(b) On the surface, the proposed re-definition of “Protection System” appears mainly applicable to PRC-005 based upon the Standards Announcement and proposed Implementation Plan. However, NERC standard PRC-004-1 Analysis and Mitigation of Transmission and Generation Protection System Misoperations also uses the capitalized term “Protection System”. CenterPoint Energy believes it is inappropriate to require reporting of Misoperations of transmission Protection Systems and generator Protection Systems for bad trip coils within a circuit breaker. For application to PRC-004-1, CenterPoint Energy recommends revising the proposed re-definition to indicate control circuitry associated with protective functions UP TO THE TERMINALS OF the trip coil(s) of the circuit breakers or other interrupting devices.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT believes the current draft of the definition as balloted is better supported by industry.</td></tr>
<tr><td>Midwest ISO</td><td>No</td><td>We have an issue with the implementation plan. The implementation plan proposes to capitalize the term</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
		"protection system" in NUC-001-2, PER-005-1, and PRC-001-1. We disagree with capitalizing the term because protection system was a defined term when these standards were written. Thus, if the drafting teams of those standards intended for the definition in the NERC glossary of terms to apply, they would have capitalized the term. Furthermore, capitalizing the term may fundamentally alter the meaning of the standard. For PER-005-1, we believe the standard is altered because protection system as used in this standard actually refers to special protection system or remedial action schemes.
Response: Thank you for your comment. The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified. However, the SDT believes the term Protection System should be capitalized as described in the Implementation Plan for NUC-001-2 and PRC-001-1.		
American Electric Power (AEP)	No	1. This change in definition needs to occur concurrently with other related projects (PRC-005-2). Neither the SDT nor the SC should establish a practice of making changes to definitions outside the parameters of changes to standards. This will introduce opportunities for confusion and does not provide the appropriate signals to the Registered Entities to adjust their programs and make the appropriate changes. If this has to be done faster than the pace of the current PRC-005-2 project, we suggest it still be paired with that project, but a smaller scope be considered to allow for this to pass quickly as possible and then the remaining work can be accomplished in PRC-005-3. 2. We suggest that the SDT consider the creation of sub-definitions opposed to crafting a single term for complex and diverse components that could make up the Protection System. As it stands, AEP cannot support this as it still does not remove the degree of ambiguity that could result in interpretation challenges during later enforcement and monitoring activities. We understand the urgency to make progress; however, the deliverables of this team can have significant collateral impacts in the compliance process. 3. The bullet for Protective relays should be further clarified with the addition of applied on or designed to provide protection for the BES that responds to the electrical fault or disturbance conditions. 4. Below are the comments that were provided in the second draft that were not adequately addressed in the consideration of the comments. A. The definition as drafted includes "Station dc supply." While this appears reasonable and innocuous, the term is unclear and could be construed by an auditor to include a lot of equipment and infrastructure not intended by the PSMT SDT. For example, station battery chargers are typically supplied by station auxiliary power transformers, which in turn are supplied by primary-voltage bus work, primary-voltage fuses, or primary-voltage circuit breakers. An auditor for either PRC-005 or any other Standard referencing "Protection System" could read that such primary-voltage equipment is part of the Protection System and therefore subject to certain requirements in either PRC-005 or any other Standard referencing Protection System. B. The definition as drafted includes "Communications systems necessary. . . ". Once again, this term appears innocuous, but it is actually unclear. For example, if a transfer-trip channel is carried on a microwave path, an auditor may decide that the entire microwave equipment, microwave building battery, and microwave building emergency generator are all part of the Protection System, and thus subject to requirements in either PRC-005 or other existing or future Standards that refer to Protection System. AEP

Organization	Yes or No	Question 1 Comment
		recommends that the term be phrased "communications paths" opposed to "communications systems". C. Similar to the above two items, we are concerned about the inclusion of voltage and current-sensing "devices" in the Definition. As written, applicability can be inferred to the entire device and not merely its output quantities, not only for this Standard but any other that references a Protection System. AEP recommends the phrase "circuitry from voltage and current-sensing devices providing inputs to protective relays" instead of "voltage and current-sensing devices providing inputs to protective relays."
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given "priority." To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1. **2. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.** **3. The SDT believes these questions are not within the scope of Project 2007-17 and should be addressed by the Regional Entities.** **4A. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The definition of Protection System with regards to dc supply has been modified and now reads:** Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). **4B. The SDT believes your comment pertains to standards and requirements, and not the definition of Protection System.** **4C. The SDT believes the current draft of the definition as balloted is better supported by industry.**		
Independent Electricity System Operator	No	While we agree with the definition itself, we do have a concern about its application. An ongoing issue that needs to be addressed is clarification of when a Bulk Electric System transmission Protection System applies to a Distribution Provider. This was addressed in part in the interpretation request regarding transmission Protection Systems, Project 2009-17. An example would be for a tee-tap off a Bulk Power System 345kV line to a step down transformer supplying distribution -- would the relaying on the low voltage side of the transformer be expected to comply with the requirements of PRC-005-2? Would the protection system configuration be considered a Protection System? Will this issue be addressed within the scope of Project 2007-17?
Response: Thank you for your comment. This clarification is provided in each requirement that uses the term, "Protection System" by identifying the responsible entity. The question relates to "application" of the definition, not to the definition."		
NRECA		My comment is related to the Implementation plan which will modify the PER-005. I am specifically concerned with changing in R3.1 "established operating guides or "protection systems" to mitigate IROL violations" to "established operating guides or "Protection Systems" to mitigate IROL violations". This modification changes the intent of requirement PER-005 R3.1. The requirement was developed by the drafting team to address an Order 693 directive to require the use of simulators by reliability coordinators, transmission operators and balancing authorities that have operational control over a significant portion of load and generation. The System Personnel Training SDT felt that the use of the phrase "established IROLs or has established operating guides

Organization	Yes or No	Question 1 Comment
		or protection systems to mitigate IROL violations" appropriately represents the impact of entities on the reliability of the BES. In the context of PER-005 R3.1, this specific language was used to broadly include anything that an entity utilizes to prevent an IROL which could be an "operating guide or a protection system" like a RAS in WECC or an SPS in the Eastern Interconnection. It was not intended to include all the items included in the term that is being defined in Project 2007-17.
Response: Thank you for your comment. The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified.		
MidAmerican Energy	No	The drafting team did not properly address previous comments to include BES references in each PRC-005 sub bullet definitions and left "DC system" wording in the definition with only a comment in parentheses. The Protection System definition affects multiple standards and must stand alone across those standards. Therefore: 1. BES references are still needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements, meeting a basic standards drafting principal being requested both by FERC and the industry. 2. "DC system" remains a wide open definition. Because regulators and auditors are auditing to "zero" defect requirements and imposing their own interpretations, only specific wording is acceptable. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters". To be a credible audit process, both the auditor and audited entity must have a clear understanding of what is being audited. DC system can be interpreted in many ways by an entity or auditor and is not an acceptable term. Further, BES references are needed to create clear and auditable boundaries for this definition.
Response: Thank you for your comments. These comments all relate to "application" of the definition; "auditable boundaries" and "auditable requirements" are part of the standard.		
Duke Energy	Yes	We agree with the revised definition. However the added language raises a question regarding how PRC-005-2 would be applied to DC supply situations where the battery is the backup to the "normal" source of DC power. Specifically, it's unclear to us that Uninterruptible Power Supplies (UPS), rectifiers and motor-generator sets that use batteries as a backup are included in the scope of Table 1.
Response: Thank you for your comment. The SDT believes your comment pertains to the standard PRC-005-2 and not the definition of Protection Systems.		
Xcel Energy	Yes	The Implementation Plan indicates that the lower case "protection system" in 3 other standards would be replaced with the capitalized term "Protection System" to properly reflect its use in those standards. In PRC-001 the term "protective system" is also used, however the Implementation Plan does not indicate whether this term will also be replaced. If not, then it would seem to imply that the term "protective system" has different meaning than "protection system/Protection System". There is concern that the use of "Protection System" in PRC-001 will require entities to 'coordinate" changes to all elements of the Protection System, which could be of no value for elements such as batteries, battery chargers. It is not clear as to if the intent that ALL elements of the

Organization	Yes or No	Question 1 Comment
		Protection System be coordinated when a new or changed Protection System occurs.
Response: Thank you for your comment. The term "protective system" is not a defined term in the NERC glossary and is not addressed by the Implementation Plan.		
LIPA	Yes	Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and ....Change to Station dc supply associated with protective functions, and....

Consideration of Comments on Third Ballot — Project 2007-17 Protection System Maintenance (Protection System definition)

Dates of Third Ballot: 10/2/10 - 10/14/10

Summary: A successive ballot of the definition of Protection System was conducted from October 2-14, 2010 and achieved a quorum and an overall weighted segment approval of 84.52%.

Numerous balloters confused the definition with its applicability in various standards. Several balloters questioned the applicability of this defined term in PER-005 and the SDT modified the Implementation Plan for the definition to remove the reference to PER-005.

Several balloters used the ballot period as a forum to show displeasure with the NERC and Regional BES definitions. Modifying the definition of Bulk Electric System is outside the scope of this drafting team.

Some balloters made suggestions to modify various portions of the definition, however most balloters supported the definition as posted and the drafting team did not adopt any suggestions for further modifications to the definition.

Several balloters opposed this ballot because they felt the definition of Protection System should not have been balloted separately from the draft standard PRC-005-2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT directed that the revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan allows entities at least 12 months to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.

Response: The SDT appreciates your support.				
1	MidAmerican Energy Co.	Terry Harbour	Negative	The drafting team did not properly address previous comments to include BES references in each PRC-005 sub bullet definitions and left "DC system" wording in the definition with only a comment in parentheses. The Protection System definition affects multiple standards and must stand alone across those standards. Therefore: 1. BES references are still needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements, meeting a basic standards drafting principal being requested both by FERC and the industry. 2. "DC system" remains a wide open definition. Because regulators and auditors are auditing to "zero" defect requirements and imposing their own interpretations, only specific wording is acceptable. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters". To be a credible audit process, both the auditor and audited entity must have a clear understanding of what is being audited. DC system can be interpreted in many ways by an entity or auditor and is not an acceptable term. Further, BES references are needed to create clear and auditable boundaries for this definition.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability.				

Segment	Entity	Member	Ballot	Comments
1	Nebraska Public Power District	Richard L. Koch	Affirmative	1. Please provide the reasoning for including the battery chargers. Where do you draw the line of what is included. For example, should the panel providing power to the chargers be included? 2. Better clarification is needed when defining the DC control circuit. The trip coils are identified on one end of the circuit but nothing is identified upstream of the trip coils. For example, control switches, indicators, auxiliary relays, power supply breakers, etc.
Response: 1. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” The definition of Protection System with regards to dc supply has been modified and now reads: Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). The SDT believes this clearly limits the dc supply. 2. The SDT believes the balloted definition includes all the control circuitry essential for the Protection System to function properly.				
1	Pacific Gas and Electric Company	Chifong L. Thomas	Negative	We disagree with the drafting team response to comments that the term BES should be included only in the standard. It is an essential part of the definition as it pertains to the purpose of NERC Standards. As a result we have changed our vote to negative. We view the basic intent of this definition is to identify what protective systems in facilities are to be utilized to protect the BES from two primary troubles 1) minimize interruption of the flow of electrical power from one portion of the BES to another, and 2) to prevent the propagation of BES trouble from one portion of the BES to another. While we agree that protection systems for all transmission related components can be adequately limited in scope by utilizing "electrical quantities", we do not feel that it is adequate for generating facilities. There are multitudes of elements in generating facilities that can remove the facility from service and impact the power flow from the facility to other portions of the BES. The efforts utilized thus far demonstrate that it is not desirable or realistically possible to address all devices from an oversight point of view and that the current definition which discriminates solely with the qualifier of "electrical quantities" is too broad and leaves much open to interpretation to define what types of protection are included in the definition. The definition, as it currently reads, leaves many protective devices to the owner/operator to manage for

Segment	Entity	Member	Ballot	Comments
				maximum reliability of the generating facility. In the interest of clarity the definition should limit the scope for protective relays to those relays designed to prevent the propagation of trouble from one portion of the BES to another. We recommend changing the proposed definition to read as follows: A control system designed to detect electrical faults or abnormal conditions in the power system and initiate corrective action(s). A protection system consists of the following components: 1. Protective relays which protect: a) Transmission BES elements, including generating facility step up transformers, and respond to power system electrical quantities such as voltage and current, b) Generating facilities by responding to power system electrical quantities, such as voltage and current, and are designed to protect against potential problems in the BES on the high side of the generator step up transformer. 2. Communications systems necessary for correct operation of protective functions, 3. Voltage and current sensing devices which transform high level power system quantities to low level inputs for protective relays, and the associated circuitry to the inputs for protective relays. 4. Station DC supply associated with protective relay power supplies and control functions (including station batteries, battery chargers, and non-battery-based DC supply), and 5. Control circuitry associated with protective relay functions (including auxiliary relays) through the trip coil(s) of the circuit breakers or other interrupting devices.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability. The applicability of the definition of Protection System will be addressed in the various standards which utilize the definition. The SDT believes the current draft of the definition as balloted is better supported by industry.				
1 3 4 5	Seattle City Light	Pawel Krupa Dana Wheelock Hao Li Michael J. Haynes	Affirmative	Seattle supports this definition with the understanding that issues that have been previously addressed through comment will be considered during the Standard development process.

Segment	Entity	Member	Ballot	Comments
6		Dennis Sismaet		
Response: The SDT appreciates your support.				
1 3	Tri-State G & T Association, Inc.	Keith V. Carman Janelle Marriott	Negative	2nd bullet - Add communication-aided before protective functions. We think that this is important because you can have correct operation of protective functions without the communication-aided tripping functions operating correctly, especially with POTT or DCUB schemes. 5th bullet - replace through with including. We think that the phrase through the trip coil could be misinterpreted to mean protective functions that cause current to flow through the trip coil rather than the inclusive meaning such as from A through Z. If the intent of the drafting team is to exclude the trip coil, then we think it should be changed to control circuitry associated with protective functions required to operate the trip coil(s) of the circuit breakers or other interrupting devices.
Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
1	Western Area Power Administration	Brandy A Dunn	Negative	The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays do not also include the "control circuitry". By the same token, voltage and current sensing devices do not include their related circuits. The definition for voltage and current sensing devices should be revised to include the term "circuits". The following language change would serve make it clear: "Voltage and current sensing devices and their respective circuits providing inputs protective relays,".
5	U.S. Bureau of Reclamation	Martin Bauer P.E.	Negative	The term "protection functions" is ambiguous as it is not related to the protection function associated with the protective relays. There are other protection functions not associated with protective relays that respond to electrical quantities. The language for Communication systems should be changed to remove the ambiguity. The following change would be clear, "Communication system necessary for the correct operation of the protective relays" The input to the relays is from voltage and current sensing devices through their respective circuits. Since the definition for protective relays separates the term "control circuitry" associated with protective relays, it is clear that protective relays do not also include the "control circuitry". Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				
2	Midwest ISO, Inc.	Jason L Marshall	Negative	We disagree with the implementation plan. The implementation plan calls for capitalizing protection system in NUC-001-2 and PER-005-1. Because Protection System had been included in the NERC Glossary of Terms before the development of these standards, we believe the drafting teams would have capitalized those terms in these standards if they had intended for the Protection System definition to apply. Furthermore, we believe the use of protection system PER-005-1 was actually intended to be special protection systems or remedial actions schemes. To capitalize protection system in PER-005-1 will fundamentally alter the requirement in which it is contained.
Response: The SDT agrees and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified. However, the SDT believes the term Protection System should be capitalized as described in the Implementation Plan for NUC-001-2.				
3 4 5	Consumers Energy	David A. Lapinski David Frank Ronk James B Lewis	Negative	We understand that this posting is intended to address perceived flaws in the currently approved definition. However, since this change, if approved, is likely to result in changes to an entity's PRC-005-1 maintenance program, we feel that it is inappropriate to approve this definition without simultaneous approval of the revised PRC-005-2 which will clarify the related changes to maintenance programs.
Response: When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now. The implementation plan now proposes at least 12 months for entities to apply the new definition to PRC-005-1, and that should give entities time to apply the new definition to PRC-005-1.				
3	MidAmerican Energy Co.	Thomas C. Mielnik	Negative	BES references are needed in each sub bullet definition to eliminate ambiguity and to create clearly auditable requirements. The term "DC system" needs to be replaced with explicit pieces of equipment such as "batteries, battery chargers, and AC / DC converters".
Response: The SDT believes these comments relative to BES are not within the scope of Project 2007-17 and should be addressed by the Regional Entities; and that the current draft of the definition as balloted is clear, concise, and contains the specific dc systems equipment you mention.

5</td><td>Wisconsin Electric Power Marketing

Wisconsin Energy Corp.

Wisconsin Electric Power Co.</td><td>James R. Keller

Anthony Jankowski

Linda Horn</td><td>Negative</td><td>1. The Protection System definition needs to indicate that the listed items after relays are intended to be associated with relays. As written, most of the items apply to undefined "protective functions". The Implementation Plan's change to PER-005-1 R3.1 restricts where R3.1 applies. For example, changing "protection systems" to "Protection Systems" will exclude an SPS that does not operate relays. Replace term "voltage & current sensing devices" with "voltage & current sensing inputs to protective relays".
2. Remove the battery chargers from the definition and make reference to station batteries only. There needs to be improved coordination between proposed changes and definitions and the associated proposed changes and testing.</td></tr>
<tr><td colspan="5">Response: 1. The drafting team does not believe that the additional language is needed in the definition. The SDT agrees with the comment on PER-005 and will revise the Implementation Plan to remove PER-005 from the list of standards to be modified.
2. When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.</td></tr>
</table>

Segment	Entity	Member	Ballot	Comments
4	Madison Gas and Electric Co.	Joseph G. DePoorter	Affirmative	Believe that Communication systems necessary for correct operation of protective "relay" functions be considered as an enhancement to the definition. This would also need to be added within the Station dc supply and Control circuitry bullets. This will provide clarity to exactly what the definition is describing.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				
5	Constellation Power Source Generation, Inc.	Amir Y Hammad	Negative	Constellation has previously voted against these revised definitions because as written, it implies that the testing of PTs and CTs in PRC-005 is required. This latest proposal is no different. Constellation agrees with the SDT in that current and voltage sensing devices are an important aspect of the Protection System. However, by including PTs and CTs in the definition, auditors have been interpreting that as stating that dielectric testing and other tests are necessary on them. This does not seem to be the intention of the SDT. The intention of the SDT seems to be to verify that the sensing devices are delivering acceptable signals to relays. Table 1 a of the PRC-005-2 standard includes: Voltage & Current Sensing Devices / 12 Calendar Years / Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays. The FAQ for PRC-005-2 is even clearer in stating that ensuring the protection system is receiving the expected values from current and voltage sensing devices. But neither the originally revised or newly revised definitions carry that implication very well. The definitions are still including the devices themselves and not their outputs. To make the definition less ambiguous with PTs and CTs, Constellation proposes the following change in the definition: Voltage and current sensing devices providing inputs to protective relays to; Voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays.

Segment	Entity	Member	Ballot	Comments
6	Constellation Energy Commodities Group	Brenda Powell	Negative	Constellation has previously voted against these revised definitions because as written, it implies that the testing of PTs and CTs in PRC-005 is required. This latest proposal is no different. Constellation agrees with the SDT in that current and voltage sensing devices are an important aspect of the Protection System. However, by including PTs and CTs in the definition, auditors have been interpreting that as stating that dielectric testing and other tests are necessary on them. This does not seem to be the intention of the SDT. The intention of the SDT seems to be to verify that the sensing devices are delivering acceptable signals to relays. Table 1 a of the PRC-005-2 standard includes: Voltage & Current Sensing Devices / 12 Calendar Years / Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays. The FAQ for PRC-005-2 is even clearer in stating that ensuring the protection system is receiving the expected values from current and voltage sensing devices. The definitions are still including the devices themselves and not their outputs. To make the definition less ambiguous with PTs and CTs, Constellation proposes the following change in the definition: Voltage and current sensing devices providing inputs to protective relays to; Voltage and current sensing device output circuits and the associated circuits to the inputs of protective relays.
Response: The SDT believes your comment is aimed at revising the definition so that it achieves a particular outcome when applied to specific requirements in the proposed PRC-005. The team is trying to develop a definition that would be applicable for use in several standards, and does not want to make modifications to the definition that would limit the term's applicability.				
5	Dynegy Inc.	Dan Roethemeyer	Affirmative	Please clarify "non-battery-based dc supply". It is vague.
Response: The SDT appreciates your support, and believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.

<tr><td colspan="5">Response: : When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.</td></tr>
</table>

Segment	Entity	Member	Ballot	Comments
5 6	RRI Energy	Thomas J. Bradish Trent Carlson	Negative	It is not appropriate to define the battery or chargers as protection system elements. For DC circuits or supply, the definition and subsequent boundary of the protection system should end at the fuses or circuit breakers of the sources supplying the individual DC control circuits of the protection system. For a typical power plant station battery, the percent of the battery capacity sized for the protection system is very small. The battery and chargers are power source elements, not protection elements. Likewise, all intermediate power distribution elements between the battery, chargers, and dedicated protection system branch circuits, do not belong in the definition of the Protection System.
Response: : When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team caused by the definition of "protection system" not including battery chargers, and directed that work to close this reliability gap should be given “priority.” To close this reliability gap the BOT has directed that revised definition be applied to PRC-005-1 as soon as practical - not years from now.				
5	TransAlta Centralia Generation, LLC	Joanna Luong-Tran	Negative	To increase the clarity of the definition, TransAlta proposes the following: Control circuitry associated with protective functions through to and including the trip coil(s) of the circuit breakers or other interrupting devices
Response: The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
8	SPS Consulting Group Inc.	Jim R Stanton	Negative	The term "Communication System" remains in the definition, despite the reality that at least for most generators, there is no communication system within the Protection System. Communication from device to device, such as a protective relay to a trip coil or alarm, it not a "system" per se but merely a wire connecting the devices. Keeping this definition as is perpetuates the confusion of generators when they design, modify and execute their protection system maintenance and testing program as the definition of the Protection System requires addressing a "communication system" which they do not have. Keeping the definition as is could lead to confused auditors who insist on literal adherence to the requirement language, clouding the audit and imposing ad hoc and perhaps inconsistent interpretations for audits, spot checks and self reports. What will most surely happen if this definition is approved is a quick request for interpretation by one or more entities seeking clarification on the requirement to include "communication systems" within their maintenance and testing program when they in fact have no such system. All this can be avoided by changing the term "communication systems" to "communication components." This is a primary example of fixing something on the front end so we don't have to go through interpretations and revisions to fix an ambiguity. This definition would also not pass a Quality Review due to the ambiguity of terms.
Response: The SDT believes the language is clear and addresses relay communication systems currently used by industry.				
8	Utility Services, Inc.	Brian Evans-Mongeon	Negative	While the language by itself is supportable, the definition is not complete. The SDT has still not addressed the question of when the definition will apply to Distribution Providers. Many DPs own and or operate the elements listed in the definition; however, the definition lacks clarity when such ownership or operation is subject to the performance obligations under the standard.
Response: This clarification is provided in each requirement that uses the term, “Protection System” by identifying the responsible entity. The comment relates to "application" of the definition, not to the definition.				

Segment	Entity	Member	Ballot	Comments
9	California Energy Commission	William Mitchell Chamberlain	Affirmative	The proposed definition is generally acceptable. However, a slight modification to the third bullet in the definition would be an improvement to the proposed wording: "DC supply sources affecting the 'Protection System' (including station batteries, battery chargers, and non-battery-based dc supply), and " In addition, a definition of non-battery-based dc supply should be included to avoid confusion we recommend the following: "The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on."
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				
9	Oregon Public Utility Commission	Jerome Murray	Affirmative	Although I voted yes, I recommend the following proposed wording for the third bullet: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and Also the definition of non-battery-based dc supply should be included to avoid confusion. I recommend the following: The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term “non-battery-based dc supply” is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				
10	Midwest Reliability Organization	Dan R. Schoenecker	Affirmative	Suggest the second bullet language replace the term correct with the intended. Communications systems necessary for the intended operation of protective functions.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry.				

Segment	Entity	Member	Ballot	Comments
10	Western Electricity Coordinating Council	Louise McCarren	Affirmative	The definition is generally acceptable. However, we believe that better language for the third bullet is as follows: DC supply sources affecting the "Protection System" (including station batteries, battery chargers, and non-battery-based dc supply), and A definition of non-battery-based dc supply should be included to avoid confusion and we offer the following: The inverter or rectifier in the circuit, dependent upon how the end use equipment is designed. Uninterruptible power supply (UPS) such as on-line, line-interactive or standby that some of the protection system could be on. The intent of the suggestion would consider that the entire protection system has to operate in order to maintain the reliability of the BES. An example would be if the protective relay and associated communications were on a UPS system and the intended device to operate were on station batteries, this would be the best case scenario as the Micro processors relays and the newer associated communications do not like the voltage drop when the station switches to the station batteries, hence the use of UPS options. Micro processors relays do have internal battery backup to keep them up and running, though a maintenance task would have to be included to be sure that they are properly maintained and tested, so the UPS option is easier and has been kind of an industry standard in the past. In the end the UPS would have to be on a maintenance schedule also.
Response: The SDT appreciates your support. The SDT believes the current draft of the definition as balloted is clear, concise, and supported by industry. The term "non-battery-based dc supply" is meant to be a broad term to capture other methods such as flywheels, compressed air, fuel cells, or any other emerging technology which is capable of supplying dc power to the Protection System.				

Consideration of Comments on Protection System Maintenance [Project 2007-17]

The Protection System Maintenance Drafting Team thanks all commenters who submitted comments on the 3rd draft of the standard for Protection System Maintenance and Testing. These standards were posted for a 30-day public comment period from November 17, 2010 through December 17, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 44 sets of comments, including comments from more than 81 different people from approximately 82 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Extensive changes were made to Requirements R1 and R3 of the Standard, and also to the Tables referenced within the Requirements. Of particular note, Requirement R1, Part 1.5 (which required entities to define their acceptance criteria for maintenance of components), and the associated discussion within Requirement R4, Part 4.2 were removed. Requirement R2 was removed because it was duplicative of Requirement R1, Part 1.4. Also, Table 1-4, addressing maintenance of Station DC Supply, was split into six separate sub-tables addressing the various specific technologies within this component.

Some commenters continued to object to various requirements within the standard. Where the standard was not revised in response to these comments, the SDT explained their rationale within the consideration-of-comments.

Based on the level of consensus on this posting, the SDT will post the Standard and associated documents for an additional 30-day comment period with concurrent ballot in the final 10-days of that comment period.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. **The SDT has restructured the tables to improve clarity, but did not appreciably change the content. Do you agree that the restructured tables are clearer? If not, please provide specific suggestions for improvement.**

Summary Consideration: Generally, commenters indicated that the rearrangement of the Tables was beneficial. Several commenters questioned the arrangement of Table 1-4 and the SDT responded by revising this Table. A few commenters suggested further rearrangement of the Tables; the SDT observed that there are many potential ways to organize the Tables and declined to adopt these suggestions. The SDT made minor changes to Table 1-3 and Table 2 verbiage based on stakeholder comments.

Organization	Yes or No	Question 1 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	
Tennessee Valley Authority	Yes	
Northeast Power Coordinating Council	No	The wording “Component Type” is not necessary in each title. Just the equipment category should be listed--what is now shown as “Component Type - Protective Relay”, should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The “Note” included in the heading is also not necessary. “Attributes” is also not necessary in the column heading, “Component” suffices.
Response: Thank you for your comments. The SDT believes that the table headings are appropriate as reflected in the draft standard.		
Platte River Power Authority System Maintenance	Yes	
Electric Market Policy	Yes	Dominion does not feel that clarity has been added to the tables. 1. A numbering structure should be added to the table for referencing each task prescribed.

Organization	Yes or No	Question 1 Comment
		2. The tables should more clearly designate and separate time based versus performance based tasks. 3. Additionally, Table 1-4 contains, in several places, an activity to "Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline." This seems to suggest that each time the batteries are checked, the measured cell/unit internal ohmic value should agree with some baseline value. This appears to be overly prescriptive as the values reading-to-reading should fall within the tolerances established per Requirement R1.5, not equal a baseline. The activities for other component types are not this prescriptive.
Response: Thank you for your comments. **1. The SDT believes that numbering the tasks within the Tables as you suggest would make the Tables more complex and would not add clarity.** **2. Performance-based maintenance requires that the same tasks be completed, but at intervals determined per Attachment A.** **3. The station battery baseline value is up to the entity to determine. Please see Section 15.4.1 of the Supplementary Reference for a discussion of this. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that R1 part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Bonneville Power Administration	Yes	
Santee Cooper	Yes	
NERC Staff	Yes	
FirstEnergy	Yes	While we agree that the clarity of the tables has improved, there are still items that warrant further clarity. 1.In Table 1-1, references to "Verify acceptable measurement of power system input values" is made for microprocessor relays on 6 and 12 calendar year intervals. Wouldn't this also be prudent on non-microprocessor based relays as well on the 6 year interval? 2. Also, in Table 1-3, "Verify that acceptable measurement of the current and voltage signals are received by the protective relays" is shown on a 12 calendar year interval. What is the difference between this activity and the similar activity performed in Table 1-1? 3. In Table 1-4, this table is complex and the detailed maintenance activities in this particular table is puzzling when compared to the more generic detail in the other tables within this section. For example, an incorrect operation due to a deteriorated signal from a CT or VT has a higher probability than a failure of a battery bank

Organization	Yes or No	Question 1 Comment
		to perform when called upon. 4. In Table 1-5, Please provide clarity on the "Unmonitored Control circuitry associated with protective functions" component attribute. This would most likely be an FAQ item.
Response: Thank you for your comments. 1. **For non-microprocessor relays, this activity is fundamentally performed as a part of the calibration process.** 2. **This activity is used to verify the performance of the voltage and current sensing devices, where the activity in Table 1-1 is used to verify that the protective relay is performing properly. In some cases, the activity in Table 1-1 may also serve to satisfy the requirement in Table 1-3.** 3. **Table 1-4 is more detailed than the other tables because of the variability in the technologies of the station dc supply.** 4. **The draft definition of Protection System establishes "Control circuitry" as "…control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices". Please see Section 15.3 of the Supplementary Reference for a discussion of this.**		
Florida Municipal Power Agency	Yes	
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	
MRO's NERC Standards Review Subcommittee	Yes	
Western Area Power Administration	Yes	
TransAlta Centralia Generation Partnership	Yes	
NextEra Energy	Yes	
City of Austin DBA Austin Energy		
PacifiCorp	Yes	

Organization	Yes or No	Question 1 Comment
Southern Company Transmission	Yes	The Standard Drafting Team should be commended for making the tables much easier to understand
Response: Thank you for your support.		
Clark Public Utilities	No	The SDT has greatly improved the clarity of this document in the areas of relays, communication systems, voltage and current sensing devices, control circuitry, and alarming paths. The recommendations on station dc supply are still confusing. First, there are five different attribute categories for unmonitored dc supply. Are these five categories mutually exclusive? Are we supposed to follow just the category applicable to the type of battery? Are we supposed to follow the first category and any of the subsequent four battery type categories as they apply? I suspect some of the 3 month and 18 month items in the first category are considered to be necessary by the SDT regardless of battery type. The current categorization is confusing. If we are required to perform the 3 month and 18 month activities listed in the first category regardless of battery type AS WELL AS the other applicable battery type activities, please indicate this in Table 1-4. As a different option, just eliminate the first category entirely and place the appropriate 3 month and 18 month verification and inspection requirements in the four battery type specific categories. It may be repetitive but clarity is paramount in this standard. Second, the FAQ examples seem to indicate that the SDT views the performance of an internal ohmic battery test or a battery performance test as valid forms for verifying the individual battery cell states (i.e. state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance). It would be helpful if this were more obviously stated in table 1-4. Currently it could be interpreted that we need to do all of the individual cell-cell verification in addition to the ohm test or the full performance test. I don't believe this is the intent of the SDT (based on the FAQ examples) but we need to see the intent in Table 1-4.Third, does a monitored dc supply have to monitor some or all of each of the different line items listed? The FAQ examples indicate that if only some are monitored, the dc supply can still be treated as monitored as long as the unmonitored items are verified. This means that for a VLA battery with a low voltage alarm and unintentional ground alarm, all that is needed is to check electrolyte level every 3 months, check float voltage and battery rack every 18 months and perform either an internal ohm check at 18 months or a battery performance test at 6 years. Also battery alarms need to be verified at 6 years. This is not clear in Table 1-4 and it could be interpreted by some that a monitored station dc supply monitors ALL of the listed items not just SOME. The FAQs imply that partial monitoring is acceptable but Table 1-4 does not indicate this very clearly. I do wish to say once again that this proposed standard is much easier to understand and that with a little more clarification in the dc supply section I would vote in the affirmative.
Response: Thank you for your comments. Table 1-4 has been modified in consideration of your comments. Specifically, Table 1-4 has been revised to		

Organization	Yes or No	Question 1 Comment
remove "state of charge" from the activities.		
Exelon		
Manitoba Hydro	No	The maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the state of charge of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition, which are indicated as 18 month interval tasks in table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Dynegy Inc.	Yes	
Oncor Electric Delivery Company LLC	Yes	
Ingleside Cogeneration LP	Yes	The tables clearly tie to each component type in a Protection System. This is consistent with the required PSMP format, making it straight forward to incorporate the intervals and to demonstrate compliance.
Response: Thank you for your support.		
Indiana Municipal Power Agency	Yes	
South Carolina Electric and Gas	Yes	
Entergy Services	No	The tables are generally much clearer and the SDT is to be commended on their efforts. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an "alarm producing device" is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn't necessarily a maximum interval established as there is for Protection System components. Also, if an entity's alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing

Organization	Yes or No	Question 1 Comment
		device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification?
Response: Thank you for your comments. For clarity, the ‘Maximum Maintenance Interval’ column entry in Table 2 has been revised to state, “When alarm producing Protection System component is verified”.		
Duke Energy	Yes	
Wisconsin Electric Power Company	Yes	
Independent Electricity System Operator		
American Electric Power	No	1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. 2. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 3. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs. 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. 4. AEP suggests repeating the heading “Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):” for the bullet points on this page.
Response: Thank you for your comments. **1. The 6-year activities are all related to components with “moving parts”, and the 12-year activities are related to the other portions of the control**		

Organization	Yes or No	Question 1 Comment
circuitry. 2. The capitalized term has been corrected. 3. Table 1-4 has been modified in consideration of your comments. 4. Table 1-4 has been modified in consideration of your comments.		
ITC	Yes	The following question concerns Table 1-3. 1. Our testing program includes "impedance testing" of the current transformers (CTs) along with insulation testing of the wiring and CT secondary. Impedance testing involves impressing an increasing voltage on the secondary of the CT (with primary open circuited) until 1 (one) ampere flows. This method determines the "knee" of the saturation curve that is used as a benchmark for comparison to previous testing and other CTs. This procedure has successfully identified CT problems over the past several decades. We believe this procedure to be adequate. Does the SDT agree that this method is sufficient to meet the testing requirements of Table 1-3 and that a current comparison is not needed in addition to this testing? 2. Another variation of this is for voltage device compliance. Table 1-3 indicates that we should verify the correct voltages are received by the relay. This means that the VT would need to be energized and we would measure the secondary voltages to compare with others. Power plant relay testing is normally performed during plant outages when this measurement cannot be done. Some plants do not allow any testing while the unit is on line. It would seem that the standard would be written to allow some other type of testing to be performed other than the measurement test. 3. For Table 1-1 Row 1, we believe the intent is to verify that settings are as specified for non-microprocessor relays and microprocessor relays alike. If this is the case, consider adding "Verify that settings are as specified" as a bullet under the headings for non-microprocessor relays and microprocessor relays. 4. Splitting the tables into separate sections for Protective Relays, Communication Systems, VT and CTs, and Station D.C. Supply helped the clarity.
Response: Thank you for your comments. **1. Table 1-3 has been revised in consideration of your comments. Also, please see Section 15.3 of the Supplementary Reference Document. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.** **2. Table 1-3 has been revised in consideration of your comments. Also, please see Section 15.3 of the Supplementary Reference Document. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**		

Organization	Yes or No	Question 1 Comment
3. "Verify that settings are as specified" is specified as an activity that applies to all Protective Relays, regardless of technology. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity. **4. Thank you for your support.**		
ISO New England Inc.	No	The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices.
Response: Thank you for your comments. The SDT believes that the table headings are appropriate as reflected in the draft standard.		
Nebraska Public Power District	Yes	
CenterPoint Energy	Yes	
American Transmission Company	Yes	
Consumers Energy	Yes	
Southern Company Generation	Yes	
US Bureau of Reclamation		No Comment
Alliant Energy	Yes	
LCRA Transmission Services Corporation	No	1. It would help to add a column to the left labeled Category. I.E. a relay could be classified under Category 1 attributes unmonitored or Cat 2, Cat 3. 2. Table 1-4, Station DC is very difficult to follow.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. **1. The SDT believes that the table headings are appropriate as reflected in the draft standard.** **2. Table 1-4 has been modified in consideration of your comments.**		
MidAmerican Energy	Yes	
Ameren	Yes	
Xcel Energy	Yes	

2. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Several commenters objected to the "percentage" steps in several VSLs. The SDT observes that the 'percentage' steps follow the VSL Guidelines which can be found on the NERC website in the 'Resource Documents' area of the 'Reliability Standards' section. Other commenters requested that the VSLs permit some level of non-compliance before incurring a 'Low' VSL, again the SDT notes that this is not acceptable per the VSL Guidelines.

Organization	Yes or No	Question 2 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	
Tennessee Valley Authority	No	1. There is no allowance for deferral of maintenance because of factors beyond the control of the TO, GO, or DP. These include the unavailability of customer outages, generation outages, system configuration, high risk of loss of generation or customer load or impact to power quality. Proposed Change: Provide a process for acceptable deferral of maintenance activities. 2. Table 1-4 The requirement to perform cell internal ohmic resistance measurements every 18 months for vented lead-acid batteries is excessive. Our normal battery life is 20+ years. A 3-year internal resistance test frequency is adequate to prove battery integrity. IEEE 1188 recommends verification of internal ohmic resistance to be on a quarterly basis. It appears other intervals take into account recommended inspection interval plus some grace period. Proposed Change: Change maintenance interval from 3 months to 6 months. 3. Section: R1.5 This new requirement will require significant documentation with no known improvement to the reliability of the BES. What data is being used to determine the need for this requirement? How far does this requirement go? 4. Table 1-4 requires the inspection of "physical condition of battery rack" What are "identify calibration tolerance or other equivalent parameters" for this task? You already have verified, test, inspect, and calibrate defined. Leave out R1.5 which requires more than meeting the definitions.
Response: Thank you for your comments.		

Organization	Yes or No	Question 2 Comment
1. FERC Order 693 directs NERC to establish maximum allowable intervals. A "deferral process" would not satisfy this directive. **2. The SDT disagrees, and believes that 18-months is the proper interval for this activity.** **3. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section 8 for a discussion of this. The associated VSL has also been revised.** **4. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Northeast Power Coordinating Council	No	1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 4. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response: Thank you for your comments. **1. Consideration of the VRFs, in association with the VRF Guidelines, yields the VRFs as established within the draft Standard.** **2. The SDT has reviewed the time horizons, and feels that R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components is performed within the related time period. The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).** **3. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** **4. The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**		

Organization	Yes or No	Question 2 Comment
Platte River Power Authority System Maintenance	No	The 5%, 10%, and 15% levels for R2 & R4 exaggerate the severity levels for small companies. A small DP with only 9 relays in a protection system would only have to be missing 1 record for a severe VSL.
Response: Thank you for your comments. The percentage levels for Requirement R4 are consistent with many other NERC Standards and are also consistent with the guidance within the VSL Guidelines. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
Electric Market Policy	No	VSL R3. How do you measure a percentage of countable events over a period of time? How are you to determine what the total population to be considered? An entity should not be penalized if they are following their program, correcting issues, and documenting all actions, even if there is a high failure rate in an instance.
Response: Thank you for your comments. Attachment A, to which Requirement R3 refers, specifies that countable events are assessed on the basis of " for the greater of either the last 30 components maintained or all components maintained in the previous year."		
Bonneville Power Administration	Yes	
Santee Cooper		
NERC Staff		
FirstEnergy	No	The VSL for R2 need to be adjusted since "Condition Based Maintenance" has been removed from the standard.
Response: Thank you for your comments. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
Florida Municipal Power Agency	No	The VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: Thank you for your comments. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entities' individual PSMP.		
PSEG Companies ("Public Service Enterprise Group Companies")		No comment

Organization	Yes or No	Question 2 Comment
MRO's NERC Standards Review Subcommittee	Yes	
Western Area Power Administration	Yes	
TransAlta Centralia Generation Partnership	No	Please provide acronyms list and its explanations in the standard.
Response: Thank you for your comments. In accordance with established NERC custom, acronyms are either established at the first use of the term, or are general acronyms used throughout NERC Standards.		
NextEra Energy	Yes	
City of Austin DBA Austin Energy		
PacifiCorp	Yes	
Southern Company Transmission	No	We disagree with the inclusion of the VSLs, VRFs, and time Horizons associated with the new Requirements 1.5 and 4.2
Response: Thank you for your comments. The SDT determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.		
Clark Public Utilities	Yes	
Exelon		
Manitoba Hydro	No	The high VSL for R1 "Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5" may be interpreted in different ways and should be further clarified.
Response: Thank you for your comments. The SDT does not understand your concern; further details are needed.		

Organization	Yes or No	Question 2 Comment
Dynegy Inc.	No	For R4, the VRF has been changed to high. We question the need to change to high since there are numerous elements that will still protect the system while repairs are being made.
Response: Thank you for your comments. Requirement R4 addresses implementation of the overall PSMP; that is – maintaining all devices within the program. This VRF is consistent with the "high" assigned to R2 of PRC-005-1.		
Oncor Electric Delivery Company LLC	No	Oncor strongly disagrees with the modification to the Violation Severity Levers (VSL) table under the High VSL column where it states that it is a high VSL for "Failed to establish calibration tolerance or equivalent parameters to determine if components are within acceptable parameters." Oncor feels modifying the standard by adding a requirement that requires a Transmission Owner, Generation Owner or Distribution Provider to "identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities" is too intrusive and divisive for what it brings to the reliability of the BES. The requirement (Requirement R1 part 1.5) and its associated High VSL should be removed from PRC-005-2.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.		
Ingleside Cogeneration LP		
Indiana Municipal Power Agency	No	IMPA does not agree with the percentage in the VSL table for R4. For smaller entities that have six or less of any one type of Protection System Component and they fail, for whatever reason (even if it's a matter of incomplete documentation), to complete scheduled program maintenance on that component they will be subjected to the severe VSL penalty Matrix. Consideration should be given to entities having less than say, 100 of a component. There should be some type of tiered sub table within the VSL matrix for this consideration - registered entities having a certain component in quantities greater than or equal to 100 and registered entities having quantities of that certain component of less than 100.
Response: Thank you for your comments. The percentage levels within Requirement R4 are consistent with many other NERC Standards, and are also consistent with the guidance within the VSL Guidelines. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
South Carolina Electric and Gas	Yes	

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td>Entergy Services</td><td>No</td><td>R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria....” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4?</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed.   Requirement R4 has also been re-drafted to address various related concerns noted within comments.   The associated VSL has also been revised.</td></tr>
<tr><td>Duke Energy</td><td>No</td><td>1. R1.3 appears to be missing from the VSL for R1.
2. Also, it’s unclear to us what the expectation is for compliance documentation for “monitoring attributes and related maintenance activities” in R1.4 and “calibration tolerances or other equivalent parameters” in R1.5. This is fairly straightforward for relays, but not for other component types.
3. R4 - More clarity must be provided on the expectation for compliance documentation. This is a High VRF requirement, and there may only be a small number of maintenance-correctable items, hence a significant exposure to an extreme penalty.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The High VSL for Requirement R1 has been revised in consideration of your comment.
2. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted R2 (together with the associated Measure and VSL).
3. Examples of compliance documentation are included within Measure M4 and discussed within Section 15.7 of the Supplementary Reference Document.</td></tr>
<tr><td>Wisconsin Electric Power Company</td><td></td><td></td></tr>
<tr><td>Independent Electricity System Operator</td><td>No</td><td>1. R1 Lower - We suggest including a second part as follows: “Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. “</td></tr>
</table>

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>2. R1 Moderate - We suggest similar to the Lower VSL but catering for two Protection System component types.R1 High - We suggest changing the wording of the 3rd part to match the requirement and to cater for more than two Protection System component types.

3. Editorial Comment to Severe VSL for R3: In part 3, replace “less” with “fewer”.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.

2. The ‘Moderate’ VSL for Requirement R1 appears to be similar to the ‘Lower’ VSL for Requirement R1 as you suggest. The SDT believes that, if more than two Protection System component types are not addressed, the ‘Severe’ VSL is appropriate.

3. Thank you. The SDT elected not to change the VSL for Requirement R3 as suggested.</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>1. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL.

2. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1.

3. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.

2. The SDT concluded that Requirement R2 is redundant with R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).

3. If the indicated monitoring attributes are present, no “hands-on” periodic maintenance is required, as the monitoring of the component is</td></tr>

Organization	Yes or No	Question 2 Comment
providing a continuing indication of its functionality.		
ITC	Yes	
ISO New England Inc.	No	1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. 4. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. 5. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 6. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response: Thank you for your comments. **1. The SDT set the VRFs in accordance with the FERC's and NERC's VRF guidance.** **2. The SDT has reviewed the time horizons, and feels that Requirement R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components is performed within the related time period. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** **4. The 'Moderate' VSL for Requirement R1 appears to be similar to the 'Lower' VSL for Requirement R1 as you suggest.** **5. The SDT believes that, if more than two Protection System component types are not addressed, the 'Severe' VSL is appropriate.** **6. The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**		
Nebraska Public Power District	No	VRF's: 1. The definition of a Medium Risk Requirement included on page 8 of the SAR states: "A requirement that,

Organization	Yes or No	Question 2 Comment
		if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system." The PSMP does not "directly" affect the electrical state or the capability of the bulk electric system. A failure of a Protection System component is required to "directly" affect the BES. Therefore, the PSMP has only an "indirect" affect on the electrical state or the capability of the BES. Requirements R1 through R3 and their subparts are administrative in nature in that they are comprised entirely of documentation. Therefore, I recommend changing the Violation Risk Factor of Requirements R1, R2, and R3 to Lower to be consistent with the Violation Risk Factors defined in the SAR. VSL's: 2. R2: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "condition-based" to "time-based" in all four severity levels. 3. SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less complaint recommend revising the percentages of the violation severity levels to be consistent with the SAR. 4. R3: The performance-based maintenance program identified in PRC-005 Attachment A provides the requirements to establish the technical justification for the initial use of a performance-based PSMP and the requirements to maintain the technical justification for the ongoing use of a performance-based PSMP. However, it appears the VSLs for Requirement R3 only addresses the ongoing use of the technical justification. a. I recommend revising the VSLs for R3 to include the initial use of the technical justification. Item 2) of R3 Severe VSL is a duplicate of Item 2) of R3 Lower VSL. This item is administrative in nature therefore I recommend deleting Item 2) from R3 Severe VSL. b. The first and third bullets of item 4) of R3 Severe VSL are administrative in nature and should be moved to the Lower VSL c. R4: SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less complaint recommend revising the percentages of the violation severity levels to be consistent with the SAR.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. **1. Requirements R1, R2, and R3 are not administrative; they are foundational. Without the fundamental development of a PSMP, an entity is unlikely to actually implement a PSMP that satisfies the reliability needs of the BES. The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **2. The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **3. The guidelines within the SAR have been superseded by subsequent revisions to the VSL Guidelines. The VSLs in the draft standard adhere to the latest VSL Guidelines and to the June 19, 2008 FERC order on VSLs in Docket No RR08-04-000.** **4. Part a – The VSL for Requirement R3 has been modified in consideration of your comments.** **Part b – These requirements are not administrative; they are foundational. Without compliance with these requirements, an entity does not have an effective performance-based PSMP, and may be detrimentally affecting reliability.** **Part c – The latest VSL Guidelines also provide examples of VSLs similar to those in the draft standard.**		
CenterPoint Energy		
American Transmission Company	Yes	
Consumers Energy	Yes	
Southern Company Generation	Yes	
US Bureau of Reclamation	Yes	The tables rely on a reference document which is not a part of the standard and as such may be altered without due process. Either the relevant text from the reference needs to be inserted into the standard or the reference itself incorporated into the standard. Specific References such as
Response: Thank you for your comments. The Tables do not provide a reference to either the Supplementary Reference Document. An entity must comply with the standard when approved. The reference documents provide additional explanation, discussion, and rationale, but are not part of the mandatory standard. Since the reference documents are being developed to accompany the standard, the NERC Standard Development Procedure requires that they be posted with the draft standard and undergo stakeholder review, both initially and with any revision of the standard.		
Alliant Energy	Yes	

Organization	Yes or No	Question 2 Comment
LCRA Transmission Services Corporation	Yes	
MidAmerican Energy	Yes	
Ameren	No	(1)The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: “Entity has failed to complete scheduled program on 1% to 5% of total Protection System components.” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties.
Response: Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.		
Xcel Energy	Yes	

3. **The SDT has provided the "Supplementary Reference" document to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for improvements?**

Summary Consideration: Some commenters questioned whether the Supplementary Reference Document was a part of the Standard and thus mandatory and enforceable; the SDT responded that this document is not a part of the standard but instead offers guidance/rationale to assist in the implementation of the standard. Various other comments were offered regarding the content of the Supplementary Reference Document, to which the SDT responded accordingly.

Electric Market Policy	Yes	The document on page 3 states that data available from EPRI (et.al) was utilized by the Standard Drafting Team; however, there are no references to EPRI documents in Section 16. Suggest including EPRI references for completeness.
Response: Thank you for your comments. Page 3 of the Supplementary Reference Document has been revised to remove reference to EPRI documents.		
Bonneville Power Administration		
Santee Cooper	No	

Organization	Yes or No	Question 3 Comment
NERC Staff	Yes	1. In section 2.3, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. 2. In Section 2.4, NERC staff recommends changing the phrase "relays that use measurements of voltage, current, frequency and/or phase angle" with "protective relays that respond to electrical quantities" for consistency with recent changes to the proposed definition of Protection System.
Response: Thank you for your comments. **1. The SDT believes that it is not advisable to reference future activities, but notes that the standard will be applicable to whatever is defined to be the BES, either today or in the future.** **2. The Supplementary Reference Document has been revised as suggested.**		
FirstEnergy	Yes	The discussions surrounding implementing the PSMP on pages 10 and 11 of the clean copy are troublesome for the following reasons. 1. On Pg. 10, under Sec. 8.1, the 4th bullet item states "If your PSMP (plan) requires more activities then you must perform and document to this higher standard". This statement's use of the word "must" implies that an entity will be audited to their documented maintenance practices, even if those practices exceed the requirements of the PRC-005 standard. The PRC-005 standard, and any standard, details the minimum requirements that must be met to achieve a certain reliability goal. For example, if an entity's program states that it will do maintenance on a relay every 4 years, but the standard only requires maintenance every 6 years, the entity shall be held compliant to the standard's 6 year interval. If the entity in this example decides that in year 4 it must delay its maintenance to year six, that should be allowable since the standard PRC-005-2 requires maintenance every 6 years. 2. Since the standard no longer discusses Condition Based Maintenance, it should be removed from the reference document for consistency.
Response: Thank you for your comments. **1. This text is in the Supplementary Reference Document as a caution to entities that they may be expected to be held accountable for their entire documented PSMP, even if it exceeds the minimum requirements of the standard.** **2. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed.**

</table>

Organization	Yes or No	Question 3 Comment
		Comment ->> Standard does not state that an operational/full functional test is required. Please clarify. 3. Page 22, 15.3, Control Circuitry Functions, paragraph 1 ("verify, with a volt-meter, the existence of proper voltage at the open contacts" Comment ->> The example of measuring the proper voltage with a volt-meter at the open contacts to verify the circuit indicates that the 12-year "full functional" trip test of control circuits is not required. Please clarify. 4. Page 22, 15.3, Control Circuitry Functions, paragraph 3 ("UVLS or UFLS scheme are excluded from the tripping requirement, but not from the circuit test requirements") Comment ->> This indicates to me that measuring the proper voltage with a volt-meter at the open contacts will verify the circuit. Please confirm. Please clarify - If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be "extended beyond 12 years". Standard indicates that no periodic maintenance is required. Consider changing "extended beyond 12 years" to "eliminated". 5. Page 23, 15.3, Control Circuitry Functions, paragraph 5 ("When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly.") Comment ->> This indicates that we must verify that trip and auxiliary device contacts change state. Please confirm. The standard does not state that the contacts must be verified to change states. If this is required, please add to the standard.

Response: Thank you for your comments.

1. **These notes are provided as application guidance relative to the Tables, which as you note, does not reference them.**
2. **This note has been revised within the Supplementary Reference Document in consideration of your comment.**
3. **This example is stated within the Supplementary Reference Document as an example method of testing the dc control circuitry. The draft standard no longer requires a "functional trip test", although it does require that lockout relays and auxiliary relays be operated at least once every 6 years to verify that they function properly.**
4. **The Supplementary Reference Document has been revised as suggested.**
5. **The draft standard specifies "Verify electrical operation" of these components every 6 years. This seems implicitly to require a change of state of the contacts. However, it may be possible to verify electrical operation without having to check the change of state of the individual contacts, but the contacts will have to be checked as part of the 12-year full test. The cited clause/paragraph Supplementary Reference Document has been revised to clarify.**

Organization	Yes or No	Question 3 Comment
Clark Public Utilities	No	
Exelon		
Manitoba Hydro	No	
Dynegy Inc.	No	
Oncor Electric Delivery Company LLC	No	
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration, LP, believes that the Section 15.5 of the Supplementary Reference "Associated communications equipment (Table 1-2)" properly reflects the intent of the validation of relay-to-relay communications. It states that any "evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates can fulfill the requirements." However, Table 1-2 - which will be the ultimate reference used by audit teams - only clearly allows for the measurement of channel parameters. Although the newer technology relays provide read-outs of signal level or data-error rates that do not require intrusive testing, older relays do not. The tools required to perform such testing are not easily available - and may leave the communications channel in worse shape after testing than it was prior to testing. We believe that Table 1-2 should be updated to clearly state that an operational test is sufficient for the testing of relay-to-relay communication - consistent with the Supplementary Reference.
Response: Thank you for your comments. The standard does not explicitly require measurement of channel parameters, but instead specifies that they may be verified. The Supplementary Reference Document has been revised to remove the discussion of operational testing of the communications channel.		
Indiana Municipal Power Agency	No	
South Carolina Electric and Gas	No	
Entergy Services	Yes	R1.5 calls for "identification of calibration tolerances or equivalent parameters for each Protection System Component Type....". We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any "equivalent" parameters which would be required for compliance

Organization	Yes or No	Question 3 Comment
		for a component type besides protective relays.
Response: Thank you for your comments. The SDT determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed.		
Duke Energy	No	
Wisconsin Electric Power Company	No	
Independent Electricity System Operator	No	
American Electric Power	Yes	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: 1. Section 5 of the Supplementary Reference, refers to "condition-based" maintenance programs. However, no where in the standard is the term "condition-based" used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 2. Section 15.7, page 26, appears to have a typographical error "...can all be used as the primary action is the maintenance activity..." 3. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups.
Response: Thank you for your comments. The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard. **1. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference Document to clarify the manner in which condition-based maintenance is discussed.** **2. This clause has been corrected.**		

Organization	Yes or No	Question 3 Comment
3. A higher-quality version of Figure 2 has been substituted.		
ITC	Yes	1. Auxiliary Relay Testing: We repeat our objection to the 6 year requirement for testing of auxiliary relays. The STD response to our previous objection was: Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. Auxiliary relays are, of course, electromechanical relays, but much less complicated than impedance, differential or even time-overcurrent electromechanical relays. It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplementary Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in a such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle. 2. High Speed Ground Switch Testing: We repeat our recommendation that the standard state that a high speed ground switch is an interrupting device. We also recommend that testing requirements for High-Speed ground switches be clearly stated in the standard. Section 15.3 of the Supplementary Reference contains the following: It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "...applied on, or designed to provide protection for the BES..." then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade. We disagree that a high-speed ground switch can be adequately tested by disconnecting the solenoid triggering unit. The ability of the trip coil to "operate the circuit breaker" must be verified per Table 1-5 Row 1. The ability of the "solenoid triggering unit" to operate the ground switch should be required also. A high-speed ground switch is a unique device. Its maintenance requirements should be specifically included in the standard itself. Based on Draft 3 of the standard, this is a electromechanically operated device and would have to be tested every 6 years. A logical location would be in Table 1-5. Is there test

Organization	Yes or No	Question 3 Comment
		data to support the test method of disconnecting the solenoid triggering unit?
Response: Thank you for your comments. **1. The SDT believes that the appropriate interval for electromechanical devices such as aux or lockout relays should remain at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.** **2. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems". There is currently an unapproved interpretation response (project 2009-17) addressing what is a "transmission protection system." When this interpretation is approved, the SDT will incorporate it within PRC-005-2. Section 15.3 of the Supplementary Reference Document will be revised to clarify the discussion of testing of the ground-switch trip coil.**		
ISO New England Inc.	No	
Nebraska Public Power District	Yes	The Supplementary Reference Documents identified are unapproved and in draft form. I believe that only approved documents should be referenced in the Standard. Therefore, I recommend updating the Supplementary Reference Documents section with approved versions of the documents.
Response: Thank you for your comments. The SDT revised the Supplementary Reference Document section of the draft Standard.		
CenterPoint Energy		
American Transmission Company	No	
Consumers Energy	No	
Southern Company Generation	Yes	1. On Page 4, Paragraph 2.2 is no longer proposed - the paragraphs just before 2.2 need to be revised. 2. On Page 12, item 7, the phrase "operational trip test" is not used in the standard. Please consider using this phrase in the standard. 3. On Pages 14-15, several paragraphs describing the contents of Sections 9, 10, 11, & 13 are given – these appear to be out of place and don't seem to belong here (just before "9. Performance-Based Maintenance Process). 4. On Page 24, correct the bulleted Protection System Definition to match the most recent definition.

Response: Thank you for your comments. **1. This Section of the Supplementary Reference Document has been corrected.** **2. This Section of the Supplementary Reference Document has been revised.** **3. The Supplementary Reference Document has been revised to address your comment.** **4. The Supplementary Reference Document has been revised to address your comment.** **5. The Supplementary Reference Document has been revised to address your comment.** **6. The Supplementary Reference Document has been revised to address your comment.** **7. The Supplementary Reference Document has been revised to address your comment.**		
US Bureau of Reclamation	Yes	The Supplementary reference provides significant clarity to the intent and application of standard; however, in doing so, it reveals conflicts and ambiguity in the text of the standard. It is suggested that some of the clarifying language be inserted into the text of the standard.
Response: Thank you for your comments. To the extent possible, the clarifying language of the Supplementary Reference Document will be incorporated into the next version of PRC-005 when the standard is drafted in the Results-based format.		
Alliant Energy	No	
LCRA Transmission Services Corporation	Yes	Well written and helpful document. In Section 8.1, the document states that if your PSMP requires activities more often than the Tables maximum, then you must perform to that higher standard. While it is understandable that an entity may desire to maintain their PRS at a higher level, they should not be fined or penalized for achieving less than their standard but within the intervals stated in the Tables. This point should be clarified, preferably within the standard itself.
Response: Thank you for your comments. Requirement R1, Part 1.3 and Requirement R4 within the Standard has been revised in a manner which addresses your comment. However, the SDT re-emphasizes that entities may be expected to be held to their PSMP developed in accordance to		

Organization	Yes or No	Question 3 Comment
Requirement R1, whether it minimally addresses the remainder of the requirements in the standard or exceeds those requirements.		
MidAmerican Energy	Yes	The Supplementary Reference should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Response: Thank you for your comments. NERC establishes that only the Standard is mandatory and enforceable, and Section F of the standard introduces the Supplementary Reference Document as presenting supporting discussion. The introductory area of the Supplementary Reference Document will be revised to clarify this.		
Ameren	No	
Xcel Energy	Yes	1. Requirement R1 of the standard has been changed and no longer states that only relays which sense current, voltage, and phase angle to detect anomalies are in scope. However, it is noted that the new definition of Protection System states “Protective Relays which respond to electrical parameters.” Does Section 2.4 of the Supplementary Reference and, in particular, the last sentence of this section, still align with the standard such that sudden pressure devices are not classified as a relay requiring calibration per Table 1-1? Is the tripping path through the Sudden Pressure Device included as DC Control Circuitry per Table 1-5? FAQ II.4.F would indicate testing of trips from 63 devices are also not required. If so, perhaps this should be restated in Section 2.4 of the Supplementary reference. 2. Section 2.4 could be read to imply that “applicable relays” includes IEEE device #86, lockout relays and IEEE device #94, tripping or trip free relays. However, it is apparent from Table 1-1 “Component Type – Protective Relays” that there are no maintenance activities applicable to 86 or 94 devices. On the other hand, Table 1-5 “Component Type - Control Circuitry” does include maintenance activities for electromechanical trip or auxiliary devices. Thus the tables of the standard imply that 86 and 94 devices would be more accurately classified as DC control circuitry rather than relays. We suggest that Section 2.4 be written to clarify the SDT’s intent for the component type classification of devices 86 and 94. Note that auditors of PRC-005-1 frequently ask for a list of in scope relays and it would nice to have a definite rationale for excluding 86 and 94 devices from these relay lists.
Response: Thank you for your comments. **1. The Supplementary Reference Document has been revised to clarify this point.** **2. The SDT re-emphasizes that auxiliary and lockout relays are included within the standard as mechanical-operating devices that must be verified to operate within a 6-year interval, and also as devices which must be verified within the verification of all paths of the trip circuits on a 12-year interval. It is left to the entity to determine how to best demonstrate compliance with that requirement to the compliance monitor. The**		

Organization	Yes or No	Question 3 Comment
Supplementary Reference Document has been revised to clarify this point.		

4. The SDT has provided the "Frequently-Asked Questions" (FAQ) document to address anticipated questions relative to the standard. Do you have any specific suggestions for improvements?

Summary Consideration: Commenters suggested corrective language and requested additional discussions within the FAQ document. The SDT decided to eliminate the FAQ document and incorporate its contents into the Supplementary Reference Document as appropriate. The SDT considered all commenters' suggestions during that activity.

Organization	Yes or No	Question 4 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	WECC does not use the definition of the BES that NERC supplied to FERC via http://www.nerc.com/docs/docs/ferc/RM06-16-6-14-07CompFilingPar77ofOrder693FINAL.pdf,so the answer to III.1.3 (page 19-20) is not accurate.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Tennessee Valley Authority	No	
Northeast Power Coordinating Council	Yes	See response to Question 5 below.
Response: Thank you for your comments. Please see our response to your comments in Question 5.		
Platte River Power Authority System Maintenance	No	
Electric Market Policy	Yes	The FAQ's do not appear to have kept up with the current draft Standard. 1. For example, Question B under Section 2 for Protective Relays, refers to the use of the word "Restoration" in the definition of a Protection System Maintenance Program. The current definition uses the word "Restore." 2. Additionally, Answers B, I, and J under Section 2 for Protective Relays each refer to Requirement R4.3,

Organization	Yes or No	Question 4 Comment
		which in not in the current Standard. Suggest a final edit of the FAQ's to clean-up these type of issues.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Bonneville Power Administration		
Santee Cooper	No	
NERC Staff	Yes	1. At a minimum, the response to Question II.1.A should be revised to reflect the present revision of Requirement R1. In the current proposed response to the FAQ, the answer refers to text that was deleted from Requirement R1 in the current posting of the standard; i.e., this standard covers protective relays "that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES." The removal of this text from Requirement R1 makes it less clear whether the standard applies to reclosing functions and protective functions used to supervise automatic or manual closing of a circuit breaker to ensure the voltage magnitude and phase angle difference are within specified tolerances. The drafting team also should consider whether additional specificity is required to ensure applicability is clearly defined within the standard. 2. In the response to Question II.2.H, NERC staff notes that the word "than" should be changed to "then" in the phrase "If the component no longer performs Protection System functions than..." 3. In the response to Question II.2.I, NERC staff recommends noting that "When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s)." The recommended text is included in the Supplementary Reference Document and inclusion in the FAQ response provides consistency and highlights obligations in other standards necessary for BES reliability. 4. In the response to Question III.1.A, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. 5. In the response to Question III.3.A, NERC staff recommends a more generic reference to NERC UFLS requirements in place of the reference to PRC-007-0, as PRC-007 will be retired pending FERC approval of PRC-006-1.In the response to Question IV.1.A (third paragraph), NERC staff recommends changing the phrase "that are certainly coming to the industry" to "may be coming to the industry" for consistency with the change to the response to Question V.4.A. Both questions appear to address the same or similar concerns.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
FirstEnergy	No	
Florida Municipal Power Agency	Yes	
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	Suggest that the section 5 - station DC supply have some specific examples added that would be acceptable methods for verifying the "state of charge" as required by standard table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.

PacifiCorp		
Southern Company Transmission	Yes	1. Page 7, L. ("verify operation of the relay inputs ...") Comment ->> Clarification needed. Standard states that each input should be "picked up" or "turned on and off". Do you have to change states of the input contact(s) or can you just jumper positive to the input(s) to verify that the microprocessor relay verifies this change of state?

Organization	Yes or No	Question 4 Comment
		2. Page 10, 4.E ("What does functional (or operational) trip test include?") Comment ->> The words "functional (or operational) trip test" are not in the Standard. Is this required? If so, please clarify this in Standard. If not, please remove. (Reference comment regarding "verify all paths of the control and trip circuits" on page 17 of standard.) 3. Page 18, 7. (Distributed UVLS and UFLS system.) and Page 19 8. (Centralized UVLS and UFLS system.) Comment ->> Standard does not specify "distributed" or "centralized" UVLS and UFLS systems. Please consider combining section 7 & 8, omitting items 7.C., 8.E., and omitting "distributed" and "centralized" references on pages 18 and 19.
Response: Thank you for your comments. **The standard does explicitly require that auxiliary relays, lockout, and trip coils of interrupting devices be verified to have electrically operated every 6 years, and this is the only place in the standard that currently requires this sort of activity.** **The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**		
Clark Public Utilities	Yes	Provide answers to the following questions. Does the completion of a battery ohm test or a battery performance test satisfy the verification requirements for state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)?
Response: Thank you for your comments. The activities described do not satisfy all of the requirements (at the established intervals) listed in your comment. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Exelon	Yes	1. Clarify what kind of testing is required on lockout relays/86 devices. Specifically, whether functional testing is adequate or if simple calibration, similar to protective relays, is all that is are required. 2. Clarify if protective relays that trip equipment (e.g., a condensate pump that would in turn cause a main generator trip) are also included in the scope of this Standard. 3. Clarify if relays which result in generator run back, but do not trip the generator, are included in the scope of this Standard.
Response: Thank you for your comments.		

Organization	Yes or No	Question 4 Comment
1. For lockout relays, the standard requires that they be electrically operated every 6 years, and that the trip path be verified every 12 year. No calibration/etc is specified. 2. As described in FAQ III.2.A, protective relays which trip equipment within the plant which may eventually result in tripping of the generator, but do not trip the generator (either directly or via a generator lockout relay) , are not included. 3. If the generator run back scheme is characterized as a Special Protection System within your region, these relays would be included as part of that system (Section 4.2.6- Applicability of the draft Standard). The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Manitoba Hydro	Yes	As previously stated, the maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition which are indicated as 18 month interval tasks in table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Dynegy Inc.	No	
Oncor Electric Delivery Company LLC	Yes	There is still confusion in Table 1-4 concerning the "Monitored Station dc supply." The uncertainty is over whither an Owner must have all seven (7) monitoring activities (Station dc supply voltage, State of charge of the individual battery cell/units, Battery continuity of station battery, Cell-to-cell and battery terminal resistance, Electrolyte level of all cells in station battery, Unintentional dc grounds, and Cell/unit internal ohmic values of station battery) listed in the table or just one of them to take advantage of forgoing the maximum maintenance interval for an activity and going to the 6 year maximum maintenance interval to verify that the monitoring device is calibrated. A FAQ concerning this question would be beneficial to those who are concerned that they must monitor all seven activities in order to take advantage of condition based maintenance for the station dc supply. Also an explanation of how each of the 7 monitoring activities relates to a specific station dc supply maintenance activity might be beneficial.
Response: Thank you for your comments. Table 1-4 has been further revised to address your concern (see Table 1-4(f)). The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		

Organization	Yes or No	Question 4 Comment
Ingleside Cogeneration LP		
Indiana Municipal Power Agency	No	
South Carolina Electric and Gas	No	
Entergy Services	Yes	Section II.2.B references R4.3 which has been revised to R4.2.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Duke Energy	Yes	There are typographical errors on the FAQ Requirements Flowchart (should be R4.1.1 and R4.1.2 instead of R4.4.1 and R4.4.2).
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Wisconsin Electric Power Company	Yes	Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Independent Electricity System Operator	No	
American Electric Power	Yes	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications:

Organization	Yes or No	Question 4 Comment
		1. The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. 2. Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, no where in the standard is the term "condition-based" used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 3. The second sentence to the response in Section I.1 appears to have a typographical error "... an entity needs to and perform ONLY time-based...".
Response: Thank you for your comments. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
ITC	No	
ISO New England Inc.	Yes	See response to Question 5 below.
Response: Thank you for your comments. Please see our response to your comments in Question 5.		
Nebraska Public Power District	No	
CenterPoint Energy	Yes	The need for an FAQ document, in addition to an extensive Supplementary Reference document, illustrates the complexity and impracticality of the proposed Standard. CenterPoint Energy does not support the development of an additional type of document, that is, the FAQ document. CenterPoint Energy recommends eliminating the FAQ document and using only a Supplementary Reference" document. This would also provide the benefit of not having contradictory information in the two documents.
Response: Thank you for your comments. The SDT believes that entities should be able to implement the standard without either the FAQ or Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion/rationale useful, particularly to assist them in implementing the standard in an efficient manner. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate.		
American Transmission Company	Yes	1. FAQ Protective Relays 2.D: The last sentence is not consistent with the discussions at the "March 2010, Standard Drafting Team Meeting, Project 2007-17". The understanding from that meeting was that the relay settings would be verified that the "as left" settings were the same as the "as found" settings and that the intent was not to verify the settings against a Master Record. Therefore the intent is that the tester will

Organization	Yes or No	Question 4 Comment
		verify that no setting changes were made as part of the testing process. Please include this clarification with the language in the standard. 2. FAQ Group by Type of Maintenance Program 2.B: We agree with the use of either the in-service date or the commissioning date to start the initial due date calculation for maintenance. Please include this clarification with the language in the standard.
Response: **1. The intent is that the settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.** **2. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**		
Consumers Energy	No	
Southern Company Generation	Yes	1. On Page 3, please revise the flow chart references to R4.4.1 and R4.4.2. Also, add (Attachment A) to the "Performance Based" label. 2. On Page 7, Section I, correct the reference of R4.3 to R4.2. 3. Also, revise the last paragraph in Section I to the following: The entity should assure that the component performance is acceptable at the conclusion of the maintenance activities or initiate resolution of any indentified maintenance correctable issues. 4. On Page 7, Section J, correct the reference of R4.3 to R4.2. 5. On Page 10, Section D, a reference is made to "trip test" Table 1. Should this be Table 1-5? The exact phrase "trip test" is not used in the standard. Should it be? 6. On Page 10, Section e, the phrase "functional (or operational) trip test" is not used in the standard – should it be? 7. On Page 11, Section 5A, correct the reference of Table 1 to Table 1-4 in the Station Battery and Emerging Technologies paragraph. 8. On Page 12, Section B, correct the reference of Table 1 to Table 1-4. (2X)

Organization	Yes or No	Question 4 Comment
		9. On Page 13, Section F, correct the reference of Table 1 to Table 1-4. (1X) 10. On Page 14, Section G, correct the reference of Table 1 to Table 1-4. (3X) 11. On Page 14, Section G, change the text "The first maintenance activity" to The capacity testing activity". 12. On Page 14, Section G, change the text "The second maintenance activity", to The internal ohmic measurement activity". 13. On Page 14, Section H, correct the reference of Table 1 to Table 1-4. (1X) 14. On Page 17, Section C, correct the reference of Table 1 to Table 1-5. (1X) 15. Please address what is meant by "Battery terminal connection resistance" on Page 14, Table 1-4 of the standard.
Response: Thank you for your comments. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
US Bureau of Reclamation		No Comment
Alliant Energy	No	
LCRA Transmission Services Corporation	Yes	
MidAmerican Energy	Yes	The Frequently Asked Questions should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Response: Thank you for your comments. NERC establishes that only the Standard is mandatory and enforceable, and Section F of the standard introduces this (and the Supplementary Reference Document) as presenting supporting discussion. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The introductory area of the Supplementary Reference Document will be revised to address your concern.		
Ameren	No	This document is helpful.
Xcel Energy	Yes	The changes in the standard and edit attempts on the FAQ have created some problems and confusion. Examples; The new FAQ I.1 answer does not make sense "An entity needs to and perform ONLY time-based

Organization	Yes or No	Question 4 Comment
		. . .” FAQ II.1.A: Requirement R1 no longer contains the statement that “use voltage, current, or phase angle to detect anomalies” so the answer to this FAQ is now out of synch with the standard. FAQ II.2.B – “Restoration” is no longer in the PMSP and has been changed to “Restore” and R4.3 no longer exists. FAQ II.2.I and II.2.J answers also references non-existent requirement R4.3. These are just some examples of fidelity issues that have been created by the most recent edit of PRC-005-2 – we did not perform a review of the entire document. The SDT should be commended for its efforts on the FAQ document as it is exceedingly helpful and well written. However, it needs to be brought back into alignment with the Standard. It is apparent that this fidelity check between the standard and the FAQ was not done prior to this posting. Finally, it seems some FAQs would be warranted to help explain the intent of new requirements R1.5 and R4.2 especially in regards to non-quantifiable maintenance results such as battery visual inspection as well as to provide examples of “other equivalent parameters” acceptance criteria for the various component types included in the Protection System definition

Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Many commenters disagreed with Requirement R1, Part 1.5 which was added in the previous draft; in response, the SDT removed Requirement R1, Part 1.5 from the standard. Commenters also observed that Requirement R1, Part 1.4 was redundant with Requirement R2, and the SDT removed R2 in response to these comments. Many commenters objected to 4.2.5.5 in the Applicability Section; the SDT removed this clause.

