generator Owner
- Distribution Provider

Unofficial Comment Form for 4th Draft of PRC-005-2: Protection System Maintenance

Project 2007-17

Please **DO NOT** use this form to submit comments on the 4th draft of the standard for Protection System Maintenance. Comments must be submitted by 8 p.m. ET **August 27, 2012** using the electronic comment form. If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:

The standard recently passed ballot with the following results: Quorum – 79.46% and Affirmative – 79.00%; and for the VRF/VSL Non-binding poll: Quorum – 75.00% Affirmative – 70.21%. The drafting team appreciates the affirmative votes and the constructive feedback provided by the commenters. The team modified the standard based on stakeholder comments and anticipates posting the standard and associated documents in July 2012 for a 30-day formal comment period concurrent with a 10-day successive ballot.

The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) made several changes to PRC-005-2 based on comments received from industry. The changes include:

- In Table 1-2, the interval for the second portion of the first row of the table was changed from 12 years to 6 years to correct the previous posting. After posting the previous change to this interval, the SDT concluded that a 12-year interval would not be sufficient to assure BES reliability.
- In Table 1-2, “channels” was modified to “communications systems” in two locations.
- In Table 1-2, the Component Attributes in the last row were modified to clarify that all attributes must be present to use the associated intervals and activities.
- Editorial changes were made to Tables 1-4c, 1-4d., and 1-4e. The words “Protection System” were added to the headers of Tables 1-4c and 1-4d; in Table 1-4e, a redundant “only” was removed.
- The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised within comments.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

For questions 1, 2 and 3, please provide specific comments related to the individual question. Please reserve question 4 for general comments not related to questions 1, 2 and 3. Comments not related to the specific question will not be addressed.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. In response to stakeholder input, the SDT made several changes to Table 1-2 of the standard, as detailed below:

   - The interval for the second portion of the first row of the table was changed from 12 years to 6 years.
   - The term "channels" was modified to "communications systems" in two locations.
   - The Component Attributes in the last row were modified to clarify that all attributes must be present to use the associated intervals and activities.

   Do you agree with these changes? If not, please provide specific suggestions for changes to Table 1-2 in the comment area.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT modified the Implementation Plan as follows:

   - Within "Retirement of Existing Standards", the legacy standards will be retired upon full implementation of PRC-005-2, rather than upon PRC-005-2 becoming effective.
   - Within "General Considerations", each entity shall be responsible for maintaining each of their Protection System components according to their maintenance program already in place for the legacy standards (PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0) or according to their maintenance program for PRC-005-2, but not both.

   Do you agree with these changes? If not, please provide specific suggestions for changes to the Implementation Plan in the comment area.

   ☐ Yes

   ☐ No

   Comments:

3. The SDT made complementary changes in the “Supplementary Reference and FAQ Document” to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for further improvements?

   ☐ Yes

   ☐ No

   Comments:

4. If you have any other comments **that you have NOT provided in response to the above questions**, please provide them here. (Please do not repeat comments that you provided elsewhere.)

   Comments:

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

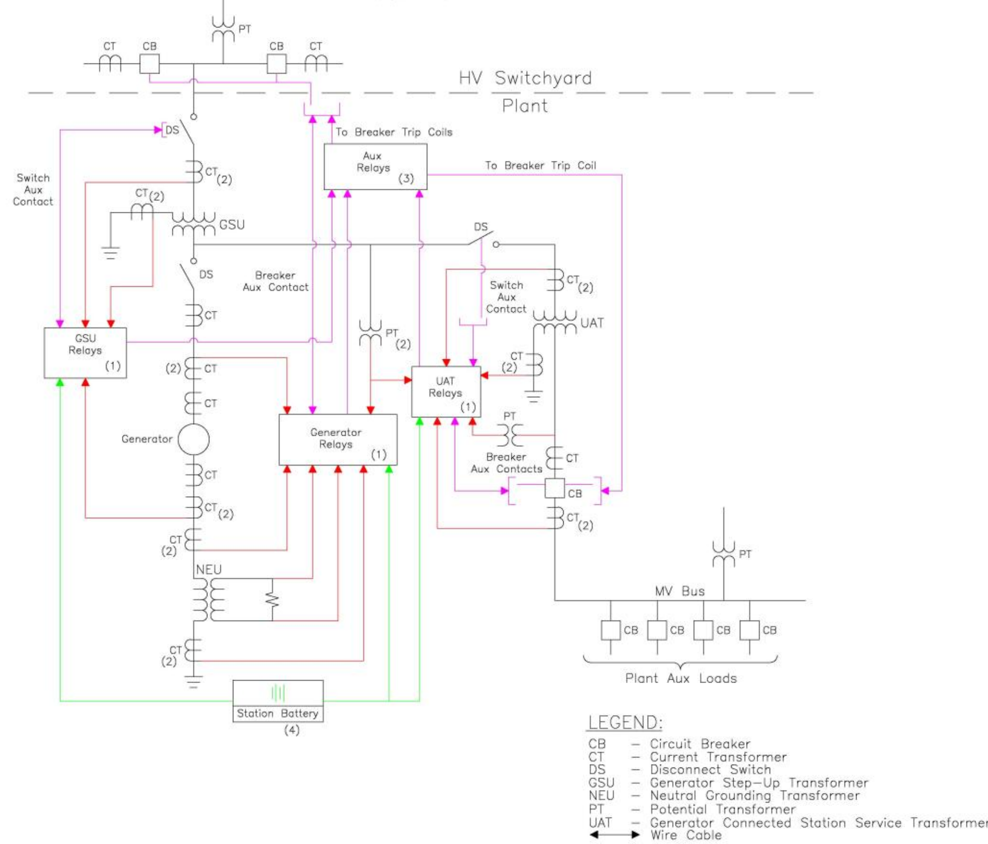
Table of Contents

Fig 2 — General Plant Protection System
(Typical)



1. Introduction and Summary

Note: This supplementary reference for PRC-005-2 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control Systems.