Organization	Yes or No	Question 5 Comment
Pepco Holding Inc & Affiliates	Yes	1. What "specific statistical data" was used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays? Comments were previously submitted that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." The 3 month interval is very burdensome and our experience does not appear to justify. A longer interval should be reconsidered.
Response: Thank you for your comments. The SDT reasserts that the 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays. If an entity's experience is that these components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.		
Pacific Northwest Small Public Power Utility Comment Group	No	
Tennessee Valley Authority	Yes	1R4 - "Identification of the resolution" and "Initiation of the resolution" are very distinct activities. In other places in this standard the requirement is for the resolution to be initiated, that is identified in a corrective maintenance work order, "identification of a resolution" requires technical expertise and can be difficult to track and might change over time for a particular problem. Proposed Change: Change "identification" to "initiation" in phrase "including identification of the resolution...". Overall: NERC is making significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting

Organization	Yes or No	Question 5 Comment
		"NO" because of the hurried fashion it is being commented, voted, and reviewed.
Response: Thank you for your comments. Requirement R4 has been revised.		
Northeast Power Coordinating Council	Yes	1. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 2. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)..." not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 3. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 4. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 5. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 6. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 7. A control circuit is not a component, it is made up of components.

Organization	Yes or No	Question 5 Comment
		8. Sub-requirement 1.5 needs to be clarified. It is not clear what “Identify calibration tolerances or other equivalent parameters...” means, and may be subject to different interpretations by entities and compliance enforcement personnel. 9. In the Implementation plan for Requirement R1, recommend changing “six” to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 10. The ‘box’ for “Monitored Station dc supply...” in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 11. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards. 12. The Drafting Team must respond to the following concerns raised in the FERC NOPR, Docket No. RM10-5-000, Interpretation of Protection System Reliability Standard, December 16, 2010) to “prevent a gap in reliability”. a. Any component that detects any quantity needed to take an action, or that initiates any control action (initial tripping, reclosing, lockout, etc.) affecting the reliability of the Bulk-Power System should be included as a component of a Protection System, as well as any component or device that is designed to detect defective lines or apparatuses or other power system conditions of an abnormal or dangerous nature and to initiate appropriate control circuit actions. b. The exclusion of auxiliary relays will result in a gap in the maintenance and testing of Protection Systems affecting the reliability of the Bulk-Power System. c. Excluding the maintenance and testing of reclosing relays will result in a gap in the maintenance and testing of relays affecting the reliability of the Bulk-Power System. d. Not establishing the specific requirements relative to the scope and/or methods for a maintenance and testing program for the DC control circuitry that is necessary to ensure proper

Organization	Yes or No	Question 5 Comment
		operation of the Protection System, including voltage and continuity.

Response: Thank you for your comments.

1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need be prescribed. If an entity's experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.**
2. **The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.**
3. **According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. As a regional entity, you can specify Supplementary regional requirements to maintain these devices more frequently if you desire.**
4. **With respect to dc supply associated only with communications systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**
5. **The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms as used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.**
6. **As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition**
7. **For purposes of this standard, the control circuit IS defined as one component type.**
8. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary. Therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
9. **In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.**
10. **Table 1-4 has been further modified for clarity**
11. **In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**

Organization	Yes or No	Question 5 Comment
12. The FERC NOPR is a notice-of-proposed-rulemaking and is not yet a directive. At such a time as a directive is published, NERC will take the necessary actions to address it.		
Platte River Power Authority System Maintenance	Yes	1. Please clarify what is required by R1.5: Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities required. Is the intent a brief summary for each component type in the PSMP that would cover all equipment within that component type, or is it a detailed list of each piece of equipment within each component type? 2. The inclusion of dated check-off lists in M4 provides much needed clarity to the list of evidence.
Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. Thank you for your support.**		
Electric Market Policy	Yes	1. The draft to PRC-005-2 contains defined terms that upon approval will remain with the standard rather than being moved to the Glossary of Terms. These terms when used in the Requirements are not designated in any way (e.g., capitalization, bold, etc.) to point the reader back to the in-standard definition. 2. Need to explicitly state the intent of the SDT to either (1) use the newly defined term “Protection System (modification)” only in this standard (PRC-005-2) or (2) replace the existing definition of the existing term in the “Glossary of Terms Used in NERC Reliability Standards” with the proposed definition for the existing term. 3. The language used in Footnote 1 on Attachment A does not agree with the definition of Countable events provided elsewhere in the draft standard. Suggest footnote be removed. 4. Requirement R1.5 uses the phrase “or other equivalent parameters” which is confusing. Suggest replacing with “or acceptance criteria.” Requirement R1.5 should read as follows: “Identify calibration program.” The currently proposed language focuses on specific calibration tolerances and acceptance parameters. These tolerances are developed on a per device, per location basis and would be captured at a procedural level, not a program level. To add this at a program level would only complicate the program and would not lend any improvement to the reliability of the bulk electric system. We recommend maintaining a general calibration requirement, similar to what is stated above, for an entity to develop their calibration program. 5. Requirement 2 Component should be replaced with Component Type. Creating a program to monitor the

Organization	Yes or No	Question 5 Comment
		equipment at this level of equipment would not add any value to the bulk electric system as all components should already be included in component type maintenance tasks. Recommend removing the definition of Component. 6. The requirement to address “monitoring attributes” in Requirement 2 for time based maintenance program is unclear, onerous and unnecessary for a reliable protection system program. 7. Requirement (R4) should identify correctible maintenance issues not the resolution of these issues. The language in R4.2 should strike correcting maintenance issues related to R1.5 and instead state: Any maintenance correctible issues found during the maintenance activity should be identified” 8. Table 1.2 change time frame from 3 months to 3 years.
Response: Thank you for your comments. **1. The standard capitalizes defined terms only when they refer to terms which are (or will be) in the NERC Glossary of Terms. Terms will generically be capitalized when appearing at the beginning of a sentence or within a title, in accordance with common editorial practice.** **2. The statement of the definition has been revised in the standard as “NERC Board of Trustees Approved Definition”, but will remain in the posted draft standard until it is successfully balloted for the convenience of stakeholders.** **3. The footnote has been removed.** **4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **5. The SDT disagrees; monitoring attributes must be present on the individual components as actually installed, not to the overall component type.** **6. The SDT believes that the verifiable presence of the monitoring attributes on the individual components as installed is a necessary element of using the extended maintenance intervals that result from the monitoring. If you consistently use specific monitoring attributes on all components within a group, they may be able to address these attributes on a global basis. If an entity does not wish to document these attributes, they are free to apply the maintenance intervals and activities specified for the unmonitored components.** **7. Requirement R4 has been revised. The SDT believes it important that the entity initiate resolution of maintenance correctable issues, in addition to simply identifying them.** **8. The SDT believes that the 3-month interval is proper for verification of the functionality of unmonitored communications systems.**		
Bonneville Power Administration	Yes	Some of the maintenance tasks need to be defined: 1. The state of charge of each individual cell may need to be better defined. There are means to verify the

Organization	Yes or No	Question 5 Comment
		state of charge of the entire bank, but not each individual cell. 2. Battery continuity needs to be defined.- There is no mention to what the limits are for the "other equivalent parameters" when performing maintenance activities, just that they need to be identified. There are a large number of battery models which creates a large contrast of parameters, which cannot be grouped together. It is also difficult to get baseline values for older battery models which could result in moving baselines until they become more accurate as the database is populated. 3. If corrective actions are required, is there a maximum allowable duration for when they need to be resolved? 4. The maximum allowable maintenance for station batteries (impedance testing and performance/service testing) is too frequent and suggest an extension or alternative testing methods to stay in compliance. The frequency with which BPA performs the 18 month maintenance tasks as prescribed in the standard are on a 24 month interval along with visual inspections and voltage measurements monthly.BPA has seen success with this maintenance program with the ability to identify suspect cells or entire banks with adequate time to perform corrective actions such as repairs or replacements. 5. BPA also does not perform routine capacity testing, this is an as required maintenance task to confirm/validate our other test results if needed. BPA would like to see clarification for these issues before we can fully support this standard.
Response: Thank you for your comments. **1. Table 1-4 has been revised to remove “state of charge” from the activities.** **2. This is thoroughly discussed in Section 15.4 of the Supplementary Reference Document.** **3. No. The SDT appreciates that some corrective actions for maintenance correctable issues may take an extended period of time to complete, and has therefore not included completion of the corrective actions within PRC-005-2.** **4. The SDT believes that the 18-month interval is proper for these activities.** **5. For vented lead-acid and valve-regulated lead batteries, alternative activities are specified if desired instead of capacity tests. If Ni-Cad batteries are used, capacity tests are required.**		
Santee Cooper	No	We do not agree with the addition of Requirements 1.5 and 4.2 without work on or review by the Power System Maintenance and Testing Drafting Team. While some maintenance activities on some component types (such as calibration testing of electromechanical relays) translate inherently well into these requirements, the requirements of tolerances and documentation do not fit as well to all maintenance activities on other types of equipment considered part of the protective system. These requirements need to

Organization	Yes or No	Question 5 Comment
		be worked on through the drafting team to make them viable and effective for all protective system component types.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
NERC Staff	Yes	1. Commissioning (Initial) Testing: During development of PRC-005-2, NERC staff has observed a trend in system disturbances involving Protection System problems that should have been identified and corrected during commissioning (initial) testing. While NERC staff recognizes that the addition of commissioning testing may be unrealistic at this stage in the standard drafting process, we want to emphasize its importance. If the SDT chooses to leave commissioning testing out at this juncture, we plan to pursue other avenues to ensure its eventual inclusion through a separate standards project. NERC staff agrees with the SDT's opinion that without commissioning testing, a registered entity responsible for compliance with this standard cannot provide proof of its interval testing period as required by the standard. As soon as the entity puts the protective scheme into service, time "0" for interval testing begins. The next testing interval would be some specific number of years in the future from time "0. "An entity's failure to properly commission new protection system equipment has caused or exacerbated several recent events, greatly impacting BPS reliability. The following are examples of errors that were not detected during commissioning. These undetected errors were observed by NERC staff during event analysis and investigation activities: oFailure to apply correct relay settings. This has occurred repeatedly and has been due to improper procedures, poor document control, misapplication or miscalibration of the relay, or a combination of the above. oFailure to install the proper CT or PT ratio occurred due to poor document control practices and resulted in an undesired protection system response after the equipment was placed in service. oFailure to conduct a functional test of new control circuits to the schematic diagram resulted in an undesired protection system response after equipment was placed in service. oAn incorrect CT ratio was not detected during commissioning, and the equipment was subsequently placed in service. Because in-service testing was not performed, the error remained undetected until the relay misoperated during a fault. Many of the above conditions can remain undetected for extended periods, until they are revealed by a

Organization	Yes or No	Question 5 Comment
		relay misoperation during fault or heavy load conditions. The affects resulting from these cases could have been prevented with proper commissioning testing. We believe that by requiring commissioning testing for new protection system equipment, the reliability of BPS would be improved. 2. Requirement 2:In Requirement 2, it is unclear what is meant by “shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5 in its PSMP” because the use of terms in the Requirement is not consistent with the column headings used in Tables 1-1 through 1-5. It also is not clear that components need not possess all attributes; rather, they must possess all attributes consistent with the Maximum Maintenance Interval specified in an entity’s PSMP. NERC staff recommends revising R2 to provide additional clarity as follows:”Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems described in Tables 1-1 through 1-5, shall verify those components possess the monitoring attributes Component Attributes identified in the first column of Tables 1-1 through 1-5 consistent with the Maximum Maintenance Interval specified in its PSMP.”
Response: Thank you for your comments. **1. Thank you for your comments.** **2. Requirement R2 of the standard has been modified as you suggested.**		
FirstEnergy	Yes	REQUIREMENTS 1. Requirement R1 - Subpart 1.5 - We do not support this subpart for the following reasons and offer the following suggestions: To satisfy R1.5, a calibration tolerance or other equivalent parameter would have to be established for each item included in the definition. Many devices which may have similar functionality may also have different performance criteria that would preclude the use of a "one size fits all" calibration tolerance. Many of these criteria are provided by the manufacturer and often vary by manufacturer for a similar device. It would be very difficult to specify in your program all of the calibration tolerances or other equivalent parameters associated with the protection system components. Therefore, we suggest the team delete Subpart 1.5 of Req. R1, and revise Subpart 4.2 of Req. R4 to read: "Initiate resolution of any identified maintenance correctable issues at the conclusion of maintenance activities for Protection System components." IMPLEMENTATION PLAN 2. On pg. 2 of the implementation plan, under "Retirement of Existing Standards", the statement "The existing standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2" is not accurate. Since the new PRC-005-2 standard allows for at least 12 months

Organization	Yes or No	Question 5 Comment
		to become compliant with Requirement R1 - establish a Protection System Maintenance Program (PSMP) -the existing standards are still effective during this time. Additionally, we have concerns with the "General Considerations" describing protocols for compliance audits conducted during the allowed 12 month development period of the PSMP and that entities could specify for "each component type" whether maintenance of that component is being performed according to its maintenance program under the "retired" PRC maintenance standards or the new PRC-005-2 standard. In our view, this creates a level of compliance complexity for both the Registered Entity and Regional Entity that should be avoided in the transition to PRC-005-2. FirstEnergy proposes that the Implementation Plan state that the existing standards remain in effect for one year past applicable approval (NERC Board or Regulatory) and that they are retired coincident with the one-year transition to Requirement R1 of PRC-005-2 which would establish all Registered Entities having a new PSMP per the expectations of PRC-005-2. At that time all entities would be required to be under the new PRC-005-2 standard and begin implementing their PSMP per the phased-in Implementation Plan for the remaining requirements. To summarize, per our above discussion we propose the team perform the following:1. Revise the Implementation Plan section titled "Retirement of Existing Standards" section to read as follows: "The existing Standards PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired on the first day of the first calendar quarter twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following the Board of Trustees adoption"2. Remove the entire "General Considerations" section from the Implementation Plan. 3. The bulleted item under the section titled "Implementation plan for R1" has a discrepancy in the time allowed to implement R1 between entities applicable to regulatory approval of the standard versus those in jurisdictions where no regulatory approval is needed and base their adherence per the Board of Trustee adoption. Please revise to reflect a 12 month transition period for each. DEFINITIONS 4. Maintenance Correctable Issue - This is a maintenance standard and this concept gets into the long term repair activities. Is this really appropriate in this standard? If NERC feels repairing is critical to BES reliability, then they should probably initiate a standard in that area. 5. Component - Regarding the phrase "local zone of protection", why is this in quotes? Is there a narrow definition for this? If so, this term should be defined also. DATA RETENTION SECTION 6. 1.3 Regarding the data retention for Req. R3 and R4, it is not practical to keep potentially 24 years of data for components that are maintained every 12 years. We suggest rewording this to "For R3 and R4, Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performances of each distinct maintenance activity for the Protection System components, or to the

Organization	Yes or No	Question 5 Comment
		previous scheduled audit date, whichever is longer". 7. ATTACHMENT A - FOOTNOTE 1This footnote regarding countable events needs to be revised to match the definition of countable events found at the beginning of the standard.
Response: Thank you for your comments. 1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** 2. **The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** 3. **The Implementation Plan for Requirement R1 has been modified as you suggest.** 4. **The SDT believes that the activities necessary to restore a Protection System component to proper service is an essential part of the PSMP. Please note that the related requirements only address initiation of the corrective actions, not completion, in deference to the extended period of time that some of these activities may take.** 5. **The quotes have been removed from the definition of component. However, the SDT believes that this term is a commonly-understood term within the industry.** 6. **In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.** 7. **This footnote has been removed.**		
Florida Municipal Power Agency	Yes	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and

Organization	Yes or No	Question 5 Comment
		may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Battery manufacturers typically do not provide this value and one manufacturer states that the baseline test are to be performed after the battery has been in regular float service for 90 days. It is unclear how to comply with the requirement for the initial 90 days. Additionally, we would recommend that this requirement be modified to permit an entity to establish a “baseline” value based on statistical analysis of multiple test results specific to a given battery manufacturer/model. Several commenters previously expressed their concerns with performing capacity tests. While this may just be an entity’s preference, allowing an entity to establish a baseline at some point beyond the initial installation period would give entities the option of using the internal resistance test in lieu of a capacity test. 5. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn’t seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to accidentally leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the

Organization	Yes or No	Question 5 Comment
		circuitry where this may not be the case is in the inter- and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. The interconnected nature of tripping circuits will make it difficult to count the number of circuits consistently for the purpose of calculating a VSL.

Response: Thank you for your comments.

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2**
3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them (which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve that gap.**
4. **Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.**
5. **Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.**
6. **The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.**

Organization	Yes or No	Question 5 Comment
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	1. The facilities listed in 4.2.5.5 include protection systems for "system connected" station service transformers associated with generators that are part of the BES. If a station service transformer is connected to a non BES bus then it would still fall under the PRC5 applicability requirements as written. The FAQs discuss relays associated with station auxiliary loads as not included in the program requirements. The non BES connected transformers should be included in that same category of equipment. 2. From the FAQ's - "Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could

Organization	Yes or No	Question 5 Comment
		result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit." Suggest the following added details be considered to be consistent with intent of BES connected facilities. Revise Description 4.2.5.5 as follows: "Protection systems for BES system connected station service transformers connected for generators that are part of the BES". 3. With respect to DC supply systems (batteries, chargers),the implementation plan is too aggressive. Some battery checks will have to be done on a 3 month interval, and entities will be required to be compliant with this new frequency in 1 Calendar year. This timeframe is unreasonable and needs to be pushed back to at least 2 years. 4. PSEG is also asking for clarification to the Supplementary reference document: On page 4, section 2.3 it states that the standard is designed to ONLY include "relays that detect a fault on the BES and take action in response to that fault". If PSEG is interpreting this correctly, this is a massive shift from the existing PRC-005-1 standard. The existing PRC-005-1 includes all distribution relays that trip a BES breaker to be part of the scope. In this revision, PRC-005-2 would exclude those distribution relays if they are designed to act for faults on the distribution system. PSEG would fully support this interpretation. PSEG would like this clarified and confirmed. This is very important.
Response: Thank you for your comments. **1. The Applicability of the draft Standard had been revised to remove "system-connected station service transformers".** **2. The FAQs have been merged into the Supplementary Reference Document; this discussion has been revised.** **3. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. Section 2.3 of the Supplementary Reference Document has been extensively revised, and the sentence to which you refer is no longer present. As for your comment, "The existing PRC-005-1 includes all distribution relays that trip a BES breaker to be part of the scope," the SDT believes that this is an element of a Regional practice regarding PRC-005-1, and entities should expect to comply with PRC-005 as established within the NERC Standard and further defined by Regional practice.**		
MRO's NERC Standards Review Subcommittee	Yes	1. In the Purpose statement delete "affecting" and replace it with "protecting". The purpose of the standard deals with systems that protect the BES. 2. In sections R1 and R4.2.1 delete "applied on" as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES.

Organization	Yes or No	Question 5 Comment
		3. The NSRS believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves not purpose. 4. The NSRS believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an "acceptable parameter" is and how it would be interpreted by the Regional Entities. 5. The NSRS believes that Article 4.2 needs to be deleted from the standard. There is no need for this article if Article 1.5 is deleted. 6. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS.4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is "applied on" or "designed to provide protection". According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of 'protecting" the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. 7. Section F Supplementary Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. 8. Table 1-4 Component Type Station dc Supply: o "Any dc supply for a UFLS or UVLS system" - This should not tied to the same testing interval as control circuits. The dc supply system is significantly different from control circuits and should have a maximum maintenance period as other dc supplies do. 9. Replace the words "perform as designed" on page 14 of Table 1-4 with "operate within defined tolerances." 10. Table 1-5 Component Type Control Circuitry: a. This table allows for unmonitored trip coils for UFLS or UVLS breakers to have "no periodic maintenance". "Unmonitored control circuitry associated with protective functions" should also have an exclusion for UFLS and UVLS circuitry that would allow for "no periodic maintenance". b. There is a concern that requiring the electrical testing and maintenance of Electromechanical trip or Auxiliary devices will force entire bus outages to be scheduled, which will compromise the BES

Organization	Yes or No	Question 5 Comment
		reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned" and therefore such testing will result in more outages than actual failures.

Response: Thank you for your comments.

1. **The "Purpose" is defined by the SAR.**
2. **Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.**
3. **The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components.**
4. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section for a discussion of this. The associated VSL has also been revised.**
5. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
6. **Applicability 4.2.1 has been revised to remove 'applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to Applicability 4.2.1. The Supplementary Reference Document has been revised to clarify.**
7. **The date in Clause F of the standard related to the Supplementary Reference Document has been revised.**
8. **The SDT disagrees. Station dc supply for UFLS/UFLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits.**
9. **"Tolerances" does not fully describe the parameters for maintenance of station dc supply; "perform as designed" is far more inclusive.**
10. **a. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document.**

    b. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals

Organization	Yes or No	Question 5 Comment
Western Area Power Administration	No	
TransAlta Centralia Generation Partnership	No	
NextEra Energy	Yes	The draft standard is too prescriptive. 1. Requirement R1, Part 1.5 would be overwhelming if approved. Requirement R1, Part 1.5 should be deleted. 2. Requirement R4, Part 4.2 phrase "established in accordance with Requirement R1, Part 1.5" should be deleted. The standard without these additional requirements would be sufficient to establish that the Protection System is maintained and protects the BES. 3. Table 1-2 Component Type Communications Systems Maximum Maintenance Interval of 3 Calendar Months to verify that the communications system is functional for any unmonitored communications system is unyielding. Most communication failures are caused by power supply failures which Next Era does monitor. Based on experience and monitoring of communication power supplies, 12 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 12 calendar months. 4. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to inspect electrolyte levels on “Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. Verifying battery charger float voltage every 18 calendar months is sufficient to prevent excessive gassing and water loss of battery cells. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months. 5. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to measure the internal ohmic values on “Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. With the standard’s requirement to verify the float voltage every 18 calendar months, measuring the internal ohmic values every 6 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months.
Response: Thank you for your comments. **1. 		activities.) Comment ->> This is too vague, broad, general and all encompassing. For example, what is the calibration tolerance for “control circuitry” which is made up of many things such as wiring, auxiliary relays, trip coils, etc. We currently have calibration tolerances on electromechanical relays but not on all components of a protection system (communications systems, voltage and current sensing devices, station dc supply, control circuitry). To try to identify calibration tolerances or other equivalent parameters for each of these components would be extremely difficult and time consuming. Clarification is needed on what components or parts of components require calibration tolerances. Another option is to remove this requirement. 3. Page 5, 4.5. (4.2. Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any identified maintenance correctable issues.)Comment ->> See comments above on 1.5. Clarification is needed on what is required to verify that the components are within acceptable parameters. We feel it should be adequate to provide a simple way to verify this requirement such as to include this in our maintenance procedure (equipment is to be left within tolerance), provide closed work order, show “checked” check box, provide a simple statement that this was completed, or etc. We feel that having to provide detailed data such as “as found” / “as left” values is too complicated and time consuming. Please clarify or consider removing this requirement. 4. Page 6, M.4. (“and initiated resolution”) Comment ->> Standard does not specify to “follow through” to completion. Is record of completion required? 5. Page 10, F.1 (July 2009) & F.2 (DRAFT 1.0 - June 2009) Comment ->> Need new dates and draft number. 6. Page 11 (For microprocessor relays, verify operation of the relay inputs and outputs that are essential ...) Comment ->> Does this require changing the state of the input contacts or can you just jumper voltage to the inputs and verify that the microprocessor relays acknowledged the change? 7. Page 17 (“Verify electrical operation(1)of EM trip and auxiliary devices(2).”) Comment ->> (1) Is it required to verify that trip and auxiliary device contacts change state? If so, please state as a requirement.(2) We recommend that this requirement only includes EM aux LO / tripping relays that trip interrupting devices directly. Other EM aux relays such as BFI aux. relays should be excluded. Please state this clearly in the Standard. Note that these aux relays such as BFI aux relays are included

Organization	Yes or No	Question 5 Comment
		in the "unmonitored control circuitry associated with protective functions" requirement and will be verified on a 12 year interval. (3) Please consider including an elementary diagram to show what is included. 8. Page 17 (Verify all paths of the control and trip circuits.) Comment ->> Clarification needed. Is it required to perform a full functional test, i.e. trip breakers? Or is reading DC across trip contacts all that is required? 9. Page 14 (Table 1.4) Change the maintenance interval for unmonitored station dc supply from "3 Calendar Months" to "4 times annually". This facilitates compliance to the standard by creating completion milestones for batteries at the end of each quarter of the year. 10. Page 15 (Table 1.4The standard requires the establishment of a battery baseline for cell/unit internal ohmic values and the comparison of impedance readings every 18 calendar months to that baseline. Due to the lack of original impedance readings at the time of installation of the battery. Since in many cases no such data is available; it needs to be made clear that establishing a baseline from , from manufacturer's data, the most recent impedance test, or the first impedance test completed after the adoption of the new standard is acceptable

Response: Thank you for your comments.

1. **No. Full resolution of maintenance correctable issues may require extensive work; the SDT intends that INITIATION of the resolution is all that is required per PRC-005-2.**
2. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 4. **No. Full resolution of maintenance correctable issues may require extensive work; the SDT intends that INITIATION of the resolution is all that is required per PRC-005-2.**
5. **The date has been revised.**
6. **The SDT believes that it would be sufficient to apply voltage to the input and observe that the relay responds accordingly.**
7. **1 – "Verify" means "Determine that the component is functioning correctly". The SDT intends that the device be electrically operated, but not that**

Organization	Yes or No	Question 5 Comment
additional verification be conducted during the electrical operation. However, the 12-year activity for unmonitored control circuitry would require verification of full functionality, including all of the related contacts. 2- The standard has been modified in consideration of your comment. 3 – An elementary diagram would be inappropriate in the standard. Additionally, the design of the control circuitry varies so widely from one application to another that it seems (to the SDT) that it would not be effective to include such an example in the Supplementary Reference Document. **8. The control circuitry can be tested in overlapping segments. It seems to the SDT that it is not necessary to trip the breakers with the functional test, as long as the entity performs the activities necessary to demonstrate that all overlapping segments will function properly.** **9. The SDT believes that your suggestion would not be effective in assuring periodic maintenance of the dc supply.** **10. The station battery baseline value is up to the entity to determine. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this.**		
Clark Public Utilities	No	
Exelon	Yes	1. In response to Exelon's comments provided to drafts 1 and 2 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. 2. In addition, although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant's routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity

Organization	Yes or No	Question 5 Comment
		or a self report of non-compliance. To ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. 3. In addition, Exelon has the following technical comments a. Sections 4.2.5.4 and 4.2.5.5 need to clearly state that only protection which affects the BES is within the scope of the PRC-005. b. There is not enough clarity in the statement “each protection system component type” for one to stay at the component level vs. dropping to sub-component level. If sub-components reviews are required, the effort becomes unmanageable. Therefore the Standard should identify calibration tolerances or other equivalent parameters. Suggest rewording to "each protection system major component type”
Response: Thank you for your comments. **1. If several different regulatory agencies have differing requirements for similar equipment, it seems that the entity must be compliant with the most stringent of the varying requirements. In the cited case, an entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant.** **2. The 18-month (and shorter) interval activities are activities that can be completed without outages – primarily inspection-related activities. An entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant.** **3. a. Applicability 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.** **b.The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Manitoba Hydro	Yes	1) We disagree with the requirements for battery maintenance outlined in table 1-4. In particular the requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience. 2) Also, the Implementation Plan is not consistent for areas requiring regulatory approval and areas requiring regulatory approval. The 6 month time frame proposed for R1 for areas not requiring regulatory approval is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective

Organization	Yes or No	Question 5 Comment
		date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval.
Response: Thank you for your comments. **1. The SDT believes that the 3-month interval specified in the standard is appropriate.** **2. In consideration of your comment, "6" has been modified to "12" in the Implementation Plan for Requiremnet R1.**		
Dynegy Inc.	Yes	For R1.5, we feel to much is being asked for since this information is not easilly controlled and the tolerances vary over time.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Oncor Electric Delivery Company LLC	Yes	Comment A: Oncor believes that Requirement R1 Part 1.5 of this Standard should be removed. It is too vague, intrusive, and divisive for what it brings to the reliability of the BES. Specifically it burdens all Transmission Owners, Generation Owners or Distribution Providers with the impossible task of having to "identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities." By definition a Protection System component type is "any one of the five specific elements of the Protection System definition" and "a component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device." What Requirement R1 part 1.5 with its associated High VSL in the Standard would decree is that all Transmission Owners, Generation Owners and Distribution Providers who "failed to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters" would be in violation of the Standard - with a High VSL. Oncor with over 98 years of Protection System maintenance experience feels that most Owners including itself would be non-compliant with this unclear, meddling and disruptive requirement no matter how long the implementation plan for the Standard is. Comment B: Oncor believes that in light of Comment "A" above Requirement R4 Part 4.2 must be modified to remove all references to Requirement R1 Part 1.5 of the Standard. The new requirement should be modified to read "Either verify that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct maintenance correctable issues." Also in order to assist both the owners and the compliance authorities who may question how one verifies that the components are within acceptable parameters the FAQ document should be modified to discuss how many

Organization	Yes or No	Question 5 Comment
		utilities are doing this with results that indicate either a pass or fail certified by the qualified persons performing maintenance. Comment C: Oncor feels that the wording “no less frequently than” found in Requirement R4 Parts 4.1.1 and 4.1.2 should be chanced back to the wording in the previous version of the Standard “not to exceed.” Comment D: Oncor recommends that in light of Comment “A” above Measure M1 be modified to remove all reference to Requirement R1 Part 1.5. Comment E: Oncor, as stated in Comment “B” above, recommends that the FAQ document be modified to provide more information on what could be used for evidence that the Transmission Owner, Generation Owner or Distribution Provider has “initiated resolution of identified maintenance correctable issues.” This will assist both the owners and the compliance authorities in answering the question of what constitutes proof that a maintenance correctable issue was identified. Comment F: The second and third paragraphs added under Compliance 1.3 Data Retention provide more information as to what data is required to be retained. Oncor feels that these two paragraphs will help the compliance authorities, the Transmission Owners, Generation Owners and Distribution Providers needed guidance of what is required for data retention.

Response: Thank you for your comments.

A. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

B. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

C. **“No less frequently than” was adopted on recommendation of NERC Staff as the preferred method of addressing this requirement.**

D. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

E. **The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**

Organization	Yes or No	Question 5 Comment
F. Thank you for your comment.		
Ingleside Cogeneration LP		The latest version of PRC-005-2 includes a new requirement (R1.5) to identify calibration tolerances or equivalent parameters that must be verified before a maintenance activity is considered complete. Although we understand the project team's intent, Ingleside Cogeneration LP is concerned that this requirement will lead to multiple interpretations of which tolerances or parameters are the most important. In addition, audit teams may expect to see certain values based upon their own sense of reliability. This is exactly the ambiguity that PRC-005-2 is trying to eliminate. In addition, calibration tolerances and reliability parameters may vary by equipment manufacturer or by configuration. It is not clear that documenting every scenario to demonstrate regulatory compliance is a benefit to BES reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Indiana Municipal Power Agency	Yes	Standard PRC-005-2 Draft 3 contains a section of "Definitions of Terms Used in Standard" that includes newly defined or revised terms uses in this proposed standard. There are a number of references made to these Terms in the Standard that are not capitalized. IMPA would propose that anywhere that the terms included in the "Definition of Terms Used" are used in the standard that they be capitalized. When any word is not capitalized in a standard then the common practice is to use the Webster Dictionary meaning. IMPA does not know why the SDT is reluctant to put these terms in the NERC Glossary of Terms, but by putting the terms in the glossary it would eliminate any confusion. When these terms are capitalized all registered entities will know that these are defined terms and will be able to consistently apply the definition without confusion. For example: 1.1 Address all Protection System component types would become1.1 Address all Protection System Component Types. If these terms are not capitalized in the standard (meaning they are not referring to the defined term) then the meaning of these terms could vary not only from utility to utility but also from Region to Region.
Response: Thank you for your comments. The standard capitalizes defined terms only when they refer to terms which are (or will be) in the NERC Glossary of Terms. Terms will generically be capitalized when appearing at the beginning of a sentence or within a title, in accordance with common editorial practice. If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.		

Organization	Yes or No	Question 5 Comment
South Carolina Electric and Gas		
Entergy Services	Yes	Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Duke Energy	Yes	1. We have previously commented that the FAQ and Supplementary Reference documents should be made part of this standard. If that cannot be done, then more of the information in those documents needs to be included in the requirements in the standard to provide clarity. Compliance will only be measured against what is in the standard, and we need more clarity. 2. R1.4 and R1.5 need more information to provide clarity for compliance. It's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. Either provide clarity or delete these requirements. 3. R4.2 - it is critical that more clarity be provided for R1.5 so that we can also understand what the compliance expectation is for R4.2 4. M4 - Need to clarify that these pieces of evidence are all "or", not "and" (i.e. any of the listed examples are sufficient for compliance). We reiterate the need for additional clarity on R1.5 and R4.2 such that compliance can be demonstrated for all component types. 5. Table 2 - We are fairly clear on the expectation for relays, but need more clarity on the expectation for other component types. Also, need to change the phrase "corrective action can be taken" to "corrective action can be initiated", consistent with the Supplementary Reference document.
Response: Thank you for your comments.		

Organization	Yes or No	Question 5 Comment
1. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. The SDT believes that entities should be able to implement the standard without the Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion/rationale/etc useful, particularly to assist them in implementing the standard in an efficient manner. **2. Requirement R1, Part 1.4 has been modified for clarity. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **4. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point.** **5. Table 2 has been modified to be clearer. "Taken" has been replaced with "initiated" in consideration of your comment.**		
Wisconsin Electric Power Company		
Independent Electricity System Operator	Yes	1. Requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and this may be subject to different interpretations by entities and compliance enforcement personnel. 2. Additionally, in the Implementation plan for Requirement R1, we recommend changing "six" to "fifteen" to restore the 3-month time difference between the durations of the implementation periods for jurisdictions that do and don't require regulatory approval, which existed in the previous draft. This change will ensure equity for those entities located in jurisdictions that do not require regulatory approval as is the case here in Ontario. More importantly it supports the IESO's strong belief in the principle that reliability standards should be implemented in an orderly and coordinated fashion across regions to ensure system reliability is not compromised.
Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference**		

Organization	Yes or No	Question 5 Comment
Document, Section 8 for a discussion of this. **2. In consideration of your comment, “6” has been modified to “12” in the Implementation Plan for Requirement R1.**		
American Electric Power		1. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. 2. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume knowledge of material in the Supplementary Reference or FAQ. 3. ”Protective relay” should be a defined term that lists relay function for applicability. There are numerous ‘relays’ used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 4. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.
Response: Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. The term, “condition-based” has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.** **3. “Protective relay” is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition within PRC-005. Further,**		

Organization	Yes or No	Question 5 Comment
the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2. **4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**		
ITC	Yes	1. We would like some further clarification on PRC-005-2 Draft 3, specifically on the statement in Table 1-4 for unmonitored station DC supply with VLA batteries. In the table it is mentioned that we are to perform either a capacity test every six years or verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline, the latter statement is a little vague and needs further clarification with regards to the expectations from the standard. Please describe an acceptable method of establishing a baseline “measured cell/unit internal ohmic value” We would like to know what exactly is required. We measure the cell internal ohmic value on an annual basis every 12 months, is that enough? What are the comparison parameters with regards to battery baseline? At what percent should we look to replace the cell? 2. Is a battery system that only supplies the SCADA RTU considered part of the protective system if alarms for the monitored protective systems utilize that SCADA RTU?
Response: Response: Thank you for your comments. **1. The station battery baseline value is up to the entity to determine. Please see Section 15.4.1 of the Supplementary Reference for a discussion of this.** **2. No. The Applicability of the standard limits the standard to only those devices within the Protection.**		
ISO New England Inc.		1. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 2. Why are “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)...” not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 3. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled “Unmonitored Control circuitry associated with protective functions”, which would include trip coils,

Organization	Yes or No	Question 5 Comment
		has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 4. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 5. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 6. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 7. A control circuit is not a component, it is made up of components. 8. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters..." means, and may be subject to different interpretations by entities and compliance enforcement personnel. 9. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 10. The 'box' for "Monitored Station dc supply..." in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation.

Response: Thank you for your comments.

1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for**

Organization	Yes or No	Question 5 Comment
compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option. **2. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.** **3. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You are free to maintain these devices more frequently if you desire.** **4. With respect to dc supply associated only with communications systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.** **5. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms as used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.** **6. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition** **7. For purposes of this standard, the control circuit IS defined as one component type.** **8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **9. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.** **10. Table 1-4 has been further modified for clarity**		
Nebraska Public Power District	Yes	Definitions: 1. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was

Organization	Yes or No	Question 5 Comment
		directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "and proper operation of malfunctioning components is restored." from the first sentence of the PSMP definition. I believe that failure to do so exceeds the scope of the SAR. 2. The definition of a Countable Event should clearly state whether or not multiple conditions on a single component will count as a single Countable Event or as multiple Countable Events. For example, a single relay fails its undervoltage setting and its under frequency setting. Is this one Countable Event or two Countable Events? 3. Applicability Part 4.2.2:The ERO does not establish underfrequency load-shedding requirements. Those requirements will be established by Reliability Standard PRC-006-1 when it is approved by FERC. I recommend changing Accountability Part 4.2.2. to "...installed to provide last resort system preservation measures." (Note this wording is consistent with the Purpose of PRC-006-0.)Applicability Part 4.2.5.4 and 4.2.5.5: 4. Station Service transformers provide energy to plant loads and not the BES. If these plant transformers are included, why not include the rest of the plant systems? I recommend deleting Applicability Part 4.2.5.4 and 4.2.5.5. 5. Requirement R1 Part 1.2: The wording of the first sentence is unclear about what information is required. For example, I could state in my PSMP that: "All Protection System component types are addressed through time-based, performance-based, or a combination of these maintenance methods" and be compliant with the Requirement. I recommend re-wording the first sentence to state: "Identify which maintenance method is used to address each Protection System component type. Options include time-based, performance-based (per PRC-005 Attachment A), or a combination of time-based and performance-based (per PRC-005 Attachment A)." Note that PRC-005 Attachment A does not address a combination of maintenance methods and therefore the second reference in the first sentence should be removed if the original wording is retained. 6. Requirement R1 Part 1.4: The column titles in Tables 1-1 through 1-5 have been revised to “Component Attributes” and “Activities”. I recommend changing "monitoring attributes" to "component attributes" and "maintenance activities" to "activities" to be consistent with the Tables. 7. Requirement R1 Part 1.5: Maintenance acceptance criteria for a given Protection System component type may very depending on the manufacturer, model, etc.. Including all acceptance criteria in the PSMP

Organization	Yes or No	Question 5 Comment
		document will over-complicate the program document. I recommend clarifying Part 1.5 to allow the incorporation of device-specific acceptance criteria in the applicable evidentiary documentation. One possible option is to add a second sentence as follows: "The calibration tolerances or other equivalent parameters may be included with the maintenance records." Note that a personal preference would be to use the phrase “acceptance criteria” instead of “calibration tolerances or other equivalent parameters”. 8. Requirement R4:The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "including identification of the resolution of all maintenance correctable issues" from the first sentence of the Requirement. I believe that failure to do so exceeds the scope of the SAR. 9. Requirement R4 Part 4.2: What is considered sufficient verification of parameters? Does this require an engineer or technician signature or simply an indication of pass/fail? The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend re-wording Requirement 4, Part 4.2 to state: "Verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities." I believe that failure to do so exceeds the scope of the SAR. 10. Measurement M2: Can a single specification document suffice for similar relay types such as one document for SEL relays? For trip circuit monitoring can a standard document be used for a group of

Organization	Yes or No	Question 5 Comment
		similar schemes ? 11. Measurement M4:I assume this is not an all inclusive list of potential forms of evidence. Please clarify what is meant by "such as". Does this mean that: 1) Any one item is sufficient?; 2) Certain combinations of evidence are necessary? If so, what combinations?; 3) Are other items that are not identified here acceptable? 12. Measurement M4 repeatedly refers to "dated" evidence. However, current audit expectations include either performer signatures or initials on the evidence in addition to the dates. Please revise Measurement M4 to clearly state the expectations regarding performer signatures or initials on the evidence documents. 13. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words: "and initiated resolution of identified maintenance correctable issues" from the last sentence of Measurement M4. I believe that failure to do so exceeds the scope of the SAR 14. .Compliance Part 1.3: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "performance-based" to "time-based" in the last sentence of the third paragraph. 15. The last paragraph of Part 1.3 of the Compliance Section states: "The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records." This appears to be a requirement of the Compliance Enforcement Authority however they are not identified in Section 4 Applicability of the Standard. It is also in conflict with the SAR Attachment B - Reliability Standard Review Guidelines which states on page SAR-10: "Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity." I recommend deleting the last paragraph of Part 1.3 of the Compliance Section to avoid conflict with the SAR. 16. Table 1-1: The Activity of row 1 states: “Verify operation of the relay inputs and outputs that are essential to ...” Please clarify what is meant by “operation of” the relay inputs and outputs. What is the criteria to determine if something is “essential”? The first line of row 2 has a double colon. Please delete one of

Organization	Yes or No	Question 5 Comment
		them. 17. For the second bullet of row 2 column 1, please clarify what is meant by the last part of this sentence "that are also performing self monitoring and alarming" and how it relates to the voltage and current sampling required. It appears the self monitoring is required in the first bullet. 18. For the first bullet of row 2 column 3, many relay settings may not be essential to the protective function of the relay. I recommend revising the first bullet to: "Settings that are essential to the proper function of the protection system are as specified." 19. The format of the Activities column for all three rows is different. Please reformat them to be consistent. My preference is the second row. 20. Table 1-2: Row 1 Column 2, verifying the functionality of communications systems on a 3 calendar months basis is excessive and unnecessary. Suggest changing the Maximum Maintenance Interval to either 6 calendar months or semi-annual. 21. Row 2 Column 1, please provide examples of typical communications systems that fit into this category, e.g. Mirror Bit or Guard systems? 22. The words "such as" are used repeatedly. Please clarify what is meant by "such as". Is this left up to the Utility to define in their PSMP? 23. Table 1-5: The Activity for row 1 requires verification that each trip coil is able to operate the device. If a control circuitry contains multiple trip coils, it is not always possible to determine which trip coil energized to trip the device. I recommend changing "each trip coil" to "at least one trip coil". 24. Please clarify what is meant by an "Electromechanical trip" device in row 3. 25. Row 3 column 3, does this mean verify the trip contact on the device operates properly but not verify the trip circuit wiring from this contact to the trip coil since the trip circuit is tested in the row below? It is difficult to separate the meaning in these two rows. 26. Row 4 column 3 requires verification of all paths of the control and trip circuits. Please clarify if this includes the control circuitry of Protection Systems located at the other end of a line if the device utilizes a remote trip scheme?

Response: Response: Thank you for your comments.

1. **Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.**

Organization	Yes or No	Question 5 Comment
2. The example cited would be one countable event. The definition has been modified to clarify. 3. Underfrequency load shedding requirements, whether established by Regional Entities (current practice) or by NERC, are ERO requirements. 4. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility. 5. Requirement R1, Part 1.2 has been modified essentially as you suggest. 6. “Monitoring attributes” are used within the respective tables; “Component attributes” can include monitoring or not. The Tables have been revised to specify “Maintenance Activities”. 7. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 8. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program. 9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 10. Yes. However, the degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point. The Measure M2 to which you refer has been deleted in conjunction with the deletion of the accompanying requirement. 11. Yes. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. “Such as” was not intended to be an all-inclusive list; additional examples are provided in Section 15.7 of the Supplementary Reference Document. The Measure has been modified to clarify this point. 12. Signatures, initials, etc, may not apply to all forms of evidence. “Dated” is more universal. 13. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program. 14. The portion of “Compliance” that referred to the Tables has been deleted. 15. The text to which you refer is part of the standard language for NERC Standards and reflects a general responsibility of the Compliance Enforcement Authority. The Compliance Enforcement Authority does not need to be indentified as an Applicable Entity. 16. If proper operation of an input or output is required such that the Protection System operate properly, it is “essential”. “Verify operation …” means		

Organization	Yes or No	Question 5 Comment
to determine that the component functions properly. The typo has been corrected. **17. The text to which you refer has been deleted in consideration of your comment.** **18. The SDT disagrees; settings beyond those "essential for proper function of the relay" may be essential to proper functioning of the monitoring, etc, which is used to extend the maximum maintenance interval of the relay.** **19. The SDT has arranged the format of each of the cells within the Maintenance Activities column for the best clarity within each individual cell.** **20. The SDT believes that the 3-month interval is proper for unmonitored communications systems.** **21. Examples such as you suggest may violate the NERC Anti-Trust Guidelines by appearing to favor specific proprietary technologies. Some examples may be found in Section 15.5 of the Supplementary Reference Document.** **22. "Such as" refers to examples pertinent to various equipment technologies, and thus are equipment-dependent, as opposed to entity-selectable. Some examples may be found in Section 15.5 of the Supplementary Reference Document.** **23. The SDT believes that each individual trip coil needs to be verified as required within PRC-005-2.** **24. "Electromechanical" refers to any device which has moving parts that respond to electrical signals, such as lockout relays and auxiliary relays. This row in Table 1-5 has been modified.** **25. Yes. The verification of the entire control circuitry is performed according to the following row in the Table, on a less-frequent interval.** **26. The testing of the "remote trip scheme" seems best characterized as testing of a "Communications System". Accordingly, testing of the remote station control circuitry is an independent activity.**		
CenterPoint Energy	Yes	(a) CenterPoint Energy cannot support this proposed Standard. Any standard that requires a 35 page Supplementary Reference document and a 37 page FAQ - Practical Compliance and Implementation document, in addition to extensive tables in the Standard, is much too prescriptive and complex to be practically implemented. (b) CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would "fix" non-existent problems. To clarify this last point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. (c) CenterPoint Energy is very concerned that a large increase in the amount of documentation will be required in order to demonstrate compliance - with no resulting reliability benefit. CenterPoint Energy

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>believes this Standard could actually result in decreasing system reliability, as the Standard proposes excessive maintenance requirements. The following is included in the Supplementary Reference document (page 8): “Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it.” System reliability can be even further reduced by the number of transmission line and autotransformer outages required to perform maintenance.

(d) The following is included in the FAQ - Practical Compliance and Implementation document: “PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.” CenterPoint Energy believes some proposed requirements, such as wire checking a relay panel, do not conform to this statement. CenterPoint Energy’s experience has been that panel wiring does not degrade with age and service and that problems with panel wiring, after thorough commissioning, is not a systemic issue.</td></tr>
<tr><td colspan="3">Response: Response: Thank you for your comments.
a. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document.
b. FERC Order 633 directed that NERC establish maximum maintenance intervals. Additionally, the SDT is directed to develop a measurable, effective continent-wide standard. Entities may continue their current practices as long as those practices meet the minimum requirements of this standard.
c. FERC Order 633 directed that NERC establish maximum maintenance intervals. The documentation required should not expand dramatically from the documentation currently required to demonstrate compliance. An entity may minimize hands-on maintenance by utilizing monitoring to extend the intervals.
d. The standard does not require “wire-checking”, but instead generically specifies “verification” – however an entity chooses to do so.</td></tr>
<tr><td>American Transmission Company</td><td>Yes</td><td>ATC recognizes the substantial efforts that the SDT has made on PRC-005 and appreciate the SDT’s modifications to this Standard based on previous comments made. ATC looks forward to continuing to have a positive influence on this process via the comment process, ballots and interaction with the SDT. ATC was very close to an affirmative vote on this Standard prior to the unanticipated changes that appeared in this most recent posting. These changes introduce a significant negative impact from ATC’s perspective.

Therefore, ATC is recommending a negative ballot in the hope that our concerns regarding R 1.5 and R 4.2 and other clarifications will be included with the standard The two items within the proposed Standard that we take exception to are not directly related to implementing FERC Order 693. Rather, it is the overly</td></tr>
</table>

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>prescriptive nature with respect to the “how” as outlined in the proposed Standard that ATC takes exception... To improve and find the proposed Standard acceptable, ATC would like to see the following modifications:

1. Change the text to require the actuation of a single trip coil (row 1 of table 1.5). This would satisfy the intent to exercise the mechanism on a regular schedule, given that the mechanism binding is a much more likely source of a coil failure. The balance of trip coils could then be tested as part of routine breaker maintenance.

2. Eliminate the additional requirements introduced by the addition of R1.5 and the associated modifications to R4.2. The additional documentation required for the range of each element is typically incorporated into the pass/fail mechanism of the existing test equipment (which is reflective of the manufacturer recommendations) used to conduct these tests. Therefore, requiring the assembly of this additional documentation from each entity would:

a. Be duplicative and voluminous as it would require us to track thousands of additional data points due to the variability in element ranges by relay manufacturer, model number and vintage.

b. Not add to the reliability of the system as this function is already being performed on a collective basis.</td></tr>
<tr><td colspan="3">Response: Response: Thank you for your comments.

1. The SDT believes that each individual trip coil needs to be verified as required within PRC-005-2.

2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.</td></tr>
<tr><td>Consumers Energy</td><td>Yes</td><td>1. Table 1-3 states, “are received by the protective relays”. Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc?

2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers.

3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete.</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
		The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the "verify the battery terminal connection resistance" activity?
Response: Response: Thank you for your comments. **1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** **2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.** **3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Section 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** **5. Re-torqueing the battery terminals would not meet this requirement.**		
Southern Company Generation	Yes	1. Please consider retaining the definitions stated to be moved to the NERC Glossary - they would be valuable to entities in the standard. 2. On Page 5, Section 1.2, please consider changing "or a combination of these maintenance methods (per PRC-005-Attachment A)." to "or a combination of these two maintenance methods." 3. On Page 5, Section 1.5: recommend deleting this section - the subjectivity of what is an acceptable value for component testing makes this requirement un-valuable. 4. On Page 5, Section 4.2, it is recommended that the requirement be the following: Either verify that the component performance is acceptable at the conclusion of the maintenance activities or initiate resolution of any identified maintenance correctable issue.

Organization	Yes or No	Question 5 Comment
		5. On Page 5, Measure M1, replace 1.5 with 1.4 (after eliminating Requirement 1.5) 6. On Page 6, Section 1.3, replace the existing Data Retention text with the following: The TO, GO, and DP shall each retain documentation for the longer of the these time periods: 1) the two most recent performances of each distinct maintenance activity for the Protection System component, or (2) all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date. The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records. 7. On Page 10, Section F, please correct the revision information for the documents listed. 8. On Pages 14 & 15, Table 1-4, move the bottom row to the next page so that it is easier to see that the maintenance activities are an “either/or” option. 9. On Page 17, Table 1-5, it seems that the 12 calendar year interval activities would automatically be included in the 6 calendar year activity for verifying the electrical operation of electromechanical trip and auxiliary devices. Is the 12 year requirement superfluous? 10. On Page 19, Attachment A, it is recommended to delete the footnote #1 since the definition is given already on Page 2.

Response: Response: Thank you for your comments.

1. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
2. **Requirement R1, Part 1.2 has been modified.**
3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
4. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Organization	Yes or No	Question 5 Comment
7. The Reference information has been corrected. **8. Table 1-4 has been revised.** **9. The 12-year interval activities are more extensive than the 6-year interval activities.** **10. Footnote #1 has been removed.**		
US Bureau of Reclamation	Yes	1. The concept of including definitions in this standard that are not a part of the Glossary of Terms will create a conflict with other standards that choose to use the term with a different meaning. This practice should be disallowed. If a definition is be introduced it should be added to the Glossary of Terms. This concept was not provided to industry for comment when the modifications to the Definition of Protection System were introduced. Additional related to this practice are included later on. 2. The Term "Protective Relays" is overly broad as it is not limited to those devices which are used to protect the BES. In the reference provided to the standard, the SDT defined "Protective Relays" as "These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. " The Definition for "Protective Relays" as well as the components associated with the them should be associated with the protection of the BES in the definition. 3. The Section 2.4 of the attached reference and the recent FERC NOPR are in conflict with the definition of "Protective Relays" which include lockout relays and transfer trip relays "The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. 4. This Draft 2: April3: November 17, 2010 Page 5 definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices." The definition should be revised to reflect that is really intended. The SDT as created an implied definition by specifically defining DC circuits associated with the trip function of a "Protective Relay" but failing to specifically define voltage and current sensing circuits providing inputs to "Protective Relays". The team clearly intended the circuits to be included but the definition does not since it only refers the "voltage and current sensing devices". 5. Starting with the Definitions and continuing through the end of the document, terms that have been defined are not capitalized. This leaves it ambiguous as to whether the defined term is to be applied or it is a generic reference. Only defined terms "Protection System Maintenance Program" and "Protection System" are consistently capitalized. 6. Protection System Maintenance Program (PSMP) definition: The Restore bullet should be revised to read

Organization	Yes or No	Question 5 Comment
		as follows: "Return malfunctioning components to proper operation by repair or calibration during performance of the initial on-site activity."Add the following at the end of the PSMP definition: "NOTE: Repair or replacement of malfunctioning Components that require follow-up action fall outside of the PSMP, and are considered Maintenance Correctable Issues." 7. Protection System (modification) definition: The term "protective functions" that is used herein should be changed to "protective relay functions" or what is meant by the phrase should become a defined term, as it is being used as if it is a well known well defined, and agreed upon term. The first bullet text should be revised to read as follows: "Protective relays that monitor BES electrical quantities and respond when those quantities exceed established parameters," the last two bullets should be reversed in order and modified to read as follows: o control circuitry associated with protective relay functions through the trip coil(s) of the circuit breakers or other interrupting devices, and o station dc supply (including station batteries, battery chargers, and non-battery-based dc supply) associated with the preceding four bullets. 8. Statement between the Protection System (modification) definition and the Maintenance Correctable Issue definition; Is this a NERC accepted practice? There does not appear to be a location in the standard for defining terms. Having terms that are not contained in the "Glossary of Terms used in NERC Reliability Standards," and are outside of the terms of the standards, and yet are necessary to understand the terms of the Requirements is not acceptable. They would become similar to the reference documents, and could be changed without notice. 9. Maintenance Correctable Issue definition: The last sentence should be modified to read as follows: "Therefore this issue requires follow-up corrective action which is outside the scope of the Protection System Maintenance Program and the Standard PRC-005-2 defined Maximum Maintenance Intervals." The definition could also be easily clarified to read "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration; therefore requires replacement." This ensures that any action to restore the equipment, short of replacement, is still considered maintenance. Otherwise ambiguity is introduced as what "maintenance" is. 10. Countable Event definition: An explanation should be made that this is a part of the technical justification for the ongoing use of a performance-based Protection System Maintenance Program for PRC-005. 11. Insert the phrase "Standard PRC-005-2" before the term "Tables 1-1..." 12. Applicability: 4.2. Facilities: 4.2.5.4 and 4.2.5.5: Delete these two parts of the applicability. Station service transformer protection systems are not designed to provide protection for the BES. Per PRC-005-2 Protection System Maintenance Draft Supplementary Reference, Nov. 17 2010, Section 2.3 - Applicability of New Protection System Maintenance Standards: "The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005: "...affecting the reliability of the Bulk

Organization	Yes or No	Question 5 Comment
		Electric System (BES)...”To the present language:”... and that are applied on, or are designed to provide protection for the BES.”The drafting team intends that this Standard will not apply to “merely possible” parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault.”Station Service transformer protection is designed to detect a fault on equipment internal to a power plant and not directly related to the BES. In addition, many Station Service protection ensures fail over to a second source in case of a problem. Thus station service transformer protection system is a power plant reliability issue and not a BES reliability issue. As such station service transformer protection should not be included in PRC 005 2.In addition; the SDT appears to have targeted generation station service without regard to transmission systems. If generating station service transformers are that important, then why are substation/switchyard station service transformers not also important? 13. B. Requirements Should the sub requirements have the "R" prefix? 14. R4.Change the phrase "... PSMP, including identification of the resolution of all ..." to read "...PSMP including identification, but not the resolution, of all ...". 15. General comment PRC005-2 is very specific in listing the maximum maintenance interval but is still very vague in listing the specific components to test. Suggest adding the following to the standard. a. A sample list of devices or systems that must be verified in a generator to meet the requirements of this Maintenance Standard: b. Examples of typical devices and relay systems that respond to electrical quantities and may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to: Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions Loss-of-field relays Volts-per-hertz relays Negative sequence overcurrent relays Over voltage and under voltage protection relays Stator-ground relays Communications-based protection systems such as transfer-trip systems Generator differential relays

Organization	Yes or No	Question 5 Comment
		Reverse power relays Frequency relays Out-of-step relays Inadvertent energization protection Breaker failure protection o lockout or tripping relays c. For generator step up transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program: Transformer differential relays o Neutral overcurrent relay Phase overcurrent relays 16. In the Lower, Moderate and Severe VSL descriptions, in addition to not being capitalized, the defined term Maintenance Correctable Issues should not be hyphenated. 17. In Attachment A Section 2 Page 51 should be modified as follows: 2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 until results of maintenance activities for the segment are available for a minimum of either 30 individual components of the segment or a significant statistical population of the individual components of a segment." Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number of components supports it. In Attachment A Section 5 Page 51 should be modified as follows: 5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population of the individual components of a segment maintained in the previous year. Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number components supports it. 18. In Attachment A Section 5 Page 52 should be modified as follows: 5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population

Organization	Yes or No	Question 5 Comment
		of the individual components of a segment components maintained in the previous year. Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number of components supports it.

Response: Thank you for your comments.

1. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
2. **"Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition within PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.**
3. **The issues raised by the FERC NOPR will be addressed as part of the response to the NOPR (and ultimately the Order). The extension to auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).**
4. **The extension to auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).**
5. **Definitions from the NERC Glossary of Terms (or those intended for the Glossary) are consistently capitalized (Protection System and Protection System Maintenance Program fall within this category). As for terms defined only for use within this standard, these terms are NOT capitalized, since they are not in the Glossary of Terms.**
6. **The "restore" portion of PSMP specifically addresses returning malfunctioning components to proper operation. The requirements regarding maintenance correctable issues are further addressed within that definition (for use only within PRC-005-2).**
7. **The SDT is currently not planning on further modifying the most recent NERC BOT-approved definition of Protection System.**
8. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
9. **Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to repair/replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstrate completion of them.**
10. **Since this term is used only in Attachment A, it seems unnecessary to provide the explanation requested.**
11. **The SDT has elected not to change the reference to the Tables throughout the standard.**
12. **Applicability 4.2.5.5 has been removed. Generator-connected station service transformers (4.2.5.4) are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.**
13. **The current style guide for NERC Standards does not preface the subparts with an "R".**
14. **Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to**

Organization	Yes or No	Question 5 Comment
repair/replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstrate completion of them. **15. The various specific components you suggest are addressed within the Facilities portion of the Applicability 4.2.5, as well as other components that satisfy the attributes within 4.2.5. These examples are in the Supplementary Reference Document (Section 8.1.3).** **16. Within the VSLs, the hyphenated term has been corrected.** **17. The SDT has determined that 30 individual components is the minimum acceptable statistically-significant population for use to establish performance-based intervals. Multiple entities may aggregate component populations to establish this component population, provided that the programs are sufficiently similar to make the aggregation valid. See Supplementary Reference Document Section 9 for a discussion.** **18. The SDT has determined that 30 individual components is the minimum acceptable statistically-significant population for use to establish performance-based intervals. Multiple entities may aggregate component populations to establish this component population, provided that the programs are sufficiently similar to make the aggregation valid. See Supplementary Reference Document Section 9 for a discussion.**		
Alliant Energy	Yes	1. In the Purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. 2. In sections R1 and R4.2.1 delete “applied on” as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES. 3. Alliant Energy believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves no purpose. 4. Alliant Energy believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. 5. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS.4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. We request clarification that the examples listed below do not constitute components of a BES Protection

Organization	Yes or No	Question 5 Comment
		System: 1. Older distribution substations that lack a transformer high side interrupting device and therefore trip a transmission breaker or a portion of the transmission system or bus, or 2. Newer distribution substations that contain a transformer high side interrupting device but also incorporate breaker failure protection that will trip a transmission breaker or a portion of the transmission system or bus. 6. Since distribution provider systems are typically radial and do not contain the level of redundancy of transmission or generation protection systems, it is not cheap, safe, maintaining BES reliability, or easy to coordinate companies to test these protection systems to the level of PRC-005-2 draft recommendations. 7. Section F Supplementary Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. 8. Table 1-4 Component Type Station dc Supply: a. “Any dc supply for a UFLS or UVLS system” - This should not have the same testing interval as control circuits, but should have a maximum maintenance period as other dc supplies do. b. Replace the words “perform as designed” on page 14 of Table 1-4 with “operate within defined tolerances.”Table 1-5 Component Type Control Circuitry: c. This table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. The PRC-005-2 Supplementary Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components. d. Alliant Energy is concerned that the addition of mandatory 86 and 94 auxiliary lockout relays (Electromechanical trip or Auxiliary devices) will force entire bus outages that will compromise the BES reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned” and therefore such testing will result in more outages than actual failures. An equivalent non-destructive test needs to be identified to allow entities to sufficiently trace and test trip paths without taking multiple substation line outages to physically test a lockout or breaker failure scheme.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. **1. The “Purpose” is defined by the SAR.** **2. Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.** **3. The SDT instead elected to remove Requirement R2.** **4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **5. Applicability 4.2.1 has been revised to remove ‘applied on”. The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to 4.2.1. The Supplementary Reference Document has been revised to clarify. PRC-005-2 would appear to apply to both cited examples.** **6. This is properly a concern to be addressed within the current SDT that is developing a revised definition of Bulk Electric System.** **7. The date in Clause F of the standard related to the Supplementary Reference Document has been revised.** **8. a. The SDT disagrees. Station dc supply for UFLS/UFLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits.** **b. “Tolerances” does not fully describe the parameters for maintenance of station dc supply; “perform as designed” is far more inclusive.** **c. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document.** **d. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals**		
LCRA Transmission Services Corporation	No	
MidAmerican Energy	Yes	1. MidAmerican remains concerned that including requirements for testing of electromechanical trip or auxiliary devices (Table 1-5 Row 3) will in some cases require entire bus outages that will compromise the BES reliability due to the need for entities across the US to take multiple BES elements out of service during the testing. If this requirement is retained additional time should be included in the implementation plan to allow for system modifications, such as the installation of relay test switches, to potentially allow

Organization	Yes or No	Question 5 Comment
		for this testing while minimizing testing outages. 2. Clarify that in the definition of Component Type that Transmission Owners are allowed the latitude to designate their own definitions for each of the Component Types, not just control circuits. 3. In the implementation schedule time periods are provided within which compliance deadlines and percentages of compliance are given. The following clarifications are recommended: 1. In calculating percentage of compliance for purposes of demonstrating progress on the implementation plan the percentages are calculated based on the total population of the protection system components that an entity has that fit the component category and allowable interval. 2. To obtain compliance with the percentage completion requirements of the implementation schedule an entity needs to have completed at least one prescribed maintenance activity of that component type and interval. 4. In the purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. 5. In sections R1 and R4.2.1 delete “applied on or” as unneeded and potentially confusing. The goal is to cover protection systems designed to protect. 6. Clarify the meaning of “state of charge” on page 14 in Table 1-4. 7. In Table 1-4 Component Type Station dc Supply, “Any dc supply for a UFLS or UVLS system” should have the same maximum maintenance period as other dc supplies. 8. Table 1-5 Component Type Control Circuitry, the table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. The PRC-005-2 Supplementary Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components.

Response: Thank you for your comments.

1. **The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.**

Organization	Yes or No	Question 5 Comment
2. For components other than control circuitry, the SDT believes that identification of the components as established within the draft Standard is appropriate. There is no latitude regarding component types. **3. The SDT believes that the Implementation Plan clearly agrees with your interpretation, and no clarification seems necessary.** **4. The "Purpose" is defined by the SAR.** **5. Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.** **6. Table 1-4 has been revised to remove "state of charge" from the activities.** **7. The SDT disagrees. Station dc supply for UFLS/UVLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits is appropriate.** **8. For the control circuitry of UFLS/UVLS, the relatively frequent breaker operations may not be reflective of proper functioning for UFLS/UVLS function. Therefore, minimal maintenance activities are necessary for these cases.**		
Ameren	Yes	(1) We believe that R1.5 and R4.2 "Calibration tolerances or other equivalent parameters" requirements should be removed. Neither the Supplement nor the FAQ address the expectation for them. While we agree that tolerances are needed and used, they need not be specified as part of this standard. (2) The Data retention is too onerous (a) For those components with numerous cycles between on-site audits, retaining and providing evidence of the two most recent distinct maintenance performances and the date of the others should be sufficient. Additionally, we are subject to self-certification, spot audits and/or inquiries at any time between on-site audits as well. (b) For those components with cycles exceeding on-site audit interval, retaining and providing evidence of the most recent distinct maintenance performance and the date of the preceding one should be sufficient. Auditors will have reviewed the preceding maintenance record. Retaining these additional records consumes resources with no reliability gain. (3) Definition of the BES perimeter should be included in accordance with Project 2009-17 Interpretation. (a)Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. (4)System-connected station service transformers (4.2.5.5) should be omitted, because (a) Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load. Omit 4.2.5.5 from the standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. (b) system-connected station service transformers in the same table as well as from table-to-table can be overwhelming. This would help keep Regional Entities and System Owners from

Organization	Yes or No	Question 5 Comment
		making errors. (5) Retention of maintenance records for replaced equipment should be omitted. FAQ II 2B final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We disagree with this because the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. (6) Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. (7) PSMP Implement Date should commence at the beginning of a Calendar year. This is the most practical way to transition assets from our existing PRC-005-1 plans. (8) Please clarify the meaning of “state of charge” for batteries. Does this mean specific gravity testing or what? (9) Please clarify that instrument transformer itself is excluded. Please clarify that the instrument transformer itself is excluded. The standard indicates that only voltage and current signals need to be verified in Table 1-3, but the recently approved Protection System definition wording can be mis-interpreted to mean they are included. FAQ 11.3.A is helpful.

Response: Thank you for your comments.

1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
2. **In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**
3. **When the interpretation (Project 2009-17) is approved, the SDT for PRC-005-2 will consider if the interpretation is appropriate for PRC-005-2 and**

Organization	Yes or No	Question 5 Comment
make associated changes. **4. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.** **5. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity. The SDT believes that entities should retain the evidence necessary to demonstrate compliance for the entire period reflected within Data Retention, and the discussion within the Supplementary Reference Document suggests that this includes records of retired equipment.** **6. The SDT believes that the 3-month interval specified in the Standard is appropriate.** **7. The guidance provided to the SDT provides that the implementation dates should begin on the first day of a calendar quarter.** **8. Table 1-4 has been revised to remove "state of charge" from the activities.** **9. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document.**		
Xcel Energy	Yes	1. Requirement R1.4 in part requires that the entity's PSMP includes all monitoring attributes to include those specified in Tables 1-1 through 1-5. Requirement R2 requires that entities that use maintenance intervals for monitored Protection Systems shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5. The intent and differences between these 2 requirements is unclear. If an entity does not choose to use monitored intervals, it makes no sense to require them to include the monitoring attributes identified in Tables 1-1 through 1-5 within their PSMP. Furthermore if an entity fails to meet requirement R1.4 for including identified monitoring attributes in its program, it will by default also have violated R2. There seems the possibility of double jeopardy between R1.4 and R2. The intent of R2 is fairly obvious but the intent of including monitoring attributes in R1.4 is not evident. Please provide a discussion within the FAQ to better explain the differences between these two requirements as they relate to monitoring attributes. 2. As written, requirement R1.5 and application of R1.5 acceptance criteria via requirement R4.2 would open entities up to vague interpretations by compliance personnel as to what constitutes adequate acceptance criteria – particularly in the area of subjective inspection results – e.g., battery cell visual inspections. We recommend that R1.5 be re-stated to clarify that acceptance criteria need only be provided for numerically measurable parameters. FAQs should be written to better explain the intent of R1.5 and to provide examples of acceptance criteria and to hopefully drive consistency amongst compliance personnel interpretation of acceptance criteria requirements. Consideration should be given to identifying which maintenance requirements in the Tables would generate quantifiable and measurable test results for which acceptance

Organization	Yes or No	Question 5 Comment
		criteria would be expected.

Response: Thank you for your comments.

1. **The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).**
2. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

END OF REPORT

Consideration of Comments on Non-binding Poll of VRFs and VSLs associated with PRC-005-2 – Protection System Maintenance (Project 2007-17)

The Project 2007-17 Drafting Team thanks all commenters who submitted comments on the non-binding poll of VRFs and VSLs associated with the proposed revisions to PRC-005-2. The standard and associated VRFs and VSLs were posted for a 30-day public comment period from November 17, 2010 through December 17, 2010, with a 10-day ballot beginning on December 10, 2010 through December 21, 2010. The stakeholders were asked to provide feedback on the VRFs and VSLs. There were 28 sets of comments, including comments from more than 46 different people from approximately 26 companies representing 6 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

Segment	1
Organization	Ameren Services
Member	Kirit S. Shah
Comment	The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: “Entity has failed to complete scheduled program on 1% to 5% of total Protection System components.” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties.
Response	**Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.**
Segment	1,3,6
Organization	American Electric Power, AEP Marketing

Comment	1. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL. 2. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. 3. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. 4. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what

	those three programs entail. These programs should be described within the standard itself and not assume knowledge of material in the Supplementary Reference or FAQ.
Response	**Thank you for your comments.** 1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** 2. **The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** 3. **If the indicated monitoring attributes are present, no “hands-on” periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.** 4. **The term, “condition-based” has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.**
Segment	1
Organization	Beaches Energy Services
Member	Joseph S. Stonecipher
Comment	The VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response	**Thank you for your comments. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity’s individual PSMP.**
Segment	3
Organization	City of Green Cove Springs
Member	Gregg R Griffin

Comment	1. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 2. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. 3. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the "baseline" values ought to be if an entity recently began performing this test (assuming it's several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design? 4. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control

	circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 5. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 6. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response	**Thank you for your comments.** **1. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.** **2. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.** **3. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.** **4. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **5. This interpretation is not yet approved. When this interpretation is approved, the SDT will**

	incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1. **6. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them (which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

Comment	VSL/VRF Ballot Comments: The Modified VSL's and VRF's – 1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. 4. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. 5. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 6. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response	**Thank you for your comments.** **1. Consideration of the VRFs, in association with the VRF Guidelines, yields the VRFs as established within the draft Standard.** **2. The SDT has reviewed the time horizons, and believes that Requirement R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components are performed within the related time period. The SDT concluded that Requirement R2 is redundant to Requirement R1 and has deleted Requirement R2 (together with the Measure and**

	VSL). 3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** 4. **Requirement R1 ‘Moderate’ appears to be similar to Requirement R1 ‘Lower’ as you suggest.** 5. **The SDT believes that, if more than two Protection System component types are not addressed, the ‘Severe’ VSL is appropriate.** 6. **The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**

Comment	1. Table 1-3 states, “are received by the protective relays”. Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not

	permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the "verify the battery terminal connection resistance" activity?
Response	**Thank you for your comments.** **1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** **2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2** **3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Section 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** **5. Re-torqueing the battery terminals would not meet this requirement.**

Comment	VSL R3. How do you measure a percentage of countable events over a period of time? How are you to determine what the total population to be considered? An entity should not be penalized if they are following their program, correcting issues, and documenting all actions, even if there is a high failure rate in an instance.
Response	**Thank you for your comments. Attachment A, to which Requirement R3 refers, specifies that countable events are assessed on the basis of "for the greater of either the last 30 components maintained or all components maintained in the previous year."**

Comment	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control

	circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response	**Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **2. This interpretation is not yet approved. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** 3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. Comment	The Violation Risk Factors should not be the same for all registered entities because the risk in a violation by a 20 MW wind farm connected at 115 kV is de minimis compared to that same violation at a 2,000 MW transmission substation or generator. The basic structure of this revision to PRC-005 is totally defective. Combining 4 standards that each have something to do with relays into one omnibus standard was wrongheaded. The Violation Severity Levels need to match the violation and four arbitrary categories cannot do so for the myriad of components, systems and varying numbers of them for one registered entity that are covered by this draft standard.
Response	**Thank you for your comments. The VRFs are not dependent on size, and must be assigned on a requirement-by-requirement basis.**

Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. the VRF of R1 should be Low since the attached tables are essentially the PSMP. 5. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the “baseline” values ought to be if an entity recently began performing this test (assuming it’s several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a

	given battery manufacturer and design? 6. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 7. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths.
Response	**Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **2. This interpretation is not yet approved. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.** **4. The SDT disagrees; the Tables establish the intervals and activities and Requirement R1 addresses the establishment of an entity's individual PSMP.**

	5. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending. **6. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.** **7. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.**

Comment	1. We disagree with the VRFs for R3, R4, and R5. R3, R4, and R5 are administrative requirements and duplicate to requirements in FAC-008 and FAC-009 that already require communication of facility ratings including those limited by relays. Thus, it should be Lower. 2. We disagree with the High VRF for Requirement R6 because the criteria in attachment will identify circuits that are not critical. If the criteria is modified per our comments on the standard and in the ballot, then we would agree with a High VRF. 3. Requirement R7 should be deleted as it represents double jeopardy. Thus, we do not agree with any VRF for it.