These standards are:

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a Fault or other power system problem requires that they operate to protect power system Elements, or even the entire Bulk Electric System (BES). Lacking Faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A Misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide-area Disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components, such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries, which are an important part of the station dc supply, are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear Faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications Systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the Element is a BES Element, then the Protection System protecting that Element should then be included within this standard. If there is regional variation to the definition, then there will be a corresponding regional variation to the Protection Systems that fall under this standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the standard language should simply be applicable to Protection Systems for BES Elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC Glossary of Terms for the present, in-force definition. See the applicable Regional Reliability Organization for any applicable allowed variations.

While this standard will undergo revisions in the future, this standard will not attempt to keep up with revisions to the NERC definition of BES, but, rather, simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GOs and TOs have equipment that is BES equipment. The standard brings in Distribution Providers (DP) because, depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution

Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example, the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as stipulated in any requirement in this standard.

Additionally, since this standard will now replace PRC-011, it will be important to make the distinction between under-voltage Protection Systems that protect individual Loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an under-voltage load-shedding scheme that is not applicable to this standard is one in which the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission system that was intact except for the line that was out of service, as opposed to preventing a Cascading outage or Transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus, a standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems, and replace some other standards at the same time.

2.3.1 Frequently Asked Questions:

What exactly is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, Interconnections with neighboring Systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission Facilities serving only Load with one transmission source are generally not included in this definition.

The BES definition is presently undergoing the process of revision.

Each regional entity implements a definition of the Bulk Electric System that is based on this NERC definition; in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a June 14, 2007 Informational Filing.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant Facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an under voltage load-shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation, as stated, indicates that the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission System that was intact, except for the line that was out of service, as opposed to preventing Cascading outage or Transmission system collapse.

This standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary Load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

We have a UFLS scheme that, in some locales, sheds the necessary Load through non-BES circuit breakers and, occasionally, even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements, and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as, for example, a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE Device No. 86 (lockout relay) and IEEE Device No. 94 (tripping or trip-free relay), as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage-sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. This standard covers protective relays that use electrical quantity measurements to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close, as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC standards. There is one notable exception: Since PRC-017 will be superseded by PRC-005-2, then if a Special Protection System (previously covered by PRC-017) incorporates automatic closing of breakers, then the SPS-related closing devices must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.). Protective relays, providing only the functions mentioned in the question, are not included.

Are Reverse Power Relays installed on the low-voltage side of distribution banks considered to be components of "Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)"?

Reverse power relays are often installed to detect situations where the transmission source becomes de-energized and the distribution bank remains energized from a source on the low-voltage side of the transformer and the settings are calculated based on the charging current of the transformer from the low-voltage side. Although these relays may operate as a result of a fault on a BES element, they are not 'installed for the purpose of detecting' these faults.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the Device No.# 94 to auxiliary tripping relays. Sudden pressure relays are assigned Device No.# 63. Sudden pressure relays are presently excluded from the standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing elements. The SDT believes that

Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1a, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of any trip circuit that is a part of a Protection System. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not presently cover testing of devices, such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters, rather than electrical parameters. There is an expectation that Fault pressure relays and other non-electrically initiated devices may become part of some maintenance standard. This standard presently covers trip paths. It might seem incongruous to test a trip path without a present requirement to test the device; and, thus, be arguably more work for nothing. But one simple test to verify the integrity of such a trip path could be (but is not limited to) a voltage presence test, as a dc voltage monitor might do if it were installed monitoring that same circuit.

The standard specifically mentions auxiliary and lock-out relays. What is an auxiliary tripping relay?

An auxiliary relay, IEEE Device No.# 94, is described in IEEE Standard C37.2-2008 as: “A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed.”

What is a lock-out relay?

A lock-out relay, IEEE Device No.# 86, is described in IEEE Standard C37.2 as: “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System both depends on the technological generation of the relays, as well as how long they have been in service. Unlike many other transmission asset groups, protection and control Systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices, such as primary measuring relays, monitoring devices, control Systems, and telecommunications equipment.

Modern microprocessor-based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs, such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture Fault records showing how the Protection System responded to a Fault in its zone of protection, or to a nearby Fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-Fault times. The relays can compute values, such as MW and MVAR line flows, that are sometimes used for operational purposes, such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages, or from relay front panel button requests.
- Construction from electronic components, some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of battery chargers, associated communications equipment, voltage and current-measuring devices, and even the control circuitry (in the form of software-latches replacing lock-out relays, etc.).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a “lock-out.” Thus, the software-latch 86 that replaces an electro-

mechanical 86 does not require routine trip testing. Any trip circuitry associated with the "soft 86" would still need applicable verification activities performed, but the actual "86" does not have to be "electrically operated" or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.
- Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components.
- Component Type - Any one of the five specific elements of the Protection System definition.
- Component – A Component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit Components. Another example of where the entity has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component.*
- Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures, as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the Tables 1-1 through 1-5, Table 2 and Table 3 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program," PRC-005-2 establishes the activities and time basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by "restore" in the definition of maintenance.

The description of "restore" in the definition of a Protection System Maintenance Program addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the standard does require that the entity "shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." Some examples of restoration (or correction of Unresolved Maintenance Issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to microprocessor-based relays following the discovery of failed components. Restoration, as used in this context, is not to be confused with restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices, and keeps them in working order. If an equipment item is repaired or replaced, then the entity can restart the maintenance-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

Please clarify what is meant by "...demonstrate efforts to correct an Unresolved Maintenance Issue..."; why not measure the completion of the corrective action?

Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex Unresolved Maintenance Issues might require greater

than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requiring battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely; the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self-monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self-diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the standard itself, it is important to note that the concepts of CBM are a part of the standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the standard, the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

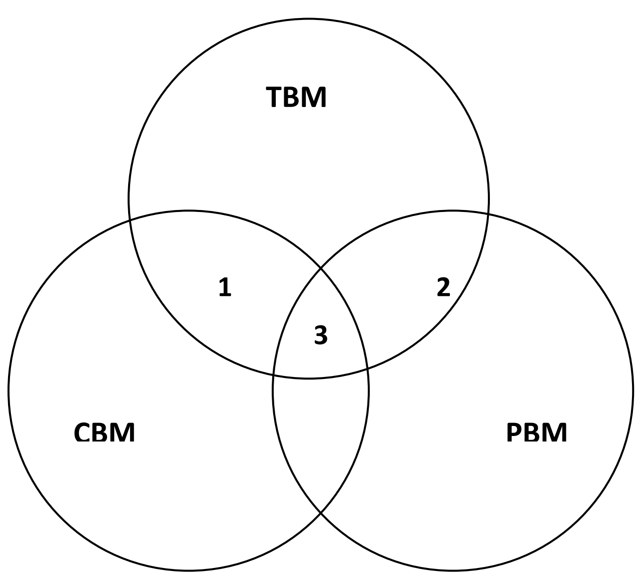
Microprocessor-based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours, or even milliseconds between non-disruptive self-monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram, the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



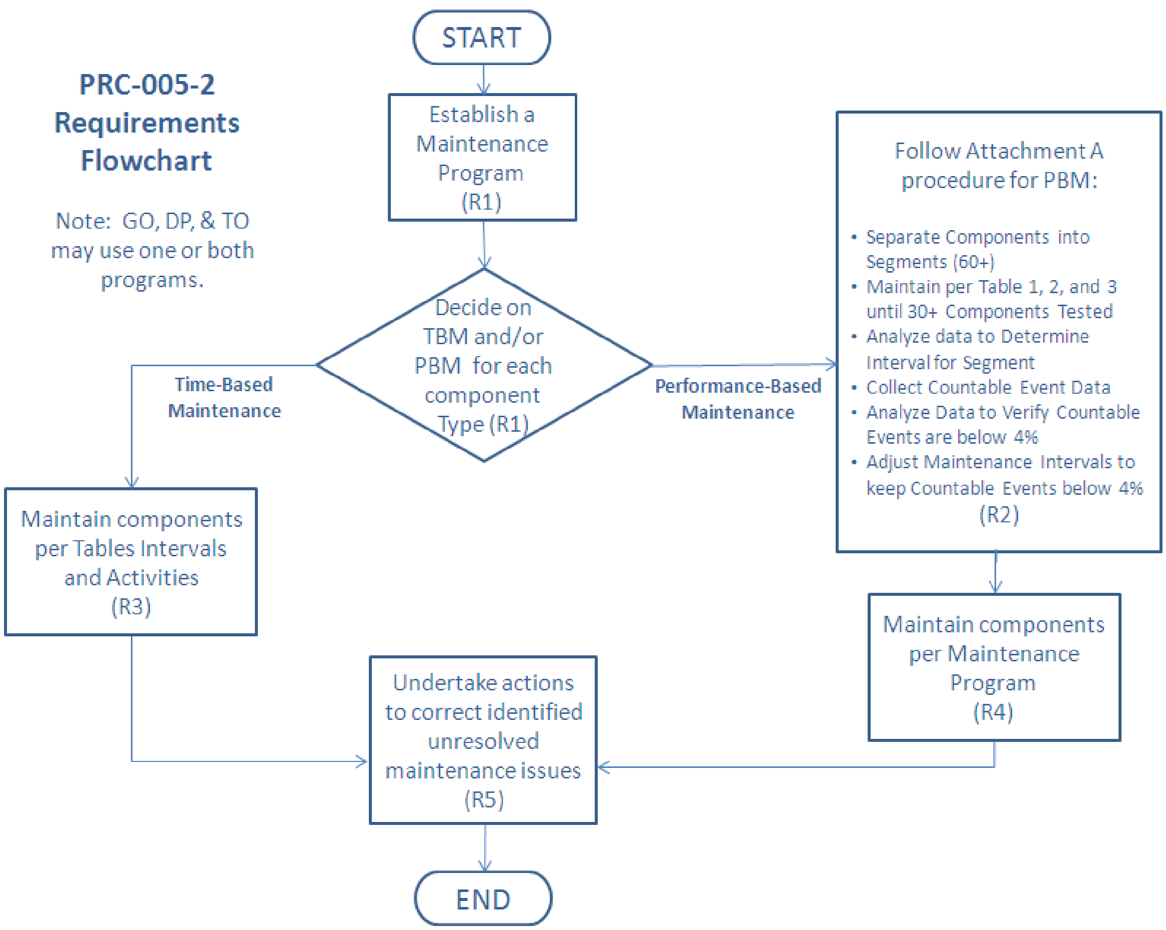
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2), in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals, then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer’s high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based

maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended, while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance, or PBM. It is also sometimes referred to as reliability-centered maintenance, or RCM; but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a Fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Questions:

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for Faults and Disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of Fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. **Non-invasive Maintenance:** The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. **Virtually Continuous Monitoring:** CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

To use the extended time intervals available through Condition Based Maintenance, simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring, as per Requirement R1 (Part 1.4) of the standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device-level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements, as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure, but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule, dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a “One Calendar Year Interval,” the next event would have to occur on or before December 31, 2010.

Please provide an example of “4 Calendar Months”.

If a maintenance activity is described as being needed every four Calendar Months then it is performed in a (given) month and due again four months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a four-month inspection was performed in January is due in May, but if performed in March (instead of May)

would still be due four months later therefore the activity is due again July. Basically every "four Calendar Months" means to add four months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but is not limited to, an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2, the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests or **other measurements indicative of battery performance** are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power System input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored Control Circuitry Associated with Protective Functions" section'
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank **trending of** ohmic values **or other measurements indicative of battery performance** to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions" section
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)

- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components shall have maximum activity intervals of:

Every four calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank trending of ohmic values other measurements indicative of battery performance to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests other measurements indicative of battery performance are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions section
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example, a battery will always need some kind of inspection.

We have a 30-year-old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years, or when an Unresolved Maintenance Issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every six years. ***What is a mitigating device?***

A mitigating device is the device that acts to respond as directed by a Special Protection System. It may be a breaker, valve, distributed control system, or any variety of other devices.

8. Maximum Allowable Verification Intervals

The maximum allowable testing intervals and maintenance activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no Fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying Fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2 and Table 3 in the standard specify maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various sub-systems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions; and, therefore, have the same maintenance needs.

Distributed UFLS and UVLS Systems, which use local sensing on the distribution System and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;

- Table 1-1 is for protective relays,
- Table 1-2 is for the associated communications systems,
- Table 1-3 is for current and voltage sensing devices,
- Table 1-4 is for station dc supply and
- Table 1-5 is for control circuits.
- Table 2, is for alarms; this was broken out to simplify the other tables.
- Table 3 is for components which make-up distributed UFLS and UVLS Systems.

- Next look within that table for your device and its degree of monitoring. The Tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance-Based Maintenance (PBM) plan requires <u>more activities,</u> then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the maximum maintenance interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your Performance-Based Maintenance plan requires activities <u>more often</u> than the Tables maximum, then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every four months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the five Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the

minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. If an entity has a Performance-Based Maintenance program, then that plan must be followed, even if the plan proves to be more stringent than the minimums laid out in the Tables.

8.1.2 Additional Notes for Tables 1-1 through 1-5 and Table 3

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components, physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might want to follow the guidelines in the applicable IEEE recommended practices for battery maintenance and testing. However, the committee has tailored the battery maintenance and testing guidelines in PRC-005-2 for the Protection System owner which are application specific for the BES Facilities. While the IEEE recommendations are all encompassing, PRC-005-2 is a more economical approach while addressing the reliability requirements of the BES.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus, these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected (phase value and phase relationships are both equally important to verify).

7. “End-to-end test,” as used in this Supplementary Reference, is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test, it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc control circuitry. A documented Real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a Real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.
8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.
9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities, but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology- and method-neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor- based relays. For relay maintenance departments that choose to test microprocessor-based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled, but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the standard states “…settings are as specified.”

Many of the microprocessor- based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement, a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require “…that the relay settings be correct…” because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have “drifted” since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection; and, thus, the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable, as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system Disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known Fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?

As in all of the Protection System requirements, SPS segments can be tested individually, thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for non-distributed UFLS or UVLS Systems?

Since components of the SPS, UFLS and UVLS are the same types of components as those in Protection Systems, then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the

exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example, an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the Real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance, as required, due to a major natural disaster (hurricane, earthquake, etc.), how will this affect my compliance with this standard?

The Sanction Guidelines of the North American Electric Reliability Corporation, effective January 15, 2008, provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays; or, even worse, I am experiencing numerous relay Misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But any entity can choose to test some or all of their Protection System components more frequently (or to express it differently, exceed the minimum requirements of the standard). Particularly if you find that the maximum intervals in the standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest.

We believe that the four-month interval between inspections is unneccessary. Why can we not perform these inspections twice per year?

The Standard Drafting Team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections, the four-month interval was chosen. In lieu of station visits, many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years. If we are unable to achieve this schedule, but we are able to complete the procedures in less than the maximum time interval ,then are we in or out of compliance?

According to R3, if you have a time-based maintenance program, then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables.

According to R4, if your device in question is part of a Performance-Based Maintenance program, then you will be in violation of the standard if you fail to meet your PSMP, even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in the Tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, generator connected station service or generator connected excitation transformer to meet the requirements of this maintenance standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay, may include, but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step-up, generator-connected station service transformers, or generator connected excitation transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit; and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary Loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program, even if the loss of the those Loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program, even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the Protection Systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating Facility?

The SDT does not intend that the system-connected station service transformers be included in the Applicability. The generator-connected station service transformers and generator connected excitation transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping," one needs to realize that sometimes there are more inputs and outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every six years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent Load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and Load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an SPS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three-year retention cycle, the records of verification for a Protection

System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electromechanical protective relays be tested every three calendar years, with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus, its test records would have a latest routine test, as well as its previous routine test. The interval between tests is, therefore, provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements, while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance-Based Maintenance, then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced, then the entity can restart the maintenance-time-interval-clock if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a Facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-Fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation, and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components, such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content; and, therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing, as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates, then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized, there are cases when degradation can take place, even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2% or 8% when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its 100 Protection System components, which would equate to 2% for application to the VSL Table for Requirement R3. This VSL is written to compare missed components to total components. In this case two components out of 100 were missed, or 2%.

How do I achieve a "grace period" without being out of compliance?