Comment	VRF's: The definition of a Medium Risk Requirement included on page 8 of the SAR states: "A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system." 1. The PSMP does not "directly" affect the electrical state or the capability of the bulk electric system. A failure of a Protection System component is required to "directly" affect the BES. Therefore, the PSMP has only an "indirect" affect on the electrical state or the capability of the BES. Requirements R1 through R3 and their subparts are administrative in nature in that they are comprised entirely of documentation. Therefore, I recommend changing the Violation Risk Factor of Requirements R1, R2, and R3 to Lower to be consistent with the Violation Risk Factors defined in the SAR. VSL's: 2. R2: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "condition-based" to "time-based" in all four severity levels. 3. SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with

	the SAR. 4. R3: The performance-based maintenance program identified in PRC-005 Attachment A provides the requirements to establish the technical justification for the initial use of a performance-based PSMP and the requirements to maintain the technical justification for the ongoing use of a performance-based PSMP. However, it appears the VSLs for Requirement R3 only addresses the ongoing use of the technical justification. I recommend revising the VSLs for R3 to include the initial use of the technical justification. a. Item 2) of R3 Severe VSL is a duplicate of Item 2) of R3 Lower VSL. This item is administrative in nature therefore I recommend deleting Item 2) from R3 Severe VSL. b. The first and third bullets of item 4) of R3 Severe VSL are administrative in nature and should be moved to the Lower VSL c. R4: SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with the SAR.
Response	**Thank you for your comments.** **1. Requirements R1, R2, and R3 are not administrative; they are foundational. Without the fundamental development of a PSMP, an entity is unlikely to actually implement a PSMP that satisfies the reliability needs of the BES.** **2. The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** **3. The guidelines within the SAR have been superseded by subsequent revisions to the VSL Guidelines. The VSLs in the draft standard adhere to the latest VSL Guidelines and to the June 19, 2008 FERC order on VSLs in Docket No RR08-04-000.** **4. Part a – The VSL for Requirement R3 has been modified in consideration of your comments.** **Part b – These requirements are not administrative; they are foundational. Without compliance with these requirements, an entity does not have an effective performance-based PSMP, and may be detrimentally affecting reliability.** **Part c – The latest VSL Guidelines also provide examples of VSLs similar to those in the draft standard.**

Member	Dennis Sismaet
Comment	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals

	introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response	**Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence".** **2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**

Comment	We disagree with the inclusion of the VSLs, VRFs, and time Horizons associated with the new Requirements 1.5 and 4.2
Response	**Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
Segment	5
Organization	U.S. Bureau of Reclamation
Member	Martin Bauer P.E.
Comment	The VSL levels are not consistent with the true impact on reliability. Severe levels are assigned for failing to document rather than failing to maintain components. Documentation requirements that are not met should not be assigned a Severe level. The concept of penalizing an entity for failed components without regard to why they failed is unreasonable. The severely levels should be based on avoidable failures or failures that could have been detected if the entity had performed maintenance.
Response	**Thank you for your comments.** **VSLs depict the level to which an entity has failed to comply with the standard; VRFs reflect the risk to the BES. Escalations within the VSLs specifically address more egregious (severe) violations of the standard in accordance with the NERC VSL Guidelines.**

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Consideration of Comments on Initial Ballot — Protection System Maintenance and Testing (Project 2007-17)
Date of Initial Ballot: December 10 – 20, 2010

Summary Consideration: Many commenters opposed R1 part 1.5 and the associated text, and the SDT responded by removing this text. Most of these comments were duplicates of those submitted in response to the formal comment period; the SDT responses are duplicated as well. Please see the Summary Consideration for each of the posted questions within the Consideration of Comments.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Voter	Entity	Segment	Vote	Comment
Rodney Phillips	Allegheny Power	1	Negative	Allegheny Power applauds the hard work that the Standards Draft Team has exhibited in producing a clear and enforceable standard that will increase the reliability of the Bulk Electric System. However, the addition of requirement 1.5 is such a significant change in scope from the last draft that a further review of the potential impact and any implementation concerns is required by AP and the industry in general before we can consider voting in-favor of this standard.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Kirit S. Shah	Ameren Services	1	Negative	(1)We believe that R1.5 and R4.2 “Calibration tolerances or other equivalent parameters” requirements should be removed. Neither the Supplement nor the FAQ address the expectation for them. While we agree that tolerances are needed and used, they need not be specified as part of this standard. (2)
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Paul B. Johnson	American Electric Power	1	Negative	Restructured Tables: 1) Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2) In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
				because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading “Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):” for the bullet points on this page. VSLs, VRFs and Time Horizons: 3) The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL. 4) All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. 5) In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference: 6) With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a) Section 5 of the Supplementary Reference, refers to “condition-based” maintenance programs. However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1.

Voter	Entity	Segment	Vote	Comment
				b) Section 15.7, page 26, appears to have a typographical error "...can all be used as the primary action is the maintenance activity..." c) Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. 7) "Frequently-Asked Questions": With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a) The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. b) Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. c) The second sentence to the response in Section I.1 appears to have a typographical error "... an entity needs to and perform ONLY time-based...". 8) General: a) Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. b) Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary

Voter	Entity	Segment	Vote	Comment
				Reference or FAQ. c) "Protective relay" should be a defined term that lists relay function for applicability. There are numerous 'relays' used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions.

Response: Thank you for your comments.

1. The 6-year activities are all related to components with "moving parts", and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected.
2. Table 1-4 has been modified in consideration of your comments.
3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.
4. The SDT concluded that Requirement R2 is redundant with R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).
5. If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.
6. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.
   A. The Supplemental Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplemental Reference document to clarify the manner in which condition-based maintenance is discussed.
   B. This clause has been corrected.
   C. A higher-quality version of Figure 2 has been substituted.
7. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

a) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
b) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
c) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference

Voter	Entity	Segment	Vote	Comment
Document as appropriate. The SDT considered your comments during this activity. 8. A) The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. B) The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used. C) "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.				
Jason Shaver	American Transmission Company, LLC	1	Negative	ATC recognizes the substantial efforts that the SDT has made on PRC-005 and appreciate the SDT's modifications to this Standard based on previous comments made. ATC looks forward to continuing to have a positive influence on this process via the comment process, ballots and interaction with the SDT. ATC was very close to an affirmative vote on this Standard prior to the unanticipated changes that appeared in this most recent posting. These changes introduce a significant negative impact from ATC's perspective. Therefore, ATC is recommending a negative ballot in the hope that our concerns regarding R 1.5 and R 4.2 and other clarifications will be included with the standard.
1. **Response**: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
John Bussman	Associated Electric Cooperative, Inc.	1	Negative	AECI want to thanks the team for the efforts being put forth by the drafting team. The table is much easier to follow and less confusing. AECI is voting negative because of the battery inspection intervals. 1. We have commented before about the 3 months being excessive and think it should be annually. However, with that being stated if you are going to use three months as the interval then that means inspections will have to be scheduled every 2 months to ensure the inspections happen every 3 months. Therefore AECI request that the battery inspection schedule be extended to every 4 months and then entities can schedule inspections to be performed every 3 months to ensure that the inspections are completed every 4 months.

Voter	Entity	Segment	Vote	Comment
				2. The same comment applies the the unmonitored communication circuits. Change the time interval to 4 months. Then scheduling can be every 3 months instead of every 2 months. 3. When you go to Table 1-4 there is confusion with the the DC for a UFLS or UVLS system. For the interval it states "When control circuits are verified" Then I go to Table 1-5 the second line that discusses trip coils for UFLS and UVLS the interval states "No periodic maintenance specified" Is this what was intended?
Response: **Thank you for your comments.** **1. The SDT believes that the 3-month interval is proper.** **2. The SDT believes that the 3-month interval is proper for unmonitored communications systems.** **3. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document**				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What we see as a problem is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves, in part, to ensure that the regionsl UFLS program is being met; but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution line breakers are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about nill. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that

Voter	Entity	Segment	Vote	Comment
				trips a BES Facility." 3. Applicability, 4.2. - does not reflect the interpretation of Project 2009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical.
Response: **Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.** **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1. in consideration of your comment.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**				
Donald S. Watkins	Bonneville Power Administration	1	Negative	Please see BPA's formal comments submitted on 12/16/10. Our concerns have not been adequately addressed.
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				
Paul Rocha	CenterPoint Energy	1	Negative	1) CenterPoint Energy cannot support this proposed Standard. Any standard that requires a 35 page Supplementary Reference document and a 37 page FAQ - Practical Compliance and Implementation document is much too prescriptive and complex. 2) CenterPoint Energy is very concerned that a large increase in the amount of documentation will be required in order to demonstrate compliance - with no resulting reliability benefit. CenterPoint Energy believes this Standard could actually result in decreasing system reliability, as the Standard proposes excessive maintenance requirements. The following is included in the

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td></td><td>Supplementary Reference document (page 8): “Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it.” System reliability can be even further reduced by the number of transmission line and autotransformer outages required to perform maintenance.

3) In addition, the following is included in the FAQ - Practical Compliance and Implementation document: “PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.” CenterPoint Energy believes some proposed requirements, such as wire checking a relay panel, do not conform to this statement. CenterPoint Energy’s experience has been that panel wiring does not degrade with age and service and that problems with panel wiring, after thorough commissioning, is not a systemic issue.</td></tr>
<tr><td colspan="5">Response: Thank you for your comments.
1. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate.

2. FERC Order 693 directed that NERC establish maximum maintenance intervals. The documentation required should not expand dramatically from the documentation currently required to demonstrate compliance. An entity may minimize hands-on maintenance by utilizing monitoring to extend the intervals.

3. The standard does not require “wire-checking,” but instead generically specifies “verification” – however an entity chooses to do so.</td></tr>
<tr><td>Jack Stamper</td><td>Clark Public Utilities</td><td>1</td><td>Negative</td><td>My no vote reflects my concern regarding the testing of Station DC Supply (Table 1-4) and Alarming Paths (Table 2). The SDT has provided much clarity to this standard in the testing requirements for relays, communication systems, voltage and current sensing devices, and control circuitry.

1. Table 1-4 is still confusing. There are five separate categories of unmonitored Station DC Supply testing requirements. It is unclear whether these categories are to be combined or if they are mutually exclusive. The first category applies to “Any unmonitored station dc supply not having the monitoring attributes of a category below” and appears to be a set of inspection and verification</td></tr>
</table>

Voter	Entity	Segment	Vote	Comment
				requirements that are generally applicable to all unmonitored Station DC Supplies. The next four categories are applicable to Station DC Supply with specified types of batteries. If a station has unmonitored vented lead-acid batteries, are the batteries ONLY subject to the testing requirements for VLA batteries? OR would these batteries ALSO be subject to the requirements of the first category? It appears that the intent is for all Station DC Supply not having any monitoring attributes to be tested and maintained in accordance with the first category as well as the second through fifth category that is applicable. If this is the case, the SDT should consider revising the Component Attributes in Table 1-4 for the first category of Unmonitored Station DC Supplies to the following: Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS). Station DC Supply devices applicable under these Table 1-4 general requirements will have additional testing requirements as described below for non-battery systems, VRLA battery systems, VLA battery systems, and Ni-Cad battery systems. 2. Do monitored batteries need to have all of the monitoring attributes listed or does having some of the monitoring attributes qualify a device as "Monitored?" The frequently asked questions examples on pages 30 - 32 seem to indicate that if only some of the items are monitored, the Station DC Supply is considered “Monitored” as long as other items are tested or verified. If this is the case, the SDT should consider revising the Component Attributes in Table 1-4 for the first category of Monitored Station DC Supplies to the following: Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2): o Station dc supply voltage (voltage of battery charger) o State of charge of the individual battery cell/units o Battery continuity of station battery o Cell-to-cell (if available) and battery terminal resistance. Monitored Station dc supply will have one or more of the above listed conditions monitored or alarmed with the remainder of the conditions subject to inspection and verification activities. 3. In Table 2, the first Component Attribute for Alarm Paths contains the requirement that “Alarms are automatically reported within 24 hours of DETECTION to a location where corrective action can be taken.” I believe the term “automatically” should be removed. This term implies an automated process without human intervention. However, many facilities (i.e. generator

Voter	Entity	Segment	Vote	Comment
				protection devices or manned substations) have protective devices that while not being subject to continuous monitoring, are visually inspected in daily or twice daily inspections. If protection devices have internal self-diagnostics that provide an alarm (i.e. failure indication on faceplate, relay interrogation, or LED failure indicator) and these devices are inspected one or more times per day, failures or malfunctions would be reported within the 24 hour DETECTION time. This appears to be within the intent of the standard which is to make sure that failed protective devices do not remain in failure longer than 24 hours without notification to a location where corrective action can be taken.
Response: **Thank you for your comments.** **1. Table 1-4 has been modified in consideration of your comments.** **2. Table 1-4 has been modified in consideration of your comments, and has been revised to remove "state of charge".** **3. "Automatically" has been removed from Table 2 in consideration of your comment.**				
Danny McDaniel	Cleco Power LLC	1	Negative	Cleco applies its' UFLS on the distribution grid with each UF relay individually tripping a relatively low value of load thru breakers and reclosers. Since our program is implemented via a large number of individual components, breakers, reclosers, and individual batteries, the failure of any one component will have a minimal impact on the effectiveness of the overall UFLS program within our region. Therefore, the verification of sensing devices, dc supply voltages, and the paths of the control circuit and trip circuits on the UFLS systems implemented on the distribution grid is unnecessary.
Response: **Thank you for your comments. The SDT disagrees; the sensing devices, control circuitry and dc supply related to UFLS has an effect on the performance of the UFLS. The SDT has, however, respected the overall impact on the control circuitry of individual UFLS on BES reliability by requiring that UFLS be subjected to a subset of the overall sensing devices, control circuitry and dc supply maintenance activities.**				
Paul Morland	Colorado Springs Utilities	1	Negative	CSU offers the following comments: 1. The document refers to the "BES" or "Bulk Electrical System" yet we have been unable to get a clear definition as to what that is. 2. 1.5 Because some calibration tolerances, such as communications schemes, change with the weather conditions, establishing tolerances could be difficult if the weather conditions are not factored into the tables. 3. 4.2.5.4 There needs to be a clear definition for "Station Service Transformers". 4. The reference to testing tolerances implies that test equipment must be calibrated to some standard, which this document does not discuss, and leaves a very wide interpretation for what this standard is, or the required calibration is required. 5. Table 1-3 Voltage and current devices may be connected to a meter and compared to a reference source to verify proper operation of the CT or PT. This seems to be at error in thinking that only microprocessor relays can be

Voter	Entity	Segment	Vote	Comment
				used to verify CT or PT's. Also in many PT's there is more than one winding and tap, or which this standard seems to imply that only one needs to be monitored to verify the correct function of all of the windings and taps. If I were to follow this logic, I only need to monitor one winding of a dual core CT.
Response: Thank you for your comments. 1. Bulk Electric System is defined by NERC, and further defined by the Regional Entities. Please refer to these definitions. 2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 3. Station Service transformer provide power to the auxiliary busses of generating plants. Some alternative names for these devices are "unit auxiliary transformers", "station auxiliary transformers", The SDT believes that these devices are commonly understood throughout industry and therefore require no definition. 4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 5. Table 1-3 does not prescribe how the voltage and current sensing device inputs to the protective relays shall be verified, just that they be verified according to the established intervals. Please see Section 15.2 of the Supplementary Reference Document for a discussion on this topic.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Negative	PRC-005 Initial Ballot Comments: 1. The Tables - The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices. 2. Other Comments - In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 3. Why are "Relays that respond to non-electrical inputs or impulses (such

Voter	Entity	Segment	Vote	Comment
				as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…" not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 4. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 5. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 6. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 7. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 8. A control circuit is not a component, it is made up of components. 9. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance

Voter	Entity	Segment	Vote	Comment
				enforcement personnel. 10. In the Implementation plan for Requirement R1, recommend changing “six” to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 11. The ‘box’ for “Monitored Station dc supply…” in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 12. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: Thank you for your comments.

1. The SDT believes that the table headings are appropriate as reflected in the draft standard.

2. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities’ experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.

3. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.

4. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire.

5. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to

Voter	Entity	Segment	Vote	Comment
eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 6. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable. 7. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition. 8. For purposes of this standard, the control circuit IS defined as one component type.. 9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 10. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan. 11. Table 1-4 has been further modified for clarity. 12. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
Robert W. Roddy	Dairyland Power Coop.	1	Negative	In Table 1-5 it is unclear which devices the Maximum Maintenance Intervals would be held to, such as trip coils of circuit breakers and coils of electromechanical trip or auxiliary relays whose continuity and energization are monitored and alarmed.
Response: Thank you for your comments. Trip coils of circuit breakers have a 6-year interval for physical operation. Coils of lockout and auxiliary relays also have a 6-year interval for physical operation. Control circuitry whose continuity and energization or ability to operate are monitored and alarmed require no hands-on maintenance.				
John K Loftis	Dominion Virginia Power	1	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				

Voter	Entity	Segment	Vote	Comment
George R. Bartlett	Entergy Corporation	1	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case, are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria....” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one" or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type....”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated

Voter	Entity	Segment	Vote	Comment
				documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Robert Martinko	FirstEnergy Energy Delivery	1	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting.
Response: **Thank you for your comments.** **Please see our responses to your comments from the formal comment period.**				
Gordon Pietsch	Great River Energy	1	Negative	1. We believe that requiring an entity to identify calibration tolerances in their PSMP does not add a material benefit and does not contribute to increased reliability. In addition we believe that R1.5 should be rewritten to state that a Relay test report should show when a Relay fell out of tolerance. R4.2 should be rewritten to state that if a test report does show that a Relay was out of tolerance it should be required to show that resolution was initiated. 2. The Activities section of Table 1.3 should be revised to include that the signals do not have to come from energized voltage or current sensing devices. The current or voltage signals can come from a test set. Note: It may be difficult to energize CTs or VTs for large capacitor banks, reactors, or generating units.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 2. Table 1-3 has been modified in consideration of your comments.				
Ajay Garg	Hydro One Networks, Inc.	1	Negative	Hydro One is casting a negative vote with the following comments: 1. The added requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and as written will be subject to different interpretations by entities and compliance enforcement personnel. The addition of this new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is onerous and contributes little to the reliability of the BES. 2. Changes introduced to the Implementation Plan since the last posting are not consistent with respect to jurisdictions where no regulatory approval is required. The previously posted implementation for Requirement R1 required entities to be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption. The amended implementation plan changed the three-month time to twelve months in jurisdictions with regulatory approval required but left the same six-month time for the others. For consistency, the six months timeframe should be changed to fifteen months.
Response: **Thank you for your comments.** **1. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.**				
Michael Moltane	International Transmission Company Holdings Corp	1	Negative	1. ITC votes "Negative" for the following reasons: Our negative ballot is based on our objection to the 6 year test interval for auxiliary relays. We believe our present maintenance period for auxiliary relays of 10 years is adequate. 2. We also object to the requirement to verify acceptable levels of current values are received by the protective relays. We believe our present current transformer testing practice adequately insures acceptable levels of current are received by the relays and have requested that this procedure be approved. Detailed comments are included with our

Voter	Entity	Segment	Vote	Comment
				responses to the 5 questions in the Comment Form associated with this proposed Standard revision.
Response: Thank you for your comments. 1. The SDT believes that the appropriate interval for devices such as aux or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable. 2. Please see our response in the Comment Form.				
Stan T. Rzad	Keys Energy Services	1	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td></td><td>that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the “baseline” values ought to be if an entity recently began performing this test (assuming it’s several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design? o Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating

Voter	Entity	Segment	Vote	Comment
				these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration to your comment.**
3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**
4. **The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity's individual PSMP.**
5. **Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.**
6. **The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.**

Joe D Petaski	Manitoba Hydro	1	Negative	1. Implementation Plan (Timeline) for R1: In areas not requiring regulatory approval, the 6 month time frame proposed for R1 is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval. 2. VSLs: The high VSL for R1 "Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5" may be interpreted in different ways and should be further clarified. 3. Table 1-4: The requirements for batteries listed in Table 1-4 do not appear to be consistent with the comments in the FAQ Section (V 1A Example 1). Please see comments submitted during formal comment period for further detail. 4. Table 1-4: The requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan. 2. The SDT does not understand your concern; further details are needed. 3. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 4. The SDT believes that the 3-month interval specified in the Standard is appropriate.				
Terry Harbour	MidAmerican Energy Co.	1	Negative	MidAmerican remains concerned that including requirements for testing of electromechanical trip or auxiliary devices (Table 1-5 Row 3) will in some cases require entire bus outages that will compromise the BES reliability due to the need for entities across the US to take multiple BES elements out of service during the testing. If this requirement is retained additional time should be included in the implementation plan to allow for system modifications, such as the installation of relay test switches, to potentially allow for this testing while minimizing testing outages.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Saurabh Saksena	National Grid	1	Negative	National Grid believes that this new Requirement as written subjects the Transmission Owner, Generation Owner or Distribution Provider to vague interpretations of what the requirement means by compliance officials. The addition of the new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Richard L. Koch	Nebraska Public Power District	1	Negative	1. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the

Voter	Entity	Segment	Vote	Comment
				applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "and proper operation of malfunctioning components is restored." from the first sentence of the PSMP definition. I believe that failure to do so exceeds the scope of the SAR. 2. Applicability Part 4.2.2: The ERO does not establish underfrequency load-shedding requirements. Those requirements will be established by Reliability Standard PRC-006-1 when it is approved by FERC. I recommend changing Accountability Part 4.2.2. to "...installed to provide last resort system preservation measures." (Note this wording is consistent with the Purpose of PRC-006-0.) 3. Applicability Part 4.2.5.4 and 4.2.5.5: Station Service transformers provide energy to plant loads and not the BES. If these plant transformers are included, why not include the rest of the plant systems? I recommend deleting Applicability Part 4.2.5.4 and 4.2.5.5. 4. Requirement R4: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "including identification of the resolution of all maintenance correctable issues" from the first sentence of the Requirement. I believe that failure to do so exceeds the scope of the SAR. 5. Requirement R4 Part 4.2: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis

Voter	Entity	Segment	Vote	Comment
				of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend re-wording Requirement 4, Part 4.2 to state: "Verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities." I believe that failure to do so exceeds the scope of the SAR. 6. Measurement M4: The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words: "and initiated resolution of identified maintenance correctable issues" from the last sentence of Measurement M4. I believe that failure to do so exceeds the scope of the SAR.

Response: **Thank you for your comments.**

1. **Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.**

Voter	Entity	Segment	Vote	Comment
2. Under frequency load shedding requirements, whether established by regional Entities (current practice) or by EC, are ERO requirements. **3. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.** **4. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) in included. The SDT considers the inclusion to be appropriate and necessary as part of the maintenance program.** **5. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **6. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) in included. The SDT considers the inclusion to be appropriate and necessary as part of the maintenance program.**				
David H. Boguslawski	Northeast Utilities	1	Negative	1) Requirement 1.5 states “Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities”. This requirement is too vague and requires that the owner develop his own acceptable calibration tolerances for “each” protection system component type. The Owners internally generated calibration tolerances would then be subjected to the personal interpretation of what this requirement means by compliance officials and auditors. The confusion and divisiveness that this requirement will create far outweigh its potential benefits. 2) Due to the critical nature of the trip coil, it should be maintained more frequently if it is not monitored. Hence, it would be prudent to increase the test frequency of unmonitored trip coil so that it is more frequent than monitored trip coil. 3) In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 4) In section D.1.3., the statement regarding data retention for R2 needs to be reworded. The words “performance based maintenance program” should be changed to “time based maintenance program”, since R2 refers to a time based maintenance program.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 2. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire. 3. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments have been considered within that activity. 4. The SDT concluded that R2 is redundant with R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL), and data retention that reflects the previous R2.				
Douglas G Peterchuck	Omaha Public Power District	1	Negative	The three newly added requirements not approved by the drafting team are confusing. 1. OPPD believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves no purpose. 2. OPPD believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. 3. OPPD believes that Article 4.2 needs to be deleted from the standard. There is no need for this article if Article 1.5 is deleted.
Response: Thank you for your comments. 1. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the SDT has revised R1.4 and has also removed R2 because of redundancy to Requirement R1, Part 1.4. 2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 3. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this..				
Chifong L. Thomas	Pacific Gas and Electric Company	1	Negative	1. PG&E submits a Negative vote on Draft 3 of PRC-005-2 due to the addition of Requirement R1, Part 1.5. We do not agree with the addition of Requirement R1, Part 1.5 to the standard, which requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type". We feel this is too prescriptive and does not belong in the PSMP which should remain at a higher level of detail. This new requirement, as written, can subject the Transmission Owner, Generation Owner or Distribution Provider to vague interpretations

Voter	Entity	Segment	Vote	Comment
				of what the requirement means by compliance officials. Additionally, the new requirement could require documenting thousands of calibration tolerances or other equivalent parameters for companies such as PG&E that use many different types of relays. This level of detail does not belong in the PSMP and would make it nearly impossible to manage. Rather, the calibration tolerances used to test the protection system components should reside in the Transmission Owner, Generation Owner and Distribution Provider's test procedure documents, test macros, or relay instruction manuals. PG&E also has comments on the Implementation Plan document. 2. PG&E does not agree with the time frames listed for implementation of Requirements R1, R2, R3 and R4, as explained below: a. Implementation plan for Requirement R1: Time was extended from three months to twelve months following regulatory approval which we agree with. For those jurisdictions where no regulatory approval is required it would seem that the time frame should also be extended to at least twelve months following NERC Board approval. However, it is still listed as six months following NERC Board approval. b. Implementation plan for Requirements R2, R3 and R4: For Protection System Components with maximum allowable intervals less than 1 year, it does not make sense to require 100% compliance after twelve months following regulatory approval, when this is the same time frame for compliance with Requirement R1 for establishment of the new PSMP. The implementation time window for Requirements R2, R3 and R4 should follow the implementation of Requirement R1 which establishes the new PSMP. So the dates listed for 100% compliance with Requirements R2, R3 and R4 should all be pushed out by 12 months each. c. Following is a summary time line for suggested implementation requirements. o Months 1-12 Establish PSMP per R1 i. Month 12+ Begin performing maintenance under new PSMP ii. Month 24 100% compliance date for R2, R3, R4, for components with max allowable intervals less than 1 year. iii. 3 Calendar Years 100% compliance date for R2, R3, R4, for components with max allowable intervals 1 year or more, but 2 years or less.

Voter	Entity	Segment	Vote	Comment
				iv. 3 Calendar Years 30% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. v. 5 Calendar Years 60% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. vi. 7 Calendar Years 100% compliance date for R2, R3, R4, for components with max allowable intervals of 6 years. 3. Overall the updated standard is a huge improvement over Draft 2 in terms of structure of the tables and presentation, which simplifies the standard quite a bit. PG&E would have been in support of Draft 3 if the requirement R1.5 had not been added.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. The Implementation Plan for R1 has been changed from six months to twelve months, and the Implementation Plan for Protection System Components with maximum allowable intervals less than 1 year has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for R4 has been revised to add one year to all established dates.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition and that Requirement R1, Part 1.5 is not necessary. Therefore, it has been removed. The associated VSL has also been revised.**				
Brenda L Truhe	PPL Electric Utilities Corp.	1	Negative	PPL Electric Utilities ("PPL EU") appreciate the hard work and efforts of the Standards Drafting Team in reaching this point in the standards development process. The basis for the negative vote is the addition of Requirement R1.5 (calibration tolerances) and R4.2 to the standard. This requirement will provide the opportunity for auditors to decide if the testing criteria for whether a relay passes a test or not is acceptable. PPL EU recommends that Requirement R1.5 be deleted from the standard.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Kenneth D. Brown	Public Service Electric and Gas Co.	1	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				

Voter	Entity	Segment	Vote	Comment
Pawel Krupa	Seattle City Light	1	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called "bookend" issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a

Voter	Entity	Segment	Vote	Comment
				separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasability exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence".** **2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
Horace Stephen Williamson	Southern Company Services, Inc.	1	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. Note: We have also made various requests for clarification to the FAQ and Supplemental Reference document in our Response to Comments which we are not including here.
Response: **Thank you for your comments. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				

Voter	Entity	Segment	Vote	Comment
Larry Akens	Tennessee Valley Authority	1	Negative	NERC is making significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting "NO" because of the hurried fashion it is being commented, voted, and reviewed.
Response: **Thank you for your comments. Because of the urgent priority placed on this Standard by NERC, this Standard was posted for a 30-day formal comment period with a concurrent 10-day ballot period at the conclusion of that comment period, even though the Standard Development Process allows for a maximum 45-day formal comment period.**				
Brandy A Dunn	Western Area Power Administration	1	Negative	1) Western disagrees with the requirement R1, Part 1.5 that requires identifying "calibration tolerances or equivalent parameters for each Protection System component~" This requirement will add a burdensome, manual documentation of thousands of tolerances and parameters that are now part of multiple automated software programs and routines. These programs were purchased and developed over numerous years of testing experience by Western and testing equipment manufacturers. The fact that these tolerance and parameters are automated to Pass/Fail program notifications, gives our Maintenance Divisions repeatable testing programs that are not dependent on personnel interpretations. Extracting all these tolerances and parameters from these programs provides no benefit for our PSMP. 2) Western disagrees with the wording of the R4.2 requirement referencing the Part 1.5 of R1. The requirements of R4 are that you are to perform the appropriate maintenance activity and the associated testing. The fact that the testing was done and the equipment passed the testing meets the compliance for R4. If the equipment fails the testing, it then becomes a maintenance correctable issue, that requires adjustment or replacing, with further testing until the equipment passes the required testing. Documenting thousands of tolerances and parameters, for possibly thousands of components, serves no useful purpose for our PSMP or compliance documentation.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Gregory L Pieper	Xcel Energy, Inc.	1	Negative	"We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments."
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				

Voter	Entity	Segment	Vote	Comment
Kim Warren	Independent Electricity System Operator	2	Negative	1. Requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and this may be subject to different interpretations by entities and compliance enforcement personnel. 2. Additionally, in the Implementation plan for Requirement R1, we recommend changing "six" to "fifteen" to restore the 3-month time difference between the durations of the implementation periods for jurisdictions that do and don't require regulatory approval, which existed in the previous draft. This change will ensure equity for those entities located in jurisdictions that do not require regulatory approval as is the case here in Ontario. More importantly it supports the IESO's strong belief in the principle that reliability standards should be implemented in an orderly and coordinated fashion across regions to ensure system reliability is not compromised.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan**				
Richard J. Mandes	Alabama Power Company	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. Bob Reeping	Allegheny Power	3	Negative	Allegheny Power applauds the hard work that the Standards Draft Team has exhibited in producing a clear and enforceable standard that will increase the reliability of the Bulk Electric System. However, the addition of requirement 1.5 is such a significant change in scope from the last draft that a further review of the potential impact and any implementation concerns is required by AP and the industry in general before we can consider voting in-favor of this standard.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Raj Rana	American Electric Power	3	Negative	Restructured Tables: 1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading “Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):” for the bullet points on this page. VSLs, VRFs and Time Horizons: 3. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL. 4. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. 5. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference:

Voter	Entity	Segment	Vote	Comment
				6. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. Section 5 of the Supplementary Reference, refers to "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. b. Section 15.7, page 26, appears to have a typographical error "...can all be used as the primary action is the maintenance activity..." c. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. "Frequently-Asked Questions": 7. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. b. Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. c. The second sentence to the response in Section I.1 appears to have a typographical error "... an entity needs to and perform ONLY time-based...". General:

Voter	Entity	Segment	Vote	Comment
				8. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. 9. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary Reference or FAQ. 10. “Protective relay” should be a defined term that lists relay function for applicability. There are numerous ‘relays’ used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 11. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.

Response: **Thank you for your comments.**

1. **The 6-year activities are all related to components with “moving parts”, and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected and additional changes have been made.**

2. **Table 1-4 has been modified in consideration of your comments.**

3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.**

Voter	Entity	Segment	Vote	Comment

4. The SDT concluded that Requirement R2 is redundant to Requirement R1, Part 1.4 and has deleted Requirement R2 (together with the Measures and & VSL).

5. If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.

6. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

   D. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

   E. This clause has been corrected.

7. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard.

   b) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
   c) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.
   d) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

9. The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.

10. "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.

11. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.

Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				
Steve Alexanderson	Central Lincoln PUD	3	Affirmative	WECC does not use the definition of the BES that NERC supplied to FERC via http://www.nerc.com/docs/docs/ferc/RM06-16-6-14-07CompFilingPar77ofOrder693FINAL.pdf, so the answer to FAQ III.1.3 (page 19-20) is not accurate.
Response: **Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**				
Gregg R Griffin	City of Green Cove Springs	3	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry.

Voter	Entity	Segment	Vote	Comment
				2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: **Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.** **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.** **4. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entity's individual PSMP.**				
Bruce Krawczyk	ComEd	3	Negative	The addition of the requirement R1.5 and associated wording has resulted in Exelon to vote No on the standard. While Exelon does specify Protection System tolerances and parameters in many maintenance documents; attempting to establish documented requirements for each component type is not practical. Additionally, this can leave much to the discretion of an auditor as to how in-depth tolerances need to be. There are many equipment and applications variations, many of which can utilize generic values while others require very specific value

Voter	Entity	Segment	Vote	Comment
				ranges. There are many instances where a very specific component tolerance is required for one application, but the same component doesn't require a tolerance in a different application. This could lead to entities having to justify why one application with a common component requires a narrow range versus the same component in another application can use a generic value or no tolerance. The last part of the requirement is also not clear. If a parameter is established, the R1.5 requirement is inferring component must meet an acceptable parameter to conclude the maintenance activity. There are many instances when a component is found out of a tolerance, but the level does not require immediate action and can even be scheduled for remediation at the next maintenance cycle. The wording in R1.5 appears to conflict with the R4.2 which indicates maintenance activities can be conclude as long as corrective maintenance is initiated as a result of identifying the condition.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Peter T Yost	Consolidated Edison Co. of New York	3	Negative	The Tables - 1. The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. 2. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices. Other Comments – 3. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 4. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)..." not included? The output contacts from these devices

Voter	Entity	Segment	Vote	Comment
				are oftentimes connected in tripping or control circuits to isolate problem equipment. 5. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 6. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 7. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 8. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 9. A control circuit is not a component, it is made up of components. 10. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance enforcement personnel. 11. In the Implementation plan for Requirement R1, recommend changing

Voter	Entity	Segment	Vote	Comment
				“six” to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 12. The ‘box’ for “Monitored Station dc supply…” in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 13. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. The SDT believes that the table headings are appropriate as reflected in the draft standard.

2. The SDT believes that the table headings are appropriate as reflected in the draft standard.

3. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities’ experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.

4. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.

5. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire

6. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The

Voter	Entity	Segment	Vote	Comment
specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. **7. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard.** **8. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition.** **9. For purposes of this standard, the control circuit IS defined as one component type.** **10. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **11. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for R1, making it consistent with the remainder of the Implementation Plan.** **12. Table 1-4 has been further modified for clarity.** **13. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**				
David A. Lapinski	Consumers Energy	3	Negative	We have the following comment on the revisions, specifically sub-requirement R1.12a, which states, "Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer.". We have no issue with this requirement on transmission lines that are 200 kV or greater. However, we do have a concern with applying requirement R1.12a on lower voltage lines now that the Transmission Relay Loadability Standard is being revised to included selected equipment 200 kV and below. The positive-sequence line angle on lower voltage lines, such as 69 kV or 46 kV, is significantly lower than 90 degrees. The positive-sequence line angle for 3/0 ACSR, for example, is only 55 degrees. Setting a 90 degree MTA on these lines would require a much larger reach setting to provide adequate line protection. In some cases, especially for lines with long spurs and poor line conductor, the increased reach setting may actually provide less loadability than a reach setting based on an MTA set at the positive-sequence line angle. A 90 degree MTA also dramatically reduces the resistive fault coverage for these lines. For these reasons, we would propose a modification to sub-

Voter	Entity	Segment	Vote	Comment
				requirement R1.12a as follows: Set the maximum torque angle (MTA) to 90 degrees or the highest supported by the manufacturer on 200 kV or greater transmission lines. Set the maximum torque angle (MTA) to the positive-sequence line angle on transmission lines less than 200 kV.
Response: **Thank you for your comments. This comment appears to apply to PRC-023-2 (Project 2010-17), which is a separate activity, and is not apparently relevant to PRC-005-2.**				
Michael F Gildea	Dominion Resources Services	3	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Henry Ernst-Jr	Duke Energy Carolina	3	Negative	1. R1.4 and R1.5 need more information to provide clarity for compliance. It's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. Either provide clarity or delete these requirements. 2. R4.2 - it is critical that more clarity be provided for R1.5 so that we can also understand what the compliance expectation is for R4.2 3. M4 - Need to clarify that these pieces of evidence are all "or", not "and" (i.e. any of the listed examples are sufficient for compliance). We reiterate the need for additional clarity on R1.5 and R4.2 such that compliance can be demonstrated for all component types. 4. Table 2 - We are fairly clear on the expectation for relays, but need more clarity on the expectation for other component types. Also, need to change the phrase "corrective action can be taken" to "corrective action can be initiated", consistent with the Supplementary Reference document. 5. VSL for R1 - Sub-requirement R1.3 appears to be missing. 6. Also, it's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. 7. VSL for R4 - More clarity must be provided on the expectation for compliance documentation. This is a High VRF requirement, and there may only be a small number of maintenance-correctable items, hence a significant exposure to an extreme penalty. 8. There are typographical errors on the FAQ Requirements Flowchart (should

Voter	Entity	Segment	Vote	Comment
				be R4.1.1 and R4.1.2 instead of R4.4.1 and R4.4.2). 9. We have previously commented that the FAQ and Supplementary Reference documents should be made part of this standard. If that cannot be done, then more of the information in those documents needs to be included in the requirements in the standard to provide clarity. Compliance will only be measured against what is in the standard, and we need more clarity.

Response: Thank you for your comments.

1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

2. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

3. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point.

4. Table 2 has been modified to be clearer. "Taken" has been replaced with "Initiation" in consideration of your comment.

5. The High VSL for Requirement R1 has been revised in consideration of your comment.

6. The issues of "monitoring attributes" are discussed within Section 15.7 of the Supplementary Reference Document. As for Requirement R1, Part 1.5, the SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.

7. Examples of compliance documentation are included within Measure M4 and discussed within various clauses of the FAQ and within Section 15.7 of the Supplementary Reference Document.

8. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.

9. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT believes the entities should be able to implement the standard without the Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion rationale etc useful particularly to assist them in implementing the standard in an efficient manner.

Voter	Entity	Segment	Vote	Comment
Joel T Plessinger	Entergy	3	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria….” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type….”. 3. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated

Voter	Entity	Segment	Vote	Comment
				documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				
Lee Schuster	Florida Power Corporation	3	Negative	Implementation Plan for PRC-005-2 1. Since R2, R3, and R4 requirements would be performed after establishment of the program documentation, an additional year should be added to all implementation dates for Requirements R2, R3, and R4 as shown below: • Maintenance on components with intervals less than one year must be completed within two years after applicable regulatory approval (within one year of completion of R1 Program Documentation). • Maintenance on components with intervals between one year and two years must be completed within three years after applicable regulatory approval (within two years of completion of R1 Program Documentation). • Maintenance on components with intervals of six years must be completed within three-, five-, and seven-year milestones after

Voter	Entity	Segment	Vote	Comment
				applicable regulatory approval (within two, four, and six years of completion of R1 Program Documentation). • Maintenance on components with intervals of twelve years must be completed within five-, nine-, and thirteen-year milestones after applicable regulatory approval (within four, eight, and twelve years of completion of R1 Program Documentation). Standard PRC-005-02 1. 2. Table 1-2: Rows 1 and 2 require different intervals for the activity "Verify essential signals to and from Protection System components." Unless these inputs and outputs are monitored for Row 2, it would seem that they should be performed at the same interval for both Rows 1 and 2. Therefore, EITHER: • Row 1 should be broken into the following three activities: • 3 months - Verify communications system is functional • 6 years - Verify channel meets performance criteria • 12 years - Verify essential signals to and from other Protection System components OR: • Row 2 should be broken into the following two activities: • 12 years - Verify channel meets performance criteria • 6 years - Verify essential signals to and from other Protection System components 3. Table 1-4: Only Row 1 addresses dc supplies associated with UFLS or UVLS systems. All other rows state that UFLS or UVLS systems are excluded. What is required to "Verify dc supply voltage" for the UFLS/UVLS systems? Does it require that the overall station battery voltage be checked or just the dc voltage available to the UFLS/UVLS circuit of interest? If a voltage measurement is taken at the UFLS/UVLS circuit (e.g., in distribution breaker cabinet), can the batteries/chargers at these facilities be excluded from the PRC-005-2 scope as long as they do not also supply transmission-related protection? 4. PRC-005-2 FAQ's Document Section V.1.A, Example #2: The instrument transformer should be classified as "unmonitored" not "monitored."

Response: **Thank you for your comments.**

1. **The Implementation Plan for Requirement R1 has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.**
2. **The first and second rows differ in that the first row is for unmonitored communications systems, and the second row is for monitored communications systems. The activities in both rows are appropriate and correct.**
3. **Table 1-4 has been completely re-structured. For station dc supply for only UFLS/UVLS, the only activity is to verify the dc**

voltage. 4. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.				
Anthony L Wilson	Georgia Power Company	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. Note: We have also made various requests for clarification to the FAQ and Supplemental Reference document in our Response to Comments which we are not including here.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Michael D. Penstone	Hydro One Networks, Inc.	3	Negative	1. The added requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and as written will be subject to different interpretations by entities and compliance enforcement personnel. The addition of this new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is onerous and contributes little to the reliability of the BES. 2. Changes introduced to the Implementation Plan since the last posting are not consistent with respect to jurisdictions where no regulatory approval is required. The previously posted implementation for Requirement R1 required entities to be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption. The amended implementation plan changed the three-month time to twelve months in jurisdictions with regulatory approval required but left the same six-month time for the others. For consistency, the six months timeframe should be changed to fifteen months.
Response: Thank you for your comments. 1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td colspan="5">2. In consideration of your comment, “six” has been modified to “twelve” in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.</td></tr>
<tr><td>Garry Baker</td><td>JEA</td><td>3</td><td>Negative</td><td>JEA will be voting no on PRC-005-2 because of the following:
1. In Table 1-1 for electromechanical trip or auxiliary devices requires verification of operation as opposed to verify ability to operate that was specified on trip coils. I believe it should be ability to operate in each case.

2. Between Table 1-1 and Tables 1-5 essentially would require full functional test of each station every 12 years.</td></tr>
<tr><td colspan="5">Response: Thank you for your comments.
1. The distinction in Table 1-5 is correct and as intended by the SDT.
2. A full functional test is one means of completing the required activities, but other methods are also acceptable. See Sections 8 and 15.3 of the Supplementary Reference Document for additional discussion.</td></tr>
<tr><td>Mace Hunter</td><td>Lakeland Electric</td><td>3</td><td>Negative</td><td>1. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the “baseline” values ought to be if an entity recently began performing this test (assuming it’s several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design?
2. Lakeland feels that the SDT should have taken into consideration numerous comments previously made regarding general concerns with testing Control Circuitry in energized substations. We agree that this can negatively impact reliability and would like to emphasize the following:
• Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn’t seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.)
• Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel</td></tr>
</table>

Voter	Entity	Segment	Vote	Comment
				wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. 3. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 4. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 5. the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: Thank you for your comments.

1. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.

2. A) Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.

   B) The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.

3. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.

4. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.

Voter	Entity	Segment	Vote	Comment
5. The SDT disagrees; the Tables establish the intervals and activities, and R1 addresses the establishment of an entities' individual PSMP.				
Bruce Merrill	Lincoln Electric System	3	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it. Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: Thank you for your comments. 1. Table 1-1 has been modified as you suggest. 2. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements. 3. Table 1-4 does not specify specific gravity testing.				
Charles A. Freibert	Louisville Gas and Electric Co.	3	Negative	LG&E and KU Energy LLC appreciate the hard work and efforts of the Standards Drafting Team in reaching this point in the standards development process. The basis for the negative vote is the addition of Requirement R1.5 (calibration tolerances) and R4.2 to the standard. This requirement will provide the opportunity for auditors to decide if the testing criteria for whether a relay passes a test or not is acceptable. LG&E and KU Energy recommend that Requirement R1.5 be deleted from the standard.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Greg C. Parent	Manitoba Hydro	3	Negative	1. -Implementation Plan (Timeline) for R1: In areas not requiring regulatory approval, the 6 month time frame proposed for R1 is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval.

Voter	Entity	Segment	Vote	Comment
				2. - VSLs: The high VSL for R1 "Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5" may be interpreted in different ways and should be further clarified. 3. -Table 1-4: The requirements for batteries listed in Table 1-4 do not appear to be consistent with the comments in the FAQ Section (V 1A Example 1). Please see comments submitted during the formal comment period for further detail. 4. -Table 1-4: The requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience.
Response: **Thank you for your comments.** **1. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.** **2. The SDT does not understand your concern; further details are needed.** **3. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.** **4. The SDT believes that the 3-month interval specified in the Standard is appropriate.**				
Don Horsley	Mississippi Power	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. Note: We have also made various requests for clarification to the FAQ and Supplemental Reference document in our Response to Comments which we are not including here.

Sam Waters	Progress Energy Carolinas	3	Negative	4. Implementation Plan for PRC-005-2 Since R2, R3, and R4 requirements would be performed after establishment of the program documentation, an additional year should be added to all implementation dates for Requirements R2, R3, and R4 as shown below: • Maintenance on components with intervals less than one year must be completed within two years after applicable regulatory approval (within one year of completion of R1 Program Documentation). • Maintenance on components with intervals between one year and two years must be completed within three years after applicable regulatory approval (within two years of completion of R1 Program Documentation). • Maintenance on components with intervals of six years must be completed within three-, five-, and seven-year milestones after applicable regulatory approval (within two, four, and six years of completion of R1 Program Documentation). o Maintenance on components with intervals of twelve years must be completed within five-, nine-, and thirteen-year milestones after applicable regulatory approval (within four, eight, and twelve years of completion of R1 Program Documentation). Standard PRC-005-02 1. 5. Table 1-2: 1. Rows 1 and 2 require different intervals for the activity "Verify essential signals to and from Protection System components." Unless these inputs and outputs are monitored for Row 2, it would seem that they should be performed at the same interval for both Rows 1 and 2. Therefore, EITHER: • Row 1 should be broken into the following three activities: • 3 months - Verify communications system is functional • 6 years - Verify channel meets performance criteria • 12 years - Verify essential signals to and from other Protection System components OR: • Row 2 should be broken into the following two activities: • 12 years - Verify channel meets performance criteria • 6 years - Verify essential signals to and from other Protection System components. 6. Table 1-4: Only Row 1 addresses dc supplies associated with UFLS or UVLS systems. All other rows state that UFLS or UVLS systems are excluded. What

Voter	Entity	Segment	Vote	Comment
				is required to "Verify dc supply voltage" for the UFLS/UVLS systems? Does it require that the overall station battery voltage be checked or just the dc voltage available to the UFLS/UVLS circuit of interest? If a voltage measurement is taken at the UFLS/UVLS circuit (e.g., in distribution breaker cabinet), can the batteries/chargers at these facilities be excluded from the PRC-005-2 scope as long as they do not also supply transmission-related protection? 7. PRC-005-2 FAQ's Document Section V.1.A, Example #2: The instrument transformer should be classified as "unmonitored" not "monitored."
Response: **Thank you for your comments.** **4. The Implementation Plan for Requirement R1 has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **5. The first and second rows differ in that the first row is for unmonitored communications systems, and the second row is for monitored communications systems. The activities in both rows are appropriate and correct.** **6. Table 1-4 has been completely re-structured. For station dc supply for only UFLS/UVLS, the only activity is to verify the dc voltage.** 7. **The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**				
Jeffrey Mueller	Public Service Electric and Gas Co.	3	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in our formal Comment Form.
Response: **Thank you for your comments. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**				
Anthony Schacher	Salem Electric	3	Negative	Battery testing methodologies are too specific and don't allow for different substation battery configurations.
Response: **Thank you for your comments. The SDT disagrees; the requirements within Table 1-4 establish the minimum maintenance activities required to assure that station dc supply of various technologies and configurations will perform as intended without unnecessarily prescribing specific methodologies.**				
Dana Wheelock	Seattle City Light	3	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical

Voter	Entity	Segment	Vote	Comment
				relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2) Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function

Voter	Entity	Segment	Vote	Comment
				electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence". Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic.** **2. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
James R. Keller	Wisconsin Electric Power Marketing	3	Negative	Q4: Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: **Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.**				
Michael Ibold	Xcel Energy, Inc.	3	Negative	See comments under the Transmission segment.
Response: **Thank you for your comments. Please see our responses to your comments from the Transmission segment.**				
Kenneth Goldsmith	Alliant Energy Corp. Services, Inc.	4	Negative	We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS. i. Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is "applied

Voter	Entity	Segment	Vote	Comment
				on" or "designed to provide protection". According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of 'protecting" the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES.
Response: **Thank you for your comments. Applicability 4.2.1 has been revised to remove "applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to 4.2.1. The Supplementary Reference Documentation has been revised to clarify.**				
David Frank Ronk	Consumers Energy	4	Negative	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this

Voter	Entity	Segment	Vote	Comment
				activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the "verify the battery terminal connection resistance" activity?

Response: **Thank you for your comments.**

1. **The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.**

2. **This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.**

3. **The Implementation Plan for Requirement R1 has been modified from "six" months to "twelve" months. The standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all Individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.**

4. **IEEE 450, 1188, and 1106 all recommend this activity at a 12-month interval. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this activity.**

5. **Re-torqueing the battery terminals would not meeting this requirement.**

Voter	Entity	Segment	Vote	Comment
Frank Gaffney	Florida Municipal Power Agency	4	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to

Voter	Entity	Segment	Vote	Comment
				ensure that the regionsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.**
3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 2009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Battery manufacturers typically do not provide this value

Voter	Entity	Segment	Vote	Comment
				and one manufacturer states that the baseline test are to be performed after the battery has been in regular float service for 90 days. It is unclear how to comply with the requirement for the initial 90 days. Additionally, we would recommend that this requirement be modified to permit an entity to establish a "baseline" value based on statistical analysis of multiple test results specific to a given battery manufacturer/model. Several commenters previously expressed their concerns with performing capacity tests. While this may just be an entity's preference, allowing an entity to establish a baseline at some point beyond the initial installation period would give entities the option of using the internal resistance test in lieu of a capacity test. 5. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to accidentally leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter- and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. The interconnected nature of tripping circuits will make it difficult to count the number of circuits consistently for the purpose of calculating a VSL.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.**

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td colspan="5">3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity’s Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.
4. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.
5. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.
6. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.</td></tr>
<tr><td>Bob C. Thomas</td><td>Illinois Municipal Electric Agency</td><td>4</td><td>Negative</td><td>It is IMEA's understanding from interaction with other entities that Draft 3 provides significant improvement, but that key concerns raised by many entities on Draft 2 were not addressed. <tr><td colspan="5">Response: Thank you for your comments. Please see our responses to your comments submitted during the Formal Comment period..</td></tr>
<tr><td>Christopher Plante</td><td>Integrys Energy Group, Inc.</td><td>4</td><td>Negative</td><td>Reason for No Vote:
1. Implementation plan is too aggressive given the drastic changes from PRC-005-1 to PRC-005-2
2. The drastic changes don’t appear to provide an incremental increase in the reliability of the BES
3. We support the MRO NSRS comments</td></tr>
<tr><td colspan="5">Response: Thank you for your comments.
1. The SDT has carefully considered the changes that entities will be expected to make to their program in response to PRC-005-2 and provided an Implementation Plan that should be sufficient and provided a phase-in approach to permit entities to systemically implement the revised standard. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.
2. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance.
3. Please see our responses to MRO’s NSRS comments on the Standard Comments.</td></tr>
<tr><td>Joseph G. DePoorter</td><td>Madison Gas and Electric Co.</td><td>4</td><td>Negative</td><td>The SDT has made great improvements with this Standard but please consider the following items.
1. Replace "affecting" with "protecting" in the purpose statement.</td></tr>
</table>

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td></td><td>2. 4.2.1 under Facilities, The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. Clarification is needed by the SDT that this does not include distribution assets (notwithstanding UFLS and UVLS).

3. Upon review, R1.4, R1.5, and R4.2 were added since the last posting. These are not needed and must of been added to the Standard from an outside sorce. The SDT was on the proper track to finalize this Standard. These requirements need to be left to the individual entities to determine the depth and breath of thier PMSP.</td></tr>
<tr><td colspan="5">Response: Thank you for your comments.
1. The “Purpose” is defined by the SAR.
2. Applicability 4.2.1 has been revised to remove “applied on”. The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to Applicability 4.2.1. The Supplementary Reference Documentation has been revised to clarify.
3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.</td></tr>

	County			system maintenance and testing) events do not create reliability or cascading concerns.
Response: **Thank you for your comments. PRC-005-2 is applicable to Protection Systems that are designed to provide protection for BES elements, and uses the Compliance Registry to determine applicable entities. Contributions of BES elements to cascading, etc, are immaterial in this Applicability.**				
Hao Li	Seattle City Light	4	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at

Voter	Entity	Segment	Vote	Comment
				risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2) Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence". Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic.** **2. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
James A Ziebarth	Y-W Electric Association, Inc.	4	Negative	Y-WEA appreciates the significant amount of work that the SDT has put into this revision of the standard. It is clear that the SDT is making a sincere effort to address comments and concerns from previous revisions of this standard, and that is a good thing. While Y-WEA thanks the SDT for the straightforward honesty of disagreeing with our previous comments on the battery testing interval of 3 months for VRLA batteries, we still feel that this mandatory maximum testing interval is unreasonably short, based on IEEE 1188-2005.

Voter	Entity	Segment	Vote	Comment
				The recommended testing intervals contained in that IEEE standard should be targeted as reasonable testing intervals, with some degree of leeway allowed before any mandatory maximum interval is defined. A mandatory maximum interval of four calendar months would be much more appropriate here. This would allow a reasonable testing and maintenance program to define a standard testing interval of three months (in line with the IEEE standard) and still be able to allow a one month buffer or grace period to account for unexpected delays in testing due to extreme storms or other unanticipated heavy workloads. With the draft standard as written, a company must use an unreasonably short preferred maintenance interval if any grace period is to be built in and still remain under the mandatory maximum interval of the NERC standard. In particular, this could have a substantial impact on small companies that are distributed over a large area but have limited resources to deal with such stringent testing requirements. Because this standard will ultimately have to comply with the Regulatory Flexibility Act, it would be worthwhile for the SDT to consider the potential impacts of essentially forcing entities into much more stringent testing programs than recommended by current technically-derived and peer reviewed and approved standards such as IEEE 1188-2005. Other than that, Y-WEA sincerely appreciates the clarity that has been added to this standard over that contained in previous versions of the testing and maintenance standards. This will give registered entities much more guidance as to what NERC's and the regional entities' expectations are when it comes to protection system testing and maintenance programs.
Response: **Thank you for your comments. The SDT has revised the 3-month interval specified for VRLA batteries for some activities to 6 months.**				
Francis J. Halpin	Bonneville Power Administration	5	Negative	Please see BPA's comments submitted seperately
Response: **Thank you for your comments. Please see our responses to your comments submitted during the Formal Comment period.**				
Wilket (Jack) Ng	Consolidated Edison Co. of New York	5	Negative	The Tables – 1. The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read

Voter	Entity	Segment	Vote	Comment
				Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. 2. The "Note" included in the heading is also not necessary. "Attributes" is also not necessary in the column heading, "Component" suffices. Other Comments - In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 3. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)..." not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 4. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 5. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 6. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be

Voter	Entity	Segment	Vote	Comment
				used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 7. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 8. A control circuit is not a component, it is made up of components. 9. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters…" means, and may be subject to different interpretations by entities and compliance enforcement personnel. 10. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 11. The 'box' for "Monitored Station dc supply…" in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 12. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. **The SDT believes that the table headings are appropriate as reflected in the draft standard.**

2. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.**

Voter	Entity	Segment	Vote	Comment
3. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available. 4. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire. 5. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference document. Your comments have been considered within that activity. 6. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. 7. As used in the “Maximum Maintenance Interval” column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition. 8. For purposes of this standard, the control circuit is defined as one component type. 9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 10. In consideration of your comment, “six” has been modified to “twelve” in the Implementation Plan for Requirement R1,making it consistent with the remainder of the Implementation Plan. 11. Table 1-4 has been further modified for clarity. 12. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
Amir Y Hammad	Constellation Power Source Generation, Inc.	5	Negative	Constellation Power Generation is voting against this standard for the following reasons: 1. The applicability has included more generation protective components. The current PRC-005 guidance states that only Station Service transformers for plants 75 MVA and up should be included. The proposed

Voter	Entity	Segment	Vote	Comment
				standard includes all station service transformers, regardless of plant size or connection (via generator or system). Constellation Power Generation does not see the reliability benefits of this increased scope. 2. R1.4 states that all monitoring attributes of all components must be listed and identified. For most generation facilities, it is more efficient to calibrate/check the entire protective system while the plant is in an outage, regardless of a component's monitoring capabilities. This requirement would require those facilities to maintain a list of attributes that won't ever be used, and would not alter their testing frequency. What if an entity were found non-compliant in the situation that was just described? It does not affect the reliability of the BES and therefore R1.4 should be removed. 3. M1 doesn't include a measure for R1.4. It just implies that a facility must maintain a list. 4. The battery listing in the attached table is still too prescriptive. If unmonitored, there should be a quarterly and yearly check, which is implied, but it is then broken out by battery type to be more prescriptive. 5. PTs and CTs are mentioned, but it seems as though the drafting team wants a facility to only test the outputs to ensure they are working properly. To clarify this, Constellation Power Generation suggests rewording the testing verbiage for PTs and CTs.
Response: **1. Section 4.2.5 of "Applicability" specifies that only Generation Facilities that are part of the BES are included.** **2. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the SDT has revised Requirement R1, Part 1.4 and has also removed Requirement R2 because of redundancy to Requirement R1, Part 1.4.** **3. Measure M1 has been revised in consideration of your comment.** **4. The activities for different battery types are addressed separately because the relevant activities differ.** **5. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2.**				
James B Lewis	Consumers Energy	5	Negative	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without tripping customers. The standard

<table>
<tr><th>Voter</th><th>Entity</th><th>Segment</th><th>Vote</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td></td><td>must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers.
3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4.
4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval.
5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the “verify the battery terminal connection resistance” activity?</td></tr>
<tr><td colspan="5">Response: Thank you for your comments.
1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.
2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.
3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.
4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this activity.
5. Re-torqueing the battery terminals would not meet this requirement.</td></tr>
<tr><td>Mike Garton</td><td>Dominion Resources, Inc.</td><td>5</td><td>Negative</td><td>Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.</td></tr>
<tr><td colspan="5">Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.</td></tr>
</table>

Voter	Entity	Segment	Vote	Comment
Stanley M Jaskot	Entergy Corporation	5	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters…” whereas the associated VSL references “failure to establish calibration criteria.…” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? 3. R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type.…”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how

Voter	Entity	Segment	Vote	Comment
				broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. Kenneth Dresner	FirstEnergy Solutions	5	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting
Response: **Thank you for your comments. Please see our responses to your comments submitted during the formal comment period.**				
David Schumann	Florida Municipal Power Agency	5	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either.

Voter	Entity	Segment	Vote	Comment
				Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**

2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made modifications to Applicability 4.2.1.**

3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the**

Voter	Entity	Segment	Vote	Comment
degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.				
Rex A Roehl	Indeck Energy Services, Inc.	5	Negative	The level of detail for every conceivable component of every conceivable protective system does not relate to improving reliability. For some protective systems on some equipment, following these requirements, which is undoubtedly already done, will result in good reliability, but probably not improve reliability. Applying those same requirements to the thousands, if not millions, of other protective systems with generate significant costs, generate significant numbers of violations and not have any significant impact on reliability. The costs of this type of program cannot be justified unless there is an NRC mandate or a pass through to ratepayers. Most of the industry will take the cost of this program directly from the bottom line. For minimal reliability improvement, that is not appropriate under the FPA Section 215.
Response: **Thank you for your comments. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance.**				
Dennis Florom	Lincoln Electric System	5	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it. Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: **Thank you for your comments.** 1. **Table 1-1 has been modified as you suggest.** 2. **This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.** 3. **Table 1-4 does not specify specific gravity testing.**				
Mike Laney	Luminant Generation	5	Negative	Luminant commends the PRC-005-2 Standard Drafting Team for its quality efforts in producing this version of the Standard however; Luminant must cast a negative

Voter	Entity	Segment	Vote	Comment
	Company LLC			ballot vote for this present version of the Standard. The negative vote against the present version of PRC-005-2 is solely based on the addition of Requirement R1 Part 1.5 with its associated reference to it in Requirement R4 Part 4.2 and the VSL table. It is Luminant's opinion that this new Requirement as written subjects all Transmission Owners, Generation Owners and Distribution Providers to vague interpretations of a requirement that cannot be complied with because it is impossible for any of them to draft the necessary documentation to be compliant with the Standard. As stated in the High VSL associated with Part 1.5 of Requirement R1 all owners will fail "to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters." It is Luminant's opinion that the measurement of acceptable performance during maintenance and testing activities can be accomplished with a Pass/Fail type of documentation on a test form. No company can effectively establish calibration tolerance parameters for an entire "component type" of the Protection System. Doing so could be detrimental to the reliability of the grid. Parameters are dependent on the location, application and situation specific to each Protection System device. The inclusion of Part 1.5 of Requirement R1 is a significant addition to the standard, and by NERC Rules of Procedure requires the input and consideration of the full Standard Drafting Team.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Wayne Lewis	Progress Energy Carolinas	5	Negative	1. Implementation Plan for PRC-005-2 Since R2, R3, and R4 requirements would be performed after establishment of the program documentation, an additional year should be added to all implementation dates for Requirements R2, R3, and R4 as shown below: • Maintenance on components with intervals less than one year must be completed within two years after applicable regulatory approval (within one year of completion of R1 Program Documentation). • Maintenance on components with intervals between one year and two years must be completed within three years after applicable regulatory approval (within two years of completion of R1 Program

Voter	Entity	Segment	Vote	Comment
				Documentation). • Maintenance on components with intervals of six years must be completed within three-, five-, and seven-year milestones after applicable regulatory approval (within two, four, and six years of completion of R1 Program Documentation). • Maintenance on components with intervals of twelve years must be completed within five-, nine-, and thirteen-year milestones after applicable regulatory approval (within four, eight, and twelve years of completion of R1 Program Documentation). 2. Standard PRC-005-02 1. Table 1-2: Rows 1 and 2 require different intervals for the activity “Verify essential signals to and from Protection System components.” Unless these inputs and outputs are monitored for Row 2, it would seem that they should be performed at the same interval for both Rows 1 and 2. Therefore, EITHER: 1. Row 1 should be broken into the following three activities: • 3 months - Verify communications system is functional • 6 years - Verify channel meets performance criteria • 12 years - Verify essential signals to and from other Protection System components OR: 2. Row 2 should be broken into the following two activities: 1. 12 years - Verify channel meets performance criteria 2. 6 years - Verify essential signals to and from other Protection System components 2. 3. Table 1-4: Only Row 1 addresses dc supplies associated with UFLS or UVLS systems. All other rows state that UFLS or UVLS systems are excluded. What is required to “Verify dc supply voltage” for the UFLS/UVLS systems? Does it require that the overall station battery voltage be checked or just the dc voltage available to the UFLS/UVLS circuit of interest? If a voltage measurement is taken at the UFLS/UVLS circuit (e.g., in distribution breaker cabinet), can the batteries/chargers at these facilities be excluded from the PRC-005-2 scope as long as they do not also supply transmission-related protection? 4. PRC-005-2 FAQ’s Document Section V.1.A, Example #2: The instrument transformer should be classified as “unmonitored” not “monitored.”

Response: **Thank you for your comments.**

1. **The Implementation Plan for Requirement R1 has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.**
2. **The first and second rows differ in that the first row is for unmonitored communications systems, and the second row is for monitored communications systems. The activities in both rows are appropriate and correct.**

Voter	Entity	Segment	Vote	Comment
3. Table 1-4 has been completely re-structured. For station dc supply for only UFLS/UVLS, the only activity is to verify the dc voltage. 4. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.				
Jerzy A Slusarz	PSEG Power LLC	5	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: Thank you for your comments. Please see our response to your detailed comments from the formal comment period.				
Steven Grega	Public Utility District No. 1 of Lewis County	5	Negative	Do not like the word "all" in the proposed standard. Does all components mean each piece of wire is included? Engineers are conservative in their protection system designs and have redundant relays and protection paths. Even with half the relays out of service, protection is normally retained. Would want to have 80% a compliance level with a year to test & maintenance any component testing founded to be non-compliant. This proposed standard will ensure many more violations.
Response: Thank you for your comments. The approved PRC-005-1 already requires that entities have a program to maintain their Protection System and implement that program. This already implies, "all", therefore PRC-005-2 should not have the impact suggested by your comment.				
Michael J. Haynes	Seattle City Light	5	Negative	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1. the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called "bookend" issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require

Voter	Entity	Segment	Vote	Comment
				that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxilary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechnical compenents, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proporational to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasability exceptions.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence". 2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.				
William D Shultz	Southern Company Generation	5	Negative	Please see comments submitted via the electronic comment form.
Response: Thank you for your comments. Please see our responses to your comments from the formal comment period.				
George T. Ballew	Tennessee Valley Authority	5	Negative	Project 2007-17 Protection System Maintenance for Standard PRC-005-2 Draft - NERC is recommending significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting NO because of the hurried fashion it is being commented, voted, and reviewed. Official comments to the document were entered on the NERC Portal.
Response: Thank you for your comments. Please see our responses to your comments from the formal comment period.				
Melissa Kurtz	U.S. Army Corps of Engineers	5	Negative	Paragraph 4.2.5.4 - The standard should be changed to require station service transformers only if they will cause a loss of the generator tied to the BES. Also recommend a definition of station service - we have station service that if lost would not negatively effect the BES.
Response: Thank you for your comments. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.				
Martin Bauer P.E.	U.S. Bureau of Reclamation	5	Negative	1. The tables rely on a reference document which is not a part of the standard and as such may be altered without due process. Either the relevant text from the reference needs to be inserted into the standard or the reference itself incorporated into the standard. 2. The supplemental reference provides significant clarity to the intent of standard; however, in doing so, it reveals conflicts and ambiguity in the text of the standard. It is suggested that some of the clarifying language be inserted

Voter	Entity	Segment	Vote	Comment
				into the text of the standard. 3.The concept of including definitions in this standard that are not a part of the Glossary of Terms will create a conflict with other standards that choose to use the term with a different meaning. This practice should be disallowed. If a definition is be introduced it should be added to the Glossary of Terms. This concept was not provided to industry for comment when the modifications to the Definition of Protection System was introduced. Additional related to this practice are included later on. 4. The Term "Protective Relays" is overly broad as it is not limited to those devices which are used to protect the BES. In the reference provided to the standard, the SDT defined "Protective Relays" as "These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. " The Definition for "Protective Relays' as well as the components associated with the them should be associated with the protection of the BES in the definition. 5. The Section 2.4 of the attached reference and the recent FERC NOPR are in conflict with the definition of "Protective Relays" which include lockout relays and transfer trip relays "The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. 6. This Draft 2: April3: November 17, 2010 Page 5 definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices." The definition should be revised to reflect that is really intended. The SDT as created an implied definition by specifically defining DC circuits associated with the trip function of a "Protective Relay" but failing to specifically define voltage and current sensing circuits providing inputs to "Protective Relays". The team clearly intended the circuits to be included but the definition does not since it only refers the the "voltage and current sensing devices". 7.Starting with the Definitions and continuing through the end of the document, terms that have been defined are not capitalized. This leaves it ambiguous as to whether the defined term is to be applied or it is a generic reference. Only defined terms "Protection System Maintenance Program" and "Protection System" are consistently capitalized. 8. Protection System Maintenance Program (PSMP) definition: The Restore bullet should be revised to read as follows: "Return malfunctioning components to

Voter	Entity	Segment	Vote	Comment
				proper operation by repair or calibration during performance of the initial on-site activity." Add the following at the end of the PSMP definition: "NOTE: Repair or replacement of malfunctioning Components that require follow-up action fall outside of the PSMP, and are considered Maintenance Correctable Issues." 9.Protection System (modification) definition: The term "protective functions" that is used herein should be changed to "protective relay functions" or what is meant by the phrase should become a defined term, as it is being used as if it is a well known well defined, and agreed upon term. a. The first bullet text should be revised to read as follows: "Protective relays that monitor BES electrical quantities and respond when those quantities exceed established parameters," the last two bullets should be reversed in order and modified to read as follows: o control circuitry associated with protective relay functions through the trip coil(s) of the circuit breakers or other interrupting devices, and o station dc supply (including station batteries, battery chargers, and non-battery-based dc supply) associated with the preceding four bullets. 10. Statement between the Protection System (modification) definition and the Maintenance Correctable Issue definition; Is this a NERC accepted practice? There does not appear to be a location in the standard for defining terms. Having terms that are not contained in the "Glossary of Terms used in NERC Reliability Standards," and are outside of the terms of the standards, and yet are necessary to understand the terms of the Requirements is not acceptable. They would become similar to the reference documents, and could be changed without notice. 11. Maintenance Correctable Issue definition: The last sentence should be modified to read as follows: "Therefore this issue requires follow-up corrective action which is outside the scope of the Protection System Maintenance Program and the Standard PRC-005-2 defined Maximum Maintenance Intervals." The definition could also be easily clarified to read "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration; therefore requires replacement." This ensures that any action to restore the equipment, short of replacement, is still considered maintenance. Otherwise ambiguity is introduced as what "maintenance" is. 12. Countable Event definition: An explanation should be made that this is a part of the technical justification for the ongoing use of a performance-based Protection System Maintenance Program for PRC-005. 13. Insert the phrase "Standard PRC-005-2" before the term "Tables 1-1..."

Voter	Entity	Segment	Vote	Comment
				14. Applicability: 4.2. Facilities: 4.2.5.4 and 4.2.5.5: Delete these two parts of the applicability. Station service transformer protection systems are not designed to provide protection for the BES. Per PRC-005-2 Protection System Maintenance Draft Supplementary Reference, Nov. 17 2010, Section 2.3 - Applicability of New Protection System Maintenance Standards: "The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005: "...affecting the reliability of the Bulk Electric System (BES)..." To the present language: "... and that are applied on, or are designed to provide protection for the BES." The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault." Station Service transformer protection is designed to detect a fault on equipment internal to a powerplant and not directly related to the BES. In addition, many Station Service protection ensures fail over to a second source in case of a problem. Thus station service transformer protection system is a powerplant reliability issue and not a BES reliability issue. As such station service transformer protection should not be included in PRC 005 2. In addition, the SDT appears to have targeted generation station service without regard to transmission systems. If generating station service transformers are that important, then why are substation/switchyard station service transformers not also important? 15. Requirements Should the sub requirements have the "R" prefix? 16. R4. Change the phrase "... PSMP, including identification of the resolution of all ..." to read "...PSMP including identification, but not the resolution, of all ...". 17.General comment PRC005-2 is very specific in listing the

Response: **Thank you for your comments.**

1. **The Tables do not provide a reference to either the Supplementary Reference Document or the FAQ. An entity must comply with the standard when approved. The reference documents provide additional explanation, discussion, and rationale, but are not part of the mandatory standard. Since the reference documents are developed in accordance with the standard and will be posted with the standard, the NERC Standard Development Procedure does require that they undergo industry review before being initially posted, and upon any revision.**

2. **The clarifying language is exactly that – clarifying language, and is not essential to application of the Standard. He NERC Standards Development Procedure establishes that the standard shall not include explanatory text.**

3. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**

Voter	Entity	Segment	Vote	Comment

4. “Protective relay” is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.
5. The issues raised by the FERC NOPR will be addressed as part of the response to the NOPR (and, ultimately, the Order). The extension of auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).
6. The extension of auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).
7. Definition from the NERC Glossary of Terms (or those intended for the Glossary) are consistently capitalized (Protection System and Protection System Maintenance Program fall within this category). As for terms defined only for use within this standard, these terms are NOT capitalized, since they are not in the Glossary of Terms.
8. The “restore” portion of PSMP specifically addresses returning malfunctioning components to your proper operation. The requirements regarding maintenance correctable issues are further addressed within that definition (for use only within PRC-005-2).
9. The SDT is currently not planning on further modifying the most recent NERC BOT-approved definition of Protection System.
10. If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.
11. Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to repair / replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstration completion of them.
12. Since this term is used only in Attachment A, it seems unnecessary to provide the explanation requested.
13. The SDT has elected not to change the reference to the Tables throughout the Standard.
14. Thank you for your comments. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.
15. The current style guide for NERC Standards does not preface the Parts with an “R”.
16. Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be

Voter	Entity	Segment	Vote	Comment
necessary to repair / replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstration completion of them. 17. It appears the remainder of your comment was truncated and cannot be ascertained.				
Linda Horn	Wisconsin Electric Power Co.	5	Negative	Q4: Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.				
Leonard Rentmeester	Wisconsin Public Service Corp.	5	Negative	1. Implementation plan is too aggressive given the drastic changes from PRC-005-1 to PRC-005-2 2. The drastic changes don't appear to provide an incremental increase in the reliability of the BES 3. We support the MRO NSRS comments
Response: Thank you for your comments. 1. The SDT has carefully considered the changes that entities will be expected to make to their program in response to PRC-005-2 and provided an Implementation Plan that should be sufficient and provided a phase-in approach to permit entities to systemically implement the revised standard. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates. 2. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance. 3. Please see our responses to MRO's NSRS formal comments in the Consideration of Comments document.				
Liam Noailles	Xcel Energy, Inc.	5	Negative	We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments
Response: Thank you for your comments. Please see our response to your formal comments.				
Edward P. Cox	AEP Marketing	6	Negative	Restructured Tables: 1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a

Voter	Entity	Segment	Vote	Comment
				maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading “Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):” for the bullet points on this page. VSLs, VRFs and Time Horizons: 3. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL. 4. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. 5. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference: 6. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. Section 5 of the Supplementary Reference, refers to “condition-based”

Voter	Entity	Segment	Vote	Comment
				maintenance programs. However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. b. Section 15.7, page 26, appears to have a typographical error “...can all be used as the primary action is the maintenance activity...” c. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. “Frequently-Asked Questions”: 7. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. The section “Terms Used in PRC-005-2” is blank and should be removed as it adds no value. Section I.1 and Section IV.3.G reference “condition-based” maintenance programs. However, nowhere in the standard is the term “condition-based” used in reference to defining ones PSMP. b. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. c. The second sentence to the response in Section I.1 appears to have a typographical error “... an entity needs to and perform ONLY time-based...”. General: 8. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate.