The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of six calendar years. Your plan must ensure that your unmonitored relays are tested at least once every six calendar years. You could, within your PSMP, require that your unmonitored relays be tested every four calendar years, with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders, but still has the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of four years; it also has a built-in time extension allowed within the PSMP, and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak Load, or 4% of the NERC peak Load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak Load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of five years for electromechanical or solid state relays, and seven years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond seven years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1], as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1, only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay, as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system Element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a Fault occurs, leading to failure to operate for the Fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal Fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup Fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for relay unavailability and abnormal unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay mean time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally, it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods." To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension, while still following FERC Order 693, the Standard Drafting Team arrived at a six-year interval for the electromechanical relay, instead of the five-year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10-year interval was chosen, even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus, the maximum allowed interval for these components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval." The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year number one need not be revisited until six years later (year number seven). For example, a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP, the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals, other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major System outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality Management Systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program, the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM, but does not own 60 units to comprise a population, then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment, and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries, but can be applied to all other components of a Protection System, including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003.)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005.)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968.)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason, the following assumptions are made:

B = 5%

z = 1.96 (This equates to a 95% confidence level)

π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined, then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4%Countable Events. It is notable that 4% is specifically chosen because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one Countable Event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of Countable Events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more), then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the Countable Events is less than 4%; this must be attained within three years.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No, you must use actual in-service test data for the components in the segment.

What types of Misoperations or events are not considered Countable Events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable Events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered Countable Events. Examples of excluded human errors include relay setting errors, design

errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing “86” lock-out relays (LOR). “Entity A” has two types of LOR’s type “X” and type “Y”; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type “X” failures, but human error led to tripping a BES Element 100 times; they find 100 type “Y” failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused Misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead “Entity A” to change time intervals. Type “X” LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type “Y” would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause Misoperations are not considered Countable Events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance formal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a Unresolved Maintenance Issue as a result of a Misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required Misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the Unresolved Maintenance Issue as a Countable Event within the relevant component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of four relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a Misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of four years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system Disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate. This entity is now allowed to extend the maintenance interval if they choose. The entity chooses to extend the maintenance interval of this population segment out to 10 years. This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year. After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures. This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year). In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year, they again find six failures out of the 125 units tested. 6/125= 5% failures. In response to the 5% failure rate, the entity decreases the testing interval to seven years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected. After a year, they again find six failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried five years and they were under the 4% limit and they tried seven years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to five years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to six years. This means that they will now test 167 units per year (1000/6). After a year, they again find six

failures out of the 167 units tested. 6/167= 3.6% failures. Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at six years or less. Entity chose six-year interval and effectively extended their TBM (five years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of "component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1,000 circuit breakers, all of which have two trip coils, for a total of 2,000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard, then this is greater than the minimum sample requirement of 60.

For the sake of further example, the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring, and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago, the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their control circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device

that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the operations control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2,000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored; therefore, the trip paths are continuously tested and the circuit will alarm when there is a failure. These alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification, and is taking care of this activity through other documentation of Real-time Fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12-year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval, and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific Element. This entity calls this set of protective relays a "Relay Scheme." Thus, this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages, whereas a transmission maintenance group might create a process that utilizes Real-time system values measured at the relays. Under the included definition of "component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes," all of which have three current signals supplied from bushing CTs, and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard, and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1,000) are supplied with current signals from ANSI STD C800 bushing CTs and voltage signals from PTs built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards, and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs), as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2,000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored; therefore, the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay, all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PTs). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level; thus, any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4%failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1,000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment, as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above, or Attachment A of the standard;
- Opportunistic verification using analysis of Fault records, as described in Section 11

10.1 Frequently Asked Questions:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the Unresolved Maintenance Issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve Fault event records and oscillographic records by data communications after a Fault. They analyze the data closely if there has been an apparent Misoperation, as NERC standards require. Some advanced users have commissioned automatic Fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured Digital Fault Recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of Faults in the vicinity of the relay that produce relay response records and the specific data captured.

A typical Fault record will verify particular parts of certain Protection Systems in the vicinity of the Fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external Fault records that completely verify the Protection System.

For example, Fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that Fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a Fault just outside their respective zones of protection. The ensemble of internal Fault and nearby external Fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using Fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple Faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If Fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the Fault records used, and the maintenance-related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Questions:

I use my protective relays for Fault and Disturbance recording, collecting oscillographic records and event records via communications for Fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as Disturbance Monitoring Equipment, NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements and is being addressed by a standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of Fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them; for background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple: With legacy relays (non-microprocessor protective relays), it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays, it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process, there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade, then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its

regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays, then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced, then the entity can restart the maintenance-activity-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan, and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment, then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards, then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function, then it must be maintained. If the component no longer performs Protection System functions, then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed, there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System, it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement, even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement, although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states:

"R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified Unresolved Maintenance Issues."

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC standards.

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues..." The type of corrective activity is not stated; however, it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring, the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1 and Table 3.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

This manufacturer's information can be used by the registered entity to document compliance of the monitoring attributes requirements by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission Facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an Unresolved Maintenance Issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1 and Table 3.

13.1 Frequently Asked Questions:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring, the standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator’s decisions on acceptable Loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance, but if its battery maintenance program is lacking, then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore, *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a Faulted Element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas, or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor-based equipment in the following ways; the relays should meet the asset owners' tolerances:

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.1.1 Frequently Asked Questions:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the

protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device, all the way to the protective relay. The following observations apply:

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; including, but not limited to, the following: By calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this, therefore, tests the CT, as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during Load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the Real-time Loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay, then the verification activity has been satisfied. Thus, event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars, thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current-sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current-sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds.
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay) to another protective relay monitoring the same line, with currents supplied by different CTs.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc.) and verified by calculations and known ratios to be the values expected. For example, a single PT on a 100KV bus will have a specific secondary value that, when multiplied by the PT ratio, arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring Systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay

and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions, as do microprocessor- based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment, like voltmeters and clamp on ammeters, to measure the input signals to the relays. This practice seems very risky, and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays, but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests, such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path, then the manual-intervention testing of those parallel trip paths can be eliminated; however, the actual operation of the circuit breaker must still occur at least once every six years. This six-year tripping requirement can be completed as easily as tracking the Real-time Fault-clearing operations on the circuit breaker, or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment, and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device, if this ground switch is utilized in a Protection System and forces a ground Fault to occur that then results in an expected Protection System operation to clear the forced ground Fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years, and any electromechanically operated device will have to be tested every six years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit, then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type components, then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such, there is a six-year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 and/or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Contacts of the 86 and/or 94 lock relay that operate non-BES interrupting devices are not required. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

While relays that do not respond to electrical quantities are presently excluded from this standard, their control circuits are included if the relay is installed to detect Faults on BES Elements. Thus, the control circuit of a BES transformer sudden pressure relay should be verified every 12 years, assuming its integrity is not monitored. While a sudden pressure relay control circuit is included within the scope of PRC-005-2, other alarming relay control circuits, (i.e., SF-6 low gas) are not included, even though they may trip the breaker being monitored.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry-recognized testing protocol for the sensing elements. The SDT believes

that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual component's maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as Fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3 for examples 1 and 2)Example 1: A non-BES circuit breaker that is tripped via a Protection System to which PRC-005-2 applies might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- All of the relevant communication system tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.

- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Example 2: A Transmission Owner may have a non-BES breaker that is tripped via a Protection System to which PRC-005-2 applies, which may be (but is not limited to) a 13.8 KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from a BES 115KV line relay.

- The relay must be verified
- The voltage signal to the relay must be verified
- All of the relevant dc supply tests still apply
- All of the relevant communication system tests still apply
- The unmonitored trip circuit between the relay and any lock-out (86) or auxiliary (94) relay must be verified every 12 years
- The unmonitored trip circuit between the lock-out (86) (or auxiliary (94)) relay and the non-BES breaker does not have to be proven with an electrical trip
- In the case where there is no lockout (86) or auxiliary (94) tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip

Example 3: A Generator Owner may have an non-BES circuit breaker that is tripped via a Protection System to which PRC-005-2 applies, such as the generator field breaker and low-side breakers on station service/excitation transformers connected to the generator bus.

Trip testing of the generator field breaker and low side station service/excitation transformer breaker(s) via lockout or auxiliary tripping relays are not required since these breakers may be associated with radially fed loads and are not considered to be BES breakers. An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 6.9kV station service transformer source circuit breaker but has a trip that originates from a generator differential (87) relay.

- The differential relay must be verified.
- The current signals to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

However, it is very prudent to verify the tripping of such reakers for the integrity of the overall generation plant.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

The NERC definition of a Protection System is:

- Protective relays which respond to electrical quantities,
- Communications Systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System, "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery Systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply, as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers, as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging

technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies besides the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new, the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity (no open circuits) of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity – lack of an open circuit. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal (no open circuit). Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path, the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor-based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these

harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, in most battery chargers, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional one- to two-second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed, which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery, unless the battery charger is taken out of service. At that time, a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the standard prescribes what must be accomplished during the maintenance activity, it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged, there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor-controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of lead-acid batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string; and when used in conjunction with resistance measurements of the battery's external connections, can prove continuity. Also some methods of taking internal ohmic measurements, by their very nature, can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific gravity tests can infer continuity because, without continuity, there could be no charging occurring; and if there is no charging, then specific gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified, it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as manufactured?

The answer to this question depends on the type of battery (valve-regulated lead-acid, vented lead-acid, or nickel-cadmium) and the maintenance activity chosen.

For example, if you have a valve-regulated lead-acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the six-month interval is important for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is incapable of performing as manufactured.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every three calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead-acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station battery's ability to perform as manufactured, they should be made at some point in time after the installation to allow the cell chemistry to stabilize after the initial freshening charge. An accepted industry practice for establishing baseline values is after six-months of installation, with the battery fully charged and in service. However, it is recommended that each owner, when establishing a baseline, should consult the battery manufacturer for specific instructions on establishing an ohmic baseline for their product, if available.

When internal ohmic measurements are taken, the same make/model test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Conductance" test equipment, even though both manufacturers have produced "Ohmic" test equipment. Therefore, for meaningful results to an established baseline, the same make/model of instrument should be used.

For all new installations of valve-regulated lead-acid (VRLA) batteries and vented lead-acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as manufactured, the establishment of the baseline, as described above, should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries, the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also, several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However, it is important that when using battery manufacturer-supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Although many manufacturers may have provided baseline values, which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For vented lead-acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges, the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This, in turn, reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can, therefore, be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely, if taken shortly after adding water to the cell, the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and valve-regulated lead-acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity

readings. For these two types of batteries, and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully-charged condition, which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery, a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings, or a combination of the two. There are test methods presently that can read post termination resistances and resistance values between external posts. There are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show if the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen, not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal colors (which are an indicator of sulfation or possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections, such as the bus bar connection to each plate, and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery

containing the cell, or cells, must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery, nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why is it necessary to verify the battery string can perform as manufactured? I only care that the battery can trip the breaker, which means that the battery can perform as designed. I oversize my batteries so that even if the battery cannot perform as manufactured, it can still trip my breakers.

The fundamental answer to this question revolves around the concept of battery performance "as designed" vs. battery performance "as manufactured." The purpose of the various sections of Table 1-4 of this standard is to establish requirements for the Protection System owner to maintain the batteries, to ensure they will operate the equipment when there is an incident that requires dc power, and ensure the batteries will continue to provide adequate service until at least the next maintenance interval. To meet these goals, the correct battery has to be properly selected to meet the design parameters, and the battery has to deliver the power it was manufactured to provide.