Voter	Entity	Segment	Vote	Comment
				9. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary Reference or FAQ. 10. "Protective relay" should be a defined term that lists relay function for applicability. There are numerous 'relays' used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 11. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.

Response: **Thank you for your comments.**

1. **The 6-year activities are all related to components with "moving parts", and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected.**
2. **Table 1-4 has been modified in consideration of your comments.**
3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.**
4. **The SDT concluded that Requirement R2 is redundant to Requirement R1, Part 1.4 and has deleted Requirement R2 (together with the Measures and & VSL).**
5. **If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.**
6. **The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard.**
    a) **The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed.**

Voter	Entity	Segment	Vote	Comment
b) This clause has been corrected. c) A higher-quality version of Figure 2 has been substituted. 7. The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard. a) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. b) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. c) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 9. The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used. 10. "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2. 11. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.				
Brenda S. Anderson	Bonneville Power Administration	6	Negative	Refer to BPA comments
Response: Thank you for your comments. Please see our response to the BPA comments.				
Matthew D Cripps	Cleco Power LLC	6	Negative	Cleco applies its' UFLS on the distribution grid with each UF relay individually tripping a relatively low value of load thru breakers and reclosers. Since our program is implemented via a large number of individual components, breakers, reclosers, and individual batteries, the failure of any one component will have a minimal impact on the effectiveness of the overall UFLS program within our region. Therefore, the verification of sensing devices, dc supply voltages, and the

Voter	Entity	Segment	Vote	Comment
				paths of the control circuit and trip circuits on the UFLS systems implemented on the distribution grid is unnecessary.
Response: **Thank you for your comments. The SDT disagrees; the sensing devices, control circuitry and dc supply related to UFLS has an effect on the performance of the UFLS. The SDT has, however, respected the overall impact on the control circuitry of individual UFLS on BES reliability by requiring that UFLS be subjected to a subset of the overall sensing devices, control circuitry and dc supply maintenance activities.**				
Nickesha P Carrol	Consolidated Edison Co. of New York	6	Negative	The Tables 1. The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. 2. "Attributes" is also not necessary in the column heading, "Component" suffices. Other Comments – 3. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 4. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…" not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 5. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in

Voter	Entity	Segment	Vote	Comment
				real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a “stuck” breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 6. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 7. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 8. What is the definition of “Maintenance” as used in the table column “Maximum Maintenance Interval”? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 9. A control circuit is not a component, it is made up of components. 10. Sub-requirement 1.5 needs to be clarified. It is not clear what “Identify calibration tolerances or other equivalent parameters…” means, and may be subject to different interpretations by entities and compliance enforcement personnel. 11. In the Implementation plan for Requirement R1, recommend changing “six” to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 12. The ‘box’ for “Monitored Station dc supply…” in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. Regarding station service transformers, 13. Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs

Voter	Entity	Segment	Vote	Comment
				(III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. **The SDT believes that the table headings are appropriate as reflected in the draft standard.**

2. **Please see the SDT's response to ISO New England Inc. in the formal Standard Comments**

3. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.**

4. **The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.**

5. **According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire**

6. **With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**

7. **The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.**

8. **As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition.**

9. **For purposes of this standard, the control circuit is defined as one component type.**

Voter	Entity	Segment	Vote	Comment
10. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 11. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan Please see the SDT's response to NPPC in the formal Standard Comments. 12. Table 1-4 has been further modified for clarity. 13. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
Brenda Powell	Constellation Energy Commodities Group	6	Negative	1. The applicability has included more generation protective components. The current PRC-005 guidance states that only Station Service transformers for plants 75 MVA and up should be included. The proposed standard includes all station service transformers, regardless of plant size or connection (via generator or system). Constellation Energy Commodities Group does not see the reliability benefits of this increased scope. 2. R1.4 states that all monitoring attributes of all components must be listed and identified. For most generation facilities, it is more efficient to calibrate/check the entire protective system while the plant is in an outage, regardless of a component's monitoring capabilities. This requirement would require those facilities to maintain a list of attributes that won't ever be used, and would not alter their testing frequency. What if an entity were found non-compliant in the situation that was just described? It does not affect the reliability of the BES and therefore R1.4 should be removed. 3. M1 doesn't include a measure for R1.4. It just implies that a facility must maintain a list. 4. The battery listing in the attached table is still too prescriptive. If unmonitored, there should be a quarterly and yearly check, which is implied, but it is then broken out by battery type to be more prescriptive. 5. PTs and CTs are mentioned, but it seems as though the drafting team wants a facility to only test the outputs to ensure they are working properly. To clarify this, Constellation Energy Commodities Group suggests rewording the testing verbiage for PTs and CTs.
Response: Thank you for your comments. 1. Section 4.2.5 of "Applicability" specifies that only Generation Facilities that are part of the BES are included. 2. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the				

Voter	Entity	Segment	Vote	Comment
SDT has revised Requirement R1, Part 1.4 and has also removed Requirement R2 because of redundancy to Requirement R1, Part 1.4. 3. Measure M1 has been revised in consideration of your comment. 4. The activities for different battery types are addressed separately because the relevant activities differ. 5. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2.				
Louis S Slade	Dominion Resources, Inc.	6	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Terri F Benoit	Entergy Services, Inc.	6	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria....” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to

Voter	Entity	Segment	Vote	Comment
				the severity level(s) of a "failure to specify one (or Cthe severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn't a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for "identification of calibration tolerances or equivalent parameters for each Protection System Component Type....". We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any "equivalent" parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

Response: **Thank you for your comments. Please see our response to your comments submitted separately through the formal comment period.**				
Richard L. Montgomery	Florida Municipal Power Agency	6	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry.

Voter	Entity	Segment	Vote	Comment
				What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: Thank you for your comments.

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically**

Voter	Entity	Segment	Vote	Comment
excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil. **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. Silvia P Mitchell	Florida Power & Light Co.	6	Negative	This draft standard is too perscriptive. 1. Requirement R1, Part 1.5 would be overwhelming if approved. Requirement R1, Part 1.5 should be deleted. 2. Requirement R4, Part 4.2 phrase "established in accordance with Requirement R1, Part 1.5" should be deleted. The standard without these additional requirements would be sufficient to establish that the Protection System is maintained and protects the BES. 3. Table 1-2 Component Type Communications Systems Maximum Maintenance Interval of 3 Calendar Months to verify that the communications system is functional for any unmonitored communications system is unyielding. Most communication failures are caused by power supply failures which Next Era does monitor. Based on experience and monitoring of communication power supplies, 12 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 12 calendar months. 4. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to inspect electrolyte levels on "Any unmonitored station

Voter	Entity	Segment	Vote	Comment
				dc supply not having the monitoring attributes of a category below. (Excluding UFLS and UVLS)" is too stringent. Verifying battery charger float voltage every 18 calendar months is sufficient to prevent excessive gassing and water loss of battery cells. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months. 5. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to measure the internal ohmic values on "Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)" is too stringent. With the standard's requirement to verify the float voltage every 18 calendar months, measuring the internal ohmic values every 6 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months.
Response: **Thank you for your comments.** **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed.** **2. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section 8 for a discussion of this. The associated VSL has also been revised.** **3. The activity to which you refer is an inspection-based activity based on overall functionality, and addresses functionality of various communications technologies. If an entity monitors the power supply (as suggested), doing so addresses one portion of the functionality, but does not address channel integrity, etc.** **4. The SDT disagrees, and believes that the specified activities, at the specified intervals, are appropriate.** **5. The standard has been revised as you suggested.**				
Paul Shipps	Lakeland Electric	6	Negative	Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.)
Response: **Thank you for your comments. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.**				
Eric Ruskamp	Lincoln Electric System	6	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it.

Voter	Entity	Segment	Vote	Comment
				Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: **Thank you for your comments.** **1. Table 1-1 has been modified as you suggest.** **2. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.** **3. Table 1-4 does not specify specific gravity testing.**				
Brad Jones	Luminant Energy	6	Negative	Luminant commends the PRC-005-2 Standard Drafting Team for its quality efforts in producing this version of the Standard however; Luminant must cast a negative ballot vote for this present version of the Standard. The negative vote against the present version of PRC-005-2 is solely based on the addition of Requirement R1 Part 1.5 with its associated reference to it in Requirement R4 Part 4.2 and the VSL table. It is Luminant's opinion that this new Requirement as written subjects all Transmission Owners, Generation Owners and Distribution Providers to vague interpretations of a requirement that cannot be complied with because it is impossible for any of them to draft the necessary documentation to be compliant with the Standard. As stated in the High VSL associated with Part 1.5 of Requirement R1 all owners will fail "to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters." It is Luminant's opinion that the measurement of acceptable performance during maintenance and testing activities can be accomplished with a Pass/Fail type of documentation on a test form. No company can effectively establish calibration tolerance parameters for an entire "component type" of the Protection System. Doing so could be detrimental to the reliability of the grid. Parameters are dependent on the location, application and situation specific to each Protection System device.

Voter	Entity	Segment	Vote	Comment
				The inclusion of Part 1.5 of Requirement R1 is a significant addition to the standard, and by NERC Rules of Procedure requires the input and consideration of the full Standard Drafting Team.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Daniel Prowse	Manitoba Hydro	6	Negative	1. Implementation Plan (Timeline) for R1: In areas not requiring regulatory approval, the 6 month time frame proposed for R1 is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval. 2. VSLs: The high VSL for R1 “Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5” may be interpreted in different ways and should be further clarified. 3. Table 1-4: The requirements for batteries listed in Table 1-4 do not appear to be consistent with the comments in the FAQ Section (V 1A Example 1). Please see comments submitted during the formal comment period for further detail. 4. Table 1-4: The requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience.
Response: **Thank you for your comments.** **1. In consideration of your comment, “six” has been modified to “twelve” in the Implementation Plan for R1, making it consistent with the remainder of the Implementation Plan.** **2. The SDT does not understand your concern; further details are needed.** **3. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.** **4. The SDT believes that the 3-month interval specified in the Standard is appropriate.**				
Joseph O'Brien	Northern Indiana Public Service Co.	6	Negative	We disagree with the practice of performing calibration checks on non microprocessor relays every 6 years.
Response: **Thank you for your comments. The SDT considers it important that calibration checks be performed on non microprocessor relays no less frequently than every 6 years.**				

Voter	Entity	Segment	Vote	Comment
James D. Hebson	PSEG Energy Resources & Trade LLC	6	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: **Thank you for your comments. Please see our response to your comments from the formal comment period.**				
Dennis Sismaet	Seattle City Light	6	Negative	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities

Voter	Entity	Segment	Vote	Comment
				in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxilary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence".** **2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
David F. Lemmons	Xcel Energy, Inc.	6	Negative	We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments.
Response: **Thank you for your comments. Please see our responses to your formal comments.**				
Jim R Stanton	SPS Consulting Group Inc.	8	Negative	1. The standard as written is wildly prescriptive and violates the concept of "what and not how." The standard and its Tables seek to prescribe in detail maintenance and testing processes which should be left up to the owners and operators of the protection systems.

Voter	Entity	Segment	Vote	Comment
				2. References to Tables 1-5 should be deleted from the standard itself and moved to a reference section.
Response: **Thank you for your comments.** 1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.** 2. **Tables 1-1 through 1-5 are considered by the SDT to be an integral part of the requirements of the standard and thus belong within the Standard.**				
Louise McCarren	Western Electricity Coordinating Council	10	Affirmative	Our affirmative vote reflects our belief that the proposed PRC-005-2 is an overall improvement to the four standards that it would replace. We also believe that it is appropriate to address maintenance and testing of all protection systems in one standard rather than in four individual standards.
Response: **Thank you for your comments and support.**				

END OF REPORT

Consideration of Comments on the 4th Draft of Protection System Maintenance and Testing — Project 2007-17

The Protection System Maintenance and Testing Drafting Team thanks all commenters who submitted comments on the 4th draft of the Protection System Maintenance standard, its implementation plan, and the associated reference document. The standard and associated documents were posted for a 30-day public comment period from April 13, 2011 through May 13, 2011. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 55 sets of comments, including comments from more than 176 people from approximately 103 companies representing 10 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

In addition, a successive ballot of the standard was conducted from May 3-13, 2011, and a non-binding poll of the Violation Risk Factors and Violation Severity Levels was conducted from May 3-16, 2011 and comments from the ballot and poll have been included in this report.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Purpose:

The SDT modified the Purpose to state, "To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order" in response to previous Quality Review comments.

Applicability:

Several comments were offered, suggesting that PRC-005-2 needs to be consistent with the interpretation in Project 2009-17, now implemented as PRC-005-1a, and the SDT modified Applicability 4.2.1 for better consistency with the interpretation 4.2.1 as shown below:

> 4.2.1. Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).

Requirement R1:

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Requirement R1 was modified as shown below for improved specificity, based on stakeholder comments:

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.

Tables

Most commenters seemed to agree in general that the restructured tables added clarity, and some commenters offered assorted suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" to address various comments.

Implementation Plan

Some commenters noted that for entities not subject to regulatory approvals, the implementation plan should be longer so that all entities have sufficient time for implementation. The team did modify the Implementation Plan to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines. Additionally, all "calendar year" implementation periods were revised to "months" for additional clarity.

VLSs:

VSLs for Requirement R1

- Phased VSLs were added to address R1 Part 1.1, which was previously addressed only as a "Severe" VSL.
- A reference was added within the R1 VSL to Part 1.3.
- R1 High VSL was revised to add a reference to Table 2.

VSLs for Requirement R2

- One element of the R2 VSL was made binary (Severe), rather than "phased" (in two steps), in response to several comments.
- Many commenters pointed out an error (which was corrected by the SDT) within the VSL for R2, where the Lower and High VSLs contained identical text.

VSLs for Requirement R3

- The R3 VSLs were revised to replace "complete" with "implement and follow" for consistency with the Requirement.
- Other minor editorial changes were made throughout the VSLs in response to comments.

Supplementary Reference and FAQ

- The commenters were generally supportive of the reference document.

- Several questions regarding the enforceability of this document were posed, and the SDT explained that the document is a supporting reference and not enforceable – only standard requirements are enforceable.
- A variety of suggestions were offered regarding additional information for the document, which largely resulted in modifications to the Supplementary Reference document. One specific suggestion of note (resulting in additional discussion within the document) requested a FAQ regarding "Calendar Year".
- Several commenters posed questions regarding "grace periods" and "PSMPs established by entities that are more stringent than the requirements within the standard". No additional changes were made due to these questions. If an entity develops a PSMP that includes time intervals that are more stringent than those in the standard, the entity will be audited against the intervals in its PSMP.

Definitions:

- Several comments were offered regarding Maintenance Correctable Issues, and resulted in modifying this definition to be "…such that the deficiency cannot be corrected during the performance of the maintenance activity …"

Unresolved Minority Views:

- Many comments were offered objecting to the 3-calendar-month intervals for station dc supply and communications systems, and suggesting that a 3-calendar-month interval requires entities to schedule these activities for 2-calendar-months in order to assure compliance. The SDT did not modify the standard in response to these comments, and responded that the intervals were appropriate, and that entities should be able to assure compliance on a 3-calendar-month schedule by using program oversight. The "Supplementary Reference and FAQ" document was augmented with additional explanatory text.
- Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.
- Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.
- Several comments were offered questioning various aspects of Applicability 4.2.5.4 (generation auxiliary transformers). No changes were made in response to these comments, and responses were offered illustrating why these transformers are included.
- Many comments were offered, questioning the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT explained that these Protection Systems are appropriate to be included for consistency with legacy standards PRC-008, PRC-011, and PRC-017, and noted that their inclusion is consistent with Section 202 of the NERC Rules of Procedure.
- Several comments were offered, objecting to the 6-calendar-year interval for lockout and auxiliary relays. The SDT declined to adopt the requested changes, and noted that these "electromechanical" devices with "moving parts" share failure mechanisms with electromechanical protective relays and that the intervals should be identical.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. The SDT has restructured the Table for Station DC Supply, separating it into six sub-tables individually addressing the various different technologies. Do you agree that the restructured tables provide more clarity? If not, please provide specific suggestions for improvement.

Summary Consideration: Most commenters seemed to agree in general that the restructured tables added clarity, and some commenters offered assorted suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" to address various comments.

A number of commenters continued to object to the "3 Calendar Month" maintenance intervals, and the SDT chose not to modify the standard. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems and suggestions to extend the maintenance intervals to 6 or 18 months were not adopted.

Some comments suggested extending the interval to 4 months. Additional discussion (including an example) regarding this item was added to Section 7.1 of the "Supplementary Reference and FAQ". As explained in the reference, a calendar month begins on the first day of a new month following the month in which the activity was performed. Thus every "3 Calendar Months" means to add 3 months from the last time the activity was performed.

Specific changes made to the tables in response to comments:

Tables 1-1 and 1-3 – References to Table 2 were corrected.

Table 1-4(a) and Table 1-4(d) – Modified header to clarify, "Protection System Station dc supply"

Table 1-4(b) and Table 1-4(c) - Modified header and component attributes to clarify, "Protection System Station dc supply"

Table 1-4(e) - Modified header and component attributes to clarify, "Protection System Station dc supply" and replaced, "distribution breakers" with "non-BES interrupting devices".

Table 1-4(f) - Modified header to clarify, "Protection System Station dc supply", modified the seventh table entry for clarity, and added eighth table entry.

Table 1-5 – Added "Associated with Protective Functions" to header

Organization	Yes or No	Question 1 Comment
Tri-State G & T Association, Inc.	Ballot	On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored

Organization	Yes or No	Question 1 Comment
(3) (5)	Comment – Affirmative	communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Also, if a relay is set to operate in a manner typical when communication is not used for protection (i.e. defaulting to step-distance functions with a loss of communication), is the defaulted operation of the relay considered "correct operation" thereby excluding the communication as necessary for its correct operation? Please clarify the term correct operation and how it applies to redundant communication systems and/or the performance of the relay in the absence of communication.
Response: Thank you for your comments. If communication-assisted protection is provided as described in the Applicability of PRC-005-2, it must be tested in accordance with the intervals and activities described in the standard. Redundant equipment and/or channels do not relieve the entity of the responsibility to maintain all equipment as required. An entity is entitled to use any monitoring present on the communications system to adjust its maintenance as established within Table 1-2, and, if sufficient component populations are present and the entity wishes to address the additional included requirements, performance-based maintenance is also available. Correct operation of the protective function means that if the communications system is part of the protection system and loss of it causes the system to fail to meet the schemes protection requirements it has failed. In the example you provide, loss of communications would result in time delay clearing depending on location of the fault. If time delay clearing will be sufficient for your system clearing time requirements, then high speed clearing is not required and the Comm. System would not need to be installed. If it is installed, you must meet the PRC-005 requirements. Redundant communications schemes are installed where high speed clearing is required to meet planning criteria. The second scheme is in place to prevent the line from being removed from service if the primary scheme must be maintained or fails. If redundant schemes are in place, both must meet the PRC-005 standard.		
Tri-State G&T		On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Please clarify the term correct operation and how it applies to redundant communication systems.
Response: Thank you for your comments. If communication-assisted protection is provided as described in the Applicability of PRC-005-2, it must be tested in accordance with the intervals and activities described in the standard. Redundant equipment and/or channels do not relieve the entity of the responsibility to maintain all equipment as required. An entity is entitled to use any monitoring present on the communications system to adjust its maintenance as established		

Organization	Yes or No	Question 1 Comment
within Table 1-2, and, if sufficient component populations are present and the entity wishes to address the additional included requirements, performance-based maintenance is also available. Correct operation of the protective function means that if the communications system is part of the protection system and loss of it causes the system to fail to meet the schemes protection requirements it has failed. In the example you provide, loss of communications would result in time delay clearing depending on location of the fault. If time delay clearing will be sufficient for your system clearing time requirements, then high speed clearing is not required and the Comm. System would not need to be installed. If it is installed, you must meet the PRC-005 requirements. Redundant communications schemes are installed where high speed clearing is required to meet planning criteria. The second scheme is in place to prevent the line from being removed from service if the primary scheme must be maintained or fails. If redundant schemes are in place, both must meet the PRC-005 standard.		
Consumers Energy (4)	Ballot Comment - Negative	Relating to Table 1-3, The SDT has advised that the voltage and current inputs must be checked at each individual relay. This may not be difficult if the relays are microprocessor relays (where internal metering may be used), but for the predominant population of electromechanical relays (particularly for current signals), this requirement will necessitate repeated operation of test switches and associated insertion of meters. Such activities will not only be very difficult and time consuming, but will actually be dangerous because of the dangers of accidentally opening current circuits during testing. It should be sufficient to verify the integrity of the series string of protective relays, etc during maintenance activities, as all devices within the series string will be receiving the same values.
Response: Thank you for your comments. Entities can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, secondary injection, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately “verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays”.		
Tri-State G & T Association, Inc. (3) (5)	Ballot Comment - Affirmative	The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions?
Response: Thank you for your comments. No, an independent DC Supply related only to communication equipment is not considered to be “station dc supply”. The periodic functional observation and testing of the communications equipment is included, but there are no requirements for the independent dc supply.		
Wisconsin Electric Power Co. (5) Wisconsin Electric Power	Ballot Comment - Negative	(1) The maximum maintenance intervals listed in various PRC-005-2 tables are described as “calendar years” which is an undefined term. Since maintenance intervals are critical to this standard, this term should be either clearly defined or explained in the standard. For example, if a component was last tested on 6/1/2005; does that component need to be tested by 6/1/2011 or 12/31/2011 to satisfy its 6 calendar year

Organization	Yes or No	Question 1 Comment
Marketing (3) Wisconsin Energy Corp. (4)		maximum maintenance interval? 2) Clarification and/or direction is desired on the testing of protection systems that contain components owned by various entities. For example, in the instance of non-vertical integrated utilities where a distribution provider has a Protection System that directly trips a transmission owner's circuit breaker(s), how would the distribution provider verify that the trip coil is able to operate the circuit breaker? (3) Maximum testing intervals are defined. Does this imply that there are no minimum testing intervals? In other words, is the maintenance cycle reset anytime maintenance is performed? (4) Requirement R1.1.2 states that" "All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4." Yet, in Table 1-4 under Component Attributes it refers to "…not having monitoring attributes of Table 1-4(f)." Suggest this statement be made more clear by adding "All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4., unless the dc supply has the monitoring attributes listed in Table 1-4(f)." (5) Suggest the inspection Maximum Maintenance Interval for inspection of batteries be 4 months instead of 3 months to allow for workforce constraints that may preclude an inspection being performed within a 3 month window. Every 3 months has been found to be more than adequate to observe changing conditions that affect batteries, therefore we feel 4 months would still be sufficient. (6) In Tables 1-4 (a), (b), (c) – What is your interpretation of battery continuity? In other words, what measurements or indications would be acceptable to affirm an acceptable condition? Table 1-4(b) VRLA batteries, Maximum Maintenance Interval 18 Calendar Months, Maintenance Activities, Verify: Battery terminal connection resistance, Verify: Battery intercell or unit-to-unit connection resistance - comment: Add the following qualifier to these resistance checks: "If battery posts are not readily accessible or too small to allow a good connection, follow the manufacturer's recommendation(s)."

Response: Thank you for your comments.

1. A "calendar year" refers to the years on the Julian calendar commonly used, and should be regarded as referring to a numbered year, comprising the months of January through December. For example, 2010 is one calendar year; 2011 is another. A component, with a 6-year interval, which was last tested in 2005, would next have to be tested by the end of 2011.

2. The standard does not prescribe "how" an entity must meet the requirements, only that the requirements must be met. However, all entities listed in the Applicability are "owner entities", and the SDT believes that the owner of the component should be responsible for its maintenance. However, it may be necessary to have records relating to specific activities from the associated entity in order to demonstrate compliance to an auditor.

3. No minimum intervals are provided. To the degree that any maintenance includes all required activities, that maintenance can be recorded as addressing the

Organization	Yes or No	Question 1 Comment
standard and re-setting the interval. 4. A "time-based" program includes extended intervals for those activities that can be effectively performed by condition monitoring. However, this requirement excludes an entity from utilizing performance-based maintenance per R3 and Attachment A. 5. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month" 6. In Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT gives its interpretation of battery continuity and lists several examples of measurements or indications that would be acceptable to affirm an acceptable condition and contains a discussion of connection resistance. Your comment concerning the inaccessibility of posts or being too small would fit more appropriately as a qualifier there than in the in the standard itself.		
Tennessee Valley Authority (1) (5) (6)	Ballot Comment - Negative	In Table 1-4(a), the requirement to perform battery cell internal ohmic measurements every 18 months for vented lead-acid batteries is excessive, and no technical justification is provided for an 18-month interval. A 3-year internal ohmic test frequency is adequate to prove battery integrity. IEEE 450 does not provide a recommended interval for internal ohmic measurements. For standard capacity testing, the recommended interval is no greater than 25% of expected battery life. Our normal battery life is 20+ years, so the recommended capacity test interval would be about 5 years. EPRI also recommends capacity testing at 5 year intervals. There is no justification for performing internal ohmic measurements every 18 months (which equals every 7.5% interval of the expected battery life). We feel the standard should set the interval for battery internal cell ohmic testing at 3 years.
Response: Thank you for your comments. The Maintenance Activity of evaluating the measured cell/unit internal ohmic values to station battery baseline is an optional activity to verify that the station battery can perform as designed. An owner who desires not to take internal ohmic measurements on a Vented Lead-Acid (VLA) battery can elect to verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank without ever having to perform any internal ohmic measurement on the battery. The maximum maintenance interval for performing this capacity test on a VLA battery bank is 6 Calendar Years. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" - that was posted for review with PRC-005-2 - the SDT answered several Frequently Asked Questions which explain why the 18 month Maximum Maintenance Interval is justified rather than the 3 year frequency that is assumed by some to be adequate.		
Great River Energy (1)	Ballot Comment - Affirmative	1. Table 1-4(b) VRLA Batteries---both" 6 Calendar Months" in the table should be changed to 12 months. This would avoid being in violation if we miss a bank during a "6 month maintenance cycle" 2. Table 1-4(c) Nickel-Cadmium Batteries under the Maintenance Activities column for the 6 Calendar Years--- This maintenance activity should be optional if 18 Calendar Month Activities are completed. Or increase load test to 10 years.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. 1. In the IEEE recommended Practice for Maintenance, Testing and Replacement of VRLA batteries (IEEE SDT 1188) a quarterly inspection should include “Cell/unit internal ohmic values.” Based on this recommendation the SDT believes that extending the Maximum Maintenance Interval of 6 Calendar Months in Table 1-4(b) to 12 months as suggested would be too excessive. The 6 Calendar Months for this maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few days during the quarterly maintenance cycle. 2. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT answered a Frequently Asked Question explaining why the 6 Calendar Year maintenance activity cannot be optional if the 18 Calendar Month Activity of Table 1-4(c) is performed. The SDT also in the Supplemental Reference & FAQ document justifies why the 6 Calendar Year Maximum Maintenance interval for performing the Maintenance Activity in Table 1-4(c) can not be extended to 10 years as suggested.		
AtCO Electric ltd		Table 1-4: ATCO Electric has a number of remote substations that are difficult to access. 1. The requirement for a 3 calendar month inspection for electrolyte level is too frequent. The requirement would become achievable if electrolyte level inspections were moved to the 18 calendar months category, or if the 3 calendar months frequency were increased to 8 calendar months. 2. Table 1-4(b): for the same reasons, the requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category, or if the 6 calendar months frequency were increased to 14 calendar months. 3. Table 1-4(c): the requirement of a 6 calendar year performance service or modified performance capacity test should be removed. From our experience, there is no benefit in doing battery load tests. Instead, we apply verification of battery intercell resistance as a more efficient method of monitoring battery condition, which provides an 8 to 14 month lead time to replace a battery unit/cell before it goes dead.
Response: Thank you for your comments. 1. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval. If adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. 2. In the IEEE recommended Practice for Maintenance, Testing and Replacement of VRLA batteries (IEEE SDT 1188) a quarterly inspection should include “Cell/unit internal ohmic values.” Based on this recommendation the SDT believes that extending the Maximum Maintenance Interval of 6 Calendar Months in Table 1-4(b) to the 18 calendar months category as suggested would be excessive and the SDT notes that this verification may be possible via monitoring methods.”(See Table 1-4(f), component attribute row “Any lead acid battery based …”). The 6 Calendar Months for this maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few days during the quarterly maintenance cycle.		

Organization	Yes or No	Question 1 Comment
3. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT answered a Frequently Asked Question explaining why the 6 Calendar Year maintenance activity cannot be optional if the 18 Calendar Month Activity of Table 1-4(c) is performed. The SDT also in the Supplemental Reference & FAQ document justifies why the 6 Calendar Year Maximum Maintenance interval for performing the Maintenance Activity in Table 1-4(c) can not be removed as suggested.		
Kristina M. Loudermilk (8)	Ballot Comment - Affirmative	1) In Table 1-4(b) under the Component Attributes, the sentence begins with Station dc supply; while the other 1-4 tables begin with Protection System Station dc. I propose to make it consistent with the other tables. 2) Table 1-4(e) mentions Maximum intervals and references another table. Is there an easier way in the Standard to send the same information without having them flip pages? As another example in every Component Attribute in Table 1-4(f) we mention (See Table 2). Could it be possible to make that a note, instead of placing it under each attribute? It seems overwhelming when looking at these and for each one that is read, flip over to Table 2. I feel like some of these references give the feel of a scavenger hunt. I am not sure if anything can be done, but thought I would mention it.
Response: Thank you for your comments. 1.The Tables have been modified to use "Protection System Station dc supply" 2. In this regard, the SDT has tried several methods of presentation for this information. Of all methods reviewed, including the one you suggest, the SDT has determined that the method currently represented in the Tables represents the best compromise.		
Consumers Energy (4)	Ballot Comment - Negative	Relative to the 18-month activity to measure battery terminal connection resistance in Table 1-4, measuring the battery terminal connection resistance for all terminals of the battery is an involved process that may force the battery (and thus the system) out-of-service, or alternatively the use of a temporary battery, for the duration of the activity. We suggest that a 6-year interval for this involved and invasive activity is appropriate and adequate. We also suggest that it should alternatively be sufficient to instead re-torque all battery terminal connections at the same interval.
Response: Thank you for your comments. In IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), valve-regulated lead-acid (VRLA) and nickel-cadmium (NiCd) batteries respectively state that a "yearly inspection" should include "Cell-to-cell and terminal connection resistance", "Cell-to-cell and detail resistance of entire battery", and "Condition and resistance of cable connections." Based on these IEEE recommendations the SDT believes that the Maximum Maintenance Interval of 18 Calendar Months for this Maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few weeks during the yearly maintenance cycle. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" - that was posted for review with PRC-005-2 - the SDT explains what hazards can result from high connection resistance. Also in the Supplementary Reference the SDT references where in the IEEE Standards entities can find excellent information and examples of performing this non-intrusive Maintenance Activity. The SDT respectively disagrees with the premise that the activity to		

Organization	Yes or No	Question 1 Comment
measure battery terminal connection resistance in Table 1-4 is "an involved process that may force the battery (and thus the system) out-of-service, or alternatively the use of a temporary battery, for the duration of the activity." Members of the SDT are familiar with numerous Transmission Owners, Generator Owners and Distribution Providers in NERC who yearly perform this benign maintenance activity on their battery systems while the Protection Systems that the station batteries support are in service.		
Ameren Services (1)	Ballot Comment - Affirmative	Clarify p17 Table 1-4(e) interval meaning. We think this means we need to verify the Station dc supply voltage on 12 calendar year interval if unmonitored, or no periodic maintenance if monitored as stated.
Response: Thank you for your comments. You are correct in your interpretation for Protection System dc supply used only for distribution breakers that are associated with UFLS, UVLS, or SPS, as stated in Table 1-4(e).		
Old Dominion Electric Coop. (4)	Ballot Comment - Affirmative	ODEC believes the standard is very close to being ready for approval. 1. In the Attachment A for the battery testing, you exempt the UFLS and UVLS equipment in tables and then include SPS batteries in the table with UFLS and UVLS. Either SPS should be associated with UFLS and UVLS and you need to add it to the previous tables or fix table 1(f). 2. Also, consider going to 4 calendar months instead of 3 calendar months for the battery maintenance requirements.
Response: Thank you for your comments. 1. Special Protection Systems are often a far more complex system which may comprise a combination of "transmission", distribution, and generation components, and are often installed to prevent serious system problems. Therefore, the requirements for SPS equipment maintenance align with that for other generic Protection Systems. It is also notable that the legacy PRC-017-1 includes batteries within the list of components to be addressed. However, if the breaker is a distribution breaker that is associated with SPS but is not otherwise associated with generic Protection Systems, the extended interval in Table 1.4(e) applies. 2. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month."		
Associated Electric Cooperative, Inc. (1)	Ballot Comment - Negative	AECI appreciates the effort by the drafting team. However, the 90 day inspections for batteries and communications circuits should be extended to 120 days to allow for a 30 grace period. Schedules would be set for every 90 days as what is required in this revision.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td colspan="3">unmonitored components. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”</td></tr>
<tr><td>Manitoba Hydro (1) (3) (5) (6)</td><td>Ballot Comment - Negative</td><td>1. Battery Check Interval Manitoba Hydro maintains our position that the 3 month battery check interval should be extended to 6 months. The 3 month interval is too frequent based on our experience and while IEEE SDT 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. With the 3 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval.

2. Conductance Measurements Conductance measurement should be listed in Table 1-4 as an acceptable measurement method.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

1. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”.

2. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT answered a Frequently Asked Question explaining what cell/unit internal ohmic measurements are. Conductance by definition is an ohmic measurement and although not spelled out in the standard is listed in Table 1-4 because it is an ohmic measurement.</td></tr>
<tr><td>Georgia Transmission Corporation</td><td>No</td><td>We need clarification on the UFLS or UVLS system Station DC Supply test. We trip the high side device (non-BES asset) for each of our distribution stations UFLS or UVLS schemes, not the individual distribution breakers. It is hard to distinguish what maintenance interval and maintenance activities we should engage for Station DC Supply test. Since the device is not a distribution breaker as mentioned in the Table 1-4 (a-f) we would be conservative and choose to perform maintenance at all our distribution stations with UFLS or UVLS schemes as per Table 1-4(a). Reading the statements in the Supplementary Reference and FAQ, we notice our devices perform similar functions as the distribution breakers. Reference pg 60 of Supp. Ref. and FAQ paragraph 4. Since tripping the high side device of a distribution transformer still constitutes a distributed system would our system meat the exclusion criteria although it is not a distribution breaker, would this meet the same requirements and exempt the station from Table 1-4(a) and require only maintenance for DC systems as per Table 1-4(e)? Please clarify. We recommend changing the term distribution breaker to distribution asset interruption device or non-BES equipment interruption device.</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. Table 1-4 (e) has been modified in consideration of your comment to improve clarity (“non-BES interrupting devices “). If the cited distribution transformer is not a BES element, the Protection Systems for that distribution transformer are not included per the Applicability (4.2.1) as modified.		
PNGC Comment Group	No	We agree the changes to the tables have added clarity, but disagree with the maintenance intervals for DC supply. Comments: PNGC’s comment group views the Maximum Maintenance Interval for station DC Power Supply (Table -14a/b/c/d) to be unnecessarily onerous and restrictive to many smaller-rural entities, in the west and probably throughout the US, and this prevents us from being able to support PRC-005-2 as written. We make these comments with the understanding that others have made similar comments in the past but we feel strongly that this is an important issue worthy of further review by the SDT. We believe a quarterly inspection schedule can be met while at the same time allowing entities the flexibility they need. IEEE 1188-2005 suggests a quarterly inspection schedule for lead acid batteries and we believe the standard interval for verifying and inspecting dc supply should be 3 months with a maximum interval of 6 months. This meets the quarterly threshold and gives some flexibility to account for unusual conditions. There are substations in Pacific Northwest rural areas that can be inaccessible during long periods of time during the winter, potentially exposing an entity to sanction if weather conditions prevent access to equipment for an extended period of time. Additionally, due to a smaller workforces and greater distances between equipment subject to PRC-005, small-rural entities face obstacles that large entities may not have. The three month maximum interval assumes ideal conditions and resource access and is not realistic. We thank the SDT for considering our comments.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended.		
Arizona Public Service Company	No	Although considerable clarity was achieved in the structuring of the table for the different types of technologies associated with the DC supply, there is issue on the maximum allowable intervals. The standard remains too prescriptive in the intervals and maintenance activities. As an example it is believed the intent of the interval for verifying voltages and inspecting electrolyte levels and unintentional grounds level would be every 3 months. However, for the entity to ensure compliance and not incur a violation it would have to have a shorter interval, probably every 2 months just to ensure compliance and not incur a violation. The 3 month interval is in question based on programs that have been in service for many years where four months have been proven as reliable for operation, an even shorter period than 3 or 4 months is not only a burden but an unnecessary expense without a benefit of increase reliability of the Bulk Electric System.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month".		
Southern Company Generation (5)	Ballot Comment - Affirmative	The restructured Table for Station DC supply does clarify what is being required for each type of dc system, yet the Station DC Supply requirements, however, are excessively prescriptive in comparison to the other Protection System component types.
Response: Thank you for your comments. The SDT recognizes that Table 1-4 with its tables a through f is considerably larger than any of the tables for the other four Protection System components. However the SDT does not agree that the maintenance activities of Tables 1-4 (a –f) for the station dc supply are "excessively prescriptive." As pointed out in Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the station battery which is part of the station dc supply is unique from any other Protection System component in that it is a perishable product which requires several prescribed maintenance activities to monitor and maintain its ability to perform as designed for its life cycle.		
Indeck Energy Services	No	The tables are limited to a few battery technologies and will be out of date in short order with the many types of advanced batteries already on the market. The testing requirements should be performance based as opposed to prescriptive.
Response: Thank you for your comments. While the SDT agrees that there are a few advanced batteries and new station dc supplies which have non battery based energy storage devices in them on the market, the SDT disagrees that the testing requirements for batteries used in station dc supplies should be performance based as opposed to prescriptive. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. Please note that the Standard specifically addresses requirements for non-battery based energy storage devices within Table 1-4(d). According to the NERC Reliability Standard Development Process, NERC Reliability Standards must be reviewed at least once every five years, and any changes related to new technologies can be addressed within that process.		
Tampa Electric Company	No	If during a UF operation there were ever any breakers that did not trip properly, there may be enough that do trip to return things to balance. There is more room for error with UFLS than with BES. The standard does make some allowance for differences between UFLS equipment and BES equipment. For example the DC source testing requirement for UFLS is to just test the battery voltage when the control circuit is tested. It is not necessary that the breaker be tripped for UFLS testing every six years as is the case for BES. However, every 12 years all unmonitored control circuitry must be tested, which may include tripping the breaker.
Response: Thank you for your comments. Table 1-5 does not require tripping of the breaker for UFLS/UVLS.		
Tri-State G & T Association, Inc.	Ballot	On Page 19, Table 1-5, the standard requires that electromechanical lockout control circuits be maintained

Organization	Yes or No	Question 1 Comment
(3) (5)	Comment - Affirmative	every 6 years and protective function unmonitored control circuits be maintained every 12 years. Why is there inconsistency in the interval between the electromechanical lockout and protective function control circuits?
Response: Thank you for your comments. The circuit itself is 12-years, but the interval for electromechanical devices such as auxiliary or lockout relays remains at 6 years, as these devices contain “moving parts” which must be periodically exercised to remain reliable.		
Constellation Energy Commodities Group (6)	Ballot Comment - Negative	As with previous revisions of this standard, the maintenance intervals and activities described in Table 1-1 through Table 1-5 are too prescriptive.
Constellation Power Source Generation, Inc. (5)	Ballot Comment - Negative	CPG believes, as with previous revisions of this standard, that the maintenance intervals and activities described in Table 1-1 through Table 1-5 are too prescriptive.
Response: Thank you for your comments. The SDT is not prescribing or suggesting what methods an entity employs within their program. The intervals remain as prescribed within the standard and are designed to be clear and effective to support reliability of the BES.		
Alliant Energy Corp. Services, Inc. (4)	Ballot Comment - Negative	Table 1-5 (Component Type – Control Circuitry) Item 4 – “Unmonitored control circuitry associated with protective functions” require a 12 calendar year maximum maintenance interval. We believe UFLS and UVLS control circuitry should be exempted from this requirement. It would take multiple failures to have any impact, and the impact on the BES would be minimal.
Response: Thank you for your comments. The SDT disagrees; however, the requirements related to interrupting devices used only for UFLS/UVLS are less detailed than those for other Protection Systems because of the reason cited in your comment.		
Consumers Energy (4)	Ballot Comment - Negative	Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. In the case of system elements that do not have redundant protection systems (such as those related to lower-voltage systems within the BES), it may not be possible to do so with outaging customers for the duration of the maintenance activity. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers.
Response: Thank you for your comments. The intervals and activities specified are believed by the SDT to be technically effective. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns. Entities should be able to complete the activities within the shorter intervals without outages.		
American Transmission	Ballot	1. ATC recognizes the substantial efforts and improvements to PRC-005-2 that have been made and

Organization	Yes or No	Question 1 Comment
Company, LLC (1)	Comment - Negative	appreciate the dedicated work of the SDT. ATC appreciates the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 2. ATC's remaining concerns to PRC-005-2 are with the definition and timelines established in Table 1-5. ATC is recommending a negative ballot since, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. Note: Additional Comments to overall Standard also submitted.
Response: Thank you for your comments. 1. Thank you for your support. 2. The lockout relays and trip coils contain "moving parts" which must be periodically exercised to remain reliable. Operational results, if desired by an entity, MAY be used to meet maintenance requirements to the degree that they verify, etc, the relevant performance. Whether their use is effective for a specific entity is left to the entity to determine.		
Wisconsin Electric Power Co. (5) Wisconsin Electric Power Marketing (3) Wisconsin Energy Corp. (4)	Ballot Comment - Negative	Clarification is required in Table 1-5 as to what trip and control paths should be tested. Specifically, should non-protection paths, such as local control switches, that are not part of the Protection System, but operate Protection System Component, be tested? In Table 1-5, the maintenance activity for unmonitored control circuitry associated with protective functions is to "verify all paths of the control and trip circuits". We recommend that only the protection system paths of the control and trip circuits require verification by PRC-005-2.
Response: Thank you for your comments. The SDT believes that Protection Systems that protect BES elements should be included. This position is consistent with the currently-approved PRC-005-1 and consistent with the SAR for Project 2007-17. The header section of Table 1-5 has been modified to clarify that only the control circuitry associated with protective functions is being addressed.		
Kristina M. Loudermilk (8)	Ballot Comment - Affirmative	In table 1-5 is it necessary to mention the second and last item in the table. If there is nothing to do, then why have it as an attribute making it mandatory to keep track of, well, nothing. If those items do need to stay, then could we reorganize the table so where it is in ascending order from Maximum maintenance intervals, like the other tables?
Response: Thank you for your comments. The SDT believes that inclusion of these two items add clarity. The Table entry for trip coils associated only with UVLS/UVLS has been left in the original position to relate it directly to the companion activities for other applications.		

Organization	Yes or No	Question 1 Comment
Nebraska Public Power District	No	The restructured tables are indeed an improvement; however the tables still need some work for clarity: 1. Table 1-5: Unmonitored control circuitry has a maintenance activity of "Verify all paths of the control and trip circuits." The wording of "control and trip circuits" leads to circuit verification of more than just trip circuits. In fact multiple circuits would have to verified, such as station house load transfer schemes. Providing documentation to an auditor to prove all paths have been tested will be difficult and is considered excessive. The paperwork required to prove compliance is extremely excessive for this requirement and doesn't provide a benefit to reliability. 2. Table 1-5: Table 1-5 requires trip checking every six calendar years for trip coils and electromechanical lockout and/or tripping auxiliary devices. Every six years is excessive, when suitable monitoring is used. We recommend verification of these components be completed at the same frequency as the associated relay testing when monitoring is used. For electromechanical, no more than every 6 calendar years, for microprocessor, no more than 12 calendar years.
Response: Thank you for your comments. 1. The header section of Table 1-5 has been revised to clarify that it applies to "Control Circuitry Associated with Protective Functions", and the SDT believes that this revision addresses your concerns. 2. The electromechanical devices such as auxiliary or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.		
Consolidated Edison Co. of New York (1) (3) (5)	Ballot Comment - Affirmative	1. We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend.
Consolidated Edison Co. of New York (6)	Ballot Comment - Affirmative	1. We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend. 2. We recommend that the drafting team recognize that a "fail safe" or "self-reporting" alarm design serves as an acceptable alternative to periodic testing. This "fail safe" or "self-reporting" alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to "alarm on" and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT believes that the monitoring and reporting will be generally done by automatic reporting methods such as SCADA and previously removed a reference to “automatic reporting” specifically to address those cases where the facility is manned. 2. The application discussed seems to the SDT to be an effective method of “monitoring the monitoring circuit”. (See Table 2, last row with heading “Alarm Path with monitoring.”)		
Nebraska Public Power District	No	1. Table 2: The interrelationship between Tables 1-1 through 1-5 and Table 2 is ambiguous. Tables 1-1 through 1-5 “component attributes” columns references Table 2 in many cases as the criteria for maximum interval. However, each table entry has a maximum maintenance interval listed as well. There are a few instances where the “trump” interval is not clear. Table 1-5 is a good example. 2. Table 2 states that monitored devices (1-1 through 1-5) not having monitored alarm paths shall be tested every 12 years. However, Table 1-5 states that DC circuits with monitored continuity shall have no periodic maintenance. We suspect that Table 2 attributes needs further clarification to eliminate the confusion, both Table 2 attributes at first glance appear to say the same thing. However, after study it appears to address “detection” monitoring versus continuous (control center type) monitoring. We believe further distinguishing clarifications are needed to make it evident and clear.
Response: Thank you for your comments. 1. The SDT believes that the activities and intervals, as they relate to whatever monitoring attributes are present, are clear. Table 2 is specifically labeled to address whatever maintenance is necessary to the monitoring and alarming equipment itself. The references to Table 2 have been corrected where necessary. 2. Table 1 is related to the component itself, and Table 2 relates to maintenance of the monitoring and alarming if relevant. If the monitoring specified is present, no periodic maintenance of the control circuitry itself is needed. However, as indicated in Table 2, maintenance (or monitoring) is required to assure that the monitoring on the control circuitry is operational.		
ExxonMobil Research and Engineering	No	
Ameren	Yes	Please carry the grid across in Table 1-4(f) to show the Maintenance Activities that go with the Component Attribute.
Response: Thank you for your comments. The grid in Table 1-4(f) is drawn as the SDT intended, to show “No periodic maintenance specified” for all table entries. The activity listed is the activity that is being accomplished by the monitoring mechanism.		
Tennessee Valley Authority	Yes	However, The requirement to perform battery cell internal ohmic measurements every 18 months for vented lead-acid batteries is excessive, and no technical justification is provided for an 18-month interval. A 3-year

Organization	Yes or No	Question 1 Comment
		internal ohmic test frequency is adequate to prove battery integrity. EEE 450 does not provide a recommended interval for internal ohmic measurements. For standard capacity testing, the recommended interval is no greater than 25% of expected battery life. Our normal battery life is 20+ years, so the recommended capacity test interval would be about 5 years. EPRI also recommends capacity testing at 5 year intervals. There is no justification for performing internal ohmic measurements every 18 months (which equals every 7.5% interval of the expected battery life). Recommendation: Set the interval for battery internal cell ohmic testing at 3 years.
Response: Thank you for your comments. The Maintenance Activity of evaluating the measured cell/unit internal ohmic values to station battery baseline is an optional activity to verify that the station battery can perform as designed. An owner who desires not to take internal ohmic measurements on a Vented Lead-Acid (VLA) battery can elect to verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank without ever having to perform any internal ohmic measurement on the battery. The maximum maintenance interval for performing this capacity test on a VLA battery bank is 6 Calendar Years. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" - that was posted for review with PRC-005-2 - the SDT answered several Frequently Asked Questions which explain why the 18 month Maximum Maintenance Interval is justified rather than the 3 year frequency that is assumed by some to be adequate.		
Exelon	Yes	What kind of component we are talking about in table 1.4(d) "Station DC Supply using Non Battery Based Energy Storage" for switchyard in nuclear plants?
Response: Thank you for your comments. An example of a "station dc supply" component of this nature would be fuel cells. The SDT is aware that some entities are beginning to apply non-battery-based dc supplies, but we are unaware whether anyone is using these in switchyards for nuclear plants.		
Xcel Energy	Yes	Regarding the last row of Table 1-4(f): it seems very inconsistent to require a formal trending program for a manual 6 month (VRLA)/18 month (VLA) internal ohmic reading but to require no gathering and analysis of data as an alarm for a ohmic value for each cell/unit is available. If just a raw ohmic value is an adequate predictor of cell life, than why require a trending program for the manual reading if all that is needed to determine adequacy of remaining cell life is just a simple acceptance criteria (i.e. - alarm set point) against which you need to compare your measured data? In theory these are very gradual and predictable changes in ohmic readings over the entire life of the battery, such that the benefit of real time knowledge of exactly when a threshold is reached via alarm is minimal rather than having to wait until the next manual reading to ascertain that the threshold limit has been reached.
Response: Thank you for your comments. Your comment concerning the last row of Table 1-4(f) being inconsistent with the two distinct maintenance activities for internal ohmic value measurement found in the unmonitored station dc supply tables 1-4(a) and 1-4(b) was very incisive. As pointed out in section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT recognized that there are two maintenance activities in Table 1-4(b) which appear to be the same, but require a different method of interpretation to complete the required maintenance activity. The Drafting Team has considered your comment in light of its own discussion in the Supplementary Reference & FAQ document and has divided the last row of Table 1-4(f) into two rows to reflect the		

Organization	Yes or No	Question 1 Comment
two distinct maintenance activities required in the unmonitored tables (inspection of the condition of individual VRLA cell/units, and evaluating internal ohmic measurements to a baseline to verify the station battery can perform as designed).		
Duke Energy	Yes	We believe the table could be improved further to aid compliance by adding a footnote to the term “baseline” in the sub-tables 1-4(a), 1-4(b) and 1-4(f). The following proposed footnote text is taken from page 65 of the Supplementary and FAQ Reference Document: “Often for older VLRA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to. To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, all manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to.”
Response: Thank you for your comments. The addition that you suggest is properly considered application guidance; the SDT has been advised that such information is not to be included within the standard, and that it is appropriately included in separate reference materials.		
Ingleside Cogeneration LP	Yes	1. Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test. 2. However, we have found that the remainder of the items in the Tables are logically organized and correspond effectively with the five components of a Protection System. The maintenance activities and intervals are technically solid and reasonable. In our opinion, the benefits to proceed outweigh our one concern with the validation of communications channel performance.
Response: Thank you for your comments. 1. We agree that it is not good practice to disturb fiber connections as you indicate. Draft 4 does not require that. The Entity must perform the activities in the “Maintenance Activities” column. The SDT does not interpret this as taking anything apart. 2. Thank you.		
Manitoba Hydro	Yes	The restructured tables are an improvement, but we suggest that conductance (siemens) should be listed as

Organization	Yes or No	Question 1 Comment
		an acceptable measurement in addition to the resistance measurements already included in the tables.
Response: Thank you for your comments. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT answered a Frequently Asked Question explaining what cell/unit internal ohmic measurements are. Conductance is an ohmic measurement and although not spelled out in the standard is listed in Table 1-4 because it is an ohmic measurement.		
NIPSCO	Yes	Sub-tables are good. A related question: Some devices such as reclosers and circuit breakers may include batteries within the device itself. Does Table 1-4 apply to such batteries and DC supply? Recloser batteries do not provide access to intercell connections.
Response: Thank you for your comments. In most instances Table 1-4 does not apply to recloser batteries or batteries within the device because they are not generally used to provide dc power to Protection Systems designed to provide protection for BES elements. However, these types of devices with self contained batteries may be used at the distribution level to provide Protection Systems used for underfrequency and undervoltage load-shedding. Maintenance activities and maximum maintenance intervals for such batteries are found in Table 1-4(e) of the Standard.		
MISO Standards Collaborators American Transmission Company, LLC	Yes	1. Yes, however, in the "Supplemental reference and FAQ" document on page 65 there are two areas of concern. Page 65, paragraph 4:" the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment." While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer's test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of equipment will not change during this period. 2. On Page 65, paragraph 6, it states:"all manufacturers of internal ohmic measurement devices have established libraries of baseline values." We question the availability of baseline libraries for all manufacturers considering the variety and longevity of installations.
Response: Thank you for your comments. 1. The "Supplementary Reference and FAQ" concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment. 2. Many manufacturers of "Ohmic" test equipment have established libraries of baseline data. You are correct that test equipment manufacturers may not have data on every battery in service today. Several manufacturers of batteries (not all) have libraries for some (but perhaps not all) of their products. To achieve significant results from a trending program one needs to have good baseline data. The "Supplementary Reference and FAQ" document has been revised to reflect your concern – the word, "all" was changed to "many".		

Organization	Yes or No	Question 1 Comment
MRO's NERC Standards Review Subcommittee	Yes	Yes, however, in the “Supplemental reference and FAQ” document on page 65 this is one area of concern. Page 65, paragraph 4 ”the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment” While we understand the importance of creating a baseline, it’s not feasible to expect the test equipment to be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 15 years and it is not feasible to expect that the type of test equipment will not change during this period. We suggest changing the wording to read that consistent test equipment should be used to provide consistent/comparable results.
Response: Thank you for your comments. The statements concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment.		
The Detroit Edison Company	Yes	Yes, the tables do provide more clarity. It is much easier to understand the requirements now that they are broken down by technology, and the exclusion of intervals on certain activities based on the individual monitoring attributes is helpful. I appreciate the thought that went into revising this.
Response: Thank you for your comments.

2. The SDT has modified the Implementation Periods within the Implementation Plan. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Most commenters who responded to this question agreed with the proposed Implementation Plan. There was no predominant theme in the comments. A few commenters focused on the perceived short time period allowed for the initial conversion and development of their maintenance program while and other commenters suggested specifying Jan. 1 as an interval marker to ease in calendar year interval determination.

The SDT believes that the time frames in the proposed Implementation Plan are adequate for conversion when considering the complete time frame that is likely to occur between industry approval vote and regulatory approvals.

The Implementation Plan was modified to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines. Additionally, all “calendar year” implementation periods were revised to “months” for additional clarity.

The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2, or according to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

Under Item 4a, the team corrected the reference to generating plant outages to change “two years” to “three years” to align with the time allocated for becoming 30% compliant (3 years) with maintenance of components subject to a 6 year interval.

Organization	Yes or No	Question 2 Comment
Tri-State G&T		The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions?
Response: Thank you for your comments. This comment does not apply to the Implementation Plan.		
Consumers Energy (4)	Ballot Comment - Negative	The implementation period for R1 and R3 for the component types addressed in Tables 1-3 and 1-5 is not adequate. The requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R3 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar

Organization	Yes or No	Question 2 Comment
		years for R1 and 12 calendar years after that for R4.
Response: Thank you for your comments. The SDT believes that the degree of flexibility written in the standard for categorizing (and subcategorizing) is sufficient for accomplishing the requirements within the time frames given in the Implementation Plan. For example, the voltage and current sensing devices may be individually identified or identified by group (associated with a relay). Examples of different ways to group the dc control circuitry discrete components include individual circuits, individual lockout devices, component protected, by control panel, or by station. The method chosen for the representation will impact the amount of time required to transform a maintenance program.		
Ameren Services (1)	Ballot Comment - Affirmative	PSMP Implement Date should commence at the beginning of a Calendar year (i.e., January 1st). This is the most practical way to transition assets from our existing PRC-005-1 plans
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program. The guidance provided to drafting teams by NERC suggests that standards should be effective at the beginning of a calendar quarter, rather than a calendar year.		
Independent Electricity System Operator	No	We commented on this before and we will comment again. The time periods for FERC-jurisdictional entities and non-jurisdictional entities should have at least a 3-month difference to allow some time for FERC approval after BoT adoption in an attempt to more or less put the effective dates of the two groups of entities in the same general time frame. The implementation plan as presented will always result in an effective date for the non-jurisdictional entities to be at least some months (the time between BoT adoption and FERC approval) earlier than their jurisdictional counterparts.
Response: Thank you for your comments. The Implementation Plan was modified to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines.		
NIPSCO	No	This new standard’s calibration intervals outlined here will require additional staff at our organization. In order to get people hired and trained the implementation plan should allow more time for the phase-in period. From experience, calibration should have been de-emphasized since more concerns are discovered during full tests.
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td>Tampa Electric Company</td><td>No</td><td>The new maintenance plan has to be completed in 1 year.
1. Would that mean it is required to identify and list every element that requires testing in a database within the first year? This will be a time intensive effort that probably that would be difficult to complete in a year with current personnel.
2. After 1 year, would entities be required to start implementing the plan depending on the maintenance intervals of the equipment? Qualified people would have to be in place to start the work, again this would be difficult to accomplish with current personnel.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. No. Please read R1 carefully to determine what's necessary to be implemented. There is no requirement to have a database – just to have a PSMP that identifies the component "types" and for each component type, the associated type of maintenance program, associated maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes. There is no requirement to identify and list every element.
2. Yes. The implementation of the plan must proceed as indicated.</td></tr>
<tr><td>Indeck Energy Services</td><td>No</td><td>The last part of the implementation plan is vague, if not undefined. The implementation should "follow the previous maintenance intervals until all maintenance is transitioned to the new intervals."</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT presumes that your comment is related to the last paragraph of the General Consideration section of the proposed Implementation Plan. The entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the transition is occurring, the entity should adjust its maintenance and testing schedule so that it is able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in this Implementation Plan.</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>On page 2 of the implementation plan, it is indicated that PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired and that entities will be required to identify which components will be addressed under PRC-005-1 or PRC-005-2. There is no wording to cover those components that are still being addressed under PRC-008-0, PRC-011-0 or PRC-017-0 during the implementation period.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. As noted in the "General Considerations", the entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the transition is occurring, the entity should adjust its maintenance and testing schedule so that they are able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in this Implementation Plan. The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2 or according to PRC-005-1, PRC-008-0, PRC-011-0, or PRC-017-0.</td></tr>
</table>

Organization	Yes or No	Question 2 Comment
Bonneville Power Administration	No	Many of the maintenance intervals in the standard are given in the terms calendar years or calendar months. There is no description of these terms in the NERC Glossary. My Webster's dictionary defines calendar year as the period that begins on January 1 and ends on December 31. There is no definition in my dictionary of calendar month. Is the intent of the term calendar year in the standard that maintenance intervals start on January 1 and end on December 31? This would make all maintenance due on December 31, and December would be a very busy time. Does this mean that if I do maintenance on something with a maximum interval of six calendar years in June of 2011 that it will be due again on January 1 of 2017 instead of June 1 of 2017? We believe that the drafting team intends for maintenance to be due after a given number of years that begins to elapse immediately after the previous maintenance is completed so that in the previous example the maintenance would be due on June 1, 2017. Please remove the word calendar from the maximum maintenance intervals to remove this confusion.
Response: Thank you for your comments. The intent of the term calendar year is to indicate that the maintenance is due sometime during a particular calendar year (Jan-Dec). If you perform maintenance in June 2011 and have a 6 calendar year interval, then the same maintenance is again due sometime in 2017 (2011 + 6). The NERC Compliance Application Notice CAN-0010, posted 19 Apr 2011, supports this compliance guideline. An interval of one calendar year means that the activity or event must be conducted at least once within each calendar year.		
FHEC	No	Can't locate the implementation plan in the posted materials.
Response: Thank you for your comments. The implementation plan was provided as a separate document within the posting and is available in the Standards Under Development section of the NERC website under Project 2007-17: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html		
FirstEnergy	No	Although we agree with the timeframes being afforded to achieve compliance, we suggest the following changes: 1. During the last comment period, we suggested changes to the wording regarding retirement of existing standards on page 2. We do no see a response to these comments. Therefore, we would like to reiterate that the four existing standards are to be retired upon the effective date of the new standard and not upon regulatory approval. 2. In 4a of the plan, since the timeframe for 30% completion is 3 calendar years, we suggest a change to three calendar years for the parenthetical phrase "(or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage)". Change "two" to "three" 3. We suggest the implementation plan be included within the body of the standard. It is very burdensome for

Organization	Yes or No	Question 2 Comment
		entities to have to look for the implementation plan and we believe that a "one-stop shopping" approach would alleviate this burden.
Response: Thank you for your comments. 1. The Effective Date within the Standard was stated as it is based on verbal advice of NERC Compliance – several drafts ago. 2. The Implementation Plan has been modified as you suggested. 3. The Implementation Plan is provided separately in accordance with instructions from the NERC Standards Department and Standards Committee. Further, at the end of all transition periods, it is not needed in the standard.		
ExxonMobil Research and Engineering	No	
Ameren	Yes	While we agree with the Implementation Periods, it would be best to alter R2 and R3 implementation such that components with maximum allowable intervals of 1 year or longer align with a true calendar year (i.e. begin with January 1).
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program. The guidance provided to drafting teams by NERC suggests that standards should be effective at the beginning of a calendar quarter, rather than a calendar year.		
MidAmerican Energy Company	Yes	1. In the background section of the implementation plan in item two it states "...it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: "The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. 2. In addition, it would seem appropriate to allow entities that decide to implement PRC-005-2 requirements

Organization	Yes or No	Question 2 Comment
		before the standard becomes effective to count the maintenance they do before the effective date in the implementation plan schedule and in the testing interval compliance.
Response: Thank you for your comments. 1. The Implementation Plan establishes that an entity must follow its current plan until the new standard is implemented for any specific component. Therefore, an entity should have documentation that it has maintained any given component according to its current program until it is addressed in the revised program (including all relevant activities addressed in PRC-005-2). An entity should adjust it's maintenance and testing schedule so that it is able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in the Implementation Plan. The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2 or according to PRC-005-1, PRC-008-0, PRC-011-0, or PRC-017-0. 2. If entities begin to implement the PRC-005-2 activities before the effective date, it seems to the SDT that this entity will find that they it has fully implemented PRC-005-2 sooner, and will thus have attained a stable sustainable program that much sooner.		
New York Power Authority (1)	Ballot Comment - Affirmative	2. The SDT has modified the Implementation Periods within the Implementation Plan.. Do you agree with the changes? If not, please provide specific suggestions for improvement. X0 Yes 0 No Comments:

3. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Many commenters pointed out an error (which was corrected by the SDT) within the VSL for R2, where the Lower and High VSLs contained identical text.

Many comments were offered on the VRFs that demonstrated unfamiliarity with the relationship between VSLs and VRFs. Violation Risk Factors identify the reliability-related risk associated with non-compliance; VSLs are applied after a finding of non-compliance to identify the degree of non-compliance.

Many duplicate comments were offered on the content of the standard which were not relevant to the VRFs, VSLs, or Time Horizons and these were answered elsewhere in this document

VSLs for R1:

- Phased VSLs were added to address R1 Part 1.1, which was previously addressed only as a “Severe” VSL.
- A reference was added within the R1 VSL to Part 1.3.
- R1 High VSL was revised to add a reference to Table 2.

VSLs for R2:

- One element of the R2 VSL was made binary (Severe), rather than “phased” (in two steps), in response to several comments.

VSLs for R3:

- The R3 VSLs were revised to replace “complete” with “implement and follow” for consistency with the Requirement.

Other minor editorial changes were made throughout the VSLs in response to comments.

Organization	Yes or No	Question 3 Comment
Tri-State G&T		On Page 19, Table 1-5, the standard requires that monitored electromechanical lockouts be maintained every 6 years. Why is there inconsistency in the interval between the monitored lockouts and monitored relays?
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		

Organization	Yes or No	Question 3 Comment
SPP reliability standard development Team	No	1. If the maintenance is done prior to the maximum interval would it then reset the clock. Or should it read that maintenance and testing should be done at least once per quarter etc. 2. We would like to see the plan split up into generation time horizons and transmission time horizons, these can be significantly different.
Response: Thank you for your comments. 1. Provided that all required maintenance activities are done, the activity for that interval is taken care of, and the clock is reset. 2. The options for the Time Horizons are “Long-term Planning” (a planning horizon of one year or longer), “Operations Planning” (operating and resource plans from day-ahead up to and including seasonal), “Same Day Operations” (actions required within the timeframe of a day, but not real-time), “Real-time Operations” (actions required within one hour or less to preserve the reliability of the bulk electric system), and “Operations Assessment” (follow-up evaluations and reporting of real time operations). All of the requirements are properly assigned a Time Horizon of “Long Term Planning”. There is no provision for different Time Horizon between entity types.		
Indeck Energy Services	No	1. The VSL’s for R1 should combine the ones for Lower, Moderate and High VSL into Lower VSL. The Severe VSL should be moved to the Moderate VSL. Because R1 is administrative, it shouldn’t have High or Severe VSL’s. 2. The R2 High VSL (3 yrs) is more stringent than the Severe VSL (5 yrs). 3. The R3 VSL’s need to have combined numbers of components or percentages because small generators may only have 25 relays or 1 battery and would be categorized as High or Severe VSL with a few components affected. The percentage could apply to RE’s with more than 250 components included in the PSMP. 4. The Medium VRF for R1 should be Low VRF because R1 is administrative. Only the performance of the maintenance has anything more than Low VRF. 5. The Medium VRF for R2 is OK. 6. Having a High VRF for R3 is without basis. R3 should have Medium VRF.
Response: Thank you for your comments. 1. R1 is not administrative – it is foundational to developing the program. The VSLs as established conform to the NERC Violation Severity Level Guidelines. 2. The SDT disagrees. R2 “High” reflects a failure to return the “Countable Events” to an acceptable level in three years. R2 “Severe” reflects even worse performance, in that the entity has failed to return the “Countable Events” to an acceptable level in an even longer period – five years.		

Organization	Yes or No	Question 3 Comment
3. The SDT disagrees. A smaller entity will have less to maintain in accordance with the standard, and thus the percentages are still appropriate. 4. R1 is not administrative – it is foundational to developing the program, and not having a program could “directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system” as established in the criteria for a Medium VRF, even if the devices are being maintained to some degree. Without having an established program, the remaining requirements are far less meaningful. 5. Thank you. 6. The SDT believes that failure to maintain Protection Systems could “place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures” as established in the criteria for a High VRF. This concern is borne out by observations relating to several disturbances over the last several years. Also, a High VRF for R3 is consistent with the PRC-005-1 VRF for the corresponding requirement (R2).		
FRCC (10)	Non-binding Poll Comment	The VSL's need additional work. Here are some of the issues I see: 1. For R1, the High VSL has a condition that states "Failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5. (Part 1.4)" This condition is really a combination of what is required in Part 1.3 AND Part 1.4. How would the compliance enforcement determine an appropriate VSL if the registered entity only did not do Part 1.3 (maintenance activities)? These should be separated. 2. Also the Severe VSL is also identified for failure to specify three or more component types. I believe it is more appropriate to have three in High VSL and leave the Severe VSL for 4 or more. 3. For R2, the Lower VSL lists item 1) as "Failed to reduce countable events to less than 4% within three years." This is also the same condition that is identified for the High VSL. It is also the same condition that is listed as item 2) for the Severe VSL. In Lower and Severe, the items are separated by OR so they are each distinct. So, which VSL should the compliance enforcement authority use? 4. Also for R2, Lower VSL is indicated for failure to document for countable events for 5% or less of components. Then you jump to Severe VSL for over 5%. That seems like a very huge jump. The Moderate and High VSLs should be used to make a more gradual difference. 5. Finally, for R2, the Lower VSL is indicated if a segment has 54-59 components and a Severe is more than 54 components. In reading Attachment A, it states that a segment MUST contain at least sixty (60) individual components. This would appear to me to be all or nothing. I would suggest that the only VSL for this would be a Severe if it did not have 60 or more.
Response: Thank you for your comments.		

Organization	Yes or No	Question 3 Comment
1. The SDT disagrees. For the assessment of compliance to R1, Part 1.3 and Part 1.4 work together in the fashion identified in the VSL. 2. The SDT disagrees, and believes that failure to address three or more component types (out of a total of five) indeed reflects a Severe violation of the requirement. 3. Thank you for catching this. The High VSL has been modified from three years to four years. Where elements of the VSL are separated by "or", the compliance enforcement authority should use each of them as appropriate. 4. The SDT disagrees. The documentation of countable events is so fundamental to a performance-based maintenance program that the SDT has assigned a Lower VSL to minor transgressions, with all other transgressions being regarded as a Severe VSL. 5. The SDT has modified the R2 VSL for the segment population to be binary as you suggested.		
Tri-State G & T Association, Inc. (3) (5)	Ballot Comment	1. On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs? 2. R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate?
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. VSLs have been added to Moderate and High to address lesser violations.		
Tri-State G & T Association Inc. (3)	Non-binding Poll Comment	1. Comment 1: On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs? 2. Comment 2: R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate?
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. VSLs have been added to Moderate and High to address lesser violations.		
Tri-State G & T Association Inc. (5)	Non-binding Poll	1: On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored communications system necessary for correct operation of protective functions, and

Organization	Yes or No	Question 3 Comment
	Comment	not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Also, if a relay is set to operate in a manner typical when communication is not used for protection (i.e. defaulting to step-distance functions with a loss of communication), is the defaulted operation of the relay considered "correct operation" thereby excluding the communication as necessary for its correct operation? Please clarify the term correct operation and how it applies to redundant communication systems and/or the performance of the relay in the absence of communication. 2: The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions? 3: On Page 19, Table 1-5, the standard requires that electromechanical lockout control circuits be maintained every 6 years and protective function unmonitored control circuits be maintained every 12 years. Why is there inconsistency in the interval between the electromechanical lockout and protective function control circuits? 4: On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs?
Response: Thank you for your comments. 1. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 2. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 3. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 4. Thank you for catching this. The High VSL has been modified from three years to four years.		
Farmington Electric Utility System	No	VSL on R2: Lower criteria item 1; the wording is identical High VSL. FEUS recommends keeping the criteria in the Lower VSL.

Organization	Yes or No	Question 3 Comment
City of Farmington (3)		
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Alliant Energy Corp. Services, Inc. (4)	Non-binding Poll Comment	The Lower and High VSL for Requirement 2 have the same description. The Lower VSL has other possible items, but there is a conflict where an entity could argue for both a Lower and High VSL. That needs to be clarified.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
GDS Associates	No	1. Suggest clarification of the VSL for R2. It appears that R2 Lower VSL is also contained in the R2 High VSL. 2. If the maintenance is completed prior to the maximum interval, would it then reset the clock? Or should it read that maintenance should be done at least once per quarter? 3. The plan should split into generation time horizons and transmission time horizons since these can be significantly different
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. Yes – it would reset the clock, provided that all required activities are completed during the performance of the maintenance. 3. The SDT disagrees. The options for the Time Horizons are “Long-term Planning” (a planning horizon of one year or longer), “Operations Planning” (operating and resource plans from day-ahead up to and including seasonal), “Same Day Operations” (actions required within the timeframe of a day, but not real-time), “Real-time Operations” (actions required within one hour or less to preserve the reliability of the bulk electric system), and “Operations Assessment” (follow-up evaluations and reporting of real time operations). All of the requirements are properly assigned a Time Horizon of “Long Term Planning”. There is no provision for different Time Horizon between entity types.		
Alabama Power Company (3) Georgia Power Company (3) Gulf Power (3) Mississippi Power (3)	Non-binding Poll Comment	But only if the clean version on Page 7 under Violation Severity Levels R2/High VSL match the redline dated 4/12/2011. Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within four years.
Response: Thank you for your comments. The clean version represents the content desired for the Standard. The red-line is affected by peculiarities of		

Organization	Yes or No	Question 3 Comment
the red-lining tool within Microsoft Word.		
Tampa Electric Company	No	VSL is severe for more than 4% Countable Events on R2. It does not seem feasible.
Response: Thank you for your comments. R2, by reference to Attachment A, requires that entities using performance-based maintenance reduce Countable Events to less than 4% within three years. The R2 Severe VSL reflects failure to do so within five years.		
Manitoba Hydro	No	1. VSL for Requirement 2:-Needs to use consistent terminology. The standard requirements refer to components and component types, not elements. 2. The violation “Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years” appears in both the Lower VSL column and the High VSL column. The violation cannot be both Lower and High. VSL for Requirement R3: -Suggested wording “completed its scheduled program”.
Manitoba Hydro (1) (3) (5) (6)	Non-binding Poll Comment	Manitoba Hydro is voting negative for the following reasons: 1. VSL for Requirement 2: -Needs to use consistent terminology. The standard requirements refer to components and component types, not elements. 2. The violation “Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years” appears in both the Lower VSL column and the High VSL column. The violation cannot be both Lower and High. 3. VSL for Requirement R3: -Suggested wording “completed its scheduled program”.
Response: Thank you for your comments. The term, “element” is not used in any of the VSLs. 2. Thank you for catching this. The High VSL has been modified from three years to four years. 3. The SDT disagrees; the VSL address failure to complete the scheduled program. The suggested change does not reflect this.		
Duke Energy	No	Typographical error - the High VSL for R2 has been incorrectly changed to “within three years” from “within four years”. This is now the same as the Lower VSL.
Duke Energy	Non-binding Poll	There is a typographical error on the High VSL for R2. It has been incorrectly changed to “within three years” from “within four years”. This is now the same as the Lower VSL.

Organization	Yes or No	Question 3 Comment
	Comment	
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Kristina M. Loudermilk	Non-binding Poll Comment	1. In VSL R2 I find it confusing for the Lower VSL and High VSL. In the Lower VSL for R2 #1 is mentioned, but again mentioned in High VSL. IS there an easier way to make that flow? 2. Also I found that I have forgotten a comment for the Standard itself.... In Attachment A, #5 is mentioned twice. I understand as to why, so I think, but in the "To Maintain" #5 says that one has to use the prior year's data. It matches the exact form of "how to establish the performance based PSMP". I find this confusing. So does this mean that testing will be once a year for parts of the segment. I did not get that same understanding from the support documents. Is there way to reword one of the #5's to show case a difference. Or is this on purpose? I just found it confusing.
Response: Thank you for your comments. 1. The High VSL has been modified from three years to four years. 2. The “first” #5 applies to establishing the performance-based program; the “second” one – now modified to be #4 in the second section, applies to maintaining the performance-based program on a continuing basis.		
Alliant Energy	No	The LOW and HIGH VSL for R2 are the same. There are additional possibilities for the LOW, but it is possible to be in both the LOW and HIGH VSL at the same time. We recommend removing #1 in the LOW VSL category to resolve the issue.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
The Detroit Edison Company	No	R2 - It appears that the Lower VSL point 1) and High VSL are identical.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Consolidated Edison Co. of New York (1) (3) (5) (6)	Ballot Comment - Affirmative	Clarification is needed to assure that the industry more fully understands how the percentage of “maintenance correctable issues” will be computed in the R3 VSL.
Consolidated Edison Co. of New York (1) (5) (6)	Non-binding Poll	1: Clarification is needed to assure that the industry more fully understands how the percentage of “maintenance correctable issues” will be computed in the R3 VSL.

Organization	Yes or No	Question 3 Comment
	Comment	2: We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend. 3: We recommend that the drafting team recognize that a “fail safe” or “self-reporting” alarm design serves as an acceptable alternative to periodic testing. This “fail safe” or “self-reporting” alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to “alarm on” and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments. 1. The SDT believes that this is clear; if an entity has 20 maintenance-correctable issues and has failed to initiate resolution of one, it has failed to initiate resolution of 5% of the maintenance-correctable issues. 2. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 3. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		
Independent Electricity System Operator Independent Electricity System Operator (2)	No Non-binding Poll Comment	(1) We do not agree with the High VRF for R3 which asks for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3 not executable. Hence, we suggest that the VRF for R3 be changed to Medium. (2) The Severe VSL for R2 is improper. First, the reference to R3 is incorrect. Second, the first condition that says: “Failed to establish the entire technical justification described within R3 for the initial use of the performance-based PSMP” introduces a requirement not stipulated in R2 itself. We suggest to remove this condition. If the SDT feels strongly that the technical justification (we’re not sure what exactly it is) needs to be established for the initial use of the performance-based PSMP, then R2 should be revised to capture this requirement.
Response: Thank you for your comments. 1. The SDT believes that failure to maintain Protection Systems could “place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures” as established in the criteria for a High VRF. This concern is borne out by observations relating to several disturbances over the last several years. However, even if the program is not fully documented per R1 and R2, devices may still be maintained; thus the reduced VRF for these requirements. Also, the R3 “High” VRF is consistent with the VRF assigned to the similar PRC-005-1 requirement (R2).		

Organization	Yes or No	Question 3 Comment
2. The Severe VSL for R2 has been corrected to refer to R2. The remainder of the Severe VSL for R2 is correct, in that R2 itself specifies that the procedure in Attachment A must be used, both to establish and maintain a performance-based maintenance program. The definition of maintenance correctable issue has been revised to be clearer.		
Tennessee Valley Authority	No	TVA has 590 Pilot Relay (Carrier Blocking) Terminals that are tested twice a year. After an extensive study of carrier failures over a 5-year period, it was determined that we were not having any failures that could have been prevented by a functional test. In January 2008, we reduced our frequency from 4 times per year to 2 times per year. The failure rate has remained about the same since that change. As PRC 005-2 currently states, the PM frequency would be 3 months. Allowing for a one-month grace period would actually require the interval to be set at 2 months. Therefore, the interval we used prior to 2008 (4 times per year) still would not make TVA compliant with the stated 3 month interval.TVA Power Control Systems is in the process of developing extensive PM tests for carrier terminals to complement the existing PM program. This PM would record signal levels, reflected power, line losses, and other pertinent data. It is my position that this PM will improve reliability more than increasing the frequency of the functional test.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		
American Electric Power	No	This standard encompasses a very broad range of component types and functionality. It also encompasses broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application.
Response: Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The NERC VRF Guidelines establish the criteria for assigning VRFs and do not provide for multiple VRFs for a single requirement, and the percentages (where used) assigned within the VSLs conform to the criteria established within the NERC VSL guidelines.		
FHEC	No	For Distribution Provider level equipment there should be no High or Severe VSLs
Response: Thank you for your comments. The SDT disagrees; the VSLs are intended to address the degree to which an entity fails to comply with each requirement, and the nature of the entity has no bearing on this determination.		

Organization	Yes or No	Question 3 Comment
Pepco Holdings Inc	No	1. Are the bullet items listed for the R2 Severe Violation Severity Level , Item 5 an "and" or an "or"? 5) Failed to: • Annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, • Annually analyze the program activities and results for each segment. 2. The wording of the R3 Lower Violation Severity Level seems to imply that an entity that fails to complete 0% (i.e., completes 100%) of its maintenance correctable issues is non-compliant. Entity has failed to complete scheduled program on 5% or less of total Protection System components. OR Entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues. The following re-phrasing is suggested: Entity has failed to complete scheduled program on greater than 0%, but no more than 5% of total Protection System components. OR Entity has failed to initiate resolution on greater than 0%, but less than or equal to 5% of identified maintenance correctable issues.
Response: Thank you for your comments. 1. The VSL has been modified to separate these items with “or”. 2. The SDT disagrees; this description conforms to the guidance in the NERC VSL Guidelines, and VSLs only apply if there is a failure to comply with the relevant requirement.		
Liberty Electric Power LLC (5)	Non-binding Poll Comment	The use of percentages, without accounting for the size of the entity, unfairly burdens small IPPs.
Response: Thank you for your comments. The SDT disagrees. A smaller entity will have less to maintain in accordance with the standard, and thus the percentages are still appropriate.		
Liberty Electric Power LLC	No	See comments at end.
Response: Thank you for your comments. Please see our response to your other comments.

response to NIPSC's comments on the standard provided elsewhere in this report.		
Public Utility District No. 2 of Grant County	Non-binding Poll Comment	GCPD has made it a practical practice of not voting affirmative for VRF and VSL until the standard is edited to our satisfaction and can vote affirmative on the standard.
Response: Thank you for your comments. Please see the revisions made to the standard and the drafting team's responses to the comments.		
Florida Municipal Power Agency (4) (5) FMPP (6)	Non-binding Poll Comment	· Section 4.2.1 states that the Standard is applicable to "Protections Systems designed to provide protection BES Elements." Section 15.1 of the Supplementary Reference Document defines the scope as those "devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES." These two statements are not exactly equivalent, and in fact, are in conflict with the Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State, Approved by the Board of Trustees on February 17, 2011. Section 4.2.1 should be changed to "Any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES." · Examples #1, #2 and #3 in Section 7.1 of the Supplementary Reference all indicate that it is a requirement to "verify all paths of control and trip circuits" every 12 years. As stated, there would be circuits included in the testing requirement that the SDT did not mean to include in the scope of the Standard (e.g., SCADA closing circuit.) The statements in the illustrative examples should be changed to "verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices" to be in line with the definition of a Protection System. · Section 15.5 of the Supplementary Reference Document states: "It was the intent of this Standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted". The SDT should reword this statement recognizing that tests performed on communication systems may not be performed at the same time an entity chooses to perform trip tests on the associated breaker(s). The notion of "overlapping" can be applied, for instance, by taking an outage on one relay set in a fully redundant system, initiating a trip signal from the remote end and observing

Organization	Yes or No	Question 3 Comment
		the trip signal locally. All remaining portions in the local communication-assisted trip paths can then be tested when the local line panel is taken out of service for maintenance.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
Seattle City Light (5)	Non-binding Poll Comment	Pursuant to the negative ballot relating to the Standard. Both votes will be affirmed if the comments are addressed.
Response: Thank you for your comments. Please see the drafting team's responses to the comments offered by Seattle on the proposed standard.		
Seattle City Light (6)	Non-binding Poll Comment	Seattle City Light (SCL) commends the Standard Drafting Team (SDT) for the many improvements in the latest draft of proposed standard PRC-005-2. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. Each draft has been better than that preceding, and the supporting material is very helpful in understanding the impact and implementation of the proposed Standard. However, SCL votes NO for this draft because of 1) the inclusion and treatment of electromechanical lockout relays within the scope of draft Standard and 2) confusion about language between section 4.2 and Requirement 1. Regarding electromechanical lockout relays, SCL is highly concerned about the reliability risks and logistical difficulties associated with meeting the requirements proposed for these relays. Lockout relays operate rarely and are known for reliable service. For many such relays, the proposed maintenance would require clearance of entire bus sections or even multiple bus sections (such as for a bus differential lockout relay). In SCL's opinion, the reliability risks posed by such switching and outages to the Bulk Electric System outweigh the reliability benefits of including lockout relays in the scope of PRC-005-2. If the SDT deems it necessary to include electromechnical lockout relays within PRC-005-2, SCL recommends that a difference be made between the maintenance activities specified for monitored and unmonitored types. The draft Standard describes the requirements for "electromechanical lockout and/or tripping auxiliary devices" in Table 1-5 (p.19) and assigns a 6-year maximum maintenance interval, the same as for other unmonitored relays. Modern electromechanical lockout relays may be specified with a built-in self-monitoring trip-coil alarm. SCL believes the maintenance requirements for electromechanical lockout relays with such an alarm should be similar to those for other alarmed or monitored relays. As such we recommend that a new entry be added to Table 1-5 for monitored electromechanical

Organization	Yes or No	Question 3 Comment
		lockout relays, as follows: • Component Attributes: Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil AND include built-in self-monitoring trip-coil alarm • Maximum Maintenance Interval: 12 calendar years • Maintenance Activities: Verify electrical operation of electromechanical trip and auxiliary devices. Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated. Regarding confusion over language, section 4.2 section identifies five types of Facilities that the standard is applicable to, whereas Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). As such, it is not clear if PRC-005-2 applies to five Facilities or to certain Protection Systems. SCL believes the intent is to have a PSMP for all Protection Systems identified in "Part A, Section 4.2 - Facilities" and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Facilities identified in Part A, Section 4.2.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
Beaches Energy Services (1)	Non-binding Poll Comment	We believe that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. We agree wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical

Organization	Yes or No	Question 3 Comment
		that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of distribution breakers will likely result in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on Transmission Facilities due to more frequent failures due to trees, animals
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
City of Green Cove Springs (3)	Non-binding Poll Comment	GCS believes that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. GCS agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-

Organization	Yes or No	Question 3 Comment
		before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
ReliabilityFirst	Non-binding Poll Comment	ReliabilityFirst agrees with the VRFs but votes negative on the VSLs for the following reasons: 1. VSL for R1 a. Part 1.3 is not mentioned in the VSLs b. The VSLs should start off with the phrase "The responsible entities PSMP…" c. For the VSLs dealing with Part 1.2, the term "or a combination" should be added as one of the methods for maintenance. d. The last VSL under the Severe category should reference Part 1.2 e. The VSLs for Part 1.1 should be gradated similar to Part 1.2 (e.g. what VSL does an entity fall under if they failed to address two component types included in the definition of 'Protection System'?) 2. VSL for R2 a. To be consistent with Requirement 2, the VSLs should start off with the phrase "The responsible entity uses performance-based maintenance intervals in its PSMP, but…" b. The first VSL under the "Lower" category is a duplicate of the VSL under the "High" category c. The third VSL under the "Lower" category has language stating "or containing different manufacturers." Neither R2 nor Attachment A mentions this language. This is a violation of the FERC Guideline 3: "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement" d. Recommend that the VSL regarding entities that "maintained a segment with less than X amount of components" should be a binary "Severe" VSL 3. VSL for R3 a. The VSLs should start off with the phrase "The responsible entity…"

Organization	Yes or No	Question 3 Comment
		b. R3 does not require an entity to "…complete scheduled program…" This is a violation of the FERC Guideline 3: "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement" c. The "implement and follow its PSMP" language in R3 is not mentioned in the VSLs for R3. Recommend including this language in the VSLs for R3

Response: Thank you for your comments.

1.

a. Part 1.3 has been added to the R1 High VSL.

b. The R1 Lower, Medium, and Higher VSLs have been modified as you suggest.

c. The R1 Lower, Medium, and Severe VSLs have been modified as you suggest.

d. The R1 Severe VSL has been modified as you suggest

e. The R1 Moderate and High VSLs have been modified to add graduated VSLs for part 1.1.

2.

a. The R2 VSLs have been modified as you suggest.

b. Thank you for catching this. The High VSL has been modified from three years to four years.

c. This portion of the R2 Lower VSL has been removed, making the VSL for this portion of R2 binary (with only a Severe VSL).

d. The VSL for R2 has been modified as you suggest.

3.

a. The R3 VSLs have been modified as you suggest.

b. The R3 VSLs have been modified by replacing "complete" with "implement and follow" in consideration of your comment.

c. The R3 VSLs have been modified by replacing "complete" with "implement and follow" in consideration of your comment.

4. The SDT has incorporated the FAQ document into the "Supplementary Reference" document and has provided the combined document as support for the Requirements within the standard. Do you have any specific suggestions for further improvements?

Summary Consideration: The commenters were generally supportive of the combination of documents.

Several comments were offered, repeating previous questions regarding the enforceability of this document, and the SDT repeated previous responses explaining the status of this document as a supporting reference – reference documents have no enforceability.

A variety of suggestions were offered regarding additional information for the document, which largely resulted in modifications to the Supplementary Reference document. One specific suggestion of note (resulting in additional discussion within the document) requested a FAQ regarding "Calendar Year".

Several commenters posed questions regarding "grace periods" and "PSMPs established by entities that are more stringent than the requirements within the standard". No additional changes were made due to these questions, but the SDT further explained previous guidance on these issues within the responses. Entities are always allowed to implement practices that are more stringent than those identified in a standard.

Organization	Yes or No	Question 4 Comment
Manitoba Hydro		A red line was not provided making this document difficult to review. We suggest that a redline of this document be posted.
Response: Thank you for your comments. A red-line was not provided because of overall extensive changes, resulting from merging of the previous Supplementary Reference Document and FAQ; the entire document would have been red-line. The next posting will include a red-lined document, as well as the "clean" document.		
U.S. Bureau of Reclamation (5)	Ballot Comment - Affirmative	1. The reference material provides a significant insight into the intent of the proposed changes to the standard. In some cases an interpretation is provided which is not supported by the explicit interpretation of the standard text. The SDT is encouraged to either attach the reference material to the standard or add relevant sections to standard as Background. The Background section could reference the Supplemental Reference & FAQ. 2. The reference material provides more detail indicating that "Voltage & Current Sensing Device circuit input

Organization	Yes or No	Question 4 Comment
		connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. . . . . . The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).” This interpretation is not consistent with the text of the standard and would suggest that it be incorporated into Table 1-3. 3. When protective equipment is replaced, the reference information indicates that the information associated with the original equipment must be retained to show compliance with the standard until the performance with the new equipment can be established. This is not stated in the Measurements and should be added if the expectation exists.
Response: Thank you for your comments. 1. This standard is not being developed in a “results-based” format. Attaching the extra document as you suggest would make the supporting information within the FAQ and Supplementary Reference part of the standard, and this would add extensive and unnecessary prescription to the standard. As you suggest the reference material is listed within the Standard (Section F – Supplemental Reference Document). The next revision will likely resemble your suggestion. 2. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks. 3. M1 states “Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and…” Documenting the implementation of the PSMP certainly requires evidence that maintenance was performed at the prescribed intervals and the data retention requirements state that evidence of the two most recent performances of each distinct maintenance activity be retained. Also, please see the NERC Compliance Process Bulletin #2011-001 (“Data Retention Requirements”) for similar guidance.		
Ameren Services (1)	Ballot Comment – Affirmative	1. Omit retention of maintenance records for replaced equipment. Supplement FAQ 12.1 on page 51 final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. Since BES Element protection is the objective, we suggest a compromise of keeping the evidences of last test for the removed equipment and using that with the equivalent function replacement equipment commissioning or in-service date to prove interval. 2. In Supplement examples on pp 22-23, replace “Instrumentation transformers” with “Verify that current and voltage signal values are provided to the protective relays” to be consistent with Table 1-3. 3. Remove “Reverse power relays” from the sample list of generator devices in Supplement p31 because reverse power relays are applied for mechanical protection of the prime mover, not electrical protection of the

Organization	Yes or No	Question 4 Comment
		generator. 4. Revise Supplement Figure 1 & 2 Legend p83 to align with Draft 4 (a) state "Protective relays designed to provide protection for BES Element(s)" (b) state "Current and voltage signals provided to the protective relays". 5. Please add a Performance-Based maintenance example for control circuitry, and /or voltage and current sensing.
Response: Thank you for your comments. 1. This cited reference in the Supplementary Reference Document is present to maintain consistent evidence that maintenance was performed within prescribed intervals. Please see the NERC Compliance Process Bulletin #2011-001 ("Data Retention Requirements") for similar guidance. 2. Thank you, the change has been made. 3. The commenter is correct that it is the prime mover that is protected by the Reverse Power relay; however the Standard considers relays (such as Reverse Power relays) that sense voltage and current are within the scope. Furthermore, Part 4.2.5.1 (Applicability) of the Standard includes Protection Systems for generator Facilities that are part of the BES including Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays. 4. The column marked Component of Protection System closely aligns with the definition of Protection System as approved by the NERC Board of Trustees and is included within the Standard itself. The next column ("Includes") is more explanatory in nature and is intended to give insight on the SDT's intent. 5. Thank you, the requested changes have been made. Additional Q&A (including one for control circuitry and one for voltage and current sensing devices) have been added to Section 9.2.		
National Grid (1)	Ballot Comment - Affirmative	National Grid suggests that FAQ be added: 1. Regarding Table 2 in the standard, Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring? 2. Please add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		

Organization	Yes or No	Question 4 Comment
New York Power Authority (1)	Ballot Comment - Affirmative	Comments: We suggest that FAQ be added: 1. Regarding Table 2 in the standard, Does a fail-safe “form b” contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring? 2. Please add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		
Muscatine Power & Water (3)	Ballot Comment - Affirmative	In the “Supplemental Reference and FAQ” document on page 65 there is one area of concern. In paragraph 4 “…the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.” While MP&W understands the importance of creating a valid baseline, it is disingenuous to expect the test equipment to be the same as the manufacturer’s test equipment. For that matter, it would be highly unlikely the same test equipment would be used over the life of the battery. The expected life of a battery may be in excess of 15 years in most cases and it would not be probable to expect that the type of test equipment is not going to change during this period. MP&W suggests changing the wording to read that CONSISTENT test equipment should be used to provide consistent/comparable results.
Response: Thank you for your comments, the change has been made. The statements concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment.		
Florida Municipal Power Agency (4) (5) (6) Florida Municipal Power Pool (6)	Ballot Comment - Negative	1. Examples #1, #2 and #3 in Section 7.1 of the Supplementary Reference all indicate that it is a requirement to “verify all paths of control and trip circuits” every 12 years. As stated, there would be circuits included in the testing requirement that the SDT did not mean to include in the scope of the Standard (e.g., SCADA closing circuit.) The statements in the illustrative examples should be changed to “verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices” to be in line with the definition of a Protection System. 2. Section 15.5 of the Supplementary Reference Document states: “It was the intent of this Standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action

Organization	Yes or No	Question 4 Comment
		has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted". The SDT should reword this statement recognizing that tests performed on communication systems may not be performed at the same time an entity chooses to perform trip tests on the associated breaker(s). The notion of "overlapping" can be applied, for instance, by taking an outage on one relay set in a fully redundant system, initiating a trip signal from the remote end and observing the trip signal locally. All remaining portions in the local communication-assisted trip paths can then be tested when the local line panel is taken out of service for maintenance.
Response: Thank you for your comments. 1. Thank you, the change has been made. 2. Thank you, the change has been made.		
ITC	No	We agree with the combination of the two. One document with the FAQ's grouped with the supplemental topics makes it easier to review the whole topic.
Response: Thank you for your comments.		
Central Lincoln	No	The first FAQ under 2.3.1 is incorrect, referencing a FERC informational filing. Included in the filing was a WECC test that was never approved by the WECC board and is not being used. Using this document as suggested will get WECC entities into trouble.
Response: Thank you for your comments. There are presently regional differences allowed that may cease to exist once the BES is redefined. The SDT for the BES Definition (Project 2010-17) is charged with developing a continent-wide BES definition; however, this FERC informational filing is on the public record, and was part of the basis for FERC Order 743.		
Tampa Electric Company	No	Tampa Electric requests further differentiation between BES protection elements and UFLS equipment.
Response: Thank you for your comments. UFLS equipment is presently covered under PRC-008. PRC-005-2 will cover all Protection Systems components including components used for UFLS. The Standard addresses UFLS and UVLS to the degree that they are installed per NERC Standards, even though entities may choose to install them on distribution systems. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping non-BES system elements.

Organization	Yes or No	Question 4 Comment
NIPSCO	Yes	We used the FAQ Supplemental Reference while reviewing this draft standard and found it useful.
Response: Thank you for your comments.		
FirstEnergy	Yes	1. We do not agree with the following wording on page 37 of the reference document: (1) “If your PSMP (plan) requires more activities then you must perform and document to this higher standard.” and (2) “If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.” 2. We continue to believe that the auditor is required to audit to the standard. If the standard requires maintenance intervals every 6 years, this is what the auditor should verify. This was also verified in the recent NERC Workshop at which it was confirmed that “auditors must audit to the standard”. To this end, we also suggest changes to Requirement R3 as explained in our comments in Question 5.
Response: Thank you for your comments. 1. The SDT respectfully disagrees with the commenter. R1 of the Standard states that “… shall establish a Protection System Maintenance Program (PSMP)…, and R3 states that “… shall implement and follow its (PSMP)…” Therefore, if an entity has a more stringent PSMP then they must follow their own PSMP. An example of this might be a case that has an entity with Performance Based Maintenance; this entity could find time intervals between maintenance activities that are more frequent than are laid out in the Tables. This entity must follow their PSMP. Another example might be an entity that requires CT Saturation tests every 10 years; this is a more stringent requirement than is contained within the minimum maintenance activities of the Standard. Neither the SDT nor any auditor has any idea why an entity may require more stringent requirements of themselves than the Standard requirements. Even under the present PRC-005-1 an auditor audits to the entity’s PSMP; a case in point is if an entity PSMP requires relay testing with simulated fault values of voltage and current every year then they are audited to that requirement (even though PRC-005-1 specifically does not require any particular relay testing and certainly has no time intervals stated). Please note that FERC Order 693 directs NERC to establish maximum allowable intervals not minimum intervals, and the entity’s program must, at a minimum, conform to those intervals. 2. The SDT has set no requirements that an entity have a more stringent PSMP than the minimum requirements set out in the Standard, only that any PSMP meet the minimums laid out within the Standard. But, should an entity have a PSMP that is more stringent then, according to R3, they must maintain to their own more stringent PSMP.		
BGE	Yes	1. The supplementary reference on page 30, under the question beginning “Our maintenance plan requires” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35, under the question, “How do I achieve a grace period without being out of compliance” provides an example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less in less than the maximum time of six calendar years. This is

Organization	Yes or No	Question 4 Comment
		conflicting advice. The FAQ /supplementary reference should be revised so that it does imply that an entity is out-of-compliance by performing maintenance more frequently than required. Avoiding compliance risk is one reason to do this, but there are other valid motives not directly related to reliable protection system performance. 2. Testing of PT's and CT's (12 year max) is non invasive and convenient to schedule at the same time as relays (6 year max) just to keep procedures consistent and reduce program administration. Testing of ties to other TOs or GOs may have to be scheduled more frequently than preferred in order to synchronize schedules.
Response: Thank you for your comments. 1. There is no conflict, the first commenter-cited PSMP example has language that has no grace-period built in, and the second commenter-cited PSMP example has language with a built-in grace period. Both cited examples are measurable to a time limit between testing activities. 2. Your observations are correct; an entity may choose to perform activities more often than is specified in the Standard. For that matter, an entity may choose to perform activities more often than their own PSMP; the entity simply cannot exceed their own PSMP intervals which in turn cannot exceed the intervals in the Standard.		
Pepco Holdings Inc	Yes	The Supplementary Reference and FAQ should be an attachment to the standard (Appendix A) and not just referenced. If not attached it will not be readily accessible to those that will be using the standard.
Response: Thank you for your comments. The Supplementary Reference and FAQ is referenced in Section F of the standard (which was on Page 9 of the clean version of the recent posting), in accordance with the Standards Development Process, and will be posted with the standard as "Reference Materials".		
GDS Associates	Yes	The standard should include a footnote indicating this document as reference
Response: Thank you for your comments. This document is addressed within the Standard as a reference document by listing it in Section F (which was on Page 9 of the clean version of the recent posting), in accordance with the Standards Development Process.		
ExxonMobil Research and Engineering	Yes	The SDT should provide notes that reference the sources used for developing the maximum maintenance intervals utilized in the time-based program, and provide a technical explanation as to why they have not provided a tolerance band for use with the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?
Response: Thank you for your comments. The SDT was tasked to create a standard with maximum time intervals between maintenance activities. Thus the task, in and of itself, sets the limit as absolute. Where the intervals were set at six years (or any interval for that matter), there was no assessment of risk beyond the time interval chosen as the absolute. The question always would arise as "Why not an additional thirty days after that?" The reference material cites methodology		

Organization	Yes or No	Question 4 Comment
to determine initial time intervals. The SDT took further care to try to align the initial maintenance intervals with common maintenance schedules like plant outages and other published guidelines. Please note that the Tables refer to "Calendar Year" for the intervals referenced in the comment; the noted concern would only be relevant if the entity actually completes the activity at the very end of the calendar year.		
US Army Corps of Engineers	Yes	1. The reference material provides a significant insight into the intent of the proposed changes to the standard. In some cases an interpretation is provided which is not supported by the explicit interpretation of the standard text. The SDT is encouraged to either attach the reference material to the standard or add relevant sections to standard as Background. The Background section could reference the Supplemental Reference & FAQ. 2. The reference material provides more detail indicating that "Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. . . . . . The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify)." This interpretation is not consistent with the text of the standard and would suggest that it be incorporated into Table 1-3.
Response: Thank you for your comments. 1. This standard is not being developed in a "results-based" format. As you suggest the reference material is listed within the Standard (Section F – Supplemental Reference Document). The next revision will likely resemble your suggestion. 2. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks.		
Luminant	Yes	The document was valuable in understanding PRC-005-2 by providing clarification using practical protective relay system examples. Below are two comments for further improvement. 1. It would be beneficial if the document could provide additional information for relaying in the high-voltage switchyard (transmission owned) - power plant (generation owned) interface. While Figures 1 and 2 are typical generation and transmission relay diagrams, it would be helpful if protective relays typically used in the interface also be included. For example, a transmission bus differential would remove a generator from service by tripping the generator lockout. 2. Figures 1 and 2 refer to a "Figure 1 and 2 Legend" table which provides additional information on qualifications for relay components. Should a footnote be used to point toward Reference 1 (Protective

Organization	Yes or No	Question 4 Comment
		System Maintenance: A Technical Reference) located in Section 16?
Response: Thank you for your comments. 1. There are so many variations possible that it is impractical to try to capture all configurations on a single picture or in a single document. However, for the cited example - a transmission bus Protection System would be included. All five of the Protection System component types would fall within the Standard including the trip paths and the electrical test requirements of the generator lockout device. 2. Thank you, a link has been provided to the references.		
MISO Standards Collaborators	Yes	The additional documentation seems to be quite large, and the additional content seems to go far beyond what is necessary for the PRC-005-2 standard. We recommend the SDT lessen the amount of content provided in the "Supplementary Reference" document.
Response: Thank you for your comments. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks.		
Northeast Power Coordinating Council	Yes	Suggest that to FAQ be added: 1. Regarding Table 2 in the standard, does a fail-safe "form" contact that is alarmed to a 24/7 operation center qualify as an alarm path with monitoring? 2. Add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested as per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		
Georgia Transmission Corporation	Yes	See comments for item 1 and continue clarification where we could include high side or distributed interrupting devices, exchange nomenclature removing distribution breaker and adding distributed interrupting device or non-BES equipment.
Response: Thank you for your comments. Circuit interrupting devices that only participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements. The "non-BES equipment interruption device" phrase has been inserted as suggested.		

Organization	Yes or No	Question 4 Comment
PNGC Comment Group	Yes	Section 9.2 (copied below) indicates that small entities can utilize Performance-Based PSMP if they aggregate with other entities. Does this section indicate that only a parent entity with individually owned components can aggregate, or can independent entities under a G&T aggregate? In other words, individual DP/LSE/TOs with different audits. Can they aggregate under a common PSMP for performance based maintenance? 9.2 Frequently Asked Questions: I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity? Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis. The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.
Response: Thank you for your comments. Two entities in such a shared program must have populations of components that can be aggregated and the PSMP for those components are the same between the two entities. Thus the combined entities can show total populations, total numbers of components tested and total failures found. The combined entities would thus be forced to follow the same intervals, test procedures and statistical analysis. There would have to be cooperation between entities but in the end the outcome would be the same as if the PBM process were applied to a single entity. There is no inherent advantage or disadvantage to multiple entities cooperating in such a manner. The SDT intends that small entities with small populations of equipment have the same access to PBM as the larger entities.		
FHEC	Yes	It is unclear what compliance obligations may be created or clarified with the FAQ. It is a good explanatory document and a helpful reference, but the Standard should speak for itself as it relates to what it takes to achieve compliance.
Response: Thank you for your comments. The Standard is the only "mandatory and enforceable" document. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The SDT intends that it be posted as a Reference Document, accompanying the standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc, and is not to include explanatory information like that included in the Supplementary Reference Document. The Supplementary Reference FAQ will be revised in the course of the revision process of the standard.		
Western Area Power	Yes	Can the SDT add a better definition or clarification of "Calendar Year" as it pertains to PRC-005-2 and provide

Organization	Yes or No	Question 4 Comment
Administration		examples or parameters of Compliance with the Standard requirements and tables? Calendar Year is explained in various details within Pages 35-Pages 37 of the Supplementary Reference and FAQ. This important attribute of a TBM or TBM/CBM combination program is not easily found in the Table of Contents or section sub-headings.
Response: Thank you for your comments. Per your suggestion, a "What is a Calendar Year?" Q&A has been added to the front end of Section 7.1.		
Duke Energy	Yes	Along the lines of what we have suggested in our comment to Question #1 above, we believe it would make compliance more certain if selected language from the Supplementary reference could be incorporated into the standard, either directly in requirements, or in footnotes.
Response: Thank you for your comments. The addition that you suggest is properly considered application guidance; the SDT has been advised that this information is not to be included within the standard, and that it is appropriately included in separate reference materials.		
Ameren	Yes	1. Comments: Supplement FAQ 12.1 on page 51 final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. Since BES Element protection is the objective, we suggest a compromise of keeping the evidences of last test for the removed equipment and using that with the equivalent function replacement equipment commissioning or in-service date to prove interval. 2. Clarify p17 Table 1-4(e) interval meaning. We think this means we need to verify the Station dc supply voltage on 12 calendar year interval if unmonitored, or no periodic maintenance if monitored as stated. 3. In Supplement examples on pp 22-23, replace "Instrumentation transformers" with "Verify that current and voltage signal values are provided to the protective relays" to be consistent with Table 1-3. 4. Remove "Reverse power relays" from the sample list of generator devices in Supplement p31 because reverse power relays are applied for mechanical protection of the prime mover, not electrical protection of the generator. 5. Revise Supplement Figure 1 & 2 Legend p83 to align with Draft 4 (a) state "Protective relays designed to provide protection for BES Element(s)". (b) state "Current and voltage signals provided to the protective relays" 6. Please add a Performance-Based maintenance example for control circuitry, and /or voltage and current sensing.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1. This cited reference in the proposed Standard is present to maintain consistent evidence that maintenance was performed within prescribed intervals. 2. The SDT agrees. 3. Thank you, the change has been made 4. The commenter is correct that it is the prime mover that is protected by the Reverse Power relay, however the Standard considers relays (such as Reverse Power relays) that sense voltage and current as within the scope. Furthermore, Part 4.2.5.1 of the Standard states that Protection Systems for generator Facilities that are part of the BES including Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays 5. The column marked Component of Protection System closely aligns with the definition of Protection System as approved by the NERC Board of Trustees and is included within the Standard itself. The next column ("Includes") is more explanatory in nature and is intended to give insight on the SDT intent 6. Thank you, the changes have been made. Additional Q&A have been added to Section 9.2.		
Xcel Energy	Yes	1) On page 65, paragraph 4, of the "Supplemental reference and FAQ" document, it states:"the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment." While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer's test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of test equipment will not change during this period.2) A FAQ to clarify in scope protection systems for variable energy resource facilities (wind, solar, etc) would be very helpful. 2) Does paragraph 4.2.5.3 "Facilities" imply that the only protection system associated with a wind farm that is considered in scope for PRC-005-2 is that for the aggregating transformer? If other protection systems associated with a wind farm are in scope, please clarify which systems would be in scope for PRC-005-2. For example, a typical wind farm in our system might have 30-33, 1.5MVA windmills connected to one 34.5 KV collecting feeder circuit for a total of roughly 50 MVA per collecting feeder. 4 of these 50 MVA collecting feeders are tied via circuit breakers to a low side 34.5 KV bus which in turn is connected via a low side breaker to aggregating step up transformer which then connects to the BES transmission system. Obviously per paragraph 4.2.5.3, the protection system for the aggregating step up transformer is in scope. What about the protection system for the transformer low side 34.5 KV breaker - serving 200 MVA of aggregate generation? What about the protection system of each individual 34.5 KV aggregating

Organization	Yes or No	Question 4 Comment
		feeder - 50 MVA of aggregate generation? What about the"protection system" for each individual 1.5 MVA windmill? An FAQ on this topic would be very helpful.
Response: Thank you for your comments. 1. Thank you for your suggestion; the paragraph cited has been changed. 2. Clause 4.2.5.3 states specifically that the Protection Systems on the aggregating transformer are included. The SDT has not specifically included other equipment, but, depending on what, specifically, is defined to be BES for these facilities, either within current Regional definitions or within the emerging NERC definition, other equipment may be drawn in.		
Alliant Energy	Yes	

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.

Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.

Several comments were offered, suggesting that PRC-005-2 needs to be consistent with the interpretation in Project 2009-17, now implemented as PRC-005-1a, and the SDT modified Applicability 4.2.1 for better consistency with the interpretation 4.2.1 (Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc).

Many comments were offered objecting to the 3-calendar-month intervals for station dc supply and communications systems, and suggesting that a 3-calendar-month interval requires entities to schedule these activities for 2-calendar-months in order to assure compliance. The SDT did not modify the standard in response to these comments, and responded that the intervals were appropriate, and that entities should be able to assure compliance on a 3-calendar-month schedule by using program oversight. The "Supplementary Reference and FAQ" document was augmented with additional explanatory text.

Several comments were offered questioning various aspects of Applicability 4.2.5.4 (generation auxiliary transformers). No changes were made in response to these comments, and responses were offered illustrating why these transformers are included.

Many (essentially identical) comments were offered, questioning the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT explained that these Protection Systems are appropriate to be included for consistency with legacy standards PRC-008, PRC-011, and PRC-017, and noted that their inclusion is consistent with Section 202 of the NERC Rules of Procedure.

Several comments were offered, objecting to the 6-calendar-year interval for lockout and auxiliary relays. The SDT declined to adopt the requested changes, and noted that these "electromechanical" devices with "moving parts" share failure mechanisms with electromechanical protective relays and that the intervals should be identical.

Several comments were offered regarding Maintenance Correctable Issues, and resulted in modifying this definition to be "…such that the deficiency cannot be corrected during the performance of the maintenance activity …"

Assorted additional comments were offered by individual commenters (most of them similar to comments on previous postings), which resulted in responses similar to those offered during previous posting periods.

Organization	Yes or No	Question 5 Comment
Consolidated Edison Co. of New York (1) (3) (5)	Ballot Comment - Affirmative	We recommend that the drafting team recognize that a “fail safe” or “self-reporting” alarm design serves as an acceptable alternative to periodic testing. This “fail safe” or “self-reporting” alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to “alarm on” and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments. The application discussed seems to the SDT to be an effective method of “monitoring the monitoring circuit”. (See Table 2, last row with heading “Alarm Path with monitoring.”)		
Ameren Services (1)	Ballot Comment - Affirmative	(1) Need some tolerance – require 99% of components to meet R3. Measure M3 on page 5 should apply to 99% of the components. “Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99% of its components and initiated….” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. (2) Define BES perimeter in accordance with Project 2009-17 Interpretation. Facilities Section 4.2.1 “or designed to provide protection for the BES” needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. The BOT adopted this 2/17/2011. (3) Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. 1. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 2. The referenced interpretation relates to a quasi-definition of “transmission Protection System”, and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introducing any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004-1 is not affected by PRC-005-2. 3. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes		

Organization	Yes or No	Question 5 Comment
that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Xcel Energy		1) Regarding “Facilities” paragraph 4.2.5, we are in agreement with the elimination from scope of system connected station service transformers for those plants that are normally fed from a generator connected station service transformers. However, in the cases where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team’s intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility? If the end result of the trip of the primary station service transformer is a trip of a BES generating facility, it would be more consistent to include the protection system for that transformer as in scope - whether it be connected to the system or to the generator. 2) We recommend the SDT consider an interval of 12 calendar years for the component in row 3, of Table 1-5 on page 19 of the standard. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that the SDT will consider these changes.
Response: Thank you for your comments. 1. The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. 2. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
Northeast Power Coordinating Council, Inc. (10)	Ballot Comment -	A concern exists that an entity with a very strict PSMP with intervals that are much shorter than neighboring entities or the standard will rewrite their PSMP and loosen their requirements to allow postponed maintenance

Organization	Yes or No	Question 5 Comment
	Affirmative	up the maximum specified in the standard. This standard, as written penalizes non-adherence to more stringent and better PSMPs and may inadvertently driving entities to the least common denominator. I am hopeful that Phase 2 will address this issue.
Response: Thank you for your comments. The Standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP to be necessary.		
GDS Associates		Requirement R1 1. Suggest changing the language in R1.2 to read “Identify which maintenance method such as the time-based, performance-based (detailed in PRC-005 Attachment A), or a combination of the two would be appropriate to be used for each type of Protection System component. Based upon their own constructive type, all batteries associated with the station DC supply shall be included in a time-based maintenance program consistent with Table 1-4(a) through Table 1-4(f)” 2. Suggest changing the language for the first paragraph in R1.3 to read “Establish the occurrences associated with the time-based maintenance programs up to but no less than the time intervals specified in Table 1-1 through Table 1-5, and Table 2. Consequently, include all applicable monitoring attributes and related maintenance activities characteristic to each type of Protection System component specified in Table 1-1 through Table 1-5, and Table 2” 3. Suggest adding a sub-requirement such as R1.5 to read “Include documentation of maintenance, testing interval and their basis and a summary of testing procedures” Requirement R3 4. The redline version of the standard is misleading. Requirement R3 is crossed out and then replacing requirement R7 which is also crossed out. 5. The wording “initiates resolution of any identified maintenance correctable issues” it is vague. What a responsible entity should do to become compliant with this requirement? We also believe that is not sufficient to just “initiate resolution”; the standard should call for corrective actions to be performed within the maintenance time interval. 6. The “identified maintenance correctable issues” may not be a proper choice. The name of the new term suggests that is about issues that can be corrected during maintenance, while the definition from the clean version explains otherwise?

Organization	Yes or No	Question 5 Comment
		Additional requirement 7. Suggest adding a requirement to read “The Transmission Owner, Generator Owner, and Distribution Provider shall provide documentation of its PSMP and implementation to the appropriate Regional Reliability Organizations on request (within 45 calendar days).” 8. Add measure for the evidence on documenting the PSMP from the additional requirement General comments and notes 9. If you own electro-mechanical relays and microprocessor based relays is there a need to keep two different logs for these? 10. On table 1-4 the generator CTs should be tested earlier than the suggested 12 years due to exposure of continuous mechanical stress 11. Clarify table 1-5 to address verification tests on different circuits. Suggest that the Table 1-5 to read “Complete a terminal test of unmonitored circuitry” instead of the “Unmonitored control circuitry associated with protective functions” 12. In what instances (what extent) would the standard allow using the real time breaker operation to be considered maintenance as applicable to different types of relays involved in the real time event? This is briefly emphasized under TBM at paragraph 5.1 from the supplementary reference document?

Response: Thank you for your comments.

1. It is not enough for an entity to determine if time-based, performance-based, or a combination of the two would be “appropriate”; the entity must specify which method is being used, so that it is clear to both the entity and an auditor if R2 and Attachment A apply.

2. The SDT has considered your comment and has determined that the text currently within the requirement is appropriate.

3. The requirement that you suggest is identical to one of the most troublesome requirements from the approved PRC-005-1. By providing Tables 1-1 through 1-5, as well as Table 2, the SDT is establishing maximum allowable intervals as well as minimum required activities, and thus replacing this PRC-005-1 requirement with a more prescriptive one. If an entity chooses to extend the intervals and alter the activities by using monitoring, or to apply performance-based maintenance per R2 and Attachment A, the additional requirements related to those choices effectively establish a requirement such as you suggest.

4. The red-lining tools in Microsoft Word can sometimes be misleading, but the red-line is provided in an effort to illustrate the changes made to the document. We recommend that the entity use the “clean” version in order to see the final resulting text.

5. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with

Organization	Yes or No	Question 5 Comment
other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct the maintenance correctable issue"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues within PRC-005-2 and rely on the operating focus on the degraded system to ensure that they are completed. The associated measure provides examples of relevant documentation. The definition of maintenance correctable issue has been revised to be clearer. 6. The phrase from the entire sentence states "initiate resolution of any identified maintenance correctable issues". This is to ensure follow-up for items which cannot be corrected during maintenance. The definition of maintenance correctable issue has been revised to be clearer. 7. No direct BES reliability purpose is supported by "on request documentation of a program"; this has value only for monitoring compliance. Additionally, Compliance Enforcement Authorities are empowered by the NERC Rules of Procedure to request information demonstrating compliance at any time. 8. No additional measure is necessary, as the suggested requirement is unnecessary. 9. The SDT is not specifying how the maintenance records are maintained relative to the Standard. It is up to the entity to determine how to best document the detailed implementation of their program. 10. Instrument transformers are addressed in Table 1-3, not Table 1-4. Entities are allowed to maintain components more frequently than required within the Standard if they feel it necessary. 11. The SDT does not believe that the suggested text adds clarity to the standard. Please see Section 15.3 of the Supplementary Reference Document for additional discussion. 12. The SDT suggests that observed in-service performance may be usable for any activities that are clearly verified by the in-service performance.		
Liberty Electric Power LLC		Apologies to the drafting team for submitting this with the ballot, repeated here to insure the comments are captured and addressed. While the SDT has done a very good job at responding to the most objectionable parts of the previous version, there are still a number of issues which makes the standard problematic. 1. The standard introduces the term "initiate resolution". This is an interpretable term, and has the potential for an auditor and an entity to disagree on an action. Would issuing a work order be considered "initiating resolution"? What if the WO had a completion date many years into the future? I would suggest adding the term to the list of definitions which will remain with the standard, and defining it as "performing any task associated with conducting maintenance activities, including but not limited to issuing purchase orders, soliciting bids, scheduling tasks, issuing work requests, and performing studies". 2. Some clarity is needed to differentiate system connected and generator connected station service transformers. A statement that a station service transformer connected radially to the generator bus is considered a system connected transformer if the transformer cannot be used for service unless connected to the BES. 3. The "bookends" issue, brought up in the prior round of comments, still exists. Although the SDT rightly notes a CAN has been issued regarding bookends, the CAN covers the documentation for system

Organization	Yes or No	Question 5 Comment
		components that entities were required to self-certify to on June 18, 2007. PRC-005-2 adds additional components to the protection system scheme which were not part of that certification, and has the potential to put entities into violation space due to a lack of records for those components. The SDT should add to M3 a statement that entities may demonstrate compliance with the standard by demonstrating that required activities took place twice within the maximum maintenance interval -starting from the effective date of the standard - for all components not listed in PRC-005-1.
Response: Thank you for your comments. 1. The SDT believes that issuing a work order would satisfy this requirement. M3 presents several examples of relevant evidence. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct the maintenance correctable issue”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 3. The Implementation Plan specifies that entities may implement PRC-005-2 incrementally throughout the intervals specified, and that they shall follow their existing program for components not yet implemented. The SDT believes that the “bookends” issue to which you refer is therefore addressed. Also, please see Compliance Process Bulletin 2011-001 for a discussion about data retention.		
Central Lincoln		As we stated two ballots ago, we continue to believe that IEEE battery standard quarterly maintenance was never intended to be performed at a maximum interval of three months. Instead, three months is a target value that might be extended due to emergency. We continue to support a maximum interval of four months for these activities.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Tampa Electric Company		1. As written PRC-005-2 would have a very significant impact on Tampa Electric Company with very little reliability benefit. For the testing of the DC control circuits Tampa Electric would need to remove from

Organization	Yes or No	Question 5 Comment
		service each BES element (circuit, bus, transformer, breaker) and perform an R&C checkout somewhat equivalent to what Tampa Electric does for new construction. That process would have to be repeated no less often than every six years. The testing of DC control circuits to the level described / required in the proposed standard in an energized station is a very risky proposition. Even though an element can be taken out of service for testing, the DC control circuits are often interconnected for functions such as breaker failure, bus and transformer lockouts etc. It is very easy to accidentally trip other in service equipment while doing this testing. Another concern is getting outages on equipment to perform the proposed testing. 2. Tampa Electric believes that there is an unnecessary expansion of the scope of equipment covered by the proposed PRC-005-2 standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The proposed PRC-005-2 includes the non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, the non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the proposed standard with negligible benefit to BES reliability. 3. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. 4. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load. 5. Tampa Electric's Energy Supply Department has the following comment / question regarding Data Retention: For Requirement R3 R2 and Requirement R4R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or all performances of each distinct maintenance activity for the Protection System component since or to the previous scheduled audit date, whichever is longer. If all of the data which the proposed PRC-005-2 standard requires to be collected is not be available or kept for the prescribed period of time, how does a registered entity comply with the required data retention?

Response: Thank you for your comments.

1. Entities must employ processes and training on how to best manage risk . Not performing DC control circuit verification of protection functions is a risk to the

Organization	Yes or No	Question 5 Comment
reliability of the BES. 2. Section 202 of the NERC Rules of Procedure define "Reliability standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. The SDT notes that several Table entries for components that are used only for UFLS or UVLS involve fewer activities and/or longer intervals than for other similar components for generic Protection Systems. 3. The requirements related to UFLS and UVLS, which are commonly applied on non-BES equipment, are less involved than those for other Protection System equipment in recognition of the observations by the commenter. 4. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 5. The stated data retention period is consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The entity is urged to assure that data is retained as specified within the Standard.		
American Transmission Company, LLC		1. Change the text of Standard PRC-005-2 - Protection System Maintenance Table 1-5 on page 19, Row 1, Column 3 to: "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years" Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in table 1-5 row 1 will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). 2. Change the text of Standard PRC-005-2 -Protection System Maintenance Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years" The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. In order to test the lockout relays, it

Organization	Yes or No	Question 5 Comment
		may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays.ATC recognizes the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 3. ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC believes that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comments. 1. The SDT considers it important to verify that each breaker trip coil has indeed operated within the established intervals. While breakers may be operated much more frequently at times (and allow the entity to document these operations to address this activity), other breakers may not be called on to operate for many years. 2. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 3. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
Tri-State G & T Association, Inc. (3)	Ballot Comment - Affirmative	1: Section A.4.2. They are referencing Protection Systems as if they are Facilities in the Applicability section. Facilities are BES Elements, but Protection Systems are not. That needs to be modified somehow. Perhaps the drafting team needs to add another category under Applicability entitled "Protection Systems" and then list which types are included. 2: Maintenance Correctable Issue - This definition seems to be more of a Maintenance Non-Correctable Issue since it can only be resolved by follow-up corrective action. Suggest changing the term. 3: Change Definitions as indicated below: Segment - Protection System components that are identical or share common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components in order to be considered for inclusion in a performance-based PSMP Component -An individual piece of equipment included in the definition of a Protection System., Entities are allowed some latitude to designate their own definitions of a Component. An example of where the entity

Organization	Yes or No	Question 5 Comment
		has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component. 4: M1 - Why is the document necessary to be “current or updated?” Eliminate “or updated.” 5: The Applicability section needs to be changed, regardless of whether it has been discussed before. Protection Systems are not Facilities.
Response: Thank you for your comments. 1. The standard template allows for two separate sections within Applicability, “Entities” and “Facilities”. The listing under Facilities is describing the applicable facilities to which the Protection Systems are applied, clarified further to indicate that only the Protection Systems on those Facilities are relevant. 2. The definition of maintenance correctable issue has been revised to be clearer. Please see Section 4.1 of the Supplementary Reference Document for additional discussion. The revised definition is: **Maintenance Correctable Issue** – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 3. The SDT does not believe that your suggested changes add clarity. 4. M1 has been modified as you suggest. 5. The standard template allows for two separate sections within Applicability, “Entities” and “Facilities”. The listing under Facilities is describing the applicable Facilities to which the Protection Systems are applied, clarified further to indicate that only the Protection Systems on those Facilities are relevant.		
Progress Energy		Comments on Draft Standard 1. Table 1-1, 2nd row, 2nd bullet: The comment “(see Table 2)” does not apply to this bullet, but applies to the first bullet. 2. Table 1-3, 2nd row: Need to add “(See Table 2).” Comments on Implementation Plan 1. Section 3a states that “The entity shall be at least 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval” If regulatory approval occurs on January 31, 2012, does this mean that the entity has until December 31, 2014 to be 30% compliant? It might be beneficial to provide an example explaining “calendar year.” Comments on Supplementary Reference

Organization	Yes or No	Question 5 Comment

8. Changed per your suggestion. 9 Changed per your suggestion.		
Dominion Virginia Power		Comments: IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Santee Cooper		Comments: 1. Santee Cooper does not agree with the expansion of the UFLS and UVLS requirements to include the dc supply. We understand that, in the previous consideration of comments, it is stated that "For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general." In the table, the requirement for dc supply for UFLS is to verify the station dc supply voltage when the control circuits are verified, which could be 6 or 12 years. It seems like the restraint shown in the requirement, if an indication of the level of need for the verification, is of a much longer timeframe than what would actually happen in the typical operation of a distribution system. Therefore, proof of this verification seems to be of minimal value compared to the extra documentation required due to this now being an auditable maintenance activity. 2. We also agree that maintenance activities with fast intervals, especially the 3 month ones, should be adjusted to 4 months to allow for the actual interval the entities use to be 3 months. Having the requirement at 3 months forces the utilities to schedule even faster (such as every month or 2 months) to ensure compliance.
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure define "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		

Organization	Yes or No	Question 5 Comment
2. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
The Detroit Edison Company		1. Countable Event - This definition should be clarified. As it stands, it appears that if a technician were to adjust the settings on an electromechanical relay - even if it were not outside of the entity's acceptable tolerance - it would need to be classified as a countable event. I would recommend that the definition be limited to repairing or replacing a failed component during the maintenance activity. These activities would address conditions that would potentially cause a Protection System misoperation (either a failure to trip or an unintentional trip). Routine maintenance activities to bring component test values back within tolerance should be excluded from the definition of a Countable Event. These activities are performed to keep the protection systems performance at its most ideal state. In addition, the definition as stated appears to classify battery maintenance activities such as cleaning corrosion, adding water, or applying an equalize charge, as countable events. If this is the intent, I disagree. These are activities that are expected to occur on a regular, routine basis due to the chemical properties of the battery (as described at length in the Supplementary Reference). As such, they should also not be classified as countable events. 2. Table 1-1 and Table 1-5 Based on experience with DECo equipment, a 6 year interval for testing monitored relays and performing tests on the breaker trip coil is substantially shorter than required. Currently, the interval for both is 10 years. This interval lines up both with the Transmission Owner's interval for relay maintenance as well as the maintenance interval for the associated current interrupting devices. I would recommend that these intervals be extended, at minimum, back to the 7 year interval proposed in Draft 2 - if not longer. 3. Table 1-4 (a, b, c, e) - Station dc supply using any type of battery recommend that the maintenance activity to "Verify: Station dc supply voltage" be clarified to state that the voltage should be measured at the positive and negative battery terminals. Until you get to page 72 of the Supplementary Reference, you do not know if this means to check the battery voltage or the bus voltage. The "Station dc supply" could refer to the entire dc system. It needs to be made clear in the table that you are referring to the battery. 4. Also, I noticed that there is no longer a requirement to measure individual cell voltages. I was wondering if you could explain the rationale behind that. Checking for voltages that are out of specification in individual cells helps to identify weak cells that may need to be replaced, if corrective action taken on them does not improve their condition. Individual cell voltage readings, along with ohmic readings, have been an industry standard that I believe many, if not most, companies adhere to. 5. Table 1-4 (a, b, c, d)I recommend eliminating the 3 month requirement. We have found annual inspections to be sufficient in catching problems early enough to take corrective action. Page 30 of the Supplementary

Organization	Yes or No	Question 5 Comment
		Reference states that the SDT believes that routine monthly inspections are the norm. While this may be the case at manned stations, it is not at unmanned stations. The amount of paperwork that would be required to demonstrate compliance is overwhelming and would be an immense burden. I have seen your suggestion in past draft comments of the same nature that if we don't want to do the 3 month inspections, then we should utilize more advanced monitoring. This is not something that can be implemented in a short time frame. It would take years to put all of that technology in place, and is rather cost prohibitive. Furthermore, some of the monitoring technologies that would enable you to forgo the 3 month requirement do not exist yet (to my knowledge). I recommend keeping with the 18 month requirement. If that seems too long, based on past experience I think a 12 month requirement would suffice. 6. Table 1-4 (c) I propose keeping the option to evaluate ohmic values to baseline. 7. Table 1-4 (a, b) For the requirement to evaluate the ohmic values to baseline, is a checkbox stating that you did this sufficient, or would a report/graph/etc listing the actual baseline and current value be required? 8. Table 1-4 (f) The first attribute is regarding high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. Would a low voltage alarm combined with high voltage shutdown (but not a high voltage alarm) meet this requirement? The high voltage shutdown will shut the charger down in a high voltage condition, and therefore result in a low voltage alarm, so the outcome is the same.

Response: Thank you for your comments.

1.”Tweaking the settings” on a component that is not outside tolerances is not a Countable Event, which is partially defined as “A component which has failed and requires repair or replacement, any condition discovered during the verification maintenance activities in Tables 1-1 through 1-5 which requires corrective action …”. However, as described in Clause 9.2 (Question 4) of the Supplementary Reference Document, a device which is outside tolerances should be considered to have experienced a “calibration failure” and thus has experienced a countable event.

2. If an entity’s experience is that these components require less-frequent maintenance, a performance-based program in accordance with R2 and Attachment A is an option. The intervals were revised after Draft 3 such that the various intervals are multiples of each other, such that entities may establish a systematic PSMP.

3. Your observation that in section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT stated that “verification of dc supply voltage is simply an observation of battery voltage” is correct, but the SDT does not agree that the location where voltage should be measured (verified) be contained in PRC-005-2 or the Supplementary Reference document. Due to the variances in topography of dc control circuitry for Protection Systems, a single location for verification of dc supply voltage cannot be specified and must be determined by the Protection System owner.

4. As you correctly stated taking Individual cell voltage readings has been a standard that many companies adhere to. However, this maintenance activity was removed from the standard because it was a “how to requirement”.

5. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the

Organization	Yes or No	Question 5 Comment
intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed. 6. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT explains why in Table 1-4 (c) (Station dc supply using NiCad batteries) the option to evaluate ohmic values to baseline is not available. 7. The SDT believes that just providing "a checkbox stating that you did this" is sufficient proof. Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" provides additional discussion on this topic. However, the SDT is unable to fully predict what evidence may be required by the Compliance Enforcement Authority to demonstrate compliance. 8. "A low voltage alarm combined with high voltage shutdown (but not a high voltage alarm)" would only partially meet the requirement. To ensure that the automatic shutdown of the battery charger for high voltage conditions is achieved, a high voltage alarm must be a component attribute of the monitoring system in order.		
Florida Keys Electric Cooperative Assoc. (1)	Ballot Comment - Negative	Extreme unreasonableness and undue hardships on entities, specifically smaller entities. Just one example is "battery inspections". What is an inspection - simply visual or cell readings? Some entities may have to assign full time battery maintenance duties. Can SCADA monitor DC voltage trends?
Response: Thank you for your comments. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" – that was provided for review and comment with PRC-005-2 – details what should be inspected for visual battery cells. The SDT disagrees that the PRC-005-2 with its accompanying Table 1 imposes "extreme unreasonableness and undue hardships on entities, specifically smaller entities" to maintain a reliable Protection Systems. Monitoring the dc voltages via SCADA is an option.		
FirstEnergy		FE offers the following additional comments and suggestions: We do not agree with the wording of requirement R3. The entity is only required to meet the minimum maintenance intervals of the standard as outlined in Tables 1 and 2. We offer a scenario where an entity states that they will go above the standard and maintain relays on a 4 year cycle. The standard, in meeting an adequate level of reliability, sates that this activity must be performed every 6 years. If the entity happened to miss the 4 year timeframe, deciding from a business standpoint to delay the maintenance to the 5th year, an auditor can find the entity non-compliant per the guidance and wording of the requirements in this standard. However, the entity still exceeded an adequate level of reliability by performing the maintenance within 5 years. This scenario would be very unfortunate to the entity that has essentially done their part in providing reliability to the bulk power system, yet they would be punished for not meeting their more stringent timeframes. This standard's guidance and requirements sends an adverse message to industry. It essentially punishes an entity for going above and beyond the standard except on a few rare occasions. If this were to happen, that entity, and possibly others, would not see the value in going above a standard. It would make entities meet the bare minimum requirements, essentially reducing overall system reliability. Therefore, we

Organization	Yes or No	Question 5 Comment
		suggest the following wording for requirement R3: “R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP to ensure adherence to the minimum requirements as outlined in Tables 1 and 2, and initiate resolution of any identified maintenance correctable issues.”
Response: Thank you for your comments. The Standard requires an entity to implement a PSMP that meets the minimum requirements to the standard. An entity may choose to implement a program that exceeds the requirements.		
City of Farmington (3)	Ballot Comment - Affirmative	FEUS would like to thank the Drafting Team. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. However, section 4.2 identifies five types of protection systems that the standard is applicable to, but the language of Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). We believe the intent is to have a PSMP for all Protection Systems identified in Section 4.2 and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.
Response: Thank you for your comments. R1 has been modified as you suggest.		
FirstEnergy Energy Delivery FirstEnergy Solutions Ohio Edison Company (1) (3) (4) (5) (6)	Ballot Comment - Affirmative	FirstEnergy appreciates the efforts of the drafting team and supports PRC-005-2. We would also like the team to address our comments and suggestions submitted through the separate comment period.
Response: Thank you for your comments. Please see our responses to your comments submitted with the Formal Comments.		
ITC		1. For Battery System:- Table 1-4(a)o The maximum maintenance interval for the majority of the battery maintenance is listed at “18 calendar months”. The current ITC Standard is”once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st “.

Organization	Yes or No	Question 5 Comment
		ITC would like the maximum maintenance interval at “once per calendar year” 2. Table 1-4(b) o VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the “18 calendar months” inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. 3. For Battery System:- Table 1-4(a) o The maximum maintenance interval for the majority of the battery maintenance is listed at “18 calendar months”. The current ITC Standard is “once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st “. ITC would like the maximum maintenance interval at “once per calendar year” 4. Table 1-4(b) VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the ”18 calendar months” inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. 5. Auxiliary Relays: ITC does not agree with the 6 year interval for Aux relays in the trip circuit. Although they are EM relays they are simple and have very few moving parts. We believe the maintenance period for auxiliary relays should be 12 years and they should be in conjunction with the control circuit. We recognize that Draft 4 only includes auxiliary relays that are directly in the trip path. That is an improvement in Draft 4. In general, auxiliary relays are very reliable; only certain relay types have been proven to be problematic. A known relay type (HEA) has been proven to be problematic if not exercised frequently. The standard should not require a 6 year interval period for all other auxiliary relays. We believe problematic relays should be addressed through use of a NERC Alert process. Don’t cut down the tree for a bad apple.

Response: Thank you for your comments.

1. In choosing the 18 calendar month interval for the maximum maintenance interval for the maintenance activities of table 1-4(a) the SDT was aware that the majority of these activities are recommended to be performed in IEEE 450 “Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications “at the Yearly inspection. The SDT does not agree that “once per calendar year” would be a more appropriate interval for these activities but notes that entities may choose to perform required activities more frequently than the maximum intervals expressed in the Tables.

Organization	Yes or No	Question 5 Comment
2. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" – that was provided for review and comment with PRC-005-2 explaining why the for VRLA battery systems (Table 1-4(b)) the maximum maintenance intervals and maintenance activities cannot be consistent with the intervals and activities of VLA battery systems (Table 1-4(a)). 3. In choosing the 18 calendar month interval for the maximum maintenance interval for the maintenance activities of table 1-4(a) the SDT was aware that the majority of these activities are recommended to be performed in IEEE 450 "Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications "at the Yearly inspection. However, the SDT has considered that IEEE 450 presents these activities as recommended activities in a vacuum, without considering other activities that are being performed at the 3-calendar-month interval and has established the 18-calendar-month interval to comport to the most aggressive intervals being used in common practice. The SDT does not agree that "once per calendar year" would be a more appropriate interval for these activities but notes that entities may choose to perform required activities more frequently than the maximum intervals expressed in the Tables. 4. Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" (question – "What are cell/unit internal ohmic measurements "– that was provided for review and comment with PRC-005-2 – explains why the for VRLA battery systems (Table 1-4(b)) the maximum maintenance intervals and maintenance activities cannot be consistent with the intervals and activities of VLA battery systems (Table 1-4(a)). 5. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. If an entities' experience is that these components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.		
Manitoba Hydro		-Grace periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time
Manitoba Hydro (1) (3) (5) (6)	Ballot Comment - Negative	Manitoba Hydro is voting negative for the following reasons: -Grace periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-compliance (removing an asset in a time of constraint). Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for reliability without risking non-compliance.
Response: Thank you for your comments. "Grace Periods" within the standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the		

Organization	Yes or No	Question 5 Comment
intervals within the standard.		
Georgia System Operations Corporation (3)	Ballot Comment	GSOC supports comments submitted by Georgia Transmission Corporation
Response: Thank you for your comments. Please see the SDT response to the comments submitted by Georgia Transmission Corporation.		
Electric Market Policy		IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Alliant Energy Corp. Services, Inc. (4)	Ballot Comment - Negative	1. If PRC-005-2 is going to incorporate PRC-008 (UFLS) and PRC-011 (UVLS) the Purpose needs to be revised to include Distribution Protection Systems designed to protect the BES. 2. We do not believe a distribution relaying system, designed to protect the distribution assets, that may open a transmission element (ie; breaker failure) should be considered part of the BES Protection System. R1 should add the following sentence “Distribution Protection Systems intended solely for the protection of distribution assets are not included as a BES Protection System, even if they may open a BES Element.”
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. UFLS and UVLS are described in the Applicability as being included within the Protection System addressed within the standard if they are applied per other NERC Standards. 2. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirement, as written, supports this.		