When testing batteries, it may be difficult to determine the original design (i.e., load profile) of the dc system. This standard is not intended as a design document, and requirements relating to design are, therefore, not included.

Where the dc load profile is known, the best way to determine if the system will operate as designed is to conduct a service test on the battery. However, a service test alone might not fully determine if the battery is healthy. A battery with 50% capacity may be able to pass a service test, but the battery would be in a serious state of deterioration and could fail at some point in the near future.

To ensure that the battery will meet the required load profile and continue to meet the load profile until the next maintenance interval, the installed battery must be sized correctly (i.e., a correct design), and it must be in a good state of health. Since the design of the dc system is not within the scope of the standard, the only consistent and reliable method to ensure that the battery is in a good state of health is to confirm that it can perform as manufactured. If the battery can perform as manufactured and it has been designed properly, the system should operate properly until the next maintenance interval.

How do I verify the battery string can perform as manufactured?

Optimally, actual battery performance should be verified against the manufacturer's rating curves. The best practice for evaluating battery performance is via a performance test. However, due to both logistical and system reliability concerns, some Protection System owners prefer other methods to determine if a battery can perform as manufactured. There are several battery parameters that can be evaluated to determine if a battery can perform as manufactured. Ohmic measurements and float current are two examples of parameters that have been reported to assist in determining if a battery string can perform as manufactured.

The evaluation of battery parameters in determining battery health is a complex issue, and is not an exact science. This standard gives the user an opportunity to utilize other measured parameters to determine if the battery can perform as manufactured. It is the responsibility of the Protection System owner, however, to maintain a documented process that demonstrates the chosen parameter(s) and associated methodology used to determine if the battery string can perform as manufactured.

Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, temperature, specific gravity, performance test, or combination thereof), the goal is to determine the value of the measurement (or the percentage change) at which the battery fails to perform as manufactured, or the point where the battery is deteriorating so rapidly that it will not perform as manufactured before the next maintenance interval.

This necessitates the need for establishing and documenting a baseline. A baseline may be required of every individual cell, a particular battery installation, or a specific make, model, or size of a cell. Given a consistent cell manufacturing process, it may be possible to establish a baseline number for the cell (make/model/type) and, therefore, a subsequent baseline for every installation would not be necessary. However, future installations of the same battery types should be spot-checked to ensure that your baseline remains applicable.

Consistent testing methods by trained personnel are essential. Moreover, it is essential that these technicians utilize the same make/model of ohmic test equipment each time readings are taken in order to establish a meaningful and accurate trend line against the established baseline. The type of probe and its location (post, connector, etc) for the reading need to be the same for each subsequent test. The room temperature should be recorded with the readings for each test as well. Care should be taken to consider any factors that might lead a trending program to become invalid.

Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement parameters is to establish a baseline and the point where the reading indicates that the battery will not perform as manufactured.

The establishment of a baseline may be different for various types of cells and for different types of installations. In some cases, it may be possible to obtain a baseline number from the battery manufacturer, although it is much more likely that the baseline will have to be established after the installation is complete. To some degree, the battery may still be "forming" after installation; consequently, determining a stable baseline may not be possible until several months after the battery has been in service.

The most important part of this process is to determine the point where the ohmic reading (or other measured parameter(s)) indicates that the battery cannot perform as manufactured. That point could be an absolute number, an absolute change, or a percentage change of an established baseline.

Since there are no universally-accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured (heretofore referred to as a failed cell). This is the most difficult and important part of the entire process.

To determine the point where the battery fails to perform as manufactured, it is helpful to have a history of a battery type, if the data includes the parameter(s) used to evaluate the battery's ability to perform as manufactured against the actual demonstrated performance/capacity of a battery/cell.

For example, when an ohmic reading has been recorded that the user suspects is indicating a failed cell, a performance test of that cell (or string) should be conducted in order to prove/quantify that the cell has failed. Through this process, the user needs to determine the ohmic value at which the performance of the cell has dropped below 80% of the manufactured, rated performance. It is likely that there may be a variation in ohmic readings that indicates a failed cell (possibly significant). It is prudent to use the most conservative values to determine the point at which the cell should be marked for replacement. Periodically, the user should demonstrate that an “adequate” ohmic reading equates to an adequate battery performance (>80% of capacity).

Similarly, acceptance criteria for "good" and "failed" cells should be established for other parameters such as float current, specific gravity, etc., if used to determine the ability of a battery to function as designed.

What happens if I change the make/model of ohmic test equipment after the battery has been installed for a period of time?

If a user decides to switch testers, either voluntarily or because the equipment is not supported/sold any longer, the user may have to establish a new base line and new parameters that indicate when the battery no longer performs as manufactured. The user always has a choice to perform a capacity test in lieu of establishing new parameters.

What are some of the differences between lead-acid and nickel-cadmium batteries?

There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of these two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. In contrast, the primary failure of nickel-cadmium batteries is due to the gradual linear aging of the active materials in the plates. The electrolyte of a nickel-cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel-cadmium battery does not.

Changes to the properties of a lead acid battery when periodically measured and trended to a baseline, can indicate aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate.

Because of the clear differences in the aging process of lead acid and nickel-cadmium batteries, there are no significantly measurable properties of the nickel-cadmium battery that can be measured at a periodic interval and trended to determine aging. For this reason, Table 1-4(c) (Protection System Station dc supply Using nickel-cadmium [NiCad] Batteries) only specifies one

minimum maintenance activity and associated maximum maintenance interval necessary to verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance against the station battery baseline. This maintenance activity is to conduct a performance or modified performance capacity test of the entire battery bank.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.
Because the battery rack is specifically manufactured for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously, a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the standard refers to "all cells," is it sufficient to have a documentation method that refers to "all cells," or do we need to have separate documentation for every cell? For example, do I need 60 individual documented check-offs for good electrolyte level, or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this standard refer to Station batteries or all batteries; for example, Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point, the corrective actions can be initiated.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The

inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry, these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example, in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand, dc resistance of a cell is measured by a third manufacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices, there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a baseline and trending it over time says, "…depending on the degree of change a performance test, cell replacement or other corrective action may be necessary…" (IEEE std 1188-2005, C.4 page 18).