Organization	Yes or No	Question 5 Comment
Exelon		1. In response to Exelon's comments provided to drafts 1, 2, and 3 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT previously responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. In response to draft 3 of PRC-005, the SDT stated that "If several different regulatory agencies have differing requirements for similar equipment, it seems that the entity must be compliant with the most stringent of the varying requirements. In the cited case, an entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Again this does not explain why a conflict with an existing regulatory requirement is acceptable. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon again requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. In addition, the SDT still did not fully evaluate or address the concern related to the uniqueness of nuclear generating unit refueling outage schedules. 2. Although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant's routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity or a self report of non-compliance. To ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. The SDT response to this question in draft 3 is that "(t)he 18-month (and shorter) interval activities are activities that can be completed without outages - primarily inspection-related activities. An entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Respectfully Exelon requests that the SDT review and evaluate the concern.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. 1. It appears that the SDT's response was mis-understood. The SDT intended that the response be understood as" in order to be compliant with all requirements, regardless of the different agencies imposing those requirements, the entity will likely have to be compliant with the most stringent of the requirements". Regarding PRC-005-2, an entity must be compliant with the included requirements, even if they are more stringent than other regulatory requirements. 2. The SDT believes that the activities addressed in the comment can be integrated with the 18-24 month plant refueling outage. This may result in the activities being performed more frequently than specified.		
Entergy (3) Entergy Services, Inc. (6)	Ballot Comment - Negative	In Section 4.2, 'Facilities' add the following subsection 4.2.6: Protection Systems for generating units in extended forced outage or in inactive reserve status are excluded from the requirements of this standard. However, the required maintenance and testing of the Protection Systems at these units must be completed prior to connecting the units to the Bulk Electric System (BES). Reason for the above comment: The above units are not connected to the BES and therefore do not affect the reliability of the BES. However, to ensure the reliability of the BES, required maintenance and testing of the Protection Systems at these units must be completed prior to connecting them to the BES.
Response: Thank you for your comments. Please refer to Compliance Application Notice CAN-0011, footnote 5, which states, "The registered entity's Protection System maintenance and testing program is only applicable for Protection System devices in service …" The SDT believes that this guidance will remain durable for PRC-005-2.		
Entergy Services		In Section 4.2, "Facilities" add the following subsection 4.2.6: Protection Systems for generating units in extended forced outage or in inactive reserve status are excluded from the requirements of this standard. However, the required maintenance and testing of the Protection Systems at these units must be completed prior to connecting the units to the Bulk Electric System (BES). Reason for the above comment: The above units are not connected to the BES and therefore do not affect the reliability of the BES. However, to ensure the reliability of the BES, required maintenance and testing of the Protection Systems at these units must be completed prior to connecting them to the BES.
Response: Thank you for your comments. Please refer to Compliance Application Notice CAN-0011, footnote 5, which states, "The registered entity's Protection System maintenance and testing program is only applicable for Protection System devices in service …" The SDT believes that this guidance will remain durable for PRC-005-2.		
MRO's NERC Standards Review Subcommittee		In the checkbox for Requirement R3 please change the wording to read, "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initiating on-site activity. Therefore this issue requires follow-

Organization	Yes or No	Question 5 Comment
		up corrective action.”
Response: Thank you for your comments. The definition of maintenance correctable issue has been revised to be clearer: Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Bonneville Power Administration		1. In the header of Tables 1-1, 1-2, 1-3, and 1-5 there is a note that says "Table requirements apply to all components of Protection Systems except as noted." Since each table only applies to the specific component type shown in the header, we do not understand what this note means. The definition given for component only makes the note more confusing. Please clarify the note. 2. Additionally, BPA is voting no during this round due to an issue with the Applicability Section and Section 4.2. Once this issue is clarified, BPA would be in support of a yes vote. Issue: Section 4.2 Facilities lists 5 separate items that the standard is applicable for (4.2.1. - 4.2.5). However Requirement 1 uses language that only addresses one of the items (4.2.1). There is no language contained anywhere within any of the requirements in PRC-005-2 that apply to the types of protection systems described in Applicability Sections 4.2.2 - 4.2.5. Therefore, it could be argued that this leaves it open to interpretation as to whether UFLS/UVLS/SPS are addressed by R1.In the NOPR (Â¶ 105), FERC states that “the Requirements within a standard define what an entity must do to be compliant” Further, in Order 693 (Â¶ 253) FERC explicitly states that “compliance will in all cases be measured by determining whether a party met or failed to meet the Requirement”. Given this, then from a compliance perspective, the actual applicability of the standard appears to not be as broad as intended. We ask that this issue be resolved by modifying the language in R1 in a manner that explicitly encompasses all types of protection systems to which it is intended to be applied.
Response: Thank you for your comments. 1. In Table 1-1, for example, this note means that all activities apply to all protective relay components unless specifically differentiated within individual table entries. Because Tables 1-1, 1-2, and 1-3 do not include any additional differentiation within the table, the note was removed from these tables in consideration of your comment. 2. The R1 requirement has been revised in consideration of your comments.		
JEA (3)	Ballot Comment - Negative	JEA maintains testing of lockout relays will have major reliability impact to the JEA system.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
Tri-State G&T		1. M1 - Why is the document necessary to be "current or updated?" Eliminate "or updated." 2. R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate? 3. R2 VSL - Keep the comment about the redundancy in Lower VSL and High VSL for clarifying the difference between the two.
Response: Thank you for your comments. 1. M1 has been revised as suggested and the phrase, "or updated" has been removed 2. The VSL for R1 has been revised to add phased VSLs for Moderate and High related to this item. 3. The High VSL has been modified from three years to four years.		
Ameren		1. Measure M3 on page 5 should apply to 99% of the components. "Each __shall have evidence that it has implemented the Protection System Maintenance Program for 99% of its components and initiate" PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. 2. Define BES perimeter in accordance with Project 2009-17 Interpretation. Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. The BOT adopted this 2/17/2011. 3. Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. 1. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 2. The referenced interpretation relates to a quasi-definition of "transmission Protection System", and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introduce any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004 is not affected by PRC-005-2. 3. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Madison Gas and Electric Co. (4)	Ballot Comment - Affirmative	MGE is voting affirmative with the following recommendation to the definition of Maintenance Correctable Issue. Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the "initiating" on-site activity. Therefore this issue requires follow-up corrective action. The removal of the word "initial" will cause less confusion because the industry does not understand if this is initial (commissioning) or is initial used as when a component requires repair. Recommend "initiating" replace "initial".
Response: Thank you for your comments. The definition of maintenance correctable issue has been revised to be clearer: Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Arizona Public Service Company		NERC continues to be too prescriptive in the standard. For example, Table 1-4(a) requires battery verifications and inspection every three months. We have been performing similar tests every four months for over a decade, with no adverse consequences. Although FERC Order 693 directs NERC to establish maximum allowable intervals, the maximum interval must be "appropriate to the type of protection system and its impact on the reliability of the Bulk-Power System." (Order 693 at 1475)The Standard Drafting Team (SDT) has not demonstrated a mechanism that connects the maximum maintenance interval with its impact on the reliability of the Bulk-Power System. An example can be found on the bottom of page 18 and the top of page 19 of the Consideration of Comments on Protection System Maintenance [Project 2007-17] for draft 3. Although the commenting organization provided a concrete example of successful maintenance under a longer interval, the Standards Drafting Team commented that it "believes that 18-months is the proper interval for this activity." (Emphasis added) An organization cannot challenge the SDT's beliefs, only facts. The basis for each maximum maintenance interval, with appropriate linkage to its impact on the reliability of the Bulk-

Organization	Yes or No	Question 5 Comment
		Power System, needs to be published and voted upon so that factual based proposals to modify the maximum interval can be rationally challenged.
Response: Thank you for your comments. The basis for the intervals established within the standard is described throughout the Supplementary Reference document.		
Northern Indiana Public Service Co. (3)	Ballot Comment - Negative	One of our concerns is that, while the present standard is 2 pages and is the most highly violated and fined standard, the new proposed standard is 22 pages, the implementation plan is 4 pages and the Supplemental FAQ document is 87 pages.
Response: Thank you for your comments. The SDT has established maximum allowable intervals in accordance with FERC Order 693. Additionally, the SDT has addressed many of the common program-related causes of observed violations, and has provided the Supplementary Reference and FAQ to assist entities in implementing their program.		
PJM Interconnection, L.L.C. (2)	Ballot Comment - Negative	PJM has a general problem with how this current draft defines "protection system". The issue is that PJM believes the standard should only apply to Protection relays that are designed to protect the BES. It should not apply to relays that protect the asset itself.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements as written directly support this definition.		
Western Area Power Administration		Please explain or clarify the term “mitigating devices” used in Table 1-5 Control Circuitry, Page 19. This term is not well defined in the industry and not easily understood as “interrupting device” or “circuit breaker.”
Response: Thank you for your comments. This term is primarily focused on Special Protection Systems, where they may perform some activity other than “interrupt” to address their design objectives.		
Shermco Industries		1. Please provide clarification on "Communications" in regards to the following: If our customers are utilizing Schweitzer SEL311 relays and utilizing the fiber for transfer trip, is this considered a communications circuit? Our experiences in regards to testing these devices that have transfer trips out into a main substation that could affect a main ring tie or open a major 138kV loop, are that the T&D utilities will not allow us to perform these tests and trip their breakers. Therefore, what is required to satisfy testing? 2. In regards to Function / Trip testing, if we have a sudden pressure device, this is considered an auxiliary relay and the sudden pressure relay itself is not required to be tested. However, the trip path is required to be tested for DC tripping, if it directly trips the breaker feeding the BES, on the DC Control verification

Organization	Yes or No	Question 5 Comment
		testing. Please clarify if this is correct.
Response: Thank you for your comments. 1. The fiber you indicate is a relay communications circuit. The SEL311 monitors the condition of the fiber. It will provide an alarm on loss of communications. If this alarm is not monitored then the entity will be required to check it every 3 months and verify it is still operational. If the communications alarm is brought back to the control center, and the error rate or pilot signal is verified continuously, the interval will be 12 years. 2. Yes, this is correct.		
ExxonMobil Research and Engineering		1. PRC-005-2 is a highly prescriptive standard that prevents small entities from establishing a risk-based approach to protective system maintenance that is commonly used in other industry sectors and forces the small entity to utilize the time-based program. Many registered entities do not have a population size of 60 for each type of protective device. However, they do possess historical records that can be used to calculate the mean time between failures for each equipment type that adequately reflects the service conditions in which the equipment is installed. The SDT should consider allowing registered entities to utilize historical records in their supporting documentation for defining a performance based program. 2. Additionally, by restricting populations by manufacturer model, as referenced in PRC-005-2 Attachment A, the Standard Drafting Team is bordering on anti-competitive behavior as those entities that utilize performance-based programs may be discouraged to utilize alternative suppliers because utilization of a time-based maintenance program on the alternative supplier's equipment may present a cost-benefit analysis hurdle that the supplier of the equipment is not able to overcome. 3. Lastly, the SDT has chosen not to provide a tolerance band for the maximum maintenance intervals it defines in its time-base program. Given that the SDT has not provided sound technical justification (i.e. a study, industry recommended practice, etc.), the SDT should reconsider its stance on providing a tolerance band on the time intervals specified in the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?
Response: Thank you for your comments. 1. If the historical records fully address the criteria in Attachment A, they would be useful in establishing the basis for a performance-based maintenance program. If the population is not in accordance with the definition of segment in Attachment A, the SDT does not believe that the entity has a statistically-significant sample on which to base a PBM. 2. In order to properly apply a performance-based maintenance program, the components within a segment must be such that they will exhibit similar behavior. Similarly-functioning components from different manufacturers will likely not satisfy this criterion. If an entity does not have sufficient component populations to apply performance-based maintenance, they must revert to time-based maintenance per the Tables or find another entity with whom they can aggregate		

Organization	Yes or No	Question 5 Comment
components within a performance-based maintenance program. Please see Section 9 of the Supplementary Reference Document for a discussion regarding aggregating components between entities within a performance-based maintenance program. 3. There may be minimal additional risk for missing the required interval by only a small amount. However, "grace periods" within the standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the standard. Also, this concern is only a practical one if an entity is persistently maintaining its Protection System components at the very end of each maximum allowable interval.		
Luminant		The red-lined version did not appear to agree with the clean copy. In reading the "red lined" document it appears that R3 was intended to be "Each Transmission Owner, Generation Owner, and distribution Provider shall implement and follow its PSPM and initiate resolution of any identified maintenance correctable issues."
Response: Thank you for your comments. The red-lining tools in Microsoft Word can sometimes be misleading, but the red-line is provided in an effort to illustrate the changes made to the document. We recommend that the entity use the "clean" version in order to see the final resulting text.		
MidAmerican Energy Company		Requirement R3 of the standard discusses resolution of "identified maintenance correctable issues". M3 requires evidence of "resolution of Maintenance Correctable Issues". The definition of Maintenance Correctable Issue in the standard includes "during performance of the initial on-site activity". The "initial on-site activity" seems to imply that the corrective steps that need to be tracked are those resulting from the periodic testing that is done for compliance with the standard. It is not clear if the SDT meant to require that records be kept of any required maintenance that is done as a result of a discovered problem or failure that is not identified during the periodic testing.
Response: Thank you for your comments. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised, though, to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Consumers Energy (5)	Ballot Comment - Negative	While most of the changes are quite good, I believe R3 may not be what was intended. R3 concludes with "initiate resolution of any identified maintenance correctable issues." My copy of Webster's Dictonary defines initiate as "to set going : start". Thus to meet R3, I need never order a replacement component I just need to write a purchase order (it's the start of the process). If rewiring is needed, I only need to write a maintenance order, rather than sending out an electrician with tools and wire. I believe reliability would be better served to

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>require resolution of the problem rather than just starting a process to begin work.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed.</td></tr>
<tr><td>Constellation Energy Commodities Group (6)

Constellation Power Source Generation, Inc. (5)</td><td>Ballot Comment - Negative</td><td>1. R3 is vague and can be easily interpreted in a variety of ways. For example, “initiate resolution” may mean closing a work order on a correctable issue or it may mean simply to create a work order with the intent of closing it out. The difference is not just in compliance evidence but it potentially allows an auditor to interpret the requirement to state that closed work orders should be completed in a timely manner.
2. Lastly, the technical man power and compliance documentation needed to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any entity would use it.”</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer.
Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.
2. The SDT understands that the requirements to establish and operate a performance-based PSMP may be beyond what many entities will wish to pursue. However, these are provided for the use of those entities who wish to make use of the analytical resources to optimize their field maintenance.</td></tr>
<tr><td>MISO Standards Collaborators</td><td></td><td>1. R3 speaks of a Maintenance Correctable Issue and implementing your Protection System Maintenance Program (PSMP). In the definition of Maintenance Correctable Issue, it states "...of the initial on-site activity". The intent seems to be that during any maintenance activity, and something is found not working properly, you should repair it. Some may look at the word "initial" as during the commissioning of a facility.
We recommend the SDT delete the word "initial" to cause less confusion.
2. We recommend the SDT change the text of Standard PRC-005-2 - Protection System Maintenance Table</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
		1-5 on page 19, Row 1, Column 3 to "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years." Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5, Row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). 3. We recommend the SDT change the text of Standard PRC-005-2 - Protection System Maintenance Table 1-5 on page 19, Row 3, Column 2 to "12 calendar years". The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. 4. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. 5. We recognize the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 6. Our remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. We believe that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that

Organization	Yes or No	Question 5 Comment
		the SDT will consider these changes.
Response: Thank you for your comments. 1. The word, “initial” is intended to emphasize that an identified concern becomes a Maintenance Correctable Issue when the entity is not able to immediately resolve it, and must return to correct the problem. The definition of maintenance correctable issue has been revised to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 2. The SDT considers it important to verify each breaker trip coil will indeed operate within the established intervals. While breakers may be operated much more frequently at times (and allow the entity to document these operation to address this activity), other breakers may not be called on to operate for many years. 3. The SDT believes that electromechanical devices contain moving parts and share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 4. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. 5. Thank you. 6. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
NERC - EA & I		Recommend entities be explicitly required to document the Relay Maintenance Program in one document. Many entities presently maintain their Protection Maintenance Program in several documents, such as one for relays, one for batteries, etc. This complicates compliance review and contributes to non-compliance since personnel in different departments writing these have different levels of understanding of NERC standards. Separate documents also allow inconsistencies to slip in. Recommend Requirement 1 to changed to the following to address this problem. "Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP), RECORDED AND UPDATED AS A SINGLE DOCUMNET for its Protection Systems designed to provide protection for BES Element(s). "
Response: Thank you for your comments. The SDT believes that, because of the diversity of different entities and their business arrangements that such a requirement could serve to decrease the quality of an entity’s PSMP, particularly for a vertically-integrated entity that includes several of the specified Applicable Entities. For example, the Generator Owner and Transmission Owner are likely to have significant differences for very good reasons.		
Florida Municipal Power Agency (4) (5) (6)	Ballot Comment - Negative	1. Section 4.2.1 states that the Standard is applicable to “Protections Systems designed to provide protection BES Elements.” Section 15.1 of the Supplementary Reference Document defines the scope as those “devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES.” These two statements are not exactly equivalent, and in fact, are in conflict

Organization	Yes or No	Question 5 Comment
Florida Municipal Power Pool (6)		with the Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State, Approved by the Board of Trustees on February 17, 2011. 2. Section 4.2.1 should be changed to "Any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."
Response: Thank you for your comments. 1. The referenced interpretation relates to a quasi-definition of "transmission Protection System", and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introduce any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004 is not affected by PRC-005-2. 2. Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements as written directly support this definition.		
US Army Corps of Engineers		1. Section 4.2.5.4 - please clarify generator connected station service transformer. We believe this to mean a station service transformer with no breaker between the transformer and the generator bus. 2. R3 - the term 'initiate resolution' is vague and needs to be further defined. Does this mean putting in a work order or is further action required. 3. Data Retention: The proposed standard clarifies that two of the most recent records of maintenance are to be retained to demonstrate compliance with the prescribed maintenance intervals. When equipment is replaced, the reference information indicates that the information associated with the original equipment must be retained to show compliance with the standard until the performance with the new equipment can be established. This is not explicitly stated in the requirements and warrants a comment.
Response: Thank you for your comments. 1. The commenter is correct. 2. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the		

Organization	Yes or No	Question 5 Comment
performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 3. The data retention section is stated to describe what an entity must do to demonstrate compliance to an auditor on a persistent basis. The additional clarification in the Supplemental Reference Document is provided to share the experiences of SDT members with other entities, and to suggest a possible effective practice.		
Public Utility District No. 1 of Lewis County (5)	Ballot Comment - Negative	Standard does not recognize the affects and great burdens to smaller utilities that have limited staff and great distance to travel out west. Generally, our facilities to not affect the BES. We believe that the battery testing requirements are overkill. The intervals for testing should be placed at minimum of 2 or 3 years
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed. As for the other shorter-duration activities, the SDT believes that all of these activities, at the specified intervals, are necessary to assure reliability. From the experience of the SDT members, and as supported by various IEEE Standards, it seems clear that delaying the battery maintenance activities to 2-3 years would be detrimental to the reliability of the BES.		
AtCO Electric ltd		1. Table 1-2: the requirement for 12 calendar year verification for the channel and essential signals' performance should be removed. We do not see benefit in the maintenance activities under level 2 (the 12 calendar year requirement) and suggest merging it with level 3 (the "no periodic maintenance specified" requirement). The "loss of function" alarm, will be considered as a countable event to fall under requirement R3 and dealt as maintenance correctable issue. 2. Table 1-5: the requirement of 6 calendar year verification for electrical operation of electromechanical lockout and/or tripping auxiliary devices should be revisited, considering that: " It is not feasible to exercise a lockout relay during maintenance due to high risk to the in-service facility, as well as the complexity of lockout relay connections and protection schemes. Instead, we propose a DC ring test, which verifies the continuity of control circuitry and eliminates the risk impact of lockout or auxiliary tripping device operations." The interval is too frequent. The requirement would become achievable if the 6 calendar year frequency were increased to 12 calendar years, to be in line with microprocessor relay maintenance frequency
Response: Thank you for your comments. 1. Though a channel with continuous alarming may not be in an alarm state during a quiescent state, the alarm function alone does not identify if the channel will fail during fault conditions. Fault noise level and, fault location impact a channels' noise immunity margin. The activities are specified are to ensure reliable		

Organization	Yes or No	Question 5 Comment
performance of the communication channel. 2. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.The SDT believes that electromechanical devices with moving parts share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
CPS Energy		1. Table 1-5 The new standard requires that every 6 years it is verified that "each trip coil is able to operate the breaker,". The supplementary reference states that this requirement can be met by tracking real-time fault-clearing operations on the circuit breakers. With transmission breakers typically having dual trip coils, how can tracking real-time operations meet this requirement? Would a breaker operations where relays in both the primary and secondary trip coils indicated operation be sufficient or would some type of trip coil monitoring that showed coil energization be needed? 2. Additionally, regarding the verification of all trip paths of the trip circuit. If a microprocessor relay is used to trip a breaker, and two contacts are paralleled on the relay through a single test switch for breaker tripping, would it be necessary to verify each contact independently or could an assertion of both contacts through the test switch be adequate? In this instance, the functionality of each contact would be fully identical. 3. Table 1-2A 3-month inspection is required for communications equipment that does not have "continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function" has to be verified that the communication equipment is "functional" with a 3-month site visit. Would a carrier on-off system, that did not perform periodic check back testing, but did have an alarm contact (loss of power, failure, etc.) that was monitored through SCADA would need to have a 3-month inspection? According to the supplemental reference, this inspection should be to verify that the equipment is "operable through a cursory inspection and site visit". It sounds as if this cursory inspection and site visit would accomplish the same as the alarm contact. It does not appear that end-end functional testing of the blocking signal is required by what is provided in the supplemental reference. Is this correct? 4. Table 1-3 - The maintenance activity for the 12 calendar year testing should include a little more specificity. It should have something stating the values provided to the relay are accurate. I know that this discussed in the supplemental reference, but requirement in Table1-3 sounds as if any relay that measured for loss of signal, such as a loss-of-potential function, would be sufficient when the purpose to verify that the signal not only gets to the relay but also has some accuracy as needed by the application of the relay.
Response: Thank you for your comments. 1. If you are able to independently track both trip coils via real-time operations tracking, you could use this tracking to address this activity. If not, you will likely need to perform focused maintenance activities.		

Organization	Yes or No	Question 5 Comment
2. This would be adequate. 3. This is not correct. As you indicate, the 3 month check for unmonitored relay channels is to verify that the channel is functional. For a guard signal, a visual inspection will indicate if a guard or pilot signal is being received. A blocking channel can only be verified by either a checkback test or an end to end signal check. A visual check that the equipment is not failed does not indicate that the channel medium or auxiliary devices are still intact. We will revise the supplementary reference to clear this up (See Section 15.5.1, question “What is needed for the 3-month inspection of communications-assisted trip scheme equipment?”). 4. If the voltage and current signals are measured by the relay and verified to be correct, this would satisfy the required activity in the Table. Please note that, in the definition of Protection System Maintenance Program, “verify” means, “determine that the component is functioning correctly”.		
NextEra Energy		Thank you for your diligent efforts in writing the draft standard. The draft standard and associated documents are well written and we believe, after approval, will be instrumental to improving the reliability of the BES. We have the following specific comments: a. The maximum maintenance interval of unmonitored Vented Lead-Acid (VLA) batteries should be changed from 3 calendar months to 12 calendar months. Today’s lead-calcium and lead-selenium-low antimony batteries do not have rapid water loss as compared to the legacy lead-antimony batteries. FPL’s operating experience has shown that electrolyte in today’s VLA cells do not require watering within a 12-month interval. In fact, battery manufacturers now recommend watering intervals of 2 to 3 years for some new batteries. b. The maximum maintenance interval to verify that unmonitored communications systems are functional should be changed from 3 calendar months to 12 calendar months. FPL’s operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). Automated testing such as PLC check-back schemes cannot test for failed PLC protective devices. We believe a 12 calendar month functional test is sufficient because of FPL’s operating experience. FPL’s operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). c. We believe the data retention requirements for R2 and R3 should be documentation for the two most recent maintenance activities. d. Regarding Maintenance Correctable Issue (page2) where it states: “.such that it cannot be restored to functional order during performance of the initial on-site activity”. This terminology is vague: Particularly “initial on-site activity”. Not sure what “functional order” means? The suggestion is to change to “..such that the deficiency cannot be restored to meet applicable acceptance criteria during the performance of the scheduled maintenance activity”. e. Regarding Maintenance Correctable Issue (page 2) and R4 on Page 5, the suggestion is an entirely new “Maintenance Correctable” definition especially: “Therefore this issue requires followup corrective action”.

Organization	Yes or No	Question 5 Comment
		Regarding this new definition: Why is it here? Is its purpose to ask us to do something with these issues if we discover them? Do issues identified as “Maint. Correctable” need to be tracked and reported in some manner? The referenced term “Maint. Correctable” is only used in PRC-005-2 in R4 (page 5). The suggestion is to provide clarification. Is this maintenance correctable terminology implying that NERC PRC005-2 is opening up a new requirement for tracking and reporting resolution of “Maint Correctable” issues? The suggestion is to change to: This issue includes any activity requiring further follow-up corrective action to restore operability outside of the applicable maint activity f. Regarding Countable Event (Page 3), the suggestion is an entirely new “Countable Event” definition. Why is this new term and definition “countable event” included in PRC-005-2 ? Note: In the PRC005-2 text “countable event” is actually only referred to in PRC-005-2 in Attachment A under “Performance Based Programs” (not referred to in time based programs section). The recommendation is that the PRC-005-2 version explicitly clarify the definition of â ”countable event” to clearly indicate that this term is applicable ONLY to “Performance Based Programs”. g. Regarding Countable Event (page 3), where the text says “Any failure of a component which requires repair or replacement, any condition discovered during the verification activities in Tables 1-1/1-5 which requires corrective action..”, in the definition for “countable event” what does “corrective action” mean? PRC005-2 is unclear. Does the term “countable event” have any ties to”Maint Correctable” issues. The suggestion is to Consider changing wording from “corrective action” to “which requires > 7 days to correct” and clarify whether or not “countable event” has any correlation to “Maint Correctable” events as discussed on page 2 and in R4? If so please provide language clarifying this correlation.

Response: Thank you for your comments.

a. This activity is primarily inspection-related, and addresses an inspection of electrolyte levels, dc grounds, and station dc supply voltages. Good practice is that entities will conduct a visual inspection of the overall battery condition during these activities, although the Standard does not require it. Also, please note that, while some batteries may reliably go longer between “watering”, this activity is to detect gross failures, rather than specifically to address “watering”. Please see Section 15.4 of the Supplementary Reference Document for further discussion.

b. A relay communications channel and equipment provide logic for a pilot protective relay system to operate correctly to clear faults instantaneously. Channel failure would cause the protective system to not operate or to operate incorrectly. An unmonitored channel failure will decrease reliability of that protective system until its failure is discovered. One year is too long to risk BES protective systems out of service. The three month interval is devised to maintain BES system reliability. If an entity’s experience suggests that longer intervals are appropriate, they may employ performance-based maintenance per R2 and Attachment A. The definition of maintenance correctable issue has been revised to be clearer.

c. From SDT members’ experiences, it is clear that auditors will generally wish to monitor compliance all the way back to the previous audit. Please see

Organization	Yes or No	Question 5 Comment
Compliance Application Notice CAN-008 for a discussion about pre-2007 data. d. The definition has been modified in consideration of your comment. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. e. Yes – the entity is expected to do something in response to an identified Maintenance Correctable Issue, but it is left to the entity to determine the best method for them to track the initiation of resolution of Maintenance Correctable issues. The definition of maintenance correctable issue has been revised to be clearer.. Please refer to M3 for some sample types of evidence. f. Countable events are used only within Attachment A. g. “Countable Event” applies only to performance-based maintenance, and is used solely to determine and evaluate the PBM maintenance intervals. A countable event may (or may not) be a maintenance correctable issue, depending on whether the deficiency is corrected while performing the maintenance activity or requires additional follow-up.		
U.S. Bureau of Reclamation (5)	Ballot Comment - Affirmative	The application of the PSMP should be explicitly defined in the standard. Currently the PSMP is required to protect rather than a PSMP to identify the components defined by the standard. The language should be altered to ensure the PSMP is developed for the component types specified in the standard. The following language should be considered: "Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2".
Response: Thank you for your comments. R1 has been modified as you suggest.		
NIPSCO		1. The present PRC-005 standard is 2 pages while the proposed PRC-005-2 is 22 pages, with an implementation plan of 4 pages and a supplemental document of 87 pages. The review process appears to be somewhat daunting especially considering that NERC is trying to simply things with such concepts as the “traffic ticket” approach. 2. In R3 we’re not sure if there is a time requirement regarding the completion of the resolution process. We like the use of "calendar year" in requirements which should provide flexibility in getting the work completed. 3. Another comment for our response concerns Table 1-2, Communications Systems (page 11):The first maintenance interval is 3 calendar months. Does this mean the same as 1 calendar quarter?1. Example for 3 calendar months: Maintenance performed on 1/4/11. Next maint due by 4/30/11. Maintenance performed on 4/12/11. Next maint due by 7/31/11. Maintenance performed on 7/30/11. Next maint due by

Organization	Yes or No	Question 5 Comment
		10/31/11. This would yield 3 inspections for 2011. Maintenance performed on 10/12/11. Next maint due by 1/31/12.2. Example for 1 calendar quarter: Maintenance performed on 1/4/11. Next maint due by 6/30/11. This would yield 4 inspections for 2011 (1 per quarter).
Response: Thank you for your comments. 1. The SDT has established maximum allowable intervals in accordance with FERC Order 693. Additionally, the SDT has addressed many of the common program-related causes of observed violations, and has provided the Supplementary Reference and FAQ to assist entities in implementing their program. The “traffic ticket” approach is focused on how the compliance monitor will assess violations, and has no bearing on the Standard itself. 2. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. 3. The intervals, “3 calendar months” and “once per calendar quarter” are not synonymous. “Once per calendar quarter” would effectively permit entities to have six months (less two days) between successive activities, while a “3 calendar month” interval limits an entity to four months (less two days) between activities. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month” Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Tenaska, Inc. (5)	Ballot Comment - Negative	1. The biggest concern we have with the proposed standard is the inclusion of 4.2.5.4. As written it is not clear, but more importantly it is overly broad and provides little, if any, increase to reliability. It needs to be deleted. 2. In Section 4.2, five types of protection systems are identified as being applicable, but the language of Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). We believe the intent is to have a PSMP for all Protection Systems identified in Section 4.2 and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection

Organization	Yes or No	Question 5 Comment
		System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.
Response: Thank you for your comments. 1. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. 2. R1 of the standard has been modified as you suggest.		
Seattle City Light (1) (3) (4)	Ballot Comment - Negative	Seattle City Light (SCL) commends the Standard Drafting Team (SDT) for the many improvements in the latest draft of proposed standard PRC-005-2. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. Each draft has been better than that preceding, and the supporting material is very helpful in understanding the impact and implementation of the proposed Standard. However, SCL votes NO for this draft because of 1) the inclusion and treatment of electromechanical lockout relays within the scope of draft Standard and 2) 2) confusion about language between section 4.2 and Requirement 1. 1. Regarding electromechanical lockout relays, SCL is highly concerned about the reliability risks and logistical difficulties associated with meeting the requirements proposed for these relays. Lockout relays operate rarely and are known for reliable service. For many such relays, the proposed maintenance would require clearance of entire bus sections or even multiple bus sections (such as for a bus differential lockout relay). In SCL's opinion, the reliability risks posed by such switching and outages to the Bulk Electric System outweigh the reliability benefits of including lockout relays in the scope of PRC-005-2. If the SDT deems it necessary to include electromechanical lockout relays within PRC-005-2, SCL recommends that a difference be made between the maintenance activities specified for monitored and unmonitored types. The draft Standard describes the requirements for "electromechanical lockout and/or tripping auxiliary devices" in Table 1-5 (p.19) and assigns a 6-year maximum maintenance interval, the same as for other unmonitored relays. Modern electromechanical lockout relays may be specified with a built-in self-monitoring trip-coil alarm. SCL believes the maintenance requirements for electromechanical lockout relays with such an alarm should be similar to those for other alarmed or monitored relays. As such we recommend that a new entry be added to Table 1-5 for monitored electromechanical lockout relays, as follows:

Organization	Yes or No	Question 5 Comment
		• Component Attributes: Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil AND include built-in self-monitoring trip-coil alarm • Maximum Maintenance Interval: 12 calendar years • Maintenance Activities: Verify electrical operation of electromechanical trip and auxiliary devices. Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated. 2. We also would like to comment regarding confusion over language in section 4.2.This section identifies five types of Facilities that the standard is applicable to, whereas Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). As such, it is not clear if PRC-005-2 applies to five Facilities or to certain Protection Systems. SCL believes the intent is to have a PSMP for all Protection Systems identified in "Part A, Section 4.2 - Facilities" and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Facilities identified in Part A, Section 4.2.
Response: Thank you for your comments. 1. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. The SDT believes that electromechanical devices having moving parts share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 2. R1 has been modified as you suggest.

Response: Thank you for your comments. The Standard has been modified as you suggest.		
Ingleside Cogeneration LP		The removal of R1.5 and R7 which required Protection System owners to identify and verify calibration tolerances or equivalent parameters upon conclusion of a maintenance activity was fundamental to Ingleside Cogeneration’s yes vote. The amount of ambiguity introduced by the requirements and associated documentation did not serve to improve BES reliability in our view.
Response: Thank you for your comments.		
Transmission Access Policy		The scope of the equipment to which the draft standard applies is over-broad.

Organization	Yes or No	Question 5 Comment
Study Group		Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliability, for the following reasons. In contrast to transmission and generation protection systems and SPSs, for which there are typically two protection systems per facility and therefore per fault, UFLS and UVLS deal with widespread events. For any under-voltage or under-frequency event, there are literally hundreds of UFLS/UVLS relays to respond. It is therefore far less critical if one UFLS or UVLS relay fails to operate properly. Furthermore, transmission is typically not radial (in fact, radials to load are excluded from the BES). But distribution circuits, where UFLS and UVLS systems are located, are usually radial. Testing some of the non-relay equipment to which the draft standard applies would require blacking out the customers served by that radial. In other words, the draft standard would require entities to definitely cause blackouts in an attempt to prevent very unlikely potential blackouts. This is plainly not justified from a harm/benefit perspective. Finally, many of the types of non-relay equipment to which the standard would apply are in effect tested by faults. Specifically, faults happen on distribution circuits (where UFLS and UVLS systems are located) more frequently than on transmission circuits, due to such things as animal contacts and car accidents. Any such fault is in fact a test of the all the equipment that is involved in clearing the fault. There is no need to require separate tests of that equipment, any more than we would require tests of a phone line that is used on an everyday basis; you already know that the phone works.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Illinois Municipal Electric Agency		The scope of the equipment to which the draft standard applies is still overly broad. Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliability of the BES. This comment/recommendation is provided to address the resource and customer service interests of a TO and/or DP systems serving distribution load. Illinois Municipal Electric Agency supports comments submitted by the Transmission Access Policy Study Group.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
ISO/RTO Standards Review		The SRC disagrees with the change to the term under 4.2.1. “Protection Systems designed to provide protection for BES elements.” We support keeping the previous version’s wording of 4.2.1. “Protection

Organization	Yes or No	Question 5 Comment
Committee		Systems applied on, or designed to provide protection for the BES.” The revised wording expands the fundamental purpose of the NERC PRC-005 standard from being focused on ensuring relays intended to protect the reliability of the BES are maintained to a standard whose intent is to ensure all BES facilities have relay maintenance programs. Although we do not disagree with maintaining all relays, regardless of what their intended purposes are, it should not be the purpose of a NERC standard to police all protection schemes beyond those needed for interconnected reliability. There are numerous protective relays employed on facilities interconnected to the BES but their purpose may be for operating preference or service/equipment quality purposes such as reclosing schemes and transformer sudden pressure relays. We believe the NERC PRC-005 standard should be focused on maintenance of those protective relays which are needed to ensure that the loss of a single element does not cause cascading effects on the bulk power system.
Response: Thank you for your comments. Clause 4.2.1 has been modified to improve consistency with the Interpretation that has become part of PRC-005-1a.		
Duke Energy		The Standard Drafting Team has done an outstanding job on this standard. We are voting “Affirmative” but note that implementation questions remain, particularly with regards to classifying component attributes as “monitored,” “unmonitored,” “internal self diagnosis,” “alarming,” “alarming for excessive error” and “alarming for excessive performance degradation”. The sheer size of the population of protective relays, communications systems, voltage and current sensing devices, batteries, and dc supply components means that the size of the effort required to categorize each individual component could drive us to test and maintain on the more frequent unmonitored time intervals, simply because of the difficulty in assembling “monitored” compliance documentation.
Response: Thank you for your comments. The opportunity to use “monitoring” to extend the intervals and reduce the activities, as well as the opportunity to use performance-based maintenance, is provided for those entities who wish to apply the administrative resources in order to minimize the field maintenance. If entities choose not to use those opportunities, the SDT believes that the un-monitored intervals and activities will establish an effective PSMP.		
Pepco Holdings Inc		There were numerous comments submitted for each of the previous drafts indicating that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." Statistics on the causes of BES protective system misoperations, however, do not support this assertion. The PJM Relay Subcommittee has been tracking 230kV and above protective system misoperations on the PJM system for many years. For the six year period from 2002 to 2007, the number of protective system misoperations due to communication system problems was lower (and in many cases significantly lower) than those caused by defective relays, in every year but one. Similarly, RFC has conducted an analysis of BES protection system misoperations for 2008

Organization	Yes or No	Question 5 Comment
		and 2009, and found the number of misoperations caused by communication system problems to be in line with the number attributed to relay related problems. If unmonitored protective relays have a 6 year maximum maintenance/inspection interval, it does not seem reasonable to require the associated communication system to be inspected 24 times more frequently, particularly when relay failures are statistically more likely to cause protective system misoperations. As such, a 12 or 18 calendar month interval for inspection of unmonitored communication systems would seem to be more appropriate. FAQ II 6 B states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks. The SDT responded that they still felt the 3 month interval as stated in the standard was appropriate. PHI respectfully requests that the SDT reconsider this issue and also cite what "specific statistical data" they used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays.
Response: Thank you for your comments. The SDT believes that relay communications channels are more susceptible to failure from an outside influence than a protective relay. Leased circuits from communications providers and carrier channels are highly exposed to lightning, automobiles, backhoes, etc. We believe the existing statistics from PJM and RFC on relay communications system based misoperation causes is due to the present practice of periodic channel verifications being performed. Many utilities presently use channel monitoring and carrier checkbacks to ensure reliable operation.		
Liberty Electric Power LLC (5)	Ballot Comment - Negative	While the SDT has done a very good job at responding to the most objectionable parts of the previous version, there are still a number of issues which makes the standard problematic. 1. The standard introduces the term "initiate resolution". This is an interpretable term, and has the potential for an auditor and an entity to disagree on an action. Would issuing a work order be considered "initiating resolution"? What if the WO had a completion date many years into the future? I would suggest adding the term to the list of definitions which will remain with the standard, and defining it as "performing any task associated with conducting maintenance activities, including but not limited to issuing purchase orders, soliciting bids, scheduling tasks, issuing work requests, and performing studies". 2. Some clarity is needed to differentiate system connected and generator connected station service transformers. A statement that a station service transformer connected radially to the generator bus is considered a system connected transformer if the transformer cannot be used for service unless connected to the BES. 3. The "bookends" issue, brought up in the prior round of comments, still exists. Although the SDT rightly notes a CAN has been issued regarding bookends, the CAN covers the documentation for system

Organization	Yes or No	Question 5 Comment
		components that entities were required to self-certify to on June 18, 2007. PRC-005-2 adds additional components to the protection system scheme which were not part of that certification, and has the potential to put entities into violation space due to a lack of records for those components. 4. The SDT should add to M3 a statement that entities may demonstrate compliance with the standard by demonstrating that required activities took place twice within the maximum maintenance interval -starting from the effective date of the standard - for all components not listed in PRC-005-1.
Response: Thank you for your comments. 1. The SDT believes that issuing a work order would satisfy this requirement. M3 presents several examples of relevant evidence. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct the maintenance correctable issue”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 3. The Implementation Plan specifies that entities may implement PRC-005-2 incrementally throughout the intervals specified, and that they shall follow their existing program for components not yet implemented. The SDT believes that the “bookends” issue to which you refer is therefore addressed. 4. The Standard requires that activities only take place once within the established interval.		
SPP reliability standard development Team		Would like more clarification in table 1-5 to address verification tests on different circuits. Is this an end to end test or partial test can you test one part of the circuit one way and another a different way? Should table 1-5 read Complete a terminal test of unmonitored circuitry?
Response: Thank you for your comments. The SDT does not believe that the suggested text adds clarity to the standard. Please see Section 15.3 of the Supplementary Reference Document for additional discussion.		
Lakeland Electric (1)	Ballot Comment - Negative	The new PRC-005-2 includes non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. While Lakeland Electric agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities).

Organization	Yes or No	Question 5 Comment
		However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
City of Bartow, Florida (3)	Ballot Comment - Negative	There is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. We agree wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Lakeland Electric (6)	Ballot Comment -	Unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and

Organization	Yes or No	Question 5 Comment
	Negative	PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Beaches Energy Services (1)	Ballot Comment - Negative	We believe that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. We agree wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of distribution breakers will likely result in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on Transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Keys Energy Services (1)	Ballot Comment -	1. KEYS believes that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument

Organization	Yes or No	Question 5 Comment
	Negative	transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. KEYS agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. 2. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load.
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft.		
Lakeland Electric (3)	Ballot Comment - Negative	1. LAK believes that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included

System connected station service transformers were removed from the Applicability in a previous draft.		
Gainesville Regional Utilities (1)	Ballot Comment - Negative	GRU (GVL) agrees with the following comments provided by the FMPA: 1. FMPA believes that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system

Organization	Yes or No	Question 5 Comment
		components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. FMPA agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. 2. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load.
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft.		
Alliant Energy		1. If PRC-005-2 is going to incorporate PRC-008 (UFLS) and PRC-011 (UVLS) the Purpose needs to be revised to include Distribution Protection Systems designed to protect the BES. 2. We do not believe a distribution relaying system, designed to protect the distribution assets, that may open a transmission element (ie; breaker failure) should be considered part of the BES Protection System. R1 should add the following sentence “Distribution Protection Systems intended solely for the protection of distribution assets are not included as a BES Protection System, even if they may open a BES Element.” 3. Table 1-5 (Component Type - Control Circuitry) Item 4 “Unmonitored control circuitry associated with protective functions” require a 12 calendar year maximum maintenance interval. We believe UFLS and

Organization	Yes or No	Question 5 Comment
		UVLS control circuitry should be exempted from this requirement. It would take multiple failures to have any impact, and the impact on the BES would be minimal.
Response: Thank you for your comments. 1. There is no distinction in the purpose between “Distribution Protection Systems” and “Transmission Protection Systems”. The SDT believes that the Applicability appropriately describes both the entities and the facilities. 2. The SDT modified Applicability 4.2.1 for better consistency with the interpretation that is reflected in PRC-005-1a, and believes that this change may address your concern. 3. The Table 1-5 activities for UFLS/UVLS are constrained to those activities that the SDT considers to be appropriate relative to the reliability impact of these applications. Please see Section 15.3 of the Supplemental Reference Document for additional discussion on this topic.		
Y-W Electric Association, Inc. (4)	Ballot Comment - Affirmative	Y-WEA thanks the SDT for its long, hard work on this standard and for its consideration of previous comments.
Response: Thank you for your comments.		
BGE		No comments.
PNGC Power		Thank you for the opportunity to comment on the draft Standard PRC-005-2 – Protection System Maintenance. We appreciate the work that NERC has put into a new standard to encapsulate and replace the current PRC-005, PRC-008, PRC-011 and PRC-017. But, we believe that the draft Standard needs one important revision before the NERC Board of Trustees should approve it. Specifically, NERC should revise the draft version of PRC-005-2 so that the beginning of Section 4.2 reads as follows: *“4.2. Facilities:* *Protection Systems that (1) are not facilities used in the local distribution of electricity, (2) are facilities and control systems necessary for operating an interconnected electric energy transmission network, and (3) are any of the following:”* This revision is necessary to capture the limits that Congress placed on FERC, NERC, and the Regional Entities in developing and enforcing mandatory reliability standards. Specifically, Section 215(i) of the Federal Power Act provides that the Electric Reliability Organization (ERO) “shall have authority to develop and enforce compliance

Organization	Yes or No	Question 5 Comment
		with reliability standards *for only* the Bulk-Power System." And, Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems *necessary* for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. *The term does not include facilities used in the local distribution of electric energy*." With this language, Congress expressly limited FERC, NERC, and the Regional Entities' jurisdiction with regard to local distribution facilities as well as those facilities not necessary for operating a transmission network. Given that these facilities are statutorily excluded from the definition of the BPS, reliability standards may not be developed or enforced for facilities used in local distribution. In Order No. 672, FERC adopted the statutory definition of the BPS. In Order No. 743-A, issued earlier this year, the Commission acknowledged that "Congress has specifically exempted 'facilities used in the local distribution of electric energy'" from the BPS definition. FERC also held that to the extent *any* facility is a facility used in the local distribution of electric energy, it is exempted from the requirements of Section 215. In Order No. 743-A, FERC delegated to NERC the task of proposing for FERC approval criteria and a process to identify the facilities used in local distribution that will be excluded from NERC and FERC regulation. The critical first step in this process is for NERC to propose criteria for approval by FERC to determine which facilities are used in local distribution, and are therefore <u>not</u> BPS facilities. The criteria to be developed by NERC must exclude any facilities that are used in the local distribution of electric energy, because all such facilities are beyond the scope of the statutory definition of the BPS, which establishes the limit of FERC and NERC jurisdiction. Accordingly, it is critical that NERC draft the new PRC-005-2 standard to expressly exclude facilities used in local distribution. NERC must also expressly exclude from PRC-005-2 those facilities "not necessary for operating an interconnected electric energy transmission network (or any portion thereof)". Similar to the local distribution exclusion, the facilities not necessary for operating a transmission network are not part of the BPS and therefore must be expressly excluded from the standard. We understand, but disagree with, the argument that, because the FPA clearly excludes local distribution facilities and facilities necessary for operating an interconnected electric transmission network from FERC, NERC, and Regional Entity jurisdiction, it is not necessary to expressly exclude these facilities again in reliability standards. This approach might be legally accurate, but could lead to significant confusion for entities attempting to implement the new PRC-005-2 standard. There are numerous examples of Regional Entities, particularly WECC, attempting to assert jurisdiction over such facilities, and regulated entities face significant uncertainty as to which facilities they should consider as within jurisdiction. Clarifying FERC, NERC, and Regional Entity

Organization	Yes or No	Question 5 Comment
		jurisdiction in the BES definition, even if such clarification is already provided in the FPA, would avoid such problems under the new PRC-005-2 standard. Again, we appreciate the work NERC has put in so far on a new Standard. We look forward to working within the drafting process to help implement our recommended revision.
Response: Thank you for your comments. The SDT has revised R1 to refer to Applicability 4.2. The SDT believes that your comments are otherwise already reflected in the Standard, and that no further changes are necessary. The Standard currently addresses maintenance of all Protection Systems that are applied on or to protect BES elements, as well as maintenance of UFLS installed for the BES per PRC-007, UVLS installed on or for the BES per PRC-010, and Special Protection Systems installed on or for the BES per PRC-012, PRC-013, PRC-014, and PRC-015. Therefore, the Standard is already constrained as you suggest. Additionally, Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
ReliabilityFirst	Ballot Comment - Affirmative	ReliabilityFirst votes affirmative but offers the following suggestions/comments: 1. R3 should be split into two separate requirements since there are two distinct actions being requested (e.g. “…shall implement and follow its PSMP” is one requirement and “… shall initiate resolution of any identified maintenance correctable issues” is the second requirement. 2. There are a number of terms which are defined only for the use of the PRC-005-2 standard which will not be moved to the Glossary of Terms., and even though I completely agree with this concept, I believe this concept is not mentioned nor is it allowed per the NERC Standard Processes Manual.
Response: Thank you for your comments. 1. The SDT believes that the two activities are intertwined and should remain within a single requirement. 2. The SDT has been advised by NERC Standards staff that this is acceptable, and has adopted the methodology for doing so as suggested by staff.		

NERC

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Consideration of Comments

Protection System Maintenance and Testing – Project 2007-17

The Protection System Maintenance and Testing Drafting Team would like to thank all commenters who submitted comments on the first draft of the PRC-005-2 standard for Protection System Maintenance and Testing (Project 2007-17). This standard and its associated documents were posted for a 45-day public comment period from August 15, 2011 through September 29, 2011. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 48 sets of comments, including comments from approximately 147 different people and approximately 98 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

SAR:

The SDT made several changes to the SAR. The proposed title of the standard was changed to 'Protection System Maintenance'; Reliability Principle item #4 was removed as it does not apply to the standard; and the 'Transmission and Generation' descriptor of Protection Systems was removed from the Detailed Description area of the SAR.

Applicability:

The SDT revised Applicability 4.2.5.4 to indicate that, for generator-connected station service transformers, only the Protection Systems that trip the generator, either directly or via a lockout relay, are included in the standard.

Requirements:

Requirement R1 part 1.3 has been removed.

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_Standard_Processes_Manual_20110825.pdf.

The SDT split Requirement R3 into three separate requirements for better clarity.

Requirement R3 has been revised so that, for time-based programs, entities must comply with the standard's tables rather than their PSMP. Requirement R3 now reads:

> **R3.** Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.

Requirement R4 has been added to address performance-based maintenance. The new Requirement R4 is as follows:

> **R4.** Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System components that are included within the performance-based program.

Requirement R5 has been added to address Unresolved Maintenance Issues. The definition of the term 'Unresolved Maintenance Issues' has been enhanced for additional clarity, and now reads:

> ***Unresolved Maintenance Issue*** *- A deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action.*

The new Requirement R5 is as follows:

> **R5**. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.

Measures

The SDT revised and drafted new measures to comport with the requirements.

Tables

Most commenters seemed to agree in general that the restructured Tables added clarity and some commenters offered suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" document to address various comments.

In Table 1-5 (Component Type - Control Circuitry Associated With Protective Functions), the SDT removed the auxiliary relays from the 6 year periodic maintenance associated with electromechanical lockout devices, and included them in the 12 year periodic maintenance associated with the unmonitored control circuitry associated with protective functions.

Table 1-4(f) was modified to more accurately represent the monitoring attributes and related activities for monitored Vented Lead-Acid and Valve-Regulated Lead-Acid batteries.

Implementation Plan

Minor clarifying changes were made to the Implementation Plan.

VLSs:

Changes were made to the make the VSLs conform to the new and changed requirements.

Supplementary Reference Document

Changes were made to the "Supplementary Reference and FAQ" document, corresponding to all changes to the standard.

Unresolved Minority Views:

- A few commenters continued to object to the establishment of maximum allowable intervals for the maintenance of various Protection System component types. The SDT continued to respond that FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals.

- Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.

- Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.

- Several commenters continued to question the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT obtained a position from NERC legal staff, and cited this position in responding that these devices are indeed within NERC's authority because they are installed for the reliability of the BES.

- A few commenters questioned the inclusion of the direct current (dc) control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is included because the dc control circuitry is associated with protective functions.

- A few commenters objected to the language in the Data Retention section regarding the retention of the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

1. Do you have any comments regarding the existing SAR for this project?

Summary Consideration: In response to the comments, the SDT made several changes to the SAR.

1. The proposed title of the standard was changed to 'Protection System Maintenance.'

2 Reliability Principle item #4 was removed as it does not apply to the standard.

3 The 'Transmission and Generation' descriptor of Protection Systems was removed from the Detailed Description area of the SAR.

Several comments were offered, suggesting that the SAR address validating the accuracy of settings calculations provided to the field test personnel. The SDT declined to modify the SAR because they believe validating the accuracy of settings as provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard.

Several comments were offered, suggesting that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology." The SDT declined to modify the SAR because they believe the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	Yes	Maintenance and testing of protection systems is the final step in the process that begins with the calculation of settings. The calculation of settings is followed by the application of those settings to the equipment. Maintenance and testing ensures that the settings given to testing personnel have been applied as given. This Standard addresses the Maintenance and Testing of protection systems. It should also address the need to validate the accuracy of the settings given to the field. A statement should be added to the SAR to address this need.
Response: Thank you for your comment. You are correct in your observation that the standard, as established in the project scope, addresses the maintenance and testing of Protection Systems. The SDT believes validating the accuracy of settings as		

Organization	Yes or No	Question 1 Comment
provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard. Thus, the SDT does not believe that the SAR should be modified.		
ZGlobal Engineering and Energy Solutions	Yes	Table 1-4(a-c) excludes distributed UFLS and UVLS for batteries but references Table 3. Table 3 does not mention an interval for batteries. Is this an error?
Response: Thank you for your comment. In Table 3 we address the dc supply for tripping only non-BES interrupting devices as part of the UFLS and UVLS system. Table 3 explicitly limits the activities and intervals for station dc supply (relative to distributed UVLS/UFLS) to verifying the Protection System dc supply voltage every 12 calendar years, and requires nothing beyond that for station batteries in this application. This is not an error within the standard.		
Utility Services, Inc	Yes	We would urge that the SAR be modified to include Validation of Protection System settings. Presently, the standard does not provide for the explicit validation of the settings and it is possible that such mis-settings could be the reason for a misoperation. If a validation of the settings was explicitly called for in the standard, then the misoperation would be less likely to occur for that reason.
Response: Thank you for your comment. The SDT believes validating the accuracy of settings as provided to testing personnel is an internal management issue that should be addressed by the entity, and is beyond the scope of a 'maintenance and testing' standard. Thus, the SDT does not believe that the SAR should be modified. If this becomes a "Misoperation" problem for the entity, NERC Reliability Standard PRC-004-2 requires the entity to develop and implement a Corrective Action Plan to address the cause of the Misoperation.		
Constellation Power Generation	Yes	Although Constellation Power Generation agrees with some of the refinements prescribed in the SAR, there are a few items of concern. Constellation Power Generation agrees that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology. The Registered Entity should be given the latitude to address different technologies through its PSMP, and the requirements should reflect that.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comment. The SDT believes the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.		
Constellation Energy Commodities Group	Yes	Although Constellation Energy Commodities Group agrees with some of the refinements prescribed in the SAR, there are a few items of concern. Constellation Energy Commodities Group agrees that "the requirements should reflect the inherent differences between various protection system technologies," however the requirements should not mandate different testing methods and testing intervals based on that technology. The Registered Entity should be given the latitude to address different technologies through its PSMP, and the requirements should reflect that.
Response: Thank you for your comment. The SDT believes the current PRC-005-2 draft does not mandate specific testing methods; the responsible entity has latitude in establishing its PSMP. Specific activities (such as those for various technologies of "station dc supply") are prescribed, but the entity still has discretion in determining the most appropriate method of conducting those activities.		
Saft America, Inc.	Yes	
Manitoba Hydro	No	**1.** Detailed Description: The phrase "Transmission & Generation Protection Systems" used in paragraph 1 should be "Transmission and generation Protection Systems". "Transmission" and "Protection System" are defined words in the NERC Glossary of Terms; "Generation" is not a defined term and should not be capitalized. **2.** Applicable Reliability Principles: Is item 4 [Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.] applicable to Protection System Maintenance?
Response: Thank you for your comment.		

Organization	Yes or No	Question 1 Comment
1. The SAR has been modified in consideration of your comment. The SDT removed the "Transmission & Generation" descriptors from the sentence. 2. The SAR has been modified in consideration of your comment. The Applicable Reliability Principle 4 has been unchecked as it is not applicable to this standard.

Response: Thank you for your comment.		

2. In response to comments, the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue". Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Most commenters agreed with the change in the term from "Maintenance Correctable Issue" to "Unresolved Maintenance Issue", with some offering further suggestion for improvement and clarification. Several commenters expressed concern that, without further clarity, auditors may confuse initiation of resolution for an issue with completion of the activities necessary to ultimately resolve the issue, but the SDT believes that this term (and its use within the Standard) is unequivocal. In response to comments, the SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 (shown below) and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.

Requirement R5 now reads:

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues.

Organization	Yes or No	Question 2 Comment
Occidental Chemical	Affirmative Ballot	In response to comments, the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue". Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. The original term inferred that the problem detected was correctible through follow-up maintenance – which is not always the case. The term "Unresolved Maintenance Issue" is more appropriate.
Response: Thank you for your comment and your Affirmative Ballot.		
Independent Electricity System	Yes	The IESO agrees with the revision to the term. However, we observed the inconsistent format of this defined term used throughout the draft standard and would like to point it out to the Drafting Team. The capitalized term "Unresolved Maintenance Issue" is defined on Page 2 and used as a capitalized term in the blue box on Page 5. The defined term was made

Organization	Yes or No	Question 2 Comment
Operator		lowercase and used in other areas of the document as “unresolved maintenance issues” (eg. Page 5 and Page 8). We recommend that the format of this defined term be consistent throughout the draft standard.
Response: Thank you for your comment. The SDT has capitalized the term throughout the standard for consistency.		
MidAmerican Energy Company	Yes	1. Requirement R3 includes the following: “and initiate resolution of any unresolved maintenance issues”. For clarification it is recommended that the following change be made to this phrase: “initiate resolution of any unresolved Protection System maintenance issues”. 2. Also it is recommended that the following be added to the list in M3: “work management system information”.
Response: Thank you for your comment. **1. The SDT observes that your concern is addressed by the Applicability of the standard (specifically addressing Protection Systems), and that the change you suggest is unnecessary.** **2. The language of Measure M3 specifies “*may include but is not limited to dated maintenance records …*” and could include records and information from a work management system without excluding other maintenance records an entity might have outside a work management system.**		
Utility Services, Inc	Yes	While this helps, we are concerned that during the term of the Unresolved Maintenance Issue is being resolved, a question of compliance to the standard might be pending out. It should be clarified that during this term, compliance to the standard is being satisfied and not deemed to be non-compliant.
Response: Thank you for your comment. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
Igleside	Yes	The original term inferred that the problem detected was correctible through follow-up

Organization	Yes or No	Question 2 Comment
Cogeneration LP		maintenance -which is not always the case. The term “Unresolved Maintenance Issue” is more appropriate.
Response: Thank you for your comment.		
Springfield Utility Board	Yes	This change has no impact on how Springfield Utility Board currently operates.
Response: Thank you for your comment.

Bonneville Power Administration	No	BPA agrees that the term “Maintenance Correctable Issue” is an improvement over “Unresolved Maintenance Issue”, however, BPA feels that the idea of a “Maintenance Correctable Issue” is very vague, and would perhaps be better left out of the standard. As written, it is unclear when an issue is a “Maintenance Correctable Issue” and exactly how it has to be dealt with. R3 requires the initiation of resolution of any unresolved

Organization	Yes or No	Question 2 Comment
		maintenance issues.
Response: Thank you for your comment. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.**		
MRO's NERC Standards Review Forum	No	Requirement R3 includes the following: “and initiate resolution of any unresolved maintenance issues”. The addition of unresolved maintenance issues to the standard is not included in the SAR and has the potential to cause confusion and misinterpretation. It is suggested that this phrase be removed.
Response: Thank you for your comment. The SAR was developed and submitted by the NERC System Protection and Control Task Force (SPCTF) who later prepared and submitted the Technical Reference “Protection System Maintenance” as a guide for the SDT to use in developing PRC-005-2. In crafting the elements of PRC-005-2, the SDT has endeavored to follow the SAR, which directs addressing FERC Order 693 directives; recommendations from the SPCTF Assessment of Standards PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0; and consideration of stakeholder comments received during the development of the Version 0 and Phase III & IV standards. **In the Detailed Description section of the SAR, bullet point four recommends the SDT define the terms “maintenance programs” and “testing programs” while recognizing other terms may be necessary for clarity. The SPCTF Assessment further recommends that PRC-005-2 “…should clarify that two goals are being covered: The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers’ design specifications throughout the service life” and the “testing portion should… verify the functional performance of protection systems”. Additionally, in the SPCTF Technical Reference “Protection System Maintenance”, the term “maintenance” is defined as “An ongoing program by which Protection System function is proved, and restored if needed.”** **The SDT developed and defined the term “Protection System Maintenance Program” (PSMP) and its elements (which includes the testing portion) to achieve the goal of the recommendations of the SAR, SPCTF Assessment, and guidance given in the SPCTF Technical Reference. Consistent with this guidance, a PSMP is defined in PRC-005-2 as “An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored.” The term “Unresolved Maintenance Issue” defines those things identified as needing follow-up action in order to restore them to proper**		

Organization	Yes or No	Question 2 Comment
operation. This may include repair or replacement activities that cannot be performed during the periodic PSMP activity through which the deficiency was discovered. Demonstrating the entity has initiated resolution of these issues might then include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… For clarity, the SDT has included these examples in the associated Measure for this requirement in the current draft. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.**		
Southern Company Generation	No	The measure associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. It is suggested that one of these two courses be followed: either a) eliminate the requirement to initiate resolution, or b) fully describe what evidence is expected for this part.
Response: Thank you for your comment. The SDT believes that an effective PSMP must include correction of deficiencies, but management of completion of any Unresolved Maintenance Issues is a complex topic which may involve a wide variety of activities (with varying completion timelines). The associated Measure lists examples of what may be effective evidence (more examples have been added); specific evidence, for any specific situation, will vary based on the particulars of that situation. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
American Electric Power	No	The definition's wording is satisfactory, and we agree with the removal of "failure of a component to operate within design parameters". However, we do not agree with the use of the word "unresolved" within the term itself, as we believe this word may convey that the issue was not known or identified. We suggest replacing "Unresolved Maintenance Issue" with "Corrective Maintenance Issue".
Response: Thank you for your comment. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td>Southern Company Transmission</td><td>No</td><td>The measure associated with the requirement that includes this term is non-specific with regards to what an auditor will require as proof of the initiation of resolving the issue. PNGC Comment Group	No	
Central Lincoln		Either term works if defined properly.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment.		

3. In response to comments, the SDT revised the previous "3 calendar months" interval to "4 calendar months" for communications systems and station dc supply. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Most commenters agreed with the change; however, several commenters suggested further extension of these intervals. The SDT did not make any further changes to those intervals, explaining their belief that the established intervals are appropriate maximum intervals for this continent-wide standard. A few commenters continued to object to the establishment of maximum allowable intervals as specified in FERC Order 693; the SDT did not adopt any related suggestions, and instead reminded the commenters of FERC's directives.

Organization	Yes or No	Question 3 Comment
CPS Energy	Affirmative Ballot	The 4 month maintenance and testing interval for station DC supply is too short based on programs that have been in service for many years where twelve months have been proven as reliable for operation.
Response: Thank you for your comments **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present (per Table 1-4f).**		
Occidental Chemical	Affirmative Ballot	In response to comments, the SDT revised the previous "3 calendar months" interval to "4 calendar months" for communications systems and station dc supply. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. Ingleside Cogeneration LP agrees that the intervals on the activities in question should be extended to 4 calendar months. However on Page 20 of the Supplementary Reference document, the calculation of the next due date using units of "calendar months" is inconsistent with the calculation using a "calendar year". In the case of "calendar years", an activity must take place somewhere between Jan 1 and Dec 31. For "four calendar months", a follow-up activity must be performed within four months from the completion of the prior one. We believe that "four

Organization	Yes or No	Question 3 Comment
		calendar months" should be calculated in the same manner as a "calendar year". This means that an activity should take place at least once between January 1 and April 30; and repeated once during May 1 through August 31, and again between September 1 and December 31. The pattern would continue in ongoing years. Not only is this method consistent with the "calendar year" derivation, it allows the most flexibility in scheduling – especially if an unexpected event causes a delay. The vast majority of the maintenance activities will still take place at four months plus or minus a week or two; with an occasional outlier that adds minimal risk to reliability.
Response: Thank you for your comments. **Section 7.1 of the Supplementary Reference and FAQ document has been modified in consideration of your comment.**		
Wisconsin Electric Power Co. Wisconsin Electric Power Marketing	Affirmative Ballot	Focusing on batteries which are required to be done on a time-based maintenance program: 1. The big picture is that it is not just testing anymore - there are many more mandated tasks to be performed - Table 1-4(a). - Verifications & inspections are now part of the plan criteria, and have been moved from 3 months to a 4 month maximum interval. 2. We would like to see clarification on what is meant by the extent of 4 months. Is it by the end of the same calendar day or the previous calendar day, four months later; or is it 120 days or what? Could plan to manage to every 3 months, but not greater than 4 months. Same for Battery testing - manage to 1 year, but not greater than 18 months. 3. What is meant by battery continuity? Is battery float current an acceptable test methodology? It is not defined as clearly as an "impedance" or "resistance" test.
Response: Thank you for your comments. **1. The SDT believes that all of the maintenance activities within the "definition" of PSMP and as listed in the Tables are necessary components of an effective PSMP. Testing alone cannot assure that the Protection System components are in good working order.** **2. Section 7.1 of the Supplementary Reference and FAQ document provides an expanded discussion of this topic, and has been revised to add further clarity.**		

Organization	Yes or No	Question 3 Comment
3. **"Continuity" can be tested via several methods, and is described in detail in Section 15.4 of the Supplementary Reference and FAQ document. Battery float current is one of the many methods discussed within the Supplementary Reference Document.**		
PNGC Comment Group	Yes	We agree with this change. Smaller utilities, especially in the WECC region, in many cases have large territories to cover with limited resources. In many instances sub-stations are inaccessible during the winter and the 4 month interval will assist these smaller entities in getting the work done.
Response: Thank you for your comment		
MRO's NERC Standards Review Forum	Yes	We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4(a, b, c, d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a Reliability Standard includes best maintenance practices it is encroaching on IEEE's ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible. We recommend that this time frame be a maximum of 6 Calendar Months which will allow entities to establish their own time frame based on the seasonal changes that occur where the batteries are located.
Response: Thank you for your comments. **Station dc supply (including station batteries) must perform properly for the Protection System to function correctly. In order to establish that station batteries are functioning properly, the SDT believes that all of the listed maintenance activities must be performed, within the specified maximum intervals, with due consideration for any monitoring functionality that may be present. The SDT has drawn from the relevant IEEE standards (and other sources) to determine those activities that it has deemed appropriate to assure proper performance of the station battery. The SDT specifically believes that the 4-month maximum interval is proper for these activities for unmonitored DC supply systems and is consistent with the prevailing industry practice.**		
Tacoma Power	Yes	A similar change in interval should be applied to intervals of "6 calendar months".

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments **The SDT believes that the six-month interval is appropriate.**		
Nebraska Public Power District	Yes	We agree 4 calendar months is better than 3 Calendar months. The 4 month activities should be removed from Tables 1-4 (a, b, c, d). These requirements are blurring the distinction between a best practice and functionally verifying the component. IEEE already sets the industries best practices, if a Reliability Standard includes best maintenance practices it is encroaching on IEEE's ability to keep the industry informed and optimized. The Standard Drafting Team should restrain itself to only making requirements that functionally verify components and initiate corrective action wherever possible.

Central Lincoln	Yes	Thank you for making this change. As we pointed out in draft 2, a three month maximum would require a bi-monthly target to allow for contingencies; increasing maintenance from four times a year (per the IEEE battery standards) to six.
Response: Thank you for your comment.		
Ameren	Yes	Our experience with a very large number of communication systems and station dc supplies substantiates an even longer interval as sufficient for reliable Protection Systems.
Response: Thank you for your comment. If your experience suggests that longer intervals for communications systems will produce appropriate performance, you may employ performance-based maintenance (per the draft standard). However, SDT		

Organization	Yes or No	Question 3 Comment
believes that all of the listed maintenance activities for station dc supply must be performed, within the specified maximum intervals, with due consideration for any monitoring functionality that may be present.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP agrees that the intervals on the activities in question should be extended to 4 calendar months. However on Page 20 of the Supplementary Reference document, the calculation of the next due date using units of "calendar months" is inconsistent with the calculation using a "calendar year". In the case of "calendar years", an activity must take place somewhere between Jan 1 and Dec 31. Manitoba Hydro	No	Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Our experience shows that 6 month battery inspections are more than adequate to maintain system reliability.Manitoba Hydro has more than ten years of experience using its existing battery inspection intervals, and Manitoba Hydro's reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro's battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro's installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro

Organization	Yes or No	Question 3 Comment
		and may be more than is required for many other utilities. To use a more frequent inspection interval would significantly penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. With the 4 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval.
Response: Thank you for your comments. **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present (per Table 1-4f).**		
Arizona Public Service Company	No	APS has been testing batteries nominally every 4 months plus 25% for over 20 years with no adverse consequences. Requiring a maximum of testing every 4 months doesn't allow for any flexibility, would require an additional 400 tests per year and APS does not consider the 4 months a maximum time limit for battery testing.
Response: Thank you for your comments. **This 4 month interval is an "inspect and verify" activity not testing. FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present. If an entity's experience is that some components require less-frequent maintenance than specified in the Tables, a performance-based program in accordance with Requirement R2 and Attachment A is an option unless specifically precluded.		
American Electric Power	No	Though we agree with extending the interval from what it was previously, AEP recommends that the interval in Table 1-2 for Communications Systems be increased to 6 months.
Response: Thank you for your comments **The SDT believes that the revised 4-month maximum interval is proper for unmonitored communications systems.**		
Tennessee Valley Authority	No	

4. **The SDT extracted the maintenance activities and intervals for distributed UFLS and UVLS systems from Table 1-1 through 1-5 and placed them into a new Table 3 to more clearly illustrate the requirements related to these systems. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Most commenters appreciated the break-out of distributed UFLS/UVLS maintenance activities into Table 3. Several commenters, however, continued to object to inclusion of this maintenance within the standard, and some questioned NERC's jurisdiction to address devices installed on the distribution system. The SDT consulted with NERC legal staff on the jurisdiction question, and cited the position from NERC Legal in responding that these devices are indeed within NERC's authority because they are installed for the reliability of the BES. Several commenters also objected to the requirements relating to periodic operation of electromechanical devices, maintenance of voltage and current sensing devices, and/or maintenance of the dc supply within the new Table 3, and the SDT provided responses supporting the SDT's belief that all of these activities are relevant and necessary for inclusion within the standard. Several other commenters suggested formatting changes, most of which were adopted. While considering these comments, the SDT also made assorted clarifying changes to Table 3.

Organization	Yes or No	Question 4 Comment
Occidental Chemical	Affirmative Ballot	The SDT extracted the maintenance activities and intervals for distributed UFLS and UVLS systems from Table 1-1 through 1-5 and placed them into a new Table 3 to more clearly illustrate the requirements related to these systems. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement. Yes. We believe that distributed UFLS and UVLS relay systems have a very different operating purpose than those that are not distributed. It is appropriate to separate the maintenance activities and intervals for these relay systems.
Response: Thank you for your support.		
Southern Company Generation	Yes	1. Separating this classification of equipment into its own table is a good idea to make it easier for the owners of this equipment to figure out what they must do. 2. Consider also moving the UVLS note (found in column 1 of Tables 1-4a-d) into the header with

Organization	Yes or No	Question 4 Comment
		the other "UFLS and UVLS note" to simplify the table. The header note could read "Excludes UFLS and UVLS systems - see Table 1-4e for non-distributed UFLS and UVLS systems and see Table 3 for distributed UFLS and UVLS systems"). 3. Table 1-5: Need clarification on "continuity and energization or ability to operate". What does this mean? 4. For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). There are some references to Table 2 (i.e. See Table 2), but does that mean that you have to verify the alarm(s)? We think that the Table 2 details need to be included specifically in Table 3. Or, make it very clear that this test is required for UF and UV schemes.
Response: **1. Thank you for your support.** **2. Thank you for your comment, Table 1-4 (a, b, c, d) has been revised accordingly.** **3. This entry in Table 1-5 has been modified to "Control circuitry whose integrity is monitored and alarmed". Section 15.3 of the Supplementary Reference and FAQ document provides additional discussion on this topic.** **4. The SDT has revised the Table 2 for clarity.**		
Ameren	Yes	Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.
Response: Thank you for your suggestion; the SDT has revised the standard.		
Northeast Utilities	Yes	The migration of the UFLS and UVLS requirements to Table 3 is appreciated. The Table 3 Component Attributes in rows 6 and 7 ("Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices" and Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems" respectively) do not identify that the trip coils are excluded. Although row 9 states "Trip coils of non-BES interrupting devices in UFLS or UVLS systems" do not have any period maintenance specified, our recommendation is to

Organization	Yes or No	Question 4 Comment
		annotate rows 6 and 7 to explicitly indicate the trip coils are excluded.
Response: Thank you for support. The SDT has revised Table 3 accordingly.		
MidAmerican Energy Company	Yes	None
Southern Company Transmission	Yes	For UF and UV schemes, Table 3 does not specifically state to check the alarm(s) to a control center (for monitored components). There are some references to Table 2 (i.e. See Table 2), but does that mean that you have to verify the alarm(s)? I think Table 2 details need to be included specifically in Table 3. Or make it very clear that this test is required for UF and UV schemes.
Response: Thank you for your comment. The SDT has revised Table 2 for clarity.		
Ingleside Cogeneration LP	Yes	We believe that distributed UFLS and UVLS relay systems have a very different operating purpose than those that are not distributed. It is appropriate to separate the maintenance activities and intervals for these relay systems.
Response: Thank you for your support.		
Springfield Utility Board	Yes	Although numerous tables can become overwhelming to navigate, it is far less ambiguous if specific systems are spelled out in separate and distinct tables.
Response: Thank you for your support.		
Ameren	Yes	Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.
Response: Thank you for your suggestion. The SDT has revised the standard.

Flathead Electric Cooperative	Negative Ballot	I appreciate the drafting team's effort to separate requirements for distributed UFLS, however fundamentally it is unclear how mandatory and enforceable requirements can be applied to non-BES elements as there is no statutory authority over local distribution networks.
Response: Thank you for comment. In regards to your concern, the SDT received the following position from NERC Legal: **"While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.** **FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 also covers users, owners, and operators of bulk-power facilities.** **UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES."**		
Lakeland Electric	Negative Ballot	The standard reaches further into the distribution system for UFLS and UVLS. It will be burdensome to present all the evidence of distribution class protection system maintenance and testing at audits.
Response: The existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.		
Beaches Energy	Negative	The standard reaches further into the distribution system than we would like for UFLS and UVLS

Organization	Yes or No	Question 4 Comment
Services	Ballot	(Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection.

Response: Thank you for your comment.

First, the existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.

Second, the UVLS and UFLS systems are included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical devices, such as auxiliary or lockout relays which contain "moving parts", need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.

Organization	Yes or No	Question 4 Comment
Florida Keys Electric Cooperative Assoc.	Negative Ballot	The standard reaches further into the distribution system than we would like for UFLS and UVLS (Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to preform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic.

Lincoln Electric System	Negative Ballot	Please see comments submitted in addition to the following comment. LES recommends the standard drafting team clarify the expected maintenance activities for BES related batteries that also serve UFLS systems. In particular, what would be the required maintenance activities for a battery bank serving both BES transmission elements and UFLS elements? Table 1.4 clearly

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td>excludes UFLS elements and Table 3 indicates it only applies to “non-BES interrupting devices”. As such, if a joint use battery is excluded from Table 1.4 because of its association with UFLS, BES related batteries would have no place in any of the tables.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment.

The SDT responded to your other comments in the sections where they were submitted.

A battery bank serving both BES and UFLS/UVLS protection systems would be maintained per table 1-4. A battery bank that serves only distributed UFLS or UVLS system would be maintained per table 3.

The headers of the various sections of Table 1-4 now exclude station dc supply that is used <u>only</u> for UFLS/UVLS from Table 1-4.</td></tr>
<tr><td>CenterPoint Energy</td><td>No</td><td>1. For the “Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices”, the Table 3 requirement is to “Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that wire checking a panel is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing.

2. In addition, CenterPoint Energy recommends the requirement in Table 3 to “Verify that current and/or voltage signal values are provided to the protective relays” every 12 years be revised to “No periodic maintenance specified”.

3. Likewise, we recommend the requirement in Table 3 to “Verify Protection System dc supply voltage” every 12 years be revised to “No periodic maintenance specified”. Preventive maintenance tasks such as the three above are unnecessary for distributed UFLS and UVLS system components. The overriding performance, or “risk-based”, NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount.</td></tr>
</table>

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comment. **1. While much of the control circuitry associated with a distribution device is regularly exercised, the SDT believes that the control circuitry associated directly with UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so.** **2. The SDT believes that the voltage/current signals that support proper operation of UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so. The specific degree of this verification is constrained within Table 3 to those activities necessary to assure proper operation of the UFLS/UVLS.** **3. The SDT believes that the station dc supply that supports only proper operation of UFLS/UVLS that are applied for BES reliability need be periodically verified to assure that these components will function properly when called upon to do so. The specific degree of this verification is constrained within Table 3 to only periodic measurement of the dc voltage.**		
BGE	No	Although BGE does not disagree with moving the distributed UFLS/UVLS maintenance activities and intervals into the new Table-3, BGE requests further clarification from the SDT on how to correctly interpret the headings and content of this table.
Response: Thank you for your support. Table 3 has been modified since it was last released for comment. Table 3 should be used to determine maintenance activities and intervals for distributed UFLS and UVLS systems. Distributed systems are further elaborated upon in the Supplementary Reference and FAQ document, Section 15.7.		
Constellation Power Generation	No	Moving the UFLS and UVLS systems from Tables 1-1 through 1-5 into a separate Table 3 is a useful improvement in illustrating the requirements. However, our objection is not really with the format, it is will the content of the Tables. From a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive and we are concerned that they may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. In the worst case, the specifics dictated in the Tables may move Entities away from more stringent PSMPs that are currently in practice. For this reason, Constellation suggests that the drafting team revisit the concept of the Tables to better balance to convey useful guidance without creating a

Organization	Yes or No	Question 4 Comment
		compliance requirement that may be contrary to improved reliability. The Registered Entity should be given more flexibility to dictate how a protection system component should be tested, and at what frequency. Lastly, the technical manpower and compliance documentation demands to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any small generation entity would use it.
Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The SDT believes that the intervals established within the Tables are appropriate as continent-wide maximum allowable intervals, with due consideration for any monitoring functionality that may be present. The ability to utilize performance-based maintenance is provided for those entities who wish to pursue it; it is understood that many entities may instead choose to simply implement a PSMP based on the Tables.**		
Constellation Energy Commodities Group	No	Moving the UFLS and UVLS systems from Tables 1-1 through 1-5 into a separate Table 3 is a useful improvement in illustrating the requirements. However, our objection is not really with the format, it is will the content of the Tables. From a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive and we are concerned that they may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. Florida Municipal Power Agency	No	We like the new Table 3, but, have remaining concerns. The standard reaches further into the distribution system than we would like for UFLS and UVLS. We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic.
Response: Thank you for your comment. **First, the existing standards (PRC-008 & PRC-011) already require maintenance and testing of components of UFLS and UVLS protection systems, including those installed to operate distribution-level interrupting devices.** **Second, the UVLS and UFLS systems are included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical devices, such as auxiliary or lockout relays which contain “moving parts”, need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.**		

Organization	Yes or No	Question 4 Comment
NERC Staff Technical Review	No	We agree in principle with the change; however, we have identified discrepancies among these tables with respect to the reference to UFLS and UVLS systems. The headings in Tables 1-1 through 1-4(b) and Table 1-5 refer to "Excluding distributed UFLS and UVLS"; Table 1-4(c) refers to "Excluding UFLS and non-distributed UVLS"; while Table 1-4(d) refers to "Excluding UFLS and distributed UVLS." We believe the drafting team intended for consistency among these tables and that the intent is to exclude distributed UFLS and distributed UVLS schemes as opposed to distributed UFLS and all UVLS schemes. To make this clear we recommend changing the second line in the heading of each of these tables to "Excluding distributed UFLS and distributed UVLS." Corresponding changes should be made in the "Component Attributes" sections of Tables 1-4(a) through 1-4(e) and to the title of Table 3.
Response: Thank you for your comment. The standard has been modified as you suggest.		
Tennessee Valley Authority	No	

5. The SDT has revised the "Supplementary Reference and FAQ" document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change.

Summary Consideration: Many commenters objected to Requirement R3 and to the explanation that entities would be held to compliance on "either the Tables or their PSMP, whichever is more stringent". In response to these comments, the SDT modified the standard to remove Requirement R1 part 1.3, and revised Requirement R3 so that, for time-based programs, entities shall comply with the Tables rather than their PSMP. The SDT added Requirement R4 to address performance-based maintenance, and added Requirement R5 to address Unresolved Maintenance Issues. The Supplementary Reference and FAQ document was updated to reflect these changes.

Several commenters questioned the inclusion of the dc control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is indeed included because the dc control circuitry is associated with protective functions. No change was made to the standard based on these comments.

Numerous commenters suggested minor revisions or clarifying text for the Supplementary Reference and FAQ document. These changes were generally adopted.

Organization	Yes or No	Question 5 Comment
Ameren Services	Affirmative Ballot	1. Although the explanation of 'Restore' is enlightening on page 12, 'Restore' no longer appears in the PS Maintenance definition in the last few drafts. 2. We disagree with the added burden of retaining maintenance records for removed or replaced equipment. This will actually reduce reliability because of the confusion it can cause as to what

Organization	Yes or No	Question 5 Comment
		equipment is providing BES protection. At most, only the last maintenance date of the removed or replaced component should be retained if there's really a need to prove that the interval was met regarding the BES protection. 3. Remove 'Reverse power relays' from the list on page 32. They provide thermal of the steam turbine, not electrical protection of the generator. 4. Now that FERC has approved the Project 2009-17 Interpretation, please acknowledge more directly in the Supplement that the 'transmission Protection System' that is now approved. NERC interprets "transmission Protection System," as it appears in Requirements R1 and R3 of PRC-004-1 and Requirements R1 and R2 of PRC-005-1, to mean "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES". 5. Please consistently state UFLS before UVLS; Table 1-4(e) differs from other parts of the standard.

Response:

1. **Thank you for your suggestion; the SDT has revised the Supplementary Reference and FAQ document to remove the "restore" reference from the definition.**
2. **The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period.**
3. **The SDT agrees that for many steam units, reverse power relays provide alarm only of a condition which could result in eventual overheating of steam turbine components. However, for many combustion turbine generators, a reverse power condition can lead to imminent failure of teeth on the speed reduction gear and thus, reverse power relays on combustion turbine generators are frequently wired as a direct trip to the generator breaker to immediately remove the motoring condition. Furthermore, in the Supplementary Reference document, the preface to the list of relays to which you refer is as follows: "Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:". The SDT was attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included in an**

Organization	Yes or No	Question 5 Comment
entity's PSMP. **4. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.** **5. Thank you for your suggestion; the SDT has revised the standard.**		
Madison Gas and Electric Co.	Affirmative Ballot	Note that the Guidance document over states that an entity will be held accountable for have a more restrictive PMSP than the maximum intervals in attachment 1. Please review FERC Order 693, section 278 which states: "While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, and we do not require that they exceed the Reliability Standards".
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Northeast Power Coordinating Council, Inc.	Affirmative Ballot	An issue was raised here in the Northeast regarding requiring an entity to adhere to their protection system maintenance program, PSMP. If an entity has a maintenance program in place that has shorter intervals, i.e. more stringent than those in the appendix of the standard, and the entity misses completing his maintenance, the entity will be found non-compliant irrespective of the entity to demonstrate they still were within the longer intervals listed in the actual standard. NPCC would suggest that the SDT consider revising this to only result in a non-compliance assessment result if an entity missed the intervals in the appendix of the standard not those specified in their PSMP. The concern is that some entities will forego more stringent programs and revise their documents "downward" in order to ensure compliance at the potential for a reduction in reliability. There is no mechanism currently in place to preclude entities from doing this.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Occidental Chemical	Affirmative Ballot	The SDT has revised the "Supplementary Reference" document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change. Yes. Ingleside Cogeneration LP found the Supplementary Reference document to be helpful, thorough, and technically accurate. The only suggestion we have is that demonstrated adherence to the Reference should be admissible of evidence of compliance at an audit or spot check. Today, all References have no official regulatory standing – which seems to defeat the purpose of developing them to begin with.
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.		
Occidental Chemical	Affirmative Ballot	We need to clarify the following: A transmission owner has established a maintenance cycle which is more stringent (less time between maintenance or test cycles) than the NERC Standard requires. The transmission owner fails to comply fully with the transmission owner's maintenance and testing schedule; however, the maintenance and/or testing is performed within the time frame mandated by the NERC Standard. Must the transmission owner report his failure to comply with his own maintenance/testing program even though the maintenance or testing was completed well within the time frame or interval required by the applicable NERC Standard? Must he transmission owner report such a failure of his own maintenance procedures which are more stringent than the NERC maintenance/testing standard? Will such a self report be considered a non-compliance?
Response: Thank you for your comment. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for		

Organization	Yes or No	Question 5 Comment
time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Oncor Electric Delivery Company LLC	Yes	Oncor would like to see the “Supplementary Reference & FAQ” expanded to provide examples of what documentation would satisfy that the entity is compliant with initiating “resolution of any Unresolved Maintenance Issues.” Also it would be helpful to all entities if the Drafting Team would expand on what, if any, tracking of the resolution of an unresolved maintenance issue is required. Oncor believes that keeping track of the initiation of “resolution of any unresolved maintenance issues” is necessary but that the standard does not currently address retention requirements related to this compliance obligation.
Response: Thank you for your comment. The measure related to this requirement has been expanded to include additional suggestions of relevant documentation. There is no tracking requirement listed for the resolution of unresolved maintenance issue, only the initiation of a resolution. The SDT recognizes that performance of the activities necessary to resolve an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. Requiring tracking and deadlines is not within the scope of this standard. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.		
Springfield Utility Board	Yes	Because Springfield Utility Board's (SUB) current maintenance and testing program is time-based, the revised "Supplementary Reference" document does not impact SUB operations. SUB agrees with the document changes because the changes result in alternatives for entities, rather than being prescriptive.
Response: Thank you for your comment.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP found the Supplementary Reference document to be helpful, thorough, and technically accurate. The only suggestion we have is that demonstrated adherence to the Reference should be admissible of evidence of compliance at an audit or spot check. Today, all References have no official regulatory standing - which seems to defeat the purpose of developing them to begin with.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.		
MidAmerican Energy Company	Yes	The changes to the “Supplementary Reference” document appear to be acceptable, but the following are suggested as changes to enhance clarity. 1. On page 9 of the Supplementary Reference and FAQ draft the following statement is included: “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.” On page 67, the third sentence of Section 15.3 states: “It includes [referring to control circuitry] the wiring from every trip output to every trip coil.” Later in that section the following is included: “...from a protective relay that are necessary for the correct operation of the protective functions.” While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: “Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested.” 2. On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard could result in a noncompliance finding even if the maximum intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.
Response: Thank you for your comment. **1. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is**		

Organization	Yes or No	Question 5 Comment
consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. 2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Ameren	Yes	1. Although the explanation of 'Restore' is enlightening on page 12, 'Restore' no longer appears in the PS Maintenance definition in the last few drafts. 2. We disagree with the added burden of retaining maintenance records for removed or replaced equipment. This will actually reduce reliability because of the confusion it can cause as to what equipment is providing BES protection. At most, only the last maintenance date of the removed or replaced component should be retained if there's really a need to prove that the interval was met regarding the BES protection. 3) Remove 'Reverse power relays' from the list on page 32. They provide thermal of the steam turbine, not electrical protection of the generator.
Response: 1. Thank you for your suggestion; the SDT has revised the Supplementary Reference and FAQ document to remove the "restore" reference from the definition. 2. The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period. 3. The SDT agrees that for many steam units, reverse power relays provide alarm only of a condition which could result in eventual overheating of steam turbine components. However, for many combustion turbine generators, a reverse power condition can lead to imminent failure of teeth on the speed reduction gear and thus, reverse power relays on combustion turbine generators are frequently wired as a direct trip to the generator breaker to immediately remove the motoring condition. Furthermore, in the Supplementary Reference and FAQ document, the preface to the list of relays to which you refer is as follows: "Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not		

Organization	Yes or No	Question 5 Comment
necessarily limited to:". The SDT was attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included in an entity's PSMP.		
Tacoma Power	Yes	It is not clear to what extent can an entity (or auditor) can rely on information contained within the Supplementary Reference to support their position during an audit. There is a disclaimer at the beginning of the Supplementary Reference stating that "this supplementary reference to PRC-005-2 is neither mandatory nor enforceable." It seems that interpretation of the draft standard depends heavily upon this Supplementary Reference. At the same time, the Supplementary Reference does not rise to the level of a standard.
Response: Thank you for your comment. The document is explanatory but also illustrates the intent of the SDT. The rationale and methods explained within the Supplementary Reference and FAQ document represent the thoughts of the SDT regarding approaches to application of the standard, but may (or may not) be of use to demonstrate compliance. Baltimore Gas & Electric Company	Negative Ballot	BGE's negative ballot is based on our response to Q5: While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning "Our maintenance plan calls…" states that an entity is "out of compliance" if maintenance occurs at a time longer than that specified in the entity's plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, "How do I achieve a grace period without being out of compliance?" the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out of compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance – compliance management, scheduling, operational preference, etc.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
AEP	Negative Ballot	This negative vote is driven primarily by the concerns AEP has regarding the proposed supplementary reference documentation. If an entity adopts a more stringent maintenance program but fails to meet it, that entity could be found non-compliant despite continuing to abide by the minimum requirements of the standard itself. Entities should have the ability, if they so choose, to include additional maintenance activities or more stringent intervals than specified

Organization	Yes or No	Question 5 Comment
		within the standard without concern of penalty in the event they are unable to accomplish them. In addition, AEP is concerned by the volume of information provided in the supplementation documentation, and is uncertain how much weight that documentation might carry during audits. Note: Additional comments are being submitted via electronic form by Thad Ness on behalf of American Electric Power.
Response: Thank you for your comments. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **The document is explanatory but also illustrates the intent of the SDT. FERC approves standards as mandatory and enforceable; FERC does not approve reference documents.**		
Manitoba Hydro	Negative Ballot	Maintenance Activities Exceeding NERC Requirements In both the industry webinar discussion and the supplementary reference document, it was indicated that if an entity had more maintenance activities in its plan than the minimum required by PRC-005-2, then an entity would be audited to the "higher standard". We understand that an entity could write some flexibility in its program, as long as the NERC minimums were met. We are concerned that auditing to the "higher standard" could discourage entities from performing maintenance tasks beyond the NERC minimum criteria.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
PJM Interconnection,	Negative	PJM remains concerned with a position taken by the SDT related to statements found within their Supplementary Reference & FAQ as well as the manner in which Requirement R3 has been

Organization	Yes or No	Question 5 Comment
L.L.C.	Ballot Negative Poll	drafted. The SDT's position sends industry the wrong message; a message that entities should not go beyond what is in the text of the standards and that in some cases they can even be found non-compliant by merely failing to meet their own more stringent internal practice. Therefore, PJM is voting NEGATIVE at this time. The NERC reliability standards aim to ensure an Adequate Level of Reliability (ALR). If NERC's reliability standard establishes that an ALR is achieved by a maximum allowable relay maintenance period of every 6 years in a time-based Protection System Maintenance Program (PSMP), then an entity striving to complete its maintenance every 4 years should not be found non-compliant for completing it in 5 years. We have heard NERC say in CAN Webinars and NERC Workshops that "auditors must audit to the standard", however, the position taken by the SDT within their Supplementary Reference and FAQ document and the wording of Requirement R3 is contrary to this position.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
FirstEnergy	No	We do not agree with aspects of the Supplementary Reference document as discussed in Question 6.
Response: Thank you for your comments. Please see our response to your comments in Question 6.		
NERC Staff Technical Review	No	We recommend changes to Supplementary Reference. It appears the 3 calendar month interval referenced in the second FAQ in section 7.1 on page 20, Example 1 on page 21, Example 2 on page 22, and on page 23 should be updated to 4 calendar months consistent with the changes to the standard for verification of station dc supply voltage and inspection of electrolyte level and unintentional grounds. We recommend modifying references to UFLS and UVLS to clarify the intervals for distributed systems applies to both UFLS and UVLS similar to the recommended change to the standard in our comment on question 4. See pp. 26, 30, 33, 86, and 87 of the supplementary reference.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. **1. Thank you for comment; the Supplementary Reference and FAQ document has been changed.** **2. Changes have been made to the standard and its Supplementary Reference and FAQ document.**		
MRO's NERC Standards Review Forum	No	a. Page 9, "Is a Sudden Pressure Relay an auxiliary tripping relay? "1) During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows:i. Is a Sudden Pressure Relay an auxiliary tripping relay? No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. b. On page 26 of the Supplementary Reference document, it states, "If your PSMP (plan) requires more activities than you must perform and document to this higher standard." This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, "If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards." In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards". c. Page 78, last paragraph: If the same type of ohmic testing is done (impedance, conductance or

Organization	Yes or No	Question 5 Comment
		resistance), may a different manufacturer's test equipment be used for this testing? d. Page 79, second paragraph of "Why verify voltage?": 1) "The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning." i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? 2) "The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits." i. Is it the intent of the PSMT SDT that this measurement is taken at the battery terminals, or will a reading taken from the battery charger panel meter meet this requirement? e. Except as noted above, the changes to the "Supplementary Reference" document appear to be acceptable, but the following are suggested as changes to enhance clarity. 1) On page 9 of the Supplementary Reference and FAQ draft the following statement is included: "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included." On page 67, the third sentence of Section 15.3 states: "It includes [referring to control circuitry] the wiring from every trip output to every trip coil." Later in that section the following is included: "...from a protective relay that are necessary for the correct operation of the protective functions." While this later statement may be interpreted to exclude circuitry associated with relays that do not respond to non-electrical inputs or impulses it would be better to make this more explicit. It would seem illogical to require testing of circuitry that is not needed for the protective functions covered by the standard. It is suggested that a sentence like the following be added to the first paragraph of Section 15.3: "Control circuitry associated with relays that respond to non-electrical inputs or impulses is not covered by this standard and need not be tested." 2) On page 31 of the Supplementary Reference it indicates that a procedure that includes intervals less than the standard could result in a noncompliance finding even if the maximum

Organization	Yes or No	Question 5 Comment
		intervals in the standard are complied with. This is contrary to previous Commission rulings on what is mandatory and enforceable (i.e. only the standard itself Ref. Order 733 p105). This FAQ response should be changed to reflect those rulings.

Response: Thank you for your comment.

1. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.

2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.

3. Yes. Your concern, of course should be that your results can be trended from test to test. The Supplementary Reference and FAQ document has been changed.

4. The Supplementary Reference and FAQ document has been changed to add clarity.

5. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. As to part 2, The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, R1 part 1.3 has been removed; R3 has been revised so that, for time-based programs, entities shall comply with the tables; R4 has been added to address performance-based maintenance, and R5 has been added to address Unresolved Maintenance Issues.

Organization	Yes or No	Question 5 Comment
ACES Power Collaborators	No	There are some changes that are needed to the document. 1. On Page 19, the second question refers to R1.4. There is no R1.4 in the standard. We assume

Organization	Yes or No	Question 5 Comment
		that document is intended to refer to part 1.4 under R1. This needs to be clarified and corrected. 2. The reference document creates an improper incentive to eliminate best practices and utilize the maximum time intervals established in the standard. The document states that an entity will be subject to compliance violations if it has a maintenance and testing program with time intervals that are more stringent than the maximum time intervals in the standard and it does not meet its more stringent intervals. This would hold true even if the registered entity meets the maximum intervals established in the standard. To reduce compliance risk, registered entities will be incented to increase its time intervals to the maximum allowed by the standard. This is contrary to supporting reliability. Penalizing entities for failing to meet their more stringent plan requirements is also contrary to guidance provided by the Commission. Doug Curry, General Counsel of Lincoln Electric System, spoke to the Commission at the November 18, 2010 FERC technical conference on reliability monitoring, enforcement and compliance about his company's experience with the vegetation management standard. They exceeded the requirements for annual inspections by including six aerial patrols each year but were found in violation of the standard and paid penalties when they did not complete but one aerial patrol in the first five months of the year. The auditors concluded that the company's ground patrol fully satisfied the minimum requirements of the standard. In the end, LES removed the aerial inspections from the vegetation management plan. The Commissioners acknowledged that this was contrary to their goal of an adequate level of reliability and agreed that an entity should not be penalized for failing to meet their more stringent requirements when they meet the standard requirements. 3. On Page 34, the FAQ about commissioning does not appear to be consistent with CAN-0011. While we believe the reference document is more correct, the drafting team should compare the advice given in the reference document to that in the CAN to ensure that it is not conflicting. Given that NERC is in the process of revising all of the CANs, the best approach may simply be to add a statement referencing the CAN-0011 for further information. 4. Comments about "gaming the PBM system" regarding restoring segment performance should be removed from the reference document. Comments like these indicate intent by a

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>registered entity to manipulate the compliance process. Only after a thorough investigation can such intent be determined. Thus, there shouldn’t be a presumption that registered entities will attempt this. Better comments would be to focus on the consistency that the three year period provides in determining segment performance.
5. In section 12.1 on page 58, the reference document discusses out of service equipment. NERC recently issued a lesson learned on removing unused relaying equipment on August 10, 2011. The drafting team may wish to reference that lesson learned in the reference document.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment.
1. The Supplementary Reference and FAQ document has been changed.
2. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.
3. The Supplementary Reference and FAQ document has been changed.
4. The Supplementary Reference and FAQ document has been changed.
5. The Supplementary Reference and FAQ document has been changed to incorporate a discussion of the cited Lessons Learned.</td></tr>
<tr><td>Southern Company Generation</td><td>No</td><td>Several additional edits are needed so that the document matches the proposed standard:
1) In Section 5.1.1, page 16, add "and Table 3" in the Figure and at the end of FAQ after figure in that section.
2) In Section 7.1, example #1, a 3 month battery interval is shown
3) In Section 8.1.1, a 3 month interval is shown for communication circuit
4) In Section 15.5.1, several references to "3 month" and "three month" intervals are shown for communication circuits.
5) In Appendix B, the formatting is incorrect for Al McMeekin's company name.</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comment. The Supplementary Reference and FAQ document has been changed to address each of your suggestions.		
Nebraska Public Power District	No	a. On page 26 of the Supplementary Reference document, it states, "If your PSMP (plan) requires more activities than you must perform and document to this higher standard." This penalizes utilities from including best practices in their PSMP, and encourages utilities to implement the standard maintenance practice instead of a higher maintenance practice. Why would a utility accept the additional risk of a NERC penalty or sanction when they can stay in compliance by accepting the minimum requirements of the standard? By stating this, the PSMP will include only those required items at the minimum frequency to avoid a compliance violation. For the reliability of the BES, recommend the wording be changed to, "If your PSMP (plan) requires more activities than required by PRC-005-2, you will be held accountable only to the minimum requirements in the standard. NERC encourages utilities to implement best practices to improve the reliability of the BES, so utilities will not be penalized for exceeding the standards." In FERC Order 693, section 278 FERC states: While we appreciate that many entities may perform at a higher level than that required by the Reliability Standards, and commend them for doing so, the Commission is focused on what is required under the Reliability Standards, we do not require that they exceed the Reliability Standards".
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
American Electric Power	No	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. However, AEP is uncertain how much weight the documents might carry during audits. We recommend that this additional information be included within the actual standard (for example in an appendix) but in a more compact version. Section 15.7 of the supplementary reference includes the bullet point "No verification of trip path

Organization	Yes or No	Question 5 Comment
		required between the lock-out and/or auxiliary tripping device(s).” This appears to contradict the other bullet points within Section 15.7.
Response: Thank you for your comment. **1. Doing as you suggest would make the supporting information within the Supplementary Reference and FAQ document part of the standard and this would add extensive and unnecessary prescription to the standard.** **2. The Supplementary Reference and FAQ document has been changed.**		
Lincoln Electric System	No	Please see the comments submitted by the MRO NSRF.
Response: Please see our response to the comments submitted by the MRO NSRF.		
Liberty Electric Power LLC	No	The reference contains language which makes it a violation should an entity choose a cycle time less than the maximum from the table, and then fails to meet that cycle. (See page 27, "If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.") There is no reason to hold a RE in violation if all work is performed within the maximum time from the table - either there was no reliability risk, or the table is incorrect and a reliability risk in itself.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Manitoba Hydro	No	1. Page 26: In both the industry webinar discussion and the supplementary reference document, it was indicated that if an entity had more maintenance activities in its plan than the minimum required by PRC-005-2, then an entity would be audited to the "higher standard". We understand that an entity could write some flexibility in its program, as long as the NERC minimums were met. We are concerned that auditing to the "higher standard" could

Organization	Yes or No	Question 5 Comment
		discourage entities from performing maintenance tasks beyond the NERC minimum criteria. 2. The discussion on page 9 indicates that although the relays which respond to mechanical parameters are not included in the scope of PRC-005-2, the associated trip circuits are included. We suggest that neither the relays which respond to mechanical parameters nor their associated trip circuits are within the scope of this standard 3. References to the tables should be consistently updated to include the new Table 3. “Every 3 calendar months” should be updated throughout the document to “Every 4 calendar months”. For example, Page 23: Example #3 should be revised. 4. In addition, there are a number of grammatical errors in the document, particularly capitalization and punctuation, which make it difficult to read. There are terms which are improperly capitalized implying that they are approved NERC Glossary of Terms definitions when they are not.
Response Thank you for your comment. **1. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** **2. American Transmission	No	ATC provides the following suggestions for change:

Organization	Yes or No	Question 5 Comment
Company		1. Page 9, "Is a Sudden Pressure Relay an auxiliary tripping relay? "During the webinar on Thursday, September 15th it was asked whether the trip path for a sudden pressure relay needed to be confirmed. Based on this question, we believe that the FAQ should be modified as follows: Is a Sudden Pressure Relay an auxiliary tripping relay?No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Since the sudden pressure relay is not included, it also follows that trip path testing for this relay type is also excluded. 2. Page 78, last paragraph:If the same type of ohmic testing is done (impedance, conductance or resistance), modify the FAQ to allow the use of a different manufacturer's test equipment to conduct the testing. 3. Page 80, second paragraph: "The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning." Insert the following: "A reading taken from the battery charger panel meter will meet this requirement." "The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits." Insert the following." A reading taken from the battery charger panel meter will meet this requirement."

Response: Thank you for your comments.

1. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. CenterPoint Energy	No	CenterPoint Energy appreciates that there is now only one document, instead of the two originally proposed. However, we question the name of the document which shows "Supplemental Reference and FAQ". The use of "Supplemental Reference" could infer it contains requirements not found in the PRC-005-2 standard. Also, we suggest that NERC standardize on the names of documents associated with standards and other NERC initiatives. CenterPoint Energy recommends the name of the document be "Technical Reference".
Response: Thank you for your comment. The Supplementary Reference and FAQ document is explanatory in nature.		
BGE	No	While we do not disagree with the revisions to the Supplemental Reference, there remains an important item to correct. The supplementary reference on page 31, under the question beginning "Our maintenance plan calls..." states that an entity is "out of compliance" if maintenance occurs at a time longer than that specified in the entity's plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35-36, under the question, "How do I achieve a grace period without being out of compliance?" the response provides a presumably compliant example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less than the maximum time of six calendar years. This advice conflicts with the previous guidance. The FAQ /supplementary reference should be revised so that it does not imply that an entity is out-of-compliance by performing maintenance more frequently than required than the bright-line maxima in the tables. Entities may opt to test more frequently than dictated in the tables for a variety of reasons that may or may not be related to reliable protection system performance - compliance management, scheduling, operational

Organization	Yes or No	Question 5 Comment
		preference, etc.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Response: Please see our response to your comments in Question 6.		
Tennessee Valley Authority	No	

6. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them in the comment section.

Summary Consideration:

Many commenters objected to Requirement R3 and to the explanation that entities would be held to compliance on "either the Tables or their PSMP, whichever is more stringent". In response to these comments, the SDT modified the standard to remove Requirement R1 part 1.3, and revised Requirement R3 so that, for time-based programs, entities shall comply with the Tables rather than their PSMP. The SDT added Requirement R4 to address performance-based maintenance, and added Requirement R5 to address Unresolved Maintenance Issues. The Supplementary Reference and FAQ document was updated to reflect these changes.

Several commenters questioned the inclusion of the dc control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is indeed included because the dc control circuitry is associated with protective functions.

Several comments were offered objecting that the VSLs establish that any non-compliance is a violation, and that "perfection is unrealistic". The SDT responded that the VSL Guidelines do not provide for an entity to be out of performance to some degree without incurring a violation.

Several comments were offered regarding "Unresolved Maintenance Issues". Some of these comments suggested that the entity should be required to resolve such issues, rather than initiating resolution. Others offered concerns regarding the definition of this term itself or the related VSLs. The SDT revised the definition to: "A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, and requires follow-up corrective action." The VSLs for the old Requirement R3 (new Requirement R5) were revised from graduated "%" to graduated "hard counts" of violations. The SDT also clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.

Other comments were offered regarding Data Retention, generally objecting to retaining the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

Several commenters questioned the verification of lockout and auxiliary relays every 6 years. The SDT explained their rationale for this requirement relative to lockout relays, and did move the auxiliary relays to the 12-year control circuitry verification.

Several comments were offered on the Implementation plan, resulting in several clarifying changes.

Many comments were offered, questioning the Applicability of the standard relative to the recently-approved Interpretation of "transmission Protection System". The SDT explained that PRC-005-2 does not use this term; thus the interpretation does not apply. The SDT also explained that the Applicability in PRC-005 is correct and that it supports the reliability of the BES.

In response to comments, the SDT revised Applicability 4.2.5.4 to indicate that, for generator-connected station service transformers, only the Protection Systems that trip the generator, either directly or via a lockout relay are included in the standard.

In response to comments, Table 1-4(f) was modified to more accurately represent the monitoring attributes and related activities for monitored Vented Lead-Acid and Valve-Regulated Lead-Acid batteries.

Organization	Yes or No	Question 6 Comment
City of Austin dba Austin Energy	Affirmative Ballot	(1) The following language should be clarified to make it clear that a Registered Entity does not have to include its detailed maintenance procedures in its PSMP: 1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3.
	Affirmative Poll	(2) For a modern digital relay panel, designed with monitored components and electromechanical lockouts, the maintenance interval would otherwise be a maximum of 12 years except that the lockout must be electrically operated every 6 years. We cannot see justification for a separate maintenance activity to just test the lockouts, due to the increased human error associated with testing lockouts and the low likelihood of a lockout failure. We recommend that the lockouts be tested on a 12 year basis, perhaps in association with the "Unmonitored control circuitry associated with protective functions" as found in Table 1-5. By doing so, we feel that the risk of an undesired operation due to human error can be minimized and not degrade system reliability.
		(3) If sudden pressure relays are exempt from the Standard, the DC circuitry for those relays should also be exempt.
		(4) If a Registered Entity has a PSMP that is more stringent than the intervals in PRC-005-2, the Registered Entity should not be considered out of compliance if it fails to meet its internal interval but remains within the interval set forth in PRC-005-2.

Response: Thank you for your comments.

1. The SDT's intent with the R1.4 wording is to convey that the entity's PSMP must document that the monitoring attributes of any given component type meet the Table-specified monitoring attributes in order to justify exclusion of the maintenance activities and/or the lengthening of maintenance intervals as provided for in the Tables. PRC-005-2 does not have requirements for inclusion of detailed maintenance procedures in an entity's PSMP as the tables within the standard have taken the place of the "summary of maintenance and testing procedures" required by R1.2 of PRC-005-1.
2. The SDT believes that electromechanical lockout relays need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.
3. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.
4. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.

City of Tacoma, Department of Public Utilities, Light Division, dba Tacoma Power	Affirmative Ballot	1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.
		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station DC supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program developed for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.

		5. In Table 1-2, there is a maintenance activity related to communication systems to “verify essential signals to and from other Protection System components.” It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to “verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.” This language is consistent with that used for protective relays in Table 1-1.
		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which ‘performance criteria’ are ‘pertinent.’ Additionally, it is unclear if an entity must document the ‘communications technology applied’ and the associated ‘performance criteria’ in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms ‘resistance’ and ‘ohmic values.’ If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms ‘battery terminal connection resistance’ and ‘unit-to-unit connection resistance.’ If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term ‘resistance’ with ‘impedance.’
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.

		11. Referring to Table 1-5, no periodic maintenance is required for “control circuitry whose continuity and energization or ability to operate are monitored and alarmed.” It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for “unmonitored control circuitry associated with protective functions.” It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.
		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.
Response:	**Thank you for your comments.**	
	1. The SDT agrees with your observation and has changed the relevant parts of the implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals.	
	2. The SDT agrees with your observation and has revised the Implementation plan to clarify.	

	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.
	5. The SDT agrees with your suggestion and has changed the standard accordingly.
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.
	7. As utilized on Table 1-4, the term "ohmic value" is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term "ohmic value" is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term "resistance" as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.

	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.
	14. As timing is critical to proper Protection System function, timers are considered protective relays.

Ameren Services	Affirmative Ballot	Measure M3 on page 5 should only apply to 99.5% of the components. Please revise to state: “Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated….” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. No one is perfect and it is impractical to imply perfection is achievable. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is “non-performance”. An alternate approach regarding the unrealistic perfection of M3 is to correctly recognize that the protection of the primary BES is the objective. Most Protection Systems are redundant by design and the entity needs to be afforded the opportunity to show that a redundant component met the PSMP thereby providing the required protection. The entity should be allowed a reasonable time frame of one calendar increment to maintain the component in question. Our concern stems from the tens of thousands of components in a PSMP, and the reality that rarely but occasionally a data base error or outage scheduling issue may result in a very small number component exceeding their maximum interval. As long as the entity can show that BES protection was sustained and maintains the component quickly (e.g. within one calendar month of discovery), BES reliability has been maintained.
Response: Thank you for comment. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RRO to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.**		

City of Austin dba Austin Energy	Affirmative Ballot	1. The following language should be clarified to make it clear that a Registered Entity does not have to include its detailed maintenance procedures in its PSMP: "all applicable monitoring attributes and related maintenance activities ". Reference: R1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3. 2. For a modern digital relay panel, designed with monitored components and electromechanical lockouts, the maintenance interval would otherwise be a maximum of 12 years except that the lockout must be electrically operated every 6 years. We cannot see justification for a separate maintenance activity to just test the lockouts, due to the increased human error associated with testing lockouts and the low likelihood of a lockout failure. We recommend that the lockouts be tested on a 12 year basis, perhaps in association with the “Unmonitored control circuitry associated with protective functions” as found in Table 1-5. By doing so, we feel that the risk of an undesired operation due to human error can be minimized and not degrade system reliability. 3. If sudden pressure relays are exempt from the Standard, the DC circuitry for those relays should also be exempt.

Response: Thank you for your comments.

1. **The SDT’s intent with the Requirement R1.4 (new Requirement R1.2) wording is to convey that the entity’s PSMP must document that the monitoring attributes of any given component type meet the Table-specified monitoring attributes in order to justify exclusion of the maintenance activities and/or the lengthening of maintenance intervals as provided for in the Tables. PRC-005-2 does not have requirements for inclusion of detailed maintenance procedures in an entity’s PSMP as the tables within the standard have taken the place of the “summary of maintenance and testing procedures” required by R1.2 of PRC-005-1.**

2. **The SDT believes that electromechanical lockout relays need periodic operation in order to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.**

3. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is**

omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.		
International Transmission Company Holdings Corp	Affirmative Ballot	While voting "Affirmative" on this ballot, ITC continues to have concerns with testing intervals. These comments have been submitted via the Comment Form associated with this project.
Response: Thank you for your affirmative vote. Please see our responses to our comments elsewhere in this report.		
Occidental Chemical	Affirmative Ballot	If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here. Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test.
Response: Thank you for your comment and affirmative vote. **There are less intrusive ways to verify channel performance that do not require disconnecting communication terminations. It is up to the entity to determine specific maintenance techniques.**		

Oncor Electric Delivery	Affirmative Ballot	PRC-005-2 is a vast improvement over the vagueness of the existing standard (PRC-005-1), that the new standard makes compliance much easier than the present standard. The new standard recognizes the advances in relay technology and reliability, particularly the benefits of microprocessor based relays. The standard also provides greater flexibility on its implementation while recognizing the benefits of a performance based methodology, particularly as it relates to battery testing. The revised standard eliminates the requirement for a "summary of maintenance and testing procedures" which was vague and provided no real value to the registered entities. Operational and administrative efficiencies can be realized by consolidating the relay testing and maintenance requirements into one standard (PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0)
Response: Thank you for your comment and affirmative vote.		
Public Utility District No. 2 of Grant County	Affirmative Ballot	We are ok with this standard, however, we would like to see some recognition of the use of non-calendar based maintenance practices such as predictive maintenance practices or condition based maintenance practices. When you use one of those methodologies for the basis for your plant maintenance it is very labor intensive to interpret those results to a calendar based requirement.
Response: Thank you for your comment and affirmative vote. **Please see Sections 5, 6, and 7 of the Supplementary Reference and FAQ for a discussion of how the SDT has attempted to incorporate condition-based maintenance practices (utilizing installed monitoring capabilities) and performance-based maintenance practices within PRC-005-2.**		
Tacoma Public Utilities	Affirmative Ballot	1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.

		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station dc supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program develoepd for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.
		5. In Table 1-2, there is a maintenance activity related to communication systems to “verify essential signals to and from other Protection System components.” It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to “verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System.” This language is consistent with that used for protective relays in Table 1-1.

		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which 'performance criteria' are 'pertinent.' Additionally, it is unclear if an entity must document the 'communications technology applied' and the associated 'performance criteria' in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms 'resistance' and 'ohmic values.' If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms 'battery terminal connection resistance' and 'unit-to-unit connection resistance.' If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term 'resistance' with 'impedance.'
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.
		11. Referring to Table 1-5, no periodic maintenance is required for "control circuitry whose continuity and energization or ability to operate are monitored and alarmed." It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for "unmonitored control circuitry associated with protective functions." It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.

		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.
Response:	**Thank you for your comments.**	
	1. The SDT agrees with your observation and has changed the relevant parts of the implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals	
	2. The SDT agrees with your observation and has revised the Implementation plan to clarify.	
	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.	
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.	
	5. The SDT agrees with your suggestion and has changed the standard accordingly.	
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.	

	7. As utilized on Table 1-4, the term "ohmic value" is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term "ohmic value" is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term "resistance" as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.
	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.

	14. As timing is critical to proper Protection System function, timers are considered protective relays.	
Wisconsin Electric Power Co. Wisconsin Electric Power Marketing	Affirmative Ballot	Do we need to track the maintenance of another owner's Protection System Component which is part of my Protection System? For example, if our Protection System includes and trips another owner's circuit breaker, do we need to track maintenance and testing for that circuit breaker?
Response: Thank you for your comment and affirmative ballots. **The owner is responsible for the maintenance of Protection System Components. You do not need to track the maintenance of other owner's Protection System Components.**		
Beaches Energy Services	Negative Ballot	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer".

		2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.

Response: Thank you for your comments.

1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.**
2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**

Florida Municipal Power Pool	Negative Ballot	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer", e.g., if the standard says an interval is 6 years, then, through business practice we can shorten actual maintenance and testing intervals to something like 4 years to allow ourselves a 2 year buffer to catch equipment that may have been missed due to difficulty in scheduling outages and the like. Does not cause us to vote negative.
	Negative Poll	2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard. Causes us to vote Negative.

Response: Thank you for your comments. 1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.** 2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**		
Constellation Power Source Generation, Inc.	Negative Ballot Negative Poll	Constellation Power Generation is voting against the approval of this standard because, from a generation perspective, the maintenance intervals and activities described in all of the Tables are too prescriptive. Constellation Power Generation is concerned that the Tables may conflict with the existing PSMPs built by Registered Entities based on years of operational experience with the testing methods and testing frequencies that work best for the specific asset. In the worst case, the specifics dictated in the Tables may move Entities away from more stringent PSMPs that are currently in practice. For this reason, Constellation Power Generation suggests that the drafting team revisit the concept of the Tables to better convey useful guidance without creating a compliance requirement that may be contrary to improved reliability. The Registered Entity should be given more flexibility to dictate how a protection system component should be tested, and at what frequency. Furthermore, the technical manpower and compliance documentation demands to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any small generation entity would use it. Please refer to Constellation Power Generation's submitted comments for other issues identified with this standard.
Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance.**		

Duke Energy/ Fort Pierce Utilities Authority	Negative Ballot	Duke Energy disagrees with the wording in the Applicability section 4.2.1. The wording change from PRC-005-2 draft 4 to PRC-005-2 draft 5 expands the reach of the standard to relaying schemes that detect faults on the BES but are not intended to provide protection for the BES. Duke Energy's standard protection scheme for dispersed generation at retail stations would be subject to the standard due to the changes in section 4.2.1. These protection schemes are design to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the definition used in PRC-005-1A Appendix 1 "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Lakeland Electric	Negative Ballot	First Concern is that evidence of maintenance and testing at this level will be very difficult to obtain, track and report. Second is the word exercise - what is really meant by this. This may be difficult or impossible to do without impacting or tripping the circuit. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17).
Response: Thank you for your comments 1. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Nonetheless, the SDT agrees that significant effort will be necessary to implement these requirements and to prove compliance.** 2. **The SDT is unsure to which utilization of the word "exercise" you refer.** 3. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		
Illinois Municipal Electric Agency	Negative Ballot	IMEA greatly appreciates SDT efforts to address/resolve issues, improve PRC-005, and consolidate various PRC Reliability Standards. However, IMEA is voting Negative based on the inconsistency between the current Applicability language and the PRC-004 and PRC-005 interpreation (Project 2009-17) recently approved by FERC. IMEA supports comments submitted by Florida Municipal Power Agency which address this inconsistency, and encourages the SDT to address this issue which is important to municipal entities.

Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.**		
Consumers Energy	Negative Ballot	R3 continues to have "...initiate resolution of unresolved maintenance issues." Initiate means to start or set going, it does not mean closure of the item. If a remediation project is initiated and not closed out in a timely manner an auditor could penalize an entity based on what the auditor considers timely. We suggest definitive language indicating closure of the unresolved maintenance issue. Also, it would be beneficial to specify time frame for closing the issue.
Response: Thank you for your comment. **PRC-005-2 only requires the entity "… initiate resolution" of the issue found. The SDT recognizes that performance of the activities necessary to resolve an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues. Demonstrating the entity has initiated resolution can include such things as documentation of a work order, replacement component order, invoice, or purchase order, etc… Producing evidence of this nature would then indicate adherence to the requirement.**		

Florida Keys Electric Cooperative Assoc.	Negative Ballot	The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Independent Electricity System Operator	Negative Ballot	The IESO disagrees with the concept that auditors use the standards as minimum requirements and evaluate compliance based on a registered entity's own governance. We believe that the entity could be found non-compliant with Requirement R3 if they fail to follow the internal maintenance intervals established in their PSMP, even though actual maintenance intervals are no less frequent than the prescribed maximum intervals established in the draft standard. The potential for such a finding will discourage conscientious entities from setting higher internal targets for their planned maintenance and promote compliance with only the minimum requirements of the standard. We therefore propose the following revision to Requirement R3: R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. In the case of time-based maintenance programs, each Transmission Owner, Generator Owner, and Distribution Provider is permitted to deviate from its PSMP provided that actual maintenance intervals do not exceed those specified in Tables 1-1 through 1-5, Table 2 and Table 3. [Violation Risk Factor: High] [Time Horizon: Operations Planning]
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Florida Municipal Power Agency	Negative Ballot	We have three remaining concerns. The second concern leads us to recommend a negative vote.

	Negative Poll	1. Standard requires 100% perfection, e.g., missing any one interval for any one piece of equipment leads to a violation. This is; however, mitigated by the fact that the intervals are long enough to allow implementation of business practices with shorter intervals to add some "buffer", e.g., if the standard says an interval is 6 years, then, through business practice we can shorten actual maintenance and testing intervals to something like 4 years to allow ourselves a 2 year buffer to catch equipment that may have been missed due to difficulty in scheduling outages and the like. Does not cause us to vote negative.
		2. The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard. Causes us to vote Negative.

		3. The standard reaches further into the distribution system than we would like for UFLS and UVLS (Table 3). We have two parts to this concern. First, it will be somewhat onerous to present all the evidence of distribution class protection system maintenance and testing at audits. And second, our biggest concern is in the testing required to "exercise" a lockout or tripping relay. This may require installation of test blocks to allow such exercising of the lockout or tripping relay without tripping the distribution circuit, and such a test could be difficult to perform without impacting customer continuity of service if the lockout/tripping relay for the UFLS is the same as the lockout/tripping relay for distribution fault protection. However, most of FMPA's members have microprocessor-based relays for distribution circuits with the UFLS / UVLS embedded within the microprocessor based relay where the path from the UFLS / UVLS relay to the lockout / tripping relay is internal to the micro-processor based relay, so, testing the UFLS/UVLS relay will at the same time test the internal lockout / switching relay. However, for older electro-mechanical UFLS schemes, this type of testing could be problematic. Borderline concerning whether this causes us to vote Negative or not. As a result, FMPA recommends a Negative vote with the second and third comments, emphasizing that it is the second comment that causes us to vote negative but we also would like the 3rd comment addressed. Feedback appreciated. Vote and comments are due next Wednesday, 9/28.

Response: Thank you for your comments 1. **The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 allows the RE to provide discretion when assessing severity of the violation when only a relatively small number of maintenance activities have been missed.** 2. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ Document for additional discussion. If, as in your example, a protective relay is installed to prevent back feeding (rather than for detecting BES faults), it would not be applicable even if it has a secondary result of incidentally detecting faults on the BES.** 3. **UVLS and UFLS systems are required to be included as part of the Project 2007-17 Standard Authorization Request (SAR). The SDT believes that electromechanical lockout relays require periodic operation. As such, these devices are required to be exercised at the 12 year interval for UVLS and UFLS systems. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed.**		
Lakeland Electric	Negative Poll	The "Applicability" section is not consistent with Tri-State PRC-005 interpretation.
Response: Thank you for your comments **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Liberty Electric Power LLC	Negative Ballot	With the development and publication of maximum maintenance and testing intervals (the Tables), there is no longer a reliability need for a RE to identify the associated time-based maintenance intervals for Protection System Components. Further, REs who wish to perform these activities in shorter intervals than those allowed by the standard risk non-compliance (See Supplementary Reference, page 27,"If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.")If the entity completes all activities within the maximum interval allowed by the standard, there can be no reliability concern; if there is a reliability issue, then the table interval is incorrect. I would suggest the following changes.
		1. Change R1.2 to read "Identify any Protection System component where the RE is using a performance based maintenance interval. No batteries associated with the station DC supply component type of Protection System shall be included in a performance based system"
		2. Change R1.3 to read "The intervals for time-based programs are established in Table 1-1 through 1-5, Table 2, and Table 3".
		3. Change M1 to add the phrase "for performance-based components" after the words "maintenance intervals".
		4. In M1, replace the words "the type of maintenance program applied (time-based, performance based, or a combination of these maintenance methods") with the words "the identification of any protection system components using performance based intervals".
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues. The Measures have also been revised.		
Manitoba Hydro	Negative Ballot	Manitoba Hydro is voting negative for the following reasons:

		1. Grace Periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-compliance. Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval (for example, performing a battery inspection at a remote station during severe winter weather) or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for safety and reliability without risking non-compliance. In addition, we disagree with the basis that the Drafting Team has established that grace periods are not permitted because of FERC Order 693 which requires that ‘maximum’ time intervals are established within PRC-005-2. With grace periods, a maximum time interval obviously becomes the required maintenance interval plus the maximum permitted grace period. So we strongly feel that grace periods can be added to the standard while adhering to the FERC Order. We also disagree with the line of reasoning that the Drafting Team used to establish the maximum maintenance intervals for relays as outlined on page 38 of the Supplementary Reference and FAQ document. To our knowledge, no document has been produced which provides evidence of maximum time intervals that work well for ‘maintenance cycles that have been in use in generator plants for decades’. Our Protection Systems Maintenance experience indicates that the proposed intervals are acceptable as nominal time intervals with grace periods, but not as maximum time intervals without grace periods. Without a grace period, the bulk of protection maintenance on a six year maintenance cycle will have to be done one year earlier than previously required, in order to allow for the last year of the maximum interval to be used as the grace period. Manitoba Hydro considers this an unnecessary burden on resources with no benefit to reliability. Manitoba Hydro recommends that grace periods be permitted within PRC-005-2 if an entity can demonstrate a reliability or safety related need for using a grace period. This would require the Drafting Team to develop reliability-related criteria for using a grace period.

		2. Phased Implementation Plan Manitoba Hydro does not agree with the prescribed phased implementation plan. Entities should be given a single compliance date for each of the maintenance intervals, and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-005-2. For example, if a maximum maintenance interval is 6 calendar years, the implementation plan should only require that “The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.” (item 4c.). The existing standard PRC-005-1 already requires protection systems to be maintained as part of a program. Prescribing how an entity must reach full compliance will provide a negligible improvement in reliability, while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets, and proving compliance for prescribed percentages of assets during the transition period creates unnecessary overhead with no added value. We suggest that items 3a., 3b., 4a., 4b., 5a. and 5b be removed from the implementation plan and that NERC measure progress on reaching PRC-005-2 intervals using means other than Compliance measures such as industry surveys.

Response: Thank you for your comments.

1. **FERC Order 693 directs NERC to establish maximum allowable intervals. The SDT believes a “grace period” process as you describe would not satisfy this directive. In essence, by specifying maximum allowable intervals the SDT is leaving the establishment of normal maintenance intervals and grace periods to the entities discretion and to what works best for their scheduling needs and program flexibility. Alternatively, if the SDT believes that 6 calendar years is the maximum allowable interval for a given maintenance activity, it could have done as you suggested and defined a 4 year “normal” interval with a 2 year grace period for a maximum allowable interval of 6 years. The SDT believes the management of normal maintenance intervals and grace periods is best left to the entity’s PSMP and thus chose only to specify the maximum allowed interval within which entities must comply. Note that if data is available to prove reliability is maintained, performance-based maintenance is available to achieve longer maintenance intervals.**
2. **The SDT believes that it is not practical for all entities to rapidly transition all of their Protection Systems to the new program, especially with some component types on maintenance intervals of up to 12 years. Nonetheless, all in-scope Protection Systems must be maintained by either a PRC-005-1 program or a PRC-005-2 program. The SDT believes the phased approach mapped out in the Implementation plan is practical. If an entity wishes to implement PRC-005-2 on a more rapid rate than laid out in the Implementation plan to lessen the complexity of documentation requirements, they are free to do so.**

Muscatine Power & Water	Negative Ballot	1. Section D.1.3, in Data Retention, requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable and problematic requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent test record. A compliance audit should be focused on the present day and not in the past. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent test results, we could conceivably have to retain a relay test record for up to 24 years! Hypothetically, if we have a test record from ten years ago, but we do not have the record from 12 years before that, how does that adversely affect the reliability of the BES today? The standard should focus on – Is the Entity compliant TODAY?
		2. Table 1-5 requires a maintenance activity to, “Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Recommend this be changed to, “Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Alternately, change the wording to, “Electrically operate each interrupting device every 6 years.” While requiring each trip coil to operate the breaker sounds good in theory, however, it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and are not configured to test independently. Isolating one trip coil from the other may include “lifting a wire” that may not get landed properly when the test is complete. Using an actual event only tests one coil and we may not know which coil tripped the device. The current language is a recipe for a compliance violation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.
		3. In the tables for dc Supply the term “unit-to-unit” is used along with “intercell” when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450), the standard terminology seems to be “intercell”. It is recommended that the “unit-to-unit” term be removed to avoid confusion regarding what is to be verified.

Response: Thank you for your comments. **1. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities. Obviously, Compliance Monitors should not expect entities to be able produce records for maintenance performed prior to there being requirements for that maintenance to be performed.** **2. The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.** **3. The term "unit-to-unit" is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar.**		
NorthWestern Energy	Negative Ballot	I recommend a no vote please see my comments below. 1. For Table 1-5 Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices 6 calendar years Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device. Provisions need to be added to allow non-tripping checks of coils on the BES element that will Trip load. If I am reading the purposed correct the circuit switcher feeding distribution banks at or above 100kV will need to be tripped taking out load. 2. It was my understanding the IEEE standard 450 allowed for 7 year load test interval for VLA and NiCad batteries the standard calls out for 6 years. It appears that the standard has been recently updated and should be verified. My last objection is Table 1-2 3. Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below. 4 calendar months Verify that the communications system is functional. 4 calendar months is excessive on annual maint and will discourage communications assisted tripping when not absolutely needed. 1 year is a more reasonable and doable timeline.

Response: Thank you for your comments. **1. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." If the Protection System in question is not protecting a BES component, it is not applicable to this standard. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.** **2. IEEE 450 only pertains to VLA batteries. IEEE 1106 pertains to NiCad batteries. The SDT believes that the 6 calendar year interval specified in PRC-005-2 is appropriate.** **3. The SDT believes that performing this maintenance activity at 4 month intervals is proper for unmonitored communications systems.**		
Seattle City Light	Negative Ballot	Regarding Voltage and Current Sensing Device Maintenance & Testing Activities: Table 1-3 of the standard lists the minimum required maintenance activities for voltage and current sensing devices as "Verify that current and voltage signal values are provided to the protective relay." Consistent with Table 1-3, Section 15.2.1 of the Supplementary Reference states that an entity "...must verify that the protective relay is receiving the expected values from the voltage and current sensing devices..." The Supplementary Reference further offers examples of how this requirement may be satisfied with most of the examples reference the need to verify the signal at each relay in the circuit. We recognize the need to verify a voltage signal at each protective relay, as these devices are wired in parallel and an open circuit at one location may not impact the other devices on the circuit. However, we do not agree that there is a need to verify a current signal at each protective relay. Current devices are wired in series; an open circuit at any location will impact all other devices on the circuit. For this reason, a single measurement of the current circuit is sufficient. We recommend updating Table 1-3 and the supplementary reference to account for the different physical characteristics of voltage and current circuits.
Response: Thank you for your comment. **An open circuit is not the only failure mechanism for a CT secondary circuit. Grounded CT secondary wiring can result in situations where accurate current is present in the part of the secondary circuit upstream of the ground but current would be shunted to ground and might not pass through devices downstream of the ground. Entities should not interpret PRC-005-2 as specifying "how" to test but rather that PRC-005-2 only specifies "what" to test.**		

<table>
<tr><td>Seminole Electric Cooperative, Inc.</td><td>Negative Ballot</td><td>We recommend the SDT consider an interval of 12 calendar years for the component in row 3, of Table 1-5 on page 19 of the standard. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We sincerely hope that the SDT will consider these changes.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

The SDT believes it is possible to manage the risks that you describe and that performance of this testing will be an overall benefit to the reliability of the BES. It is the majority opinion of the subject matter experts forming the SDT that testing of electromechanical devices with moving parts such as lockout relays be performed on a 6 year interval. Entities may use the PBM process to extend this interval if they desire.</td></tr>
<tr><td>Tennessee Valley Authority</td><td>Negative Ballot</td><td>It will take several years for TVA to implement checkback on 590 carrier blocking sets on the TVA system and not have to perform the PRC 005-2 requirement of verifying functionality every 4 months with no grace period. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We are also implementing an extensive PM test in October 2011 which will test 25% of the sets per year and will take readings of SWR, line loss, and receiver margin.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment.

The SDT believes that performing this maintenance activity at 4 month intervals will benefit the reliability of the BES. The Implementation plan allows for 15 months after regulatory approvals for entities to implement the program per PRC-005-2. You may also find performance-based maintenance (per Requirement R2) useful.</td></tr>
</table>

Utility Services, Inc.	Negative Ballot	While we generally agree with most of the proposal, we are concerned about the need to address validate of Protection System settings in the standard. We believe that there should be an explicit requirement on validating the settings to ensure that misoperations don't occur due to incorrect settings being programmed into the devices. Reliability will be enhanced if misoperations can be avoided due to the explicit check on the accuracy of the settings.
Response: Thank you for your comment. **Rows 1 and 2 of Table 1-1 currently require verification that relay settings are as specified.**		
Westar Energy	Negative Ballot	Westar agrees in general with most of the changes and modifications included in the proposed Standard. Specifically, the change from 3 to 4 calendar months in Table 1-4. 1. However, we believe that the terms Distributed and Non-Distributed need to be more clearly defined. 2. Clarification is also needed on an entities ability to use fault initiated trips as evidence for Table 1-5 - Control Circuitry.
Response: Thank you for your comments. **1. Please see Section 8.1.1 on pg 25-26 of the Supplementary Reference and FAQ document for discussions of the terms "distributed" and "non-distributed".** **2. Please see paragraph 7 in Section 8.1.2 of the Supplementary Reference and FAQ document for further discussion of this topic.**		
Xcel Energy, Inc.	Negative Ballot	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

Xcel Energy, Inc.	Negative Ballot	I appreciate the effort the SDT has invested in bringing PRC-005 to ballot and refer them to comments submitted by FirstEnergy. I agree with FE that PRC-005 encourages entities to set a low bar when developing protective system maintenance programs and will penalize those with robust programs that miss self-imposed schedules or targets.
Response: The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
Tennessee Valley Authority	Negative Ballot	1. It will take several years for TVA to implement checkback on 590 carrier blocking sets on the TVA system and not have to perform the PRC 005-2 requirement of verifying functionality every 4 months with no grace period. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We are also implementing an extensive PM test in October 2011 which will test 25% of the sets per year and will take readings of SWR, line loss, and receiver margin.
		2. TVA disagrees with the requirement to measure internal ohmic values of the station dc supply batteries every 18 months. The interval should be 36 months. Our experience from performing our routine maintenance program including cell impedance testing at 3-year intervals has been that the program is fully adequate in monitoring bank condition. An 18-month interval for internal resistance/impedance testing is an unnecessary burden.
		3. Are we required to test the trip circuit between the power transformer sudden pressure relay and the switch house or are we only required to test the trip circuit between the electrical sensing relays and the trip coils of the breakers?

Response: Thank you for your comments. 1. **The SDT feels that performing this maintenance activity at 4 month intervals will benefit the reliability of the BES. The Implementation Plan allows for 15 months after regulatory approvals for entities to implement the program per PRC-005-2. You may also find that performance-based maintenance (per Requirement R2) useful.** 2. **The SDT believes the required 18 month interval is better in line with accepted industry practice. Please note that for VLA batteries, an entity may entirely avoid internal ohmic measurements by implementing a VLA maintenance program using 18 month visual inspections and 6 yr capacity tests.** 3. **The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff.**		
Northeast Power Coordinating Council		The focus of the industry is on the field procedures necessary to ensure that protection systems are maintained and tested. This includes the verification that settings have been applied correctly. The accuracy of the settings calculated needs to be validated, and that step should be considered for inclusion in this Standard.
Response: Thank you for comment. **Validating the accuracy of settings calculations is more properly a design function and not a maintenance function. The SDT agrees that validating relays are left with the intended settings programmed in is important; as such, Row 1 and Row 2 of Table 1-1 require that settings be verified to be as specified.**		

PNGC Comment Group		Thank you for the opportunity to comment on the draft Standard PRC-005-2 - Protection System Maintenance. While the feedback from the last round of comments is appreciated, we still cannot support the standard as written due to our concerns outlined here. We appreciate the work that NERC has put into a new standard to encapsulate and replace the current PRC-005, PRC-008, PRC-011 and PRC-017. But, we believe that the draft Standard needs one important revision before the NERC Board of Trustees should approve it. Specifically, NERC should revise the draft version of PRC-005-2 so that the beginning of Section 4.2 reads as follows: “4. 2. Facilities:Protection Systems that (1) are not facilities used in the local distribution of electricity, (2) are facilities and control systems necessary for operating an interconnected electric energy transmission network, and (3) are any of the following:”This revision is necessary to capture the limits that Congress placed on FERC, NERC, and the Regional Entities in developing and enforcing mandatory reliability standards. Specifically, Section 215(i) of the Federal Power Act provides that the Electric Reliability Organization (ERO) “shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System.” And, Section 215(a)(1) of the statute defines the term “Bulk-Power System” or “BPS” as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.” With this language, Congress expressly limited FERC, NERC, and the Regional Entities’ jurisdiction with regard to local distribution facilities as well as those facilities not necessary for operating a transmission network. Given that these facilities are statutorily excluded from the definition of the BPS, reliability standards may not be developed or enforced for facilities used in local distribution. In Order No. 672, FERC adopted the statutory definition of the BPS. In Order No. 743-A, issued earlier this year, the Commission acknowledged that “Congress has specifically exempted ‘facilities used in the local distribution of electric energy’” from the BPS definition. FERC also held that to the extent any facility is a facility used in the local distribution of electric energy, it is exempted from the requirements of Section 215. In Order No. 743-A, FERC delegated to NERC the task of proposing for FERC approval criteria and a process to identify the facilities used in local distribution that will be excluded from NERC and FERC regulation. The critical first step in this process is for NERC to propose criteria for approval by FERC to determine which facilities are used in local distribution, and are therefore not BPS facilities. The criteria to be developed by NERC must exclude any facilities that are used in the local distribution of electric energy, because all such facilities are beyond the scope of the statutory definition of the BPS, which establishes the limit of FERC and NERC jurisdiction. Accordingly, it is critical that NERC draft the new PRC-005-2 standard to expressly exclude facilities used in local distribution. NERC must also expressly exclude from PRC-005-2 those facilities “not necessary for operating an interconnected electric energy transmission network (or any portion thereof)”. Similar to the local distribution exclusion, the facilities not necessary for operating a transmission network are not part of the BPS and therefore must be expressly excluded from the standard. We understand, but disagree with, the argument that, because the FPA clearly excludes local distribution facilities and facilities necessary for operating an interconnected electric transmission network from FERC, NERC, and Regional Entity jurisdiction, it is not necessary to expressly exclude these facilities again in reliability standards. This approach might be legally accurate, but could lead to significant confusion for entities attempting to implement the new PRC-005-2 standard. There are numerous examples of Regional Entities, particularly WECC, attempting to assert jurisdiction over such facilities, and regulated entities face significant uncertainty as to which facilities they should consider as within jurisdiction. Clarifying FERC, NERC, and Regional Entity jurisdiction in the BES definition, even if such clarification is already provided in the FPA, would avoid such problems under the new PRC-005-2 standard. Again, we appreciate the work NERC has put in so far on a new Standard. We look forward to working within the drafting process to help implement our recommended revision.

Response: Thank you for your comment.

Other than the requirement relating expressly to UFLS/UVLS Protection Systems, the Applicability currently expressly addresses Protection Systems applied for the purpose of detecting BES faults.

To the degree that such Protection Systems may be located on non-BES components, and as the Applicability addresses UFLS/UVLS systems, the SDT has received the following position from NERC Legal:

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines "bulk-power system as (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Also, section 215 covers users, owners, and operators of bulk-power facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy" despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES.

Bonneville Power Administration		1. BPA understands that the VSLs for R3 are based on the percentage of unresolved maintenance issues that an entity has failed to initiate a resolution for. This approach penalizes an entity for having less unresolved maintenance issues. For example, if an entity has only one unresolved maintenance issue and it failed to initiate a resolution for it, it would have failed to initiate a resolution for 100% of its unresolved maintenance issues, which would be a severe VSL. If another entity had 100 unresolved maintenance issues, and it failed to initiate resolution on ten of them, it would have failed to initiate a resolution on 10% of its unresolved maintenance issues, which would be a high VSL. Most likely, the first entity is doing a better job with its maintenance than the second entity, but the first entity receives a more severe penalty. The VSL for R3 is not an accurate measurement of a maintenance program's effectiveness and needs to be revised. BPA recommends removing the entire "Unresolved Maintenance Issue" topic from the standard. 2. In Table 1-1, it is not clear when a microprocessor relay meets the requirement for internal self-diagnosis and alarming. It is not clear that any microprocessor relay with a relay failure alarm would meet this requirement. 3. BPA believes that it seems like an omission in Table 1-1 for unmonitored microprocessor relays, the verification of settings is not included as a maintenance activity. 4. BPA would also like to recommend clarifying language stating that the owner of the asset is the responsible entity.

Response: Thank you for your comments. 1. **The SDT believes that, if a component cannot be returned to "good working order" during the performance of the maintenance program as defined within the entity's criteria, the maintenance program must include those actions necessary to restore the component (and thus the Protection System) to good working order. Therefore, the topic of "Unresolved Maintenance Issues" cannot be removed from the standard. The VSL for the old Requirement R3 (now Requirement R5) has been revised to indicate gradations on the actual count of violations of this requirement, rather than percentages.** 2. **Microprocessor relay failure alarms meet this requirement as long as the alarm is sent back to a location where corrective action can be initiated.** 3. **The first maintenance activity listed on Table 1-1 is to validate that relay settings are as specified and this statement is applicable to unmonitored microprocessor relays. The activity has been revised to clarify.** 4. **The preface paragraphs for R1, R2, R3, R4, and R5 each state that the Transmission Owner, Generator Owner, and Distribution Provider are responsible for implementation of the associated requirements.**		
FirstEnergy		1. We remain concerned with the proposed draft version of Requirement R3 as well as the SDT developed statements in the Supplementary Reference & FAQ. The SDT's approach sends industry the wrong message; a message that entities should not go beyond what is in the text of the standards and that in some cases they can even be found non-compliant by failing to meet their own more stringent internal practice. We have sent NERC Staff and Drafting Team leaders a separate document detailing our concerns as well as proposed redlines to the standard. The separately provided document can be viewed as FE's ballot comments.

		2. FE supports the standard from a technical standpoint but offer the following additional comments and suggestions: A clarification to the supplementary reference document is necessary regarding Maintenance Activities specified for electromechanical lockout and/or tripping auxiliary devices, as specified in Table 1-5 of the standard. The standard states, “Verify electrical operation of electromechanical trip and auxiliary tripping devices” which must be performed every 6 years. A question was asked during the September 15th Webinar requesting clarification of what “verify electrical operation....” meant. The verbal response from the SDT member was that this involves verifying that the relay actuates, but does not require verification that its contacts changed state. However, the answer to the question at the bottom of page 29 and top of page 30 in the Supplementary Reference and FAQ (dated July 29, 2011) implies that checking the contacts is necessary. The following statement in the published answer makes this clarification request necessary; “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” This statement implies that if outputs to annunciators and DME inputs do not need to be checked, then the other outputs do need to be checked. Verification of the auxiliary tripping relays appears to be covered in Table 1-5 of the standard under the "Unmonitored control circuitry associated with protective functions" section at 12 calendar years. Thus, we ask the SDT clarify in the supplementary reference the type of maintenance activities required for electromechanical lockout and/or tripping auxiliary devices to satisfy the requirements of Table 1-5 of the standard. Since the standard specifically dictates the output contacts verification for protective relays under Table 1-1, the output contacts of aux tripping relays is left up to interpretation. Therefore, we suggest the following statement be added after “Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.” on page 30 of the document: “Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the ‘Unmonitored control circuitry associated with protective functions" section’ at 12 calendar years.”

Response: Thank you for your comments. 1. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.** 2. **Output contacts and auxiliary tripping relays that are not part of a trip path or essential for proper operation of an SPS need not be tested per this standard. The Supplementary Reference and FAQ document will be revised as you suggest.**		
Southwest Power Pool Standards Review Group		1. Please update Appendix B, Drafting Team Members, of the Supplementary Reference document. 2. We request that the detail for the breaker failure protection for generator protection in the bulleted list at the bottom of page 31 and the top of page 32 of the Supplementary Reference document be removed. We are not sure what the SDT is looking for here since there are several types of breaker failure protection. 3. We ask that Section 4.2.5.4 of the draft standard under the Facilities be modified to read 'Protection Systems that trip the generator for generator-connected station service transformers for generators that are part of the BES.' 4. We suggest that Section 1.3 Data Retention be rewritten to provide clarification that no data prior to the date of the last audit need be retained.

Response: Thank you for your comments. **1. The list of SDT members has been updated.** **2. The preface to the list of relays to which you refer is as follows: "Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:". The SDT was merely attempting to provide a list of possible relays that might need to be included. The list is not meant to be all inclusive nor do all relays of the types on the list necessarily need to be included.** **3. In consideration of your comment and those of others received, the SDT has revised Section 4.2.5.4 as requested.** **4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**		
Florida Municipal Power Agency		The "Applicability" section is not consistent with the recent Y-W and Tri-State PRC-005 interpretation (Project 2009-17). The Applicability 4.2.1 states that the standard includes: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)" whereas the Y-W and Tri-State interpretation basically says that "transmission Protection Systems" both detect AND trip BES Elements; Hence, the new standard alters the existing "and" statement in the Y-W and tri-State interpretation and eliminates the consideration of tripping BES Elements from applicability. This will have the consequence of including Protection Systems on step-down transformers that "look backwards" into the BES system as applicable to the standard. For instance, a distribution network fed from multiple transmission interconnections will have protective relaying (directional overcurrent most likely) to look backwards into the transmission system to trip the step-down transformer to prevent back-feed from the distribution network). This step-down transformer protection would be included in the new standard because it's purpose to the detect faults on the BES (event though the purpose of the protection is actually to protect overloading of the distribution and for worker safety on the BES); whereas the Y-W and Tri-State interpretation excludes that protection from the existing PRC-005-1 standard.

Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		
Pepco Holdings Inc & Affiliates		Requirement 3 and the Supplementary Reference Document indicate that an entity should be held to its internal PSMP (especially for a time based program) even if the plan is more stringent than the NERC standard. This would be a deterrent for initiative and for excellence and punish utilities for going above the standards and performing best practices. It also tends to drive the industry to lowest common denominator practices. R3 and the accompanying Supplementary Reference Document should be appropriately revised to reflect that entities would only be held auditably accountable for the minimum requirements as stated in the standard and associated documents.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
MRO's NERC Standards Review Forum		a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES."

		b. Data Retention, Section 1.3 (concerning R2 and R3) requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent (past) test record. An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years. Recommend retention to be the most current record or all records since the last audit.
		c. Table 1-5 requires a maintenance activity to, “Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Recommend this be changed to, “Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, change the wording to, “Electrically operate each interrupting device every 6 years.” While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren’t configured to test independently. Isolating one trip coil from the other may include “lifting a wire” that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn’t practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don’t know which trip coil operated, then we have a “one off” device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.

		d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, monitor circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) - this ensures the operating linkages aren't bound and the breaker will operate. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications).
		e. Change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 19, Row 3, Column 2 to: "12 calendar years". 1) The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years.2) In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays.

		f. In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." A recent compliance application notice (CAN-0012) indicated that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. Please provide clarity on CAN-0012 is applicable to PRC-005-2?
		g. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words "affecting the reliability" be removed from the purpose statement
		h. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months
		i. In the tables for dc Supply the term "unit-to-unit" is used along with "intercell" when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be "intercell". It is recommended that the "unit-to-unit" term be removed to avoid confusion regarding what is to be verified.
		j. The NSRF would like to extend our thanks to the drafting team. The 96 page Supplementary Reference document allows us to discuss these issues before the standard is approved, instead of as a potential violation later. Excellent job!

Response: Thank you for your comments.

a) The SDT has modified paragraph 4.2.5.4 as you suggest.

b) In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.

c) The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.

d) The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.

e) The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such.

f) The CAN cited applies to PRC-005-1, not PRC-005-2. The SDT intends that the Implementation plan associated with PRC-005-2 will govern compliance to PRC-005-2 during the transition to the new standard.

g) The purpose of the standard expresses the general intent of the standard, and is further clarified by the Applicability.

h) The SDT believes that the 6-month interval is appropriate for these activities.

i) The term “unit-to-unit” is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar. The SDT does not believe this terminology causes wide spread confusion.

j) Thank you.

Arizona Public Service Company		While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. In addition, when technology changes for the better, industry will need the flexibility to optimize use of the new technology. Lastly, the more often protection equipment is taken out of service for testing, the more often the line is vulnerable. The balance between the correct amount of testing and correct amount of time the equipment is in the field and in service is an important consideration when assuring the reliability of the BES. APS suggests the general principles of the following two papers be applied to more equipment types than microprocessor relays with self test capabilities. 1) 'An Improved Model for Protective-System Reliability,' P.M. Anderson and S.K. Agrawal, Power Math Associates, Inc., IEEE Transactions on Reliability, Volume 41, No. 3, September 1992;2) 'Philosophies for Testing Protective Relays,' J.J. Kumm, et. al., Schweitzer Engineering Laboratory, Inc., 48th Annual Georgia Tech Protective Relaying Conference, May 1994.
Response: Thank you for your comments. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. Wherever possible, the SDT has provided entities with the flexibility to utilize capabilities of emerging technologies by using condition-based maintenance where effective, and also by using performance-based maintenance should an entity wish to modify their intervals based on past performance.		
Southern Company Generation		1) For Table 1-1 and Table 3, consider adding "(internal to the relay)" to the microprocessor relay 6 calendar year maintenance activities to clarify that these maintenance activities are not related to items external to the relay).
Response: Thank you for your comments. Since the component type being addressed is the protective relay itself, it seems that the clarification you request is unnecessary.		

Tacoma Power		1. The implementation plan for R2 and R3 is unclear on whether each maintenance activity has its own implementation schedule. The implementation plan can also be interpreted to mean that the implementation schedule for a given protection system component is driven by the smallest maximum maintenance (allowable) interval. For example, for unmonitored communications systems, it is unclear whether all maintenance activities indicated in Table 1-2, including those corresponding to 6 calendar years, must be completed on all unmonitored communications systems by the first calendar quarter 15 months following applicable regulatory approval, or if this timeline only applies to the maintenance activity specified in Table 1-2 corresponding to a maximum maintenance interval of 4 calendar months.
		2. Assuming that there is a different implementation schedule for different maintenance activities for some protection system component types (namely station DC supply and communication systems), the middle bullet on page 1 of the implementation plan does not seem to consider that it may not be possible to identify whether some protection system components are completely being addressed by PRC-005-2 or the Program developed for the previous standards. In other words, during implementation, some maintenance activities for the same protection system component may be addressed by PRC-005-2, while other maintenance activities may be addressed by the Program developed for the previous standards.
		3. It is unclear whether control circuitry (trip paths) from protective relays that respond to mechanical quantities is included. This issue is addressed in the supplementary reference but is vague in the draft standard itself.
		4. This draft of PRC-005-2 requires the Protection System Maintenance Program (PSMP) to “include all applicable monitoring attributes and related maintenance activities” per the Tables and requires an entity to “implement and follow its PSMP.” Under the draft standard, it is unclear whether an entity has to document in the PSMP and/or maintenance records how they accomplish(ed) the maintenance activities or simply to indicate that the maintenance activities are included and have been completed within the defined intervals. It is clear that entities are afforded some latitude in how they conduct the required maintenance activities. However, the level of detail required to document (1) how an entity chooses to perform the maintenance activities and (2) that applicable maintenance activities have been completed is not clear.

		5. In Table 1-2, there is a maintenance activity related to communication systems to "verify essential signals to and from other Protection System components." It is unclear if this statement is referring to control circuitry associated with the communication system end devices, end device input and output operation (as in Table 1-1 for protective relays), or something else. It is recommended that the requirement be to "verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System." This language is consistent with that used for protective relays in Table 1-1.
		6. Referring to Table 1-2, it is unclear whether an entity has the sole authority decide which 'performance criteria' are 'pertinent.' Additionally, it is unclear if an entity must document the 'communications technology applied' and the associated 'performance criteria' in its PSMP.
		7. In Table 1-4, it is unclear if there is a distinction between the terms 'resistance' and 'ohmic values.' If there is a distinction, then this distinction should be clarified.
		8. In Table 1-4, it is unclear if there is a distinction between the terms 'battery terminal connection resistance' and 'unit-to-unit connection resistance.' If there is a distinction, then this distinction should be clarified.
		9. In Table 1-4, replace the term 'resistance' with 'impedance.'
		10. Recommend that the 6 calendar month interval in Table 1-4(b) be lengthened to 18 calendar months to be more consistent with similar maintenance activities for other battery types. At minimum, lengthen the interval to at least 7 calendar months in a similar way that 3 calendar months was lengthened to 4 calendar months for other maintenance activities.

		11. Referring to Table 1-5, no periodic maintenance is required for "control circuitry whose continuity and energization or ability to operate are monitored and alarmed." It is unclear whether or not it is acceptable to verify DC voltage at the actuating device trip terminals at least once every 12 calendar years for "unmonitored control circuitry associated with protective functions." It is recommended that periodically verifying DC voltage in this manner be an acceptable means of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions.
		12. Referring to 4.2. Facilities of the draft standard, it is unclear whether protection systems for transformers that step down from over 100kV to below 15kV are applicable to the standard. Even if there are normally-open distribution feeder ties for purposes of transferring load in a make-before-break fashion, these transformers are generally not considered BES elements.
		13. Referring to 4.2.5 of the draft standard, it is unclear whether protection for generator excitation systems are applicable to the standard.
		14. It is unclear whether external timing relays (e.g., Zone 2) are considered control circuitry components (like lockout and auxiliary relays) or protective relay components.
Response:	**Thank you for your comments.**	
	1. The SDT agrees with your observation and has changed the relevant parts of the Implementation plan to clarify that they apply to the maintenance activities for the relevant maintenance intervals.	
	2. The SDT agrees with your observation and revised the Implementation plan to clarify.	

	3. The trip paths from protective relays that respond to mechanical quantities and are intended to detect faults are a part of the Protection System control circuitry. The sensing elements are omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocols for these sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1, consistent with the SAR for Project 2007-17, and the SDT understands this to be consistent with the position of FERC staff. Note that trip signals from devices sensing mechanical parameters not directly indicative of an electrical fault need not be tested per this standard.
	4. The SDT has removed parts 1.1 and 1.3 from Requirement R1, addressing part of your comment. The SDT agrees that PRC-005-2 allows some leeway in how an entity fulfills the testing requirements of the standard. Section 15 of the Supplementary Reference and FAQ document provides numerous examples of possible testing techniques for the various component types making up a Protection System. An entity's PSMP should clearly define how the testing requirements of the standard are fulfilled. The Measures for each requirement, as well as Section 15.8 of the Supplementary Reference and FAQ document, provide some examples of possible compliance documentation for completion of testing.
	5. The SDT agrees with your suggestion and has changed the standard accordingly.
	6. The entity has the authority to establish its own acceptable performance criteria. This criteria does not need to be in the PSMP, but should reside somewhere within the maintenance documentation.
	7. As utilized on Table 1-4, the term "ohmic value" is a generic reference to the measurement of a battery cell or units ability to pass current flow. This may be done using conductance, resistance or impedance measurements; the various battery test equipment manufacturers use different measurement methods and the term "ohmic value" is meant to be technology neutral. See FAQ on page 78 of the Supplementary Reference and FAQ document. The term "resistance" as used in Table 1-4 refers specifically to the dc resistance of the battery terminal connections and the battery intercell/inter-unit physical connectors. See related FAQ on pages 74-75 of the Supplementary Reference and FAQ document.