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century, EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity, but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity," they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as manufactured. By evaluation of the trending of the ohmic measurements over time, the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this condition based approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as manufactured.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4. In cases where individual cells in a multi-cell unit are in accessible, an ohmic measurement of the entire unit may be made.

I have a concern about my batteries being used to support additional auxiliary loads beyond my protection control systems in a generation station. Is ohmic measurement testing sufficient for my needs?

While this standard is focused on addressing requirements for Protection Systems, if batteries are used to service other load requirements beyond that of Protection Systems (e.g. pumps, valves, inverter loads), the functional entity may consider additional testing to confirm that the capacity of the battery is sufficient to support all loads.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and, if not corrected, the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or

above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In vented lead-acid (VLA) and nickel-cadmium (NiCad) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in valve-regulated lead-acid (VRLA) batteries cannot be observed, there is no maintenance activity listed in Table 1-4 of the standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCad station battery is a condition requiring correction. Typically, the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCad) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries, the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery, or other unforeseen events can cause rapid loss of electrolyte; the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

What are the parameters that can be evaluated in Tables 1-4(a) and 1-4(b)?

The most common parameter that is periodically trended and evaluated by industry today to verify that the station battery can perform as manufactured is internal ohmic cell/unit measurements.

In the mid 1990s, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

Other examples of measurable parameters that can be periodically trended and evaluated for lead acid batteries are cell voltage, float current, connection resistance. However, periodically

trending and evaluating cell/unit Ohmic measurements are the most common battery/cell parameters that are evaluated by industry to verify a lead acid battery string can perform as manufactured.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for valve-regulated lead-acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for vented lead-acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "…verify that the station battery can perform as manufactured by evaluating the measured cell/unit measurements indicative of battery performance (e.g. internal ohmic values) against the station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. Trending against the baseline of VRLA cells in a battery string is essential to determine the approximate state of health of the battery. Ohmic measurement testing may be used as the mechanism for measuring the battery cells. If all the cells in the string exhibit a consistent trend line and that trend line has not risen above a specific deviation (e.g. 30%) over baseline, then a judgment can be made that the battery is still in a reasonably good state of health and able to 'perform as manufactured.' It is essential that the specific deviation mentioned above is based on data (test or otherwise) that correlates the ohmic readings for a specific battery/tester combination to the health of the battery. This is the intent of the "perform **as** manufactured six-month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not necessarily have a formal trending program. When a single cell/unit changes significantly or significantly varies from the other cells (e.g. a doubling of resistance/impedance or a 50% decrease in conductance), there is a high probability that the cell/unit/string needs to be replaced as soon as possible. In other words, if the battery is 10 years old and all the cells have approached a significant change in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the six-month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a six-month basis.

It is possible to accomplish both tasks listed (trend testing for capability and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications-assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested. Besides the trip output and wiring to the trip coil(s), there is also a communications medium that must be maintained. Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology. For example, older technologies may have included Frequency Shift Key methods. This technology requires that guard and trip levels be maintained. The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests. Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals. The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore, this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be performed on any communications-assisted trip scheme, regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements, including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the four-month inspection of communications-assisted trip scheme equipment?

The four-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms; check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry, rather than those portions of the table applicable to communications equipment.

What is meant by "Channel" and "Communications Systems" in Table 1-2?

The transmission of logic or data from a relay in one station to a relay in another station for use in a pilot relay scheme will require a communications system of some sort. Typical relay communications systems use fiber optics, leased audio channels, power line carrier, and microwave. The overall communications system includes the channel and the associated communications equipment.

This standard refers to the "channel" as the medium between the transmitters and receivers in the relay panels such as a leased audio or digital communications circuit, power line and power line carrier auxiliary equipment, and fiber. The dividing line between the channel and the associated communications equipment is different for each type of media.

Examples of the Channel:

- Power Line Carrier (PLC) - The PLC channel starts and ends at the PLC transmitter and receiver output unless there is an internal hybrid. The channel includes the external hybrids, tuners, wave traps and the power line itself.
- Microwave –The channel includes the microwave multiplexers, radios, antennae and associated auxiliary equipment. The audio tone and digital transmitters and receivers in the relay panel are the associated communications equipment.
- Digital/Audio Circuit – The channel includes the equipment within and between the substations. The auxiliary communications equipment includes the relay panel transmitters and receivers and the interface equipment in the relays.

- Fiber Optic – The channel starts at the fiber optic connectors on the fiber distribution panel at the local station and goes to the fiber optic distribution panel at the remote substation. The jumpers that connect the relaying equipment to the fiber distribution panel and any optical-electrical signal format converters are the associated communications equipment

Figure 1-2, A-1 and A-2 at the end of this document show good examples of the communications channel and the associated communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria." What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally, an alarm will be indicated. For unmonitored systems, this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each Protection System communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of Protection System communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.

- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a Fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.

- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the Fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These

limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so Protection System channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria, depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system, then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot, and, thus, make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system; the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours, then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the standard technology neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe “form-b” contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center, then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and distributed UVLS systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current-sensing devices have the same maintenance activity and interval as Table 1-3. DC systems need only have their voltage read at the relay every 12 years. Control circuits have the following maintenance activities every 12 years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