	8. Battery terminal connection resistance is a measurement of the resistance of a connection at a battery terminal. Battery intercell or unit-to-unit connection resistance is a measurement of the resistance of the external conductor interconnecting two adjacent battery cells or two adjacent multi-cell battery units. The SDT believes these are common battery maintenance terms used throughout the industry.
	9. The SDT disagrees and believes that resistance as used in Table 1-4 is the appropriate term for the parameters to be measured and is consistent with standard battery system maintenance terminology.
	10. The SDT disagrees with your recommendation to standardize maintenance intervals between different battery types that have distinctly different failure mechanisms. See related FAQ on pages 80-81 of the Supplementary Reference and FAQ document for further discussion of requirements for ohmic measurements of VRLA batteries. Concerning your recommendation to allow for 7 calendar months, the SDT believes that the six-month interval specified is appropriate.
	11. The SDT has modified this specific portion of the Table, and believes that the modifications address your concern. Please see Section 15.3 of the Supplementary Reference and FAQ document for a discussion of this topic.
	12. The standard does not include the Protection Systems for transformers that step down from over 100kV to below 15kV if these transformers are not BES elements. If Protection Systems are installed for purposes of detecting Faults on BES elements, these Protection Systems are included.
	13. Paragraph 4.2.5.1 indicates that the excitation system protection system would only be in scope if the excitation system generates signals that trip the generator output breaker either directly or via lockout or auxiliary tripping relays.
	14. As timing is critical to proper Protection System function, timers are considered protective relays.

Progress Energy		1. Standard, Table 1-4(a), second sentence under Component Attributes, should state “Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded....” As written, the statement does not include the phrase “UFLS and.” I believe it should. 2. Supplemental, Section 13, 2nd paragraph, first sentence should state: “...device match the minimum requirements listed in Tables 1 and 3.”
Response: Thank you for your comments. **1. The SDT agrees. Table 1-4(a) has been modified as you suggest; this text has been relocated to the header of the table.** **2. The SDT agrees and has modified the Supplementary Reference and FAQ document as you suggest.**		

Western Area Power Administration		Comment 1:Western Area Power Administration does not agree with penalizing utilities for implementing maintenance programs that exceed the requirements defined in the NERC Standard PRC-005-2 maintenance tables. Although the intent of the language in the Supplementary Reference and FAQ document may have been to allow evolving maintenance programs to include condition-based and performance based maintenance in their programs, penalizing utilities with more stringent programs will more likely provide a disincentive for program development. Utilities will discontinue any additional maintenance activities that could put them at risk for non-compliance. This will cause maintenance programs to stagnate and new maintenance ideas to improve system reliability to not be implemented. It is the opinion of the Western Area Power Administration that the following text should be removed from the Supplementary Reference and FAQ document and entities should be audited to the minimum requirement of the standard regardless of their individual programs. Recommendation: Remove the following text from the Supplementary Reference & FAQ document:1. Page 26 - The bullet “If your PSMP (plan) requires more activities then you must perform and document to this higher standard.” 2. Page 27 - The bullet “If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.” 3. Page 27 - The paragraph “It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity’s more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity’s PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.” Revise R3 of PRC-005-2 and add statement to the Supplementary Reference & FAQ document.1. R3: Each Transmission Owner, Generator Owner and Distribution Provider shall implement and follow its PSMP plan within the prescribed intervals of Tables 1, 2 and 3. and correct any unresolved maintenance issues.2. FAQ: Any utility maintaining Protection System equipment that exceeds the requirements and tables because of historical testing data and/or failure documentation should not be held non-compliant or penalized for not meeting its PSMP, as long as they do not exceed the maximum allowable intervals or meet the minimum maintenance activities of the standard.

		Comment 2:R3 of PRC-005-2 states “Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues.” The Western Area Power Administration would like more clarification on potential data request for requirement R3 of PRC-005-2. Because the requirement uses the term initiates resolution, the entity could make the assumption that providing just a list of maintenance request for unresolved maintenance issues will serve to prove compliance. Although it would seem implied that whatever method used to initiate resolution would lead to some type of corrective maintenance, the requirement does not make that absolutely clear. To ensure the maintenance practices are meeting the intent of the requirement, the requirement needs to clarify the expectations for completing corrective maintenance that was initiated to resolve maintenance issues. Recommendation: Add additional clarification to Supplementary Reference & FAQ document to further clarify expectation for this requirement.

Response: Thank you for your comments.

1. **The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.**
2. **Additional clarification has been added to the Supplementary Reference and FAQ document. Additional examples have also been added to the Measure for this Requirement.**

PacifiCorp		1. The data retention requirement for producing evidence that the entity performed maintenance for the 2 most recent maintenance intervals is excessive. As an example, if a registered entity's maintenance/test interval is 12 years, such entity may be required to keep records for up to 35 years. PacifiCorp recommends a revision to the data retention requirement to provide for either a maximum retention period of 10 years or, in cases in which the interval exceeds 10 years, the most recent maintenance/test cycle only. 2. The requirement to identify all PTs is very onerous and not needed to verify maintenance compliance and therefore serves a limited reliability benefit. PacifiCorp believes that, as long as a registered entity can demonstrate that it can verify that all CTs/PTs providing input into a Protection System have been tested and maintained according to its established procedures, then a separate and independent requirement to maintain a list of these devices is not necessary. As an example, if an entity performed their protection system maintenance on a "scheme" basis, and as part of that maintenance documentation identified all CT's and PT's providing input into the scheme and verified their accuracy, then having a "master list" would provide no benefit. A list of all CT's associated with one device such as a circuit breaker would have little value in this case as these CT's may provide input into multiple relay schemes and would not be maintained on an individual circuit breaker basis.
Response: Thank you for your comments. **1. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.** **2. The SDT does not believe the current standard contains a "separate and independent requirement to maintain a list of these devices". As your comment correctly indicates, if an entity can provide evidence that the inputs from all CTs and PTs are accurately being received by the associated relays for in scope Protection Systems, this is acceptable. It is up to the entity to best determine how to track this – whether by a "master list" of CTs and/or PTs, on a "scheme" basis, by physical location of the instrument transformer, or some other effective tracking method.**		

Saft America, Inc.		Saft Comments on NERC Standard PRC-005-2 - Protection System Maintenance - Please find herein Saft's comments to NERC PRC-005-2 regarding ohmic testing of Nickel-Cadmium (NiCad) batteries. As drafted, the proposed NERC Standard PRC-005-2 will lead to the removal of high quality, reliable NiCad battery power units from Protection Systems, which is counter to the NERC stated purpose of PRC-005-2, which is to 'document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.' There is broad consensus within the battery industry that ohmic testing of Valve Regulated Lead-Acid (VRLA) batteries provides a means for trending the condition of the battery over time. Such a consensus does not exist for Vented Lead-Acid (VLA) batteries, because ohmic measurements are more difficult to trend, thereby providing a go/no-go assessment of the battery's availability at that precise moment in time, rather than a measure of VLA battery condition. Ohmic testing of NiCad batteries provides a similar go/no-go assessment to ohmic testing of VLA batteries. As with VLA batteries, ohmic testing of NiCad batteries does not provide meaningful trending information, but rather provides a status update of battery condition at a specific moment in time. Due to the similar information provided by ohmic testing of VLA and NiCad batteries, Saft recommends that ohmic testing of NiCad batteries be included under the Maintenance Activities for NiCad batteries. Specifically, Saft recommends that NERC add the following language to the Maintenance Activities column in Table 1-4(d), 'Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline', at a maximum maintenance interval of 18 months, as in the requirement for VLA batteries noted in Table 1-4(a).

Response: Thank you for your comments.

The SDT disagrees. The SDT is aware of studies that indicate a correlation between ohmic measurements and battery condition (or remaining life) for VLA and VRLA batteries when trended against a baseline ohmic measurement taken when the battery was new. These same studies concluded no such correlation exists for NiCad batteries. We are unaware of any published studies that conclude otherwise for NiCad batteries. The standard does not favor one technology over another but simply allows flexibility in testing techniques when the attributes of a technology allow for technically justifiable application of that flexibility and achieve the objective of the standard.

Nebraska Public Power District		a. Section 4.2.5.4 includes station service transformers for generator facilities. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. Recommend changing Section 4.2.5.4 to read, "Protection Systems that trip the generator for generator-connected station service transformers for generators that are a part of the BES."
		b. Section 1.3 requires an entity to retain the two most recent performances of each distinct maintenance activity. This is an unreasonable requirement and does not enhance reliability. Recommend the data retention be changed to require only the most recent test record. An audit should be focused on the present day and not in the past. Is an entity compliant today and not can we find a way to issue a fine for something in the past? An example exists where an entity recently registered and tested all their relays prior to registering. They have one set of documentation and not two. Why should they be forced into testing again and incurring additional expense for customers only to have two tests available for an auditor? This does not enhance reliability. PRC-005-2 allows testing intervals of up to 12 calendar years. If we are required to have the two most recent tests, we could conceivably have to retain a relay test record for 24 years! Hypothetically, if we have a test record from ten years ago, but we don't have the record from 24 years ago, how does that adversely affect the reliability of the BES today? The standard should focus on - Are we compliant today?

		c. Table 1-5 requires a maintenance activity to, "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Recommend this be changed to, "Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, change the wording to, "Electrically operate each interrupting device every 6 years." While requiring each trip coil to operate the breaker sounds good in theory, practically it creates issues in the field and may create more problems than it solves. The trip coils are located in the panel at the breaker and aren't configured to test independently. Isolating one trip coil from the other may include "lifting a wire" that may not get landed properly when the test is complete. Then, how do you prove for a compliance audit that both trip coils were independently tested to trip the breaker? Using an actual event only tests one coil and we may not know which coil tripped the device. To be compliant, it isn't practical to be able to track a real-time fault clearing operation as suggested on page 67 of the Supplementary Reference document. First, we don't know which trip coil operated, then we have a "one off" device in the substation that must be tracked separately with a different testing cycle from the other devices in the substation - this is a recipe for a compliance violation. The standard should focus on ensuring the control circuitry is intact and trips the breaker without injecting additional, unneeded risk to the BES.

		d. General comment under Table 1-5: We do extensive testing of the control circuit during commissioning and after a modification to the circuit. Testing of the control circuitry on a periodic basis is not needed. The wear and tear on the equipment from functional testing and the potential risk of the testing itself may create more issues than the benefits received from doing the tests. The functional test injects significant opportunities for human performance errors during the test (technician trips the wrong device, differential relay opens all protective devices for a bus instead of a breaker, technician bumps another relay, screw driver falls into another device, etc.) and latent errors after the test (i.e., if a wire was lifted during the test, was it landed back in proper location, was the relay tripping function activated after the test was completed or was the relay left in test mode, etc.). Request the drafting team provide a basis for requiring the functional test. Are there documented instances where the control circuitry caused a significant event on the BES? Many utilities, including us, monitor our circuit breakers for operations. If a breaker hasn't operated for a defined period of time, we set up a maintenance activity to operate the breaker (possibly to include a timing test to ensure the breaker clears in the proper amount of cycles) - this ensures the operating linkages aren't bound and the breaker will operate. We have many maintenance activities performed on devices for the BES that do not require a NERC standard. If a utility chooses not to perform best practice maintenance, customers will experience more frequent and longer outages. The utility will receive customer feedback on outages which should translate into the utility increasing its maintenance. In other words, we don't have to include a functional test as a NERC requirement. Misoperations are already monitored and reported through PRC-004. Does recent misoperation data or TADS data indicate that control circuitry/trip coils are a problem within the protection and control system? The current version of PRC-005 doesn't require functional tests. What is the basis for requiring additional compliance documentation (additional functional testing)? A possible alternative: only perform testing following modifications or major maintenance (like breaker change outs or panel modifications).

		e. Recommend NERC provide training specifically on how to audit PRC-005-2 to auditors in all eight Regional Entities. PRC-005 is the most violated standard since enforcement began on June 18, 2007. This is an excellent opportunity for NERC to get all eight regions on the same page for what to audit. NERC provides training on standard auditing guidelines and sample selection, but doesn't provide training on how to audit specific standards. RSAW's and CAN's have been an attempt to get consistency across the regions, but differences are still obvious. NERC is in the perfect position to observe potential violations (PV) from an auditor and as a PV is written that goes beyond the standard or is not in accordance with the initial training; NERC can dismiss the PV and retrain the auditor. Auditors aren't perfect, nor are any of us. Training is a basic tool for the auditor to perform their job properly.
Response: Thank you for your comments **a) The SDT has modified paragraph 4.2.5.4 as you suggest.** **b) In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.** **c) The description of the configuration of the second trip coil on circuit breakers you have provided is not typical of the redundant approach taken by most entities. Typically, second trip coils are electrically isolated from the first trip coil and are often fed by a separately fused dc control circuit with different relay trip output, lockout and auxiliary tripping contacts utilized in each circuit. The SDT believes that it is important that redundant trip paths be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment.** **d) The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.** **e) The SDT will forward this comment to NERC Compliance for their consideration.**		
Exelon		
Texas		(1) General - defined terms need to be capitalized throughout this standard.

Reliability Entity		(2) Requirement R3 only addresses initiation of resolution to any Unresolved Maintenance Issues. Requirement R3 should require completion of corrective action to deal with Unresolved Maintenance Issues within a reasonable timeframe.
		(3) Section 1.3, Data Retention, should require each entity to keep all versions of its PSMP that were in effect since its last compliance audit, in order to demonstrate compliance at all relevant times (not just the current version).
		(4) In the Severe VSL for R2, add "Annually" to the second bullet under part 5.
		5) The VSLs for R3 should contain a time frame (annual?). The second part of these VSLs should refer to initiation and completion of resolution of Unresolved Maintenance Issues. (See comment on Requirement R3 above.)
		(6) Consider making the R3 VSLs based on a percent of the number of maintenance activities required by the PSMP in a stated time period, rather than on a percent of the total number of Components.
		(7) There is no maintenance activity listed to verify that protection system component settings meet the design intent of the protection system. In other words, there is no required activity to confirm that the "specified" settings are correct and appropriate. This introduces a potential reliability gap into the Protection System maintenance program.
		(8) In Table 1-1, the term "acceptable measurement of power system input values" is somewhat vague. A tolerance value or reference to industry standards should be provided.
		(9) In Table 1-3, the activity should include verifying that the current and voltage signal values are within design tolerances, not just that signal values are present.
		(10) In Table 1-4(a) Component Attributes - the reference to UFLS systems is missing in the exclusion that refers to UVLS systems. (UFLS is included in Tables 1-4(b) through 1-4(d).)

		(11) In table 1-4(f), there should be a reference to “alarming” in addition to “monitoring” in the first cell of the next-to-last row
		(12) In table 1-4(f), why is the last row limited to VRLA station batteries? Should the same exclusion apply to VLA batteries?
		(13) In Table 1-5, a “12 calendar year” interval is too long for “Unmonitored control circuitry associated with SPS” and “Unmonitored control circuitry associated with protective functions.” We suggest this be changed to 6 years. Similar unmonitored attributes related to battery maintenance have a 6 calendar year interval.
		(14) In Table 2, the phrase “location where corrective action can be initiated” is unclear, and we suggest that a more definitive description be used. Also, why is the word “DETECTION” in all-caps?
		(15) In Table 3, the maintenance activity should include verifying that Protection System Component settings meet the design intent of the Protection System. For example, any reclosing function should be disabled on UFLS and UVLS relay systems.
		(16) In Table 3, In Table 1-1, the term “acceptable measurement of power system input values” is somewhat vague. A tolerance value or reference to industry standards should be provided.
		(17) The Implementation Plan is overly long and complicated. Entities (including Regional Entities) will have to track and apply multiple versions of this standard for 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable, recognizing that for some Components no action will be required under the standard for a number of years.

Response:	**Thank you for your comments.**
	1. The SDT will attempt to properly capitalize defined terms throughout the standard.

	2. The SDT specifically chose the phrase "initiate resolution" because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues or what documentation might be sufficient to provide proof that effective corrective action has been initiated. The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues.
	3. The SDT agrees with your observation and has modified the data retention requirements accordingly.
	4. The SDT agrees with your observation and has modified VSL for Requirement R2 accordingly.
	5. The percentages relate to the number of violations of the respective requirement reported within the compliance monitoring period relative to the number of components within that component type. PRC-005-2 only requires the entity "… initiate resolution" of the issue found. The SDT recognizes that performance of the activities necessary to resolve an issue are entirely dependent upon the circumstances surrounding that issue and, consequently, will require varying amounts of resources and time to complete the process. It is for this reason the SDT crafted the requirement to only require initiation of the process.
	6. The SDT disagrees. The entity must complete all required activities on any specific component in order to be compliant, regardless of the number of activities scheduled for that component.
	7. The SDT believes that adequacy of settings is more properly a design issue and should not be included in a maintenance standard.

	8. The SDT believes it is more appropriate for entities themselves to establish acceptance criteria that meet the performance requirements necessary for the proper operation of their Protection Systems.
	9. The action, "verify" is specified within the PSMP definition as "Determine that the component is functioning correctly." Therefore, the SDT believes that the suggested change is unnecessary.
	10. The SDT agrees. Table 1-4(a) has been modified as you suggest. The modified text has been moved to the header of the tables.
	11. The SDT agrees. Table 1-4(f) has been modified as you suggest.
	12. The SDT agrees. Table 1-4(f) has been modified as you suggest.
	13. The SDT disagrees and believes that the 12 year requirement for SPS's is in alignment with the Table 1-5 row 4 requirement for testing of unmonitored trip paths for control circuitry with protective function in other Protection Systems.
	14. Based on a lack of other comments received on this topic, the SDT believes that this description has sufficient clarity. The word "detection" on Table 2 has been corrected to lower case font.
	15. The first row of Table 3 requires that settings be verified to be as specified. The SDT believes this to be a proper maintenance function but that the determination of the adequacy of settings (or, for that matter, design criteria) is more properly a design issue and should not be included in a maintenance standard.
	16. The SDT believes it is more appropriate for entities themselves to establish acceptance criteria that meet the performance requirements necessary for the proper operation of their Protection Systems.

	17. The SDT disagrees. It is not practical for all entities to rapidly transition all of their protection systems to the new program, especially with some component types on maintenance intervals of up to 12 years. Nonetheless, all in scope Protection Systems must either be being maintained by either a PRC-005-1 program or a PRC-005-2 program. The SDT believes the graded approach mapped out in the Implementation plan is practical. Finally, if in order to lessen the complexity of documentation requirements, an entity wishes to implement PRC-005-2 on a more rapid rate than laid out in the Implementation plan, they are free to do so.	
Central Lincoln		We are concerned about what exactly “initiate resolution” means in R3. We foresee this being a potential area of disagreement between registrants and CEAs when a registrant believes an open work order suffices and the CEA wants to see schedules or purchase orders. Neither M3 nor the FAQs address this.
Response: Thank you for your comment. **The SDT has clarified the intent of the requirement to initiate resolution of Unresolved Maintenance Issues by including it separately as Requirement R5 and revising the language such that the responsible entity must demonstrate its efforts to correct Unresolved Maintenance Issues because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve. For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues or what documentation might be sufficient to provide proof that an entity is correcting these issues.**		
Dynegy Inc.		For Facilities listed under 4.2, are Reserve Auxiliary Transformers supposed to be included?

Response: Thank you for your comment.

No, Reserve Auxiliary Transformers or system connected station service transformers were intentionally removed from the Applicability in a previous draft. Generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. and are thus included. Reserve auxiliary or system connected station service transformers Protection Systems will not directly result in the trip of a generator and as such are omitted from the Applicability of the standard.

NERC

American Electric Power		1. As it stands, if an entity adopts a more stringent maintenance program but fails to meet it, that entity could be found non-compliant despite continuing to abide by the minimum requirements of the standard itself. Entities should have the ability, if they so choose, to include additional maintenance activities or more stringent intervals than specified within the standard without concern of penalty in the event they are unable to accomplish them. In short, entities should only be audited against the requirements stated within the standard. Table 1-3 of the standard lists the minimum required maintenance activities for voltage and current sensing devices as "Verify that current and voltage signal values are provided to the protective relay." 2. Consistent with Table 1-3, Section 15.2.1 of the Supplementary Reference states that an entity "...must verify that the protective relay is receiving the expected values from the voltage and current sensing devices..." The Supplementary Reference further offers examples of how this requirement may be satisfied with most examples referencing the need to verify the signal at each relay in the circuit. We recognize the need to verify a voltage signal at each protective relay, as these devices are wired in parallel and an open circuit at one location may not impact the other devices on the circuit. However, we do not agree that there is a need to verify a current signal at each protective relay. Current devices are wired in series, and an open circuit at any location will impact all other devices on the circuit. For this reason, a single measurement of the current circuit is sufficient. We recommend updating Table 1-3 and the supplementary reference to account for the different physical characteristics of voltage and current circuits. 3. This standard encompasses a very broad range of component types and functionality across broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application. Other standards have applicability for certain thresholds of voltage levels, etc. Why not this standard as well?

Response: Thank you for your comments.

1. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.
2. An open circuit is not the only failure mechanism for a CT secondary circuit. Grounded CT secondary wiring can result in situation where accurate current is present in the part of the secondary circuit upstream of the ground but current would be shunted to ground and might not pass through devices downstream of the ground. Entities should not interpret PRC-005-2 as specifying "how" to test but rather that PRC-005-2 only specifies "what" to test. Entities are free to determine creative ways to fulfill requirements.
3. VSLs characterize "how bad did you miss a requirement", rather than on the impact to the BES. The percentages indicated in the VSLs follow demarcation guidelines given by NERC to Standard Drafting Teams. With the magnitude of the total number of Protection System components for many entities likely to be very large, exceeding 5% of that total equates to failing to perform maintenance and testing on a (potentially) large number of components, and should be reflected by a Severe VSL. The SDT further believes that this standard should be applied uniformly to the applicable facilities, rather than stratifying it to reflect different system voltages.

Lincoln Electric System		In reference to the zero tolerance policy evident within PRC-005-2, LES offers the following suggestion: Set up an annual review of a random set sample (20% for example) of Protection System equipment to self-verify compliance. If issues arise, allow the entity the opportunity to correct the issue, make the necessary procedural and/or documentation adjustments and not be considered non-compliant. The idea is to allow entities the opportunity to continually improve their practices and procedures; in essence, allow them to show they are attempting to follow a "culture of compliance". If habitual problems arise, then non-compliance will be evident. One example that justifies this approach is software glitches or improper programming. As more and more systems become automated, scheduling of maintenance will be done automatically through various types of software. If a program has even one attribute set incorrectly, it could not function as intended and would potentially set up incorrect intervals for maintenance and testing. It was not intended this way by the entity and they are not intentionally disregarding the standards, but could nevertheless be put in a situation where a maintenance interval is missed. An annual review would catch things like this and allow an entity to continuously improve their program without self-reporting. This concept is expanded from a current draft version of several CIP standards; therefore, it is being at least considered by other drafting teams.
Response: Thank you for your comments. **The NERC criteria for VSLs do not permit any level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 provides for an escalating degree of severity for increasing degrees of non-compliance.**		
NIPSCO		The new standard itself, the implementation plan and supplemental reference/FAQ makes up more than 100 pages of material. Granted that several standards are being combined here, still it is simply too involved to monitor. And there is still not enough detail in the standard leaving items which are ambiguous and open to interpretation, and therefore open to fines. In order to remove such interpretation, maintenance documentation will need to be precise and extensive. This will necessitate more and more staff to control and validate data. Adding staff is great but it does not seem to ensure that there is increased reliability.

Response: Thank you for your comment. **FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance.**		
Entergy Services		We understand and disagree with the SDT position on the following recommendation. We do not agree with proposed Section 4.2.1 applicability since it captures only a portion of the previously approved applicability Interpretation (PRC-005-1a) which was developed specifically for PRC-005-1. We suggest the draft standard be revised to conform to the wording in the Interpretation: "Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements."
Response: Thank you for your comment. **The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.**		

Independent Electricity System Operator		The IESO disagrees with the concept that auditors use the standards as minimum requirements and evaluate compliance based on a registered entity's own governance. We believe that the entity could be found non-compliant with Requirement R3 if they fail to follow the internal maintenance intervals established in their PSMP, even though actual maintenance intervals are no less frequent than the prescribed maximum intervals established in the draft standard. The potential for such a finding will discourage conscientious entities from setting higher internal targets for their planned maintenance and promote compliance with only the minimum requirements of the standard. We therefore propose the following revision to Requirement R3:R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any unresolved maintenance issues. In the case of time-based maintenance programs, each Transmission Owner, Generator Owner, and Distribution Provider is permitted to deviate from its PSMP provided that actual maintenance intervals do not exceed those specified in Tables 1-1 through 1-5, Table 2 and Table 3. [Violation Risk Factor: High] [Time Horizon: Operations Planning]
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		

Liberty Electric Power LLC		With the development and publication of maximum maintenance and testing intervals (the Tables), there is no longer a reliability need for a RE to identify the associated maintenance intervals for Protection System Components. Further, REs who wish to perform these activities in shorter intervals than those allowed by the standard (See Supplementary Reference, page 27,"If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.")As noted in Question 5, if the entity completes all activities within the maximum interval allowed by the standard, there can be no reliability concern; if there is a reliability issue, then the table interval is incorrect. I would suggest the following changes.1. Change R1.2 to read "Identify any Protection System component where the RE is using a performance based maintenance interval. No batteries associated with the station DC supply component type of Protection System shall be included in a performance based system".2. Change R1.3 to read "The intervals for time-based programs are established in Table 1-1 through 1-5, Table 2, and Table 3".3. Change M1 to add the phrase "for performance-based components" after the words "maintenance intervals".4. In M1, replace the words "the type of maintenance program applied (time-based, performance based, or a combination of these maintenance methods)' with the words "the identification of any protection system components using performance based intervals".
Response Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		

Ameren		(1)Measure M3 on page 5 should only apply to 99.5% of the components. Please revise to state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. No one is perfect and it is impractical to imply perfection is achievable. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance". (2) An alternate approach regarding the unrealistic perfection of M3 is to correctly recognize that the protection of the primary BES is the objective. Most Protection Systems are redundant by design and the entity needs to be afforded the opportunity to show that a redundant component met the PSMP thereby providing the required protection. The entity should be allowed a reasonable time frame of one calendar increment to maintain the component in question. Our concern stems from the tens of thousands of components in a PSMP, and the reality that rarely but occasionally a data base error or outage scheduling issue may result in a very small number component exceeding their maximum interval. As long as the entity can show that BES protection was sustained and maintains the component quickly (e.g. within one calendar month of discovery), BES reliability has been maintained. (3) Now that FERC has approved the Project 2009-17 Interpretation, please acknowledge more directly in the Supplement that the 'transmission Protection System' that is now approved. NERC interprets "transmission Protection System," as it appears in Requirements R1 and R3 of PRC-004-1 and Requirements R1 and R2 of PRC-005-1, to mean "any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."

Response: Thank you for your comments.

1. The NERC criteria for VSLs do not permit any level of non-performance without being in violation. The graded approach of the VSL for Requirement R3 provides for an escalating degree of severity for increasing degrees of non-compliance.
2. Regarding redundancy, the SDT believes that it is important that redundant components be maintained within the indicated interval, and the prescribed interval already considers the reliability benefits of redundant equipment. It should be noted that misoperations not only occur for failure to operate for valid faults but also operation of a protection system for an invalid, non-fault condition. It is important that both components be maintained within the specified intervals to help preclude this second type of misooperation – e.g., over tripping of relays.
3. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.

Northeast Utilities		1. The definition of "Component" in PRC-005-2 Draft 1, states "Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component." However, in Section 15.2 of Supplementary Reference & FAQ it states: "The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample." Please consider reconciling these two sections (definition of "Component" and Section 15.2) to allow the entity to consider a relay as the single component versus the voltage and current sensing devices, and pursuant with Section 15.2 perform the voltage and current checks to the inventoried relays. This approach will ensure that the CT and PT check to each relay is performed. Section 15.2 of Supplementary Reference & FAQ states in the second paragraph "The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample." Please consider revising the last bullet in Section 15.2, paragraph 3 from "Any other method that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable" to "Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample." 2. As shown (see Figure A-2) and discussed in Appendix A of Supplementary Reference & FAQ list, there are four elements that are not verified. Following the identification of the four elements that are not verified, a practical solution is provided for testing methods on three of the four elements. Please provide a practical solution for the fourth element.

Response: Thank you for your comments.

1. **The SDT does not believe a discrepancy exists. CTs and PTs or other current and voltage sensing devices are indeed Protection System Components. Section 15.2 of the Supplementary Reference and FAQ document is describing a maintenance activity that is to be performed to validate proper function of that Component type. The Supplementary Reference and FAQ document has been revised to clarify.**
2. **Appendix A to the Supplementary Reference and FAQ document (with the imbedded figures) is intended to provide an example of the application of monitoring to minimize maintenance activities and maximize maintenance intervals, but is not intended to be a comprehensive treatise of the subject.**

MidAmerican Energy Company		1. The following comment was submitted in the last comment period: In the background section of the implementation plan in item two it states "..it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: " The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. The consideration of comments response to the above did not completely address the issue that led to the comment. In the Tables in PRC-005-2 there are maintenance items that an entity may not have had in their PRC-005-1 compliance program even though they did have a compliant maintenance program (e.g. battery continuity testing) for that Protection System component. As the transition is made to the PRC-005-2 requirement the above clarification should be made to better define what achievement of PRC-005-2 compliance is for that component.
		2. Section 4.2.2 includes UFLS systems installed per the ERO requirements - excluding any additional UFLS systems that a utility has on their system. Section 4.2.3 includes UVLS systems "installed to prevent system voltage collapse or voltage instability for BES reliability". It is assumed that this would only include UVLS systems required by the ERO, but it is not clear as to what is in scope. It is suggested that the wording of 4.2.3 be changed to match the wording in 4.2.2.
		3. In the implementation plan in the R2 and R3 requirements plans, in item a. of each there is a parenthetical statement regarding generating plant scheduled outage intervals. A similar parenthetical statement should be added to the b. and c. items of each of these plans.

		4. The purpose statement of the standard seems to be inconsistent with the applicability section. To correct this it is suggested that the words “affecting the reliability” be removed from the purpose statement.
		5. For consistency with the changes from 3 months to 4 months in the tables of the standard it is suggested that the second item in Table 1-4(b) be changed from 6 calendar months to 7 calendar months.
		6. In the tables for dc Supply the term “unit-to-unit” is used along with “intercell” when referring to measurement of connection resistance. From the applicable IEEE standards (e.g. IEEE 450) the standard terminology seems to be “intercell”. It is recommended that the “unit-to-unit” term be removed to avoid confusion regarding what is to be verified.

Response: Thank you for your comments. 1. **The SDT agrees with your comment and has modified the Implementation plan to better indicate that, for activities being added to an entity's program as part of PRC-005-2 implementation, evidence will be available to show only a single performance of the activity until a full maintenance interval has transpired following initial implementation.** 2. **Entities are required to install UFLS per PRC-007; there are no standards which require entities to install UVLS. However, if entities choose to install UVLS to meet minimum system performance requirements, several standards (including the current PRC-011 and the proposed PRC-005-2) apply. Section 4.2.3 is specifically intended to address these UVLS.** 3. **The SDT provided the allowance for generator plants to allow them until their first maintenance outage to begin program implementation. It is believed that the entity would then likely perform all maintenance on the protection system for a given generator, GSU and, if so equipped, generator connected station auxiliary transformer during that maintenance window. It seems unlikely that an entity would perform maintenance on only a portion of a protection system. Thus, the SDT concludes that inclusion of the parenthetical to the 2nd and 3rd bullets would only add confusion and provide little or no benefit to generator plants in the implementation of their program.** 4. **The purpose of the standard expresses the general intent of the standard, and is further clarified by the Applicability.** 5. **The SDT believes that a 6-month interval is appropriate for these activities.** 6. **The term "unit-to-unit" is used for the conductor utilized to connect one multi-celled battery jar to an adjacent multi-celled battery jar. The SDT does not believe this terminology causes wide spread confusion.**		
Manitoba Hydro		-Definition of Protection System Maintenance Program: The definition included in the proposed PRC-005-2 is not the same as the definition provided in the document "Definition for Approval", which also includes items "Upkeep" and "Restore".
Response: Thank you for your comments. **The SDT agrees with your observation and will review the associated documents to attain consistency.**		

American Transmission Company		a) Change the text of “Standard PRC-005-2 - Protection System Maintenance” Table 1-5 on page 19, Row 1, Column 3 to: ”Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternatively, “Electrically operate each interrupting device every 6 years.” Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). b) Change the text of “Standard PRC-005-2 - Protection System Maintenance” Table 1-5 on page 19, Row 3, Column 2 to: “12 calendar years” The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years.In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. c) ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC is recommending a negative ballot since, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

Response: Thank you for your comments. a) **While the SDT agrees with much of your observation about circuit breaker operations, this standard applies to Protection System maintenance and per the Protection System definition does not include the entire circuit breaker. As such we are limited to exercising the trip coils and seeing that they have the intended effect on the interrupting device. A simple cycling of the breaker should have minimal impact on the scheduling of the entities breaker maintenance program.** b) **The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT, however, has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification.** c) **As noted above, the SDT has modified Table 1-5 to remove other auxiliary relays, etc, from the 6-year activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification. However, the SDT believes that the other activities addressed in your comment need to be performed as reflected in Table 1-5.**		
Southern Company Transmission		Table 1-5: Need clarification on "continuity and energization or ability to operate". What does this mean?
Response: Thank you for comment. **This entry in Table 1-5 has been modified to “Control circuitry whose integrity is monitored and alarmed”. Section 15.3 of the Supplementary Reference and FAQ document provides additional discussion on this topic.**		
Utility Services, Inc		Thank you for the opportunity to address the new documentation and for your efforts.
Response: Thank you for comment.		

ITC Holdings		ITC Holdings continues to object to the requirement to exercise auxiliary relays on a 6 year interval. We repeat our previous comments as follows: "It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplementary Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle." Previous responses from the SDT were: "The SDT believes that the appropriate interval for electromechanical devices such as aux or lockout relays should remain at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable." ITC requests that the statistical basis for the 6 year interval be published. If it is not clear that lockout relays and other auxiliary relays must be exercised on a 6 year interval, then the requirement should be changed to 12 years.
Response: Thank you for your comments. **The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond 6 years. The SDT has modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification as you have suggested.**		
Ingleside Cogeneration LP		Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test.

Response: Thank you for your comments. **There are less intrusive ways to verify channel performance that do not require disconnecting communication terminations. It is up to the entity to determine specific maintenance techniques.**		
CenterPoint Energy		For the “Unmonitored control circuitry associated with protective functions”, the Table 1-5 requirement is to “Verify all paths of the trip circuits through the trip coil(s) of the circuit breakers or other interrupting devices” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such checks on new stations and whenever expansion or modification of existing stations dictates such testing. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping. Likewise, CenterPoint Energy recommends the requirement in Table 1-5 to “Verify all paths of the control circuits essential for proper operation of the SPS” every 12 years be revised to “No periodic maintenance specified”.
Response: Thank you for your comments. **The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES.**		
Oncor Electric Delivery Company LLC		PRC-005-2 is a vast improvement over the vagueness of the existing standard (PRC-005-1), that the new standard makes compliance much easier than the present standard. The new standard recognizes the advances in relay technology and reliability, particularly the benefits of microprocessor based relays. The standard also provides greater flexibility on its implementation while recognizing the benefits of a performance based methodology, particularly as it relates to battery testing. The revised standard eliminates the requirement for a “summary of maintenance and testing procedures” which was vague and provided no real value to the registered entities. Operational and administrative efficiencies can be realized by consolidating the relay testing and maintenance requirements into one standard (PRC-005-1, PRC-008-0, PRC-011-0, PRC-017-0).
Response: Thank you for your comments.		

City of Austin dba Austin Energy		If a Registered Entity has a PSMP that is more stringent than the intervals in PRC-005-2, the Registered Entity should not be considered out of compliance if it fails to meet its internal interval but remains within the interval set forth in PRC-005-2.
Response: Thank you for your comments. The standard and the Supplementary Reference and FAQ document have been changed to address your concerns. Specifically, Requirement R1 part 1.3 has been removed; Requirement R3 has been revised so that, for time-based programs, entities shall comply with the tables; Requirement R4 has been added to address performance-based maintenance, and Requirement R5 has been added to address Unresolved Maintenance Issues.		
BGE		When the term "Maintenance Correctable Issue" was revised to "Unresolved Maintenance Issue", it appears that the PRC-005-2 Protection System Maintenance / Supplementary Reference and FAQ document was not properly updated to reflect this change. There are inconsistencies throughout the entire document were the old term is still showing up instead of the new term, and vice versa.
Response: Thank you for your comments. **The SDT has attempted to correct the terminology inconsistencies you have mentioned between the Standard and the Supplementary Reference and FAQ document.**		
VRFs/VSLs		
Xcel Energy, Inc.	Negative Ballot	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

Ameren Services	Negative Poll	The VRF for R3 should be Low. Many entities presently do not perform some of the specified maintenance activities on some of their components. The risk to the BES is quite low as proven by the extremely reliable BES performance. We are not aware of such omissions in Protection System performance leading to widespread outages, cascading or uncontrolled separation. This coupled with NERC's insistence on 100% perfect completion of all maintenance for even the Lower VSL leads to an inappropriate and unjustified VRF/VSL combination.
Response: The VRF value of "high" stems from consideration of an entity not performing any maintenance and testing of their Protection System. Specifically, a "high" VRF, for a planning time horizon requirement, addresses violations of requirements that could directly cause or contribute to BES instability, separation, or cascading. While not every failure to properly perform maintenance WILL do these things, they can very well contribute to them, as evidenced by involvement of Protection Systems in every recent significant BES disturbance.		
Flathead Electric Cooperative	Negative Poll	do not believe the severe VSL should apply to distributed UFLS
Response: The VSL is a measure of the completeness of the execution of a requirement. Where a binary evaluation of compliance with a particular requirement is prescribed, the NERC VSL guidelines require the violation level to be severe. If the compliance can be demonstrated to be partially complete, a graduated violation severity level is allowed. The NERC Criteria for setting Violation Severity Levels states that it is preferable to have four VSLs for each requirement.		
Independent Electricity System Operator	Negative Poll	The IESO continues to disagree with the High VRF for R3 which asks for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.

Response: The VRF value of “high” stems from consideration of an entity not performing any maintenance and testing of their Protection System. Specifically, a “high” VRF, for a planning time horizon requirement, addresses violations of requirements that could directly cause or contribute to BES instability, separation, or cascading. While not every failure to properly perform maintenance WILL do these things, they can very well contribute to them, as evidenced by involvement of Protection Systems in every recent significant BES disturbance.		
Liberty Electric Power LLC	Negative Poll	The percentage structure on unresolved maintenance issues presents problems. Smaller entities are unlikely to ever have more than a handful of unresolved issues, meaning a single failure to initiate would automatically be a High VSL. There would also be a disincentive to close out issues from fear that "resolving" them could potentially increase a violation level on a discovered issue.
Response: The VSLs relating to Unresolved Maintenance Issues have been revised to graduated VSLs using a count of violations, rather than a percentage.		
Xcel Energy, Inc.	Negative Poll	The VSL for R3 is confusing because of the lack of a specified time horizon. Are the percentages quoted on an annual schedule basis, an audit period, or a continuous percentage measurement of any previously scheduled maintenance activities? Greater clarity is needed on the intent of this VSL.
Response: Thank you for your comment. **The VSLs that use a graduated VSL have been revised based, in part, on the comments you have provided. The percentages relate to the number of violations reported within the compliance monitoring period relative to the number of components within that component type.**		

END OF REPORT

Consideration of Comments

Project 2007-17

Protection System Maintenance and Testing

The Project 2007-17 Protection System Maintenance and Testing Standard Drafting Team thanks all commenters who submitted comments on PRC-005-2. These documents were posted for a 30-day public comment period from February 28, 2012 through March 28, 2012. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 56 sets of comments, including comments from approximately 118 different people from approximately 98 companies representing 9 of the 10 Industry Segments, as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Definitions:

The SDT revised the "Inspect" element of the definition of Protection System Maintenance Program (PSMP) to: "Examine for signs of component failure, reduced performance or degradation."

The definition of the term 'Unresolved Maintenance Issue' has been enhanced for additional clarity. The definition now reads: "A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action."

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The definition of Countable Event was modified to: "A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component configuration errors, or Protection System application errors are not included in Countable Events." This change was acknowledged in Attachment A.

Applicability:

The SDT revised Applicability Clause 4.2.5.4 to: "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."

Requirements:

A minor editorial change was made to Requirement R1 to remove the nested parentheticals.

Tables

In Table 1-2, the interval for the second portion of the first row of the table was changed from six years to 12 years, and extensive changes were made to the last row of the table.

Several activities within Table 1-4a, Table 1-4b, Table 1-4c, Table 1-4d, and Table 1-4f, relating to verification that the station battery can perform properly, were modified with the assistance of representatives of the IEEE Stationary Battery Committee.

Measures

Measure M5 has been revised to include: "…project schedules with completed milestones …"

VSLs

In the High VSL for R1, "entities'" was corrected to "entity's".

The VSLs for Requirement R2 were modified from "reduce Countable Events to less than 4%" to "reduce Countable Events to no more than 4%".

Supplementary Reference Document

Complementary changes were made to the Supplementary Reference Document corresponding to all changes to the standard.

Unresolved Minority Views:

- A few commenters continued to object to the establishment of maximum allowable intervals for the maintenance of various Protection System component types. The SDT continued to respond that FERC Order 693 and the approved SAR direct the SDT to develop a standard with maximum allowable intervals comments and minimum maintenance activities. The SDT believes that the intervals established within the tables are appropriate as continent-wide maximum allowable intervals.

- Several commenters were concerned that an entity has to be “perfect” in order to be compliant; the SDT responded that NERC standards currently allow no provision for any degree of non-performance relative to the requirements.

- Several commenters continued to question NERC’s propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT obtained a position from NERC legal staff, and cited this position in responding that these devices are, indeed, within NERC’s authority because they are installed for the reliability of the BES.

- A few commenters questioned the inclusion of the dc control circuitry for sudden pressure relays, even though the relays themselves are excluded from the definition of “Protection System;” the SDT reiterated its position that this dc control circuitry is included because the dc control circuitry is associated with protective functions.

- A few commenters objected to the language in the Data Retention section regarding the retention of the maintenance records for two full intervals. The SDT explained that this expectation is consistent with the Compliance Monitoring and Enforcement Program.

- Several commenters suggested removal of Requirement R5, and others expressed concerns regarding Requirement R5 and Unresolved Maintenance Issues. The SDT explained its rationale for the requirement as drafted; and made a minor change to Unresolved Maintenance Issues, as detailed above.

1. **In response to comments, the PSMTSDT revised Requirement R1 to state that an entity's Protection System Maintenance Program (PSMP) shall include, for each Protection System component type, an identification of the maintenance method(s) used, and the identification of the relevant monitoring attributes applied. Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Many commenters were in agreement with this change.

Comments were offered that the definition of PSMP is incongruous with its use in Requirement R1; the SDT disagreed, and noted that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program, and is the foundation for the standard.

Other comments questioned why Requirement R1 includes the applicable level of monitoring for a Component when this is also listed in the Component attributes within the tables; the SDT explained that the discussion in Requirement R1 is to assure that the monitoring is present to support the intervals and activities used.

The SDT responded to concerns regarding the use, within Requirement R1, of "Component Type" by noting that this term allows entities latitude in how they define their PSMP.

Other commenters noted that Requirement R1 does not require that entities maintain their Components; and is, therefore, administrative and should have a lower VRF. The SDT responded that Requirement R1 is the foundation of the standard; and, therefore, the VRF is appropriate.

The SDT accepted a suggestion to remove the imbedded parenthetical within Requirement R1.

Several comments were submitted that were unrelated to this question.

Organization	Yes or No	Question 1 Comment
Pacific Gas and Electric Company	Negative	PG&E thanks the drafting team for their efforts. PG&E agrees with overall changes to the standard and sees the current draft as an improvement over the prior draft, on which PG&E voted affirmative. PG&E however will vote negative on the current ballot due to recent experience and trouble with trying to implement the intercell connection resistance test for NiCad batteries as specified in Table 1-4c of PRC-005-2. PG&E has experienced trouble trying to implement the "Battery intercell or unit-to-unit connection resistance" maintenance activity for certain NiCad battery types. In

Organization	Yes or No	Question 1 Comment
		these cases the battery post was not exposed and was entirely covered by the intercell strap. The battery post protruded minimally from the battery and could not be accessed with a probe. PG&E requests clarification on this requirement and that provision be provided to accommodate existing battery systems without requiring modification to the battery system. Modification of the battery system to access the battery post places a hardship on the battery owner, may compromise the battery design, and ultimately may require replacing the battery to allow fulfilling the maintenance requirement. One solution may be to allow measuring intercell connection resistance from the battery post bolt when the battery post is not accessible. While this is not the optimal approach, it may still be effective since the presence of corrosion would likely show up between both the battery post and bolt and also between the bolt and intercell strap. Trending the resistance from bolt-to-bolt may still be effective in determining an increasing resistance from post-to-post. PG&E suggests the following language: Table 1-4c Verify - Battery intercell or unit-to-unit connection resistance where battery post is accessible. Where battery post is not accessible measure intercell or unit-to-unit connection resistance from bolt-to-bolt or nearest connection to the battery post.
Response: Thank you for your comment. The SDT believes that the Maintenance Activities in Table 1-4c are explicit as to the required activity and are necessary to ensure the integrity of the station battery. The SDT believes the activity you discuss is not an effective method to satisfy the intent of the requirement in Table 1-4c; and the team suggests that you consult the manufacturer of your battery system to investigate how to meet the requirement.		
Seminole Electric Cooperative, Inc.	Negative	Seminole recommends the SDT re-consider an interval of 12 calendar years for the component in row 2, of Table 1-5. The maximum maintenance interval for "Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less stable system configuration. Increasing the time the BES is in

Organization	Yes or No	Question 1 Comment
		a less stable system configuration also increases the probability of a low frequency, high impact event occurring. We believe that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. It appears that the SDT is trying to address a specific type of lockout relay with the 6 year interval that consists of a longer operating rod lockout that is subject to binding when called upon to operate. Why is it necessary to include all lockout relays when only a very specific segment of all lockout relays is subject to this one problem? Maybe a unique category of these specific types of lockouts, subject to operating rod binding should be specified at 6 years, with other lockouts not subject to this problem using a common interval like other protective components of 12 years. We sincerely hope that the SDT will consider these positive changes.
Response: Thank you for your comment. The SDT believes that electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils), regardless of the manufacturer, need to be electrically operated to prove the capability of the device to change state. The application of lockouts is typically associated with equipment limited having remote backup protection (Generators/Transformers) or higher system consequences if remote backup is called upon to operate (Buses/Breakers). A failure of a lockout to function results in decreased stability and has a higher outage impact. These tests need to be accomplished at least every six years, unless PBM methodology is applied. The contacts on the 86 that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.		
Tampa Electric Co.	Negative	The requirement to periodically test Control circuits will negatively impact reliability. The possibility of lifted wires being properly re-landed or test links being left open following testing will cause more misoperations than the finding of failed devices prevents. The outages required to do the testing will limit available transmission capability and therefore affect markets negatively for no reliability enhancement.
Response: Thank you for your comment. The SDT believes that periodic testing of control circuits is a vital part of assuring proper		

Organization	Yes or No	Question 1 Comment
operation of a protective relay system. There are several methods of accomplishing this testing. Where portions of the circuit are isolated for testing, procedures should be in place to assure proper restoration of the circuit.		
Tennessee Valley Authority	Negative	1. Regarding the functional test required every 3 months for "unmonitored communication systems" in Table 1-2 of the PRC-005-2 Draft. TVA feels that a Maximum Maintenance Interval for the Functional Test should be every 12 months until auto-checkback has been fully implemented by the utility. 2. The Implementation Plan for PRC-005-2 Step 4 on Page 2 states: "The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees." TVA feels that this is not sufficient time to implement full auto-checkback capability at some utilities. The time schedule of twelve (12) months should be forty-eight (48) months following applicable regulatory approvals
Response: Thank you for your comments. 1) The SDT believes the four-month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status. 2) The Implementation Plan is intended to facilitate implementation of the standard, not to facilitate modifications to meet the requirements of the standard.		
U.S. Bureau of Reclamation	Negative	1. The definition for PSMP is incongruous with the use of the PSMP in Requirement R1. Requirement R1, including the Measure and VSL focus on the identification of maintenance method of the Component types and not that the PSMP is in fact being used for maintenance of the component. 2. The requirement R5 indicates the entity has to "demonstrate" efforts to correct

Organization	Yes or No	Question 1 Comment
		identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP. 3. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 4. Re The definition of Components: The standard defined what constitutes a control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT believes that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program, and is the foundation for the standard. Requirements R3-R4 address implementation of the entity's PSMP. 2. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency, "…cannot be corrected during the maintenance interval." 3. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard. 4. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing of these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
DTE Energy	No	DECo does not agree. With the exception of station batteries, all components should be tested as a scheme to assure that all components are working together as designed, so the PSMP should not be required for each component type.
Response: Thank you for your comment. A PSMP allows for each component within a protective relay scheme to have a differing maintenance interval allowing for unit or station outages. A company's PSMP can perform maintenance on all the components within a particular relay scheme, but that would require the shortest of the maintenance intervals.		
PNGC Comment Group	No	Specifying "by component type" appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to "by component or component

Organization	Yes or No	Question 1 Comment
		type" when entities determine the maintenance method in their PSMP.
Response: Thank you for your comment. The SDT believes that it is acceptable for an entity to subdivide components within a component type, if desired. The SDT does not want to remove that latitude.		
Nebraska Public Power District	No	1. Since auditors will be able to request documentation necessary to validate the inclusion of the device within the appropriate level of monitoring, why does the program document require listing level of monitoring and component attributes? (Concerned about the burden of maintaining lists of components in a program document that are alike but have different levels of monitoring. Ex: Monitored and unmonitored microprocessor relays) 2. For identification of the relevant monitoring attributes applied can a single specification document suffice for similar relay types such as one document for SEL relays? 3. For trip circuit monitoring can a standard document be used for a group of similar schemes?
Response: Thank you for your comments. See Section 6.1 of the Supplementary Reference and FAQ document for a discussion of this topic. 1. The requirement to list component attributes is designed to support a company's program for the maintenance intervals used. 2. The SDT concurs with using a single specification document for similar equipment. 3. The SDT concurs with a standard document for trip circuit monitoring when consistent practices are present.		
Flathead Electric Cooperative, Inc.	No	1. Specifying "by component type" appears confusing. It seems possible that some pieces of equipment from the same component type could end up in a different type of maintenance program. We suggest changing to "by component or component type" when entities determine the maintenance method in their PSMP. 2. Generally, have concerns with all the new definitions except the NERC

Organization	Yes or No	Question 1 Comment
		definition of Protection System. The approach to creating new definitions of plain language in a standard should be avoided.
Response: Thank you for your comments. 1. The SDT believes it is acceptable for an entity to subdivide components within a component type, if desired. The SDT does not want to remove that latitude. 2. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard.		
American Electric Power	No	R1.1 binds you to the activities in the table, but our system is comprised of elements (such as a Plant Control Systems), that are not included in the table. As a result, it is not clear how an entity could develop an SPS that satisfies both the requirement and our system.
Response: Thank you for your comment. IEEE defines a relay as: "An electric device designed to respond to input conditions in a prescribed manner and after specified conditions are met to cause contact operation or similar abrupt change in associated electric control circuits." The SDT believes that protective relay functions that are embedded in control systems and/or SPSs are a part of this standard and are, therefore, under the same requirements as dedicated, stand-alone protective relays. It is left to the entity to determine how to align these requirements with operational concerns.		
Manitoba Hydro	No	Please see comments provided in Question 4.
US Bureau of Reclamation	No	The requirement R1 states that the PSMP must identify how the component is to be maintained, using time based or performance based or a combination. While R1 requires a PSMP, there is no measure that the PSMP is used for actually maintaining the components, other than for documenting which maintenance method is being used. The purpose of R1 is therefore administrative. Since there is no measure for the use of the PSMP, why is the entity required to develop the PSMP as defined? There is no VSL for R1 which requires that the entity establish a PSMP. Since there is no severity level associated a PSMP that does not contain one of the required activities it supports elimination of the definition of PSMP. PSMP definition is also weak and does not match with the VSL that the PSMP identify the maintenance method of the protection system component types. The definition is that PSMP

Organization	Yes or No	Question 1 Comment
		which must include: "A maintenance program for a specific component includes one or more of the following activities: o Verify- Determine that the component is functioning correctly. o Monitor - Observe the routine in-service operation of the component. o Test - Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. o Inspect - Detect visible signs of component failure, reduced performance and degradation. o Calibrate- Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement." Since requirement 1 essentially only requires identification of which maintenance method is to be used, there is no need for the definition. It no longer matters how the device's functionality is determined as long as it is performed on a time based or performance based method. This approach may be lowering the reliability level associated with the protection system maintenance. Since the definition of PSMP is that only one of the 5 activities is needed, is seems that one could select to "Monitor" the in-service operation of the component on a time base and no further action is needed. So that could mean observe that the relay has power and was not misoperating every six years and maintenance is performed. A PSMP is as defined does not help the reliability. It would be better require the PSMP include as a minimum all five activities defined as well as defining the maintenance method used (time based, performance based, or a combination). There needs to be a requirement that the PSMP needs to be developed. Then Requirement 1 would be to implement the PSMP.
Response: Thank you for your comments. Requirement R1 requires that the entity establishes a PSMP (with the specified attributes), and is the foundation for the standard; thus, Requirement R1 is not administrative, as without a PSMP, there is nothing on which to base the remainder of the standard. Requirements R3-R4 address implementation of the entity's PSMP.		
ExxonMobil Research and Engineering	No	As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must

Organization	Yes or No	Question 1 Comment
		be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program .
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated."		
EPRI	No	My comments are not to the point of dividing the requirements but the guidance in the PSMP tables are not technically valid for maintaining stationary battery cells. Internal ohmic measurements are related to the condition of an individual cell and not a battery bank. Also, there is not a direct correlation to ohmic measurements and battery or cell capacity. Ohmic measurements can provide an indication of a problem cell and point to a cell that should be tested. There also seems to be a misconception as to the type of capacity test that should be required. There are typically two types of tests done on batteries: service tests and performance tests. Service test are done to determine if a battery (group of cells) can meet its duty cycle whereas, a performance test is intended to test a battery against the manufacturers curve to make a determination of when the battery should be replaced. A battery could technically still meet its duty cycle but have reduced capacity. This simply means that the sizing was done properly, maintenance is timely, and there should be a timely replacement of the cells.
Response: Thank you for your comment. The drafting team agrees with statements by you and others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and		

Organization	Yes or No	Question 1 Comment
the Supplemental Reference and FAQ document has been modified to further elaborate on these concerns.		
Public Utility District No. 1 of Okanogan County	Affirmative	OCPD would like some clarification with regards to the Power Wave concept. Currently in Table 1.1 and Table 3 it states, “Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics." OCPD feels that it might be better stated as simply 60 Hz.
Response: Thank you for your comment. The values for waveform sampling are intended to be verified by referencing a specific manufacturer’s specifications.		
ACES Power Marketing Standards Collaborators	Yes	Is the use of parentheticals within another set of parentheticals in Part 1.1 intentional? It is unusual to do this and a little confusing.
Response: Thank you for your comment. The SDT agrees with your suggestion, and made the following change: “Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System component type.”		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration agrees that a Compliance Authority should be alerted to those component types which have been assigned extended maintenance intervals because they use some form of monitoring. We also agree that it is appropriate that the PSMP list the relevant monitoring attributes in these cases, so they can be confirmed to be consistent with the criteria in PRC-005-2’s interval tables.
Response: Thank you for your comments.

2. As a result of the changes to Requirement R1, the previous Requirement R3 was separated into three requirements:

   a. Requirement R3 now requires that an entity utilizing a time-based program maintain its Protection System components in accordance with the maximum maintenance intervals listed in the tables. This change removes the compliance jeopardy associated with an entity having more stringent intervals (in its PSMP) than those listed in the tables.

   b. Requirement R4 (new) requires an entity utilizing a performance-based program maintain its Protection System components in accordance with its performance-based Protection System Maintenance Program.

   c. Requirement R5 (new) requires an entity to demonstrate efforts to correct identified unresolved maintenance issues. The previous language in Requirement R3 directed that an entity initiate resolution.

   Do you agree with this change? If you do not agree, please provide specific suggestions for improvement.

Summary Consideration: Many commenters were in agreement with this change.

Numerous comments were offered relative to subject and definition of "Unresolved Maintenance Issues," per Requirement R5. As a result of these comments, the definition of this term was modified to include the phrase, "… cannot be corrected during the maintenance interval…" For those commenters objecting to the concept of Unresolved Maintenance Issues, the SDT explained the rationale behind the concept.

Several comments were submitted that were unrelated to this question.

Organization	Yes or No	Question 2 Comment
Beaches Energy Services	Negative	The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: The applicability as currently stated will sweep in distribution protection: "4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)" Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES

Organization	Yes or No	Question 2 Comment
		and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.

Response: Thank you for your comment. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.

To address your concern, the distribution protective devices and functions cited in this comment are not “installed for the purpose of detecting Faults on BES Elements” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse power relay application described is also not “installed for the purpose of detecting Faults on BES Elements,” (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system.

Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue.

Organization	Yes or No	Question 2 Comment
Fort Pierce Utilities Authority	Negative	1. The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).” Most network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). 2. There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200

Organization	Yes or No	Question 2 Comment
		kV, then the entity would not be able to meet PRC-023 as that standard is currently written. FPUA recommends the SDT should adopt the FERC approved interpretation. 3. Another concern is regarding the sudden pressure relays. These had been out of the scope in all previous draft versions of PRC-005-2 because these do not measure electrical quantities. However, the SDT just added a requirement to test the trip path from the sudden pressure device, arguing that it is captured by the definition of Protection Systems. This inconsistency does not make sense and could create “grey areas” for other devices that can trip for low oil level or high temperature, among others. By their nature, sudden pressure devices are far less reliable than their associated control circuitry. I know of at least one large entity that disables sudden pressure relays on smaller transformers to cut down on nuisance alarms. If it is expected that non-electrically initiated devices may become part of some maintenance standard in the future, I think it would be premature for the SDT to address sudden pressure relays in PRC-005-2. 4. And lastly, page 77 of the Supplementary Reference has some text clarifying the requirement for establishing a baseline test: “For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit.” This guidance does not recognize the fact that

Organization	Yes or No	Question 2 Comment
		some battery manufacturers recommend the baseline tests to be performed at some point in time after the install to allow the cell chemistry to stabilize after the initial freshening charge. The manual from a battery manufacturer (Enersys Powersafe) states that “The initial records are those readings taken after the battery has been in regular float service for 3 months (90 days). These should include the battery terminal float voltage and specific gravity reading of each cell corrected to 77F (25C), all cell voltages, the electrolyte level, temperature of one cell on each row of each rack, and cell-to-cell and terminal connection detail resistance readings. It is important that these readings be retained for future comparison”. If an entity follows the manufacturer’s recommendation, the above statements would lead an auditor to a finding of non-compliance because internal ohmic tests were not performed prior to placing a new battery string in service. A simple modification to the wording would eliminate the conflict.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.
2. To address your concern, the distribution protective devices and functions cited in this comment are not “installed for the purpose of detecting Faults on BES Elements” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse power relay application described is also not “installed for the purpose of detecting Faults on BES Elements,” (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system.

Organization	Yes or No	Question 2 Comment
Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue. 3. DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the "Control circuitry" portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. Activities associated with the schedule submitted in the filing will be included in a final SAR to further develop PRC-005. A draft SAR for a second phase of this project is posted for information only at this time. **4.** The drafting team revised the Supplemental Reference and FAQ document based on your recommendations.		
Imperial Irrigation District (IID)	No	IID disagree with item c. and does not believe item c increases the reliability of the BES. The maintenance issues will be resolved internally and should not be required as per compliance of the standard.
Response: Thank you for your comment. The practice of returning Protection System devices to good working order exists currently as a required element of a sound maintenance program as required by the existing Protection System maintenance and testing standard, PRC-005-1b. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to "…look for relay test results or field records with annotations such as "as-found" readings or pass/fail results; if failed, then adjustments made. The maintenance record for adjustments may be requested".		
Texas Reliability Entity	No	New requirement R5 states that an entity shall "demonstrate efforts" to correct identified Unresolved Maintenance Issues. This falls short of requiring completion of any corrective actions for the unresolved maintenance issue. We suggest rewording to "Each Transmission Owner, Generator Owner, and Distribution Provider shall develop a corrective action plan and work timetable to address identified Unresolved Maintenance Issues. The Registered Entity shall complete resolution of Unresolved Maintenance Issues within the time frame identified in the Entity corrective action plan." If R5 is modified, then M5 and the VSL should also be modified accordingly.
Response: Thank you for your comment.		

Organization	Yes or No	Question 2 Comment
Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
Nebraska Public Power District	No	The FAQ attempts to clarify the intent of "demonstrate efforts to correct", however, there is no explanation as to why this new term is preferable to the more concise "initiate resolution" term that was developed and agreed upon over the last year. In the Supplementary Reference and FAQ document there is a request for clarification and it is reprinted below. Please clarify what is meant by "...demonstrate efforts to correct an unresolved maintenance issue..."; why not measure the completion of the corrective action? Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requiring battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program

Organization	Yes or No	Question 2 Comment
		requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. I agree with this response and specifically the last sentence. This indicates that R5 "demonstrating efforts to correct unresolved issues" is too open ended and subjective and cannot be applied by enforcement in a consistent way. R5 should be removed from the standard.
Response: Thank you for your comment. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase, "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
Bonneville Power Administration	No	BPA believes that R5 is not worded in such a way that it can be easily or consistently audited.
Response: Thank you for your comment. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." Each entity must determine how to document the efforts to correct the Unresolved Maintenance Issue based on the specific issue and choice of remediation.		
PPL Supply NERC Registered Organizations	No	1. The maximum maintenance intervals in PRC-005-2 of 4 calendar months and 18 calendar months are not compatible with computerized maintenance-planning programs based on periodicity rather than elapsed time from the previous check. This situation could be addressed in a conservative fashion by performing work quarterly instead of at 4-month intervals, and annually in place of 18-month periods, which also provides often-needed flexibility as to scheduling the tasks. Inspections performed in April for Q2 and September for Q3 would not meet NERC's 4 calendar month criterion, however, and a similar problem exists for annual checks. The more-stringent compliance jeopardy cited above has therefore not been fully addressed. We recommend changing the 4 calendar months and 18 calendar months intervals to quarterly and annually respectively. 2. We consider addition of the expression, "causes the component to not meet the intended performance," to the previous draft's definition of Unresolved Maintenance Issues (UMIs) to constitute a step backwards, because of the unavoidable subjectivity involved in deciding whether or not a battery or other protection system device is unable to perform as intended. A battery with some "sparkle" on the plates due to sulfation would still be able to

Organization	Yes or No	Question 2 Comment
		perform adequately, for example, making this an issue to watch but not an UMI. It is impractical to provide strict, quantitative, UMI-threshold performance limits for every piece of equipment in a Protection System and every situation that may arise, however. The concept of an UMI has some appeal from a common-sense point of view; but as a regulation it is impractical and, given the breadth of the topic at hand, is likely to remain so regardless of alternative phrasing that might be attempted.
Response: Thank you for your comment. 1. The SDT believes that management issues associated with computerized maintenance management programs can be adapted to provide maintenance triggers consistent with the intervals established in the tables. Many of these systems offer the ability for the user to create custom algorithms to trigger the desired work order, reminder, or alarm, etc. The SDT also believes the four calendar-month and 18-calendar-month intervals are appropriate for the relative Protection System components. An entity may utilize the abbreviated intervals, such as you suggest, as long as they meet the explicit requirements and intervals established in the standard. **2.** The consideration of “meet the intended performance” is an issue for an entity to determine subjectively. This consideration depends heavily upon the nature of observed anomaly and upon the actual intended performance.		
Arizona Public Service Company	No	The standard does not provide basis for the enumerated “maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.” An example of such an approach is the Standard Technical Specifications in use by the nuclear power industry; e.g., NUREG 1432, volume 2. While we are supportive of the changes the SDT has made, APS is concerned the draft Standard will not give entities the flexibility to continue to improve reliability based on changing industry norms and best practices. When technology changes for the better, industry will need the flexibility to optimize use of the new technology while still maintaining an appropriate level of reliability. Lack of defined bases for intervals will prevent technically sound revision to maintenance practices.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment. The SDT established the maximum maintenance intervals for each Protection System component subject to the standard based upon research performed by the NERC System Protection and Control Subcommittee and "best practice" input from industry. The base intervals are extended in consideration of modern monitoring capabilities and new technologies. These extended intervals range from "12 calendar years" to "No periodic maintenance specified." Consistent with the FERC directive of intervals being "…appropriate to the type of protection system and its impact on the reliability of the Bulk Power System," the SDT did not provide a "No periodic maintenance specified" extended interval for high reliability impact devices, such as protective relays; but rather stipulates a six-calendar-year interval for unmonitored electromechanical and unmonitored microprocessor relays, and a 12-calendar-year verification of monitored microprocessor relays. Please see Section 8.3 of the Supplementary Reference and FAQ document for a more detailed discussion of this issue.		
Southern Company Generation	No	1. The change made to R3 was a good move. Entities should be allowed the flexibility to build grace periods into their maintenance programs to assist them in meeting common national standards for maintenance activities and intervals. 2. If possible, elimination of all possible uncertainty in the auditability of requirement R5 is desired. We prefer eliminating this requirement R5 altogether to the proposed draft that includes a requirement to demonstrate efforts to correct identified unresolved maintenance issues.
Response: 1. Thank you for your comment and support. 2. Returning Protection System devices to good working order exists currently as a required element of a sound maintenance program subject to the existing Protection System Maintenance and Testing Standard, PRC-005-1b. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to "…look for relay test results or field records with annotations such as "as-found" readings or pass/fail results; if failed, then adjustments made. The maintenance record for adjustments may be requested". Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of		

Organization	Yes or No	Question 2 Comment
		this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."
Ingleside Cogeneration LP	No	1. Ingleside Cogeneration LP strongly agrees with the change made to the language in R1 and R3 specifying that compliance is measured against the PRC-005-2's interval tables wherever time-based methods are used. The intervals were carefully designed to assure an acceptable level of BES reliability, and the regulatory authorities must be prepared to stand by them. Furthermore, a Registered Entity who may establish tighter intervals for their own internal purposes should be encouraged to do so - and without a threat of a violation hanging over their heads. 2. We also agree with the need to add a new requirement (R4) which applies to those entities that choose to use a performance-based system to determine some of their maintenance intervals. It logically maps back to requirement R2 which states that the calculated intervals must be documented in the PSMP. 3. We cannot agree with the language used in R5, which, in its previous form under R3, had specified only that the Protection System owner "initiate

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>resolution” to correct identified unresolved maintenance issues. We were actually comfortable with this language as it was unambiguous that progress did not need to be tracked start-to-finish. We would like to propose adding a phrase that tracks the statement in M5; which we find acceptable. This would result in the following: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate THAT IT HAS UNDERTAKEN <our emphasis> efforts to correct identified Unresolved Maintenance Issues.</td></tr>
<tr><td colspan="3">Response:
1. Thank you for your comment and support.
2. Thank you for your comment and support.
3. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. For the Compliance Monitoring Authority to be confident that the corrective action is being implemented, the entity should expect to demonstrate progress toward correcting the Unresolved Maintenance Issue, such as the evidence suggested in Measure M5 (with additional suggested evidence added).</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>1. R3: Table 1-5 notes a “mitigating device” as part of component attributes. Such a phrase could be open to interpretation and needs to be clearly defined.
2. Table 1-3, Maintenance Activities - there is nothing specifically regarding accuracy. Suggest incorporating the definition of “verify” as used in the FAQ or perhaps something similar to “verify values are as expected”.
3. R5: We understand the drafting team’s desire to deal with unresolved maintenance issues, however it is not clear how the adequacy of resolving</td></tr>
</table>

Organization	Yes or No	Question 2 Comment
		those issues would be determined by an auditor. If these kinds of efforts are going to be scrutinized, there needs to be some sort of boundaries established so that it is clear how unresolved maintenance issues would be evaluated.
Response: Thank you for your comment. 1. The SDT intended that "mitigating devices" address actions of SPSs, which may include activities beyond tripping of interrupting devices. For example, SPSs may perform actions like generation run-back or generation fast-valving. 2. 'Verify" is a term expressed in the PSMP definition, and the use of the term in Table 1-3 indicates that the accuracy needs to be 'whatever is necessary' for proper functioning of the connected relays. 3. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT believes corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues. Measure M5 suggests some examples of evidence.		
US Bureau of Reclamation	No	The Requirement R5 indicates the entity has to "demonstrate" efforts to correct identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP.
Response: Thank you for your comment. The term within Requirement R5, "… demonstrate efforts …" is intended for both – that the entities are acting to correct the deficiency and also (to prove compliance) maintaining documentation of the activities underway to		

Organization	Yes or No	Question 2 Comment
correct the deficiency. The SDT elected to not require a "**Corrective Action Plan**" as defined in the NERC Glossary of Terms to avoid much of the systemic, ongoing documentation attendant to that term. However, if an entity wishes to use a Corrective Action Plan as defined, that would be an acceptable method of meeting Requirement R5.		
Essential Power, LLC	No	The change to R3 is too restrictive, and removes the registered entity's ability to better define its own intervals based on its own experience and system characteristics. The comments regarding a CEA's enforcement of an RE's more stringent internal intervals is not indicative of an issue with the Requirement, but with the way in which it is enforced.
Response: Thank you for your comment. Requirement R3 still allows entities flexibility within their own Protection System Maintenance and Testing Program (PSMP), and only restricts an entity's establishment of intervals that are greater than those specified in the tables. For example, an entity may choose to establish, in its own PSMP, testing of a specific type or model of electromechanical relay more frequently than the six-calendar-year interval specified in Table 1-1 of PRC-005-2. However, should some issue come up that affects the entity's ability to complete testing of those devices within their programs established interval, but they are able complete the testing within the maximum maintenance interval provided by the standard, the standard explicitly establishes that they will not be found non-compliant for missing their own, more stringent interval.		
Xcel Energy	No	We agree with the changes to R3 and the new R4 requirement but disagree with the wording change in the new R5 requirement. The difference between "initiate resolution" and "demonstrate efforts to correct identified unresolved maintenance issues" is very unclear. Please clarify the SDT's intent with this subtle wording change. In our opinion, it would be fairly obvious if an entity met a requirement to "initiate resolution" and, thus, this would be easily measurable requirement. It seems that the phrase "demonstrate efforts to correct identified unresolved maintenance issues" will be open to more auditor judgment as to what constitutes adequate efforts to correct a deficiency and thus makes the measurement of meeting this requirement far more arbitrary. If this is not the intent, then why bother with the wording change? Furthermore, CEAs should realize that entities already have strong financial incentives in correcting identified unresolved maintenance issues to minimize the risk of costly equipment damage or equally costly outages of critical equipment. Delays in correcting identified

Organization	Yes or No	Question 2 Comment
		unresolved maintenance issues are seldom driven by cost avoidance and are more likely driven by the time it takes to develop, engineer and/or procure a better solution to a problem. Prompt band-aid type fixes are not necessarily desirable fixes and the wording of R5 should not promote the band-aid approach to the correction of a problem.
Response: Thank you for your comment and your support on Requirements R3 and R4. Requirement R5 is expressly focused on allowing entities to resolve deficiencies in an effective manner, rather than performing "band-aid" fixes. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval."		
ExxonMobil Research and Engineering	No	As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
EPRI	No	See comments in question 1
Constellation/Exelon	No	While we are fine with the structural change to separate the requirements out further, we have concerns with the content of the requirements. R5/M5 • M5 needs further clarity to reflect the intended compliance obligation for R5. In previous comments, Constellation expressed concern that compliance obligation for R5 implied a greater level of completion in attending to an identified "deficiency." We pointed out that the severity of the "deficiency" found will dictate the method and timing of a "follow up correction action". In response to the comment, the SDT stated that "PRC-005-2 only requires the entity "... initiate resolution" of the issue found." The SDT revision of R5 and M5 is an improvement; however, changes to M5 are needs to clarify that efforts to correct do not require demonstration that those efforts have concluded. • A revision to the language will clarify the SDT intent. Please consider use of the following language: R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall correct or initiate resolution of identified Unresolved Maintenance Issues. [Violation Risk Factor: Medium] [Time Horizon: Operations Planning] M5. Each Transmission

Organization	Yes or No	Question 2 Comment
		Owner, Generator Owner, and Distribution Provider shall have evidence that it has initiated resolution of, or corrected, identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence for initiated resolution may include but is not limited to work orders for future resolution, project schedules for future resolution, or other documentation of future plans. The evidence for corrected Unresolved Maintenance Issues may include but is not limited to replacement Component orders, invoices, return material authorizations (RMAs) or purchase orders.
Response: Thank you for your comment. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. Measure M5 has been modified to include "project schedules with completed milestones."		
Northeast Power Coordinating Council	Yes	
DTE Energy	Yes	
MRO NSRF	Yes	
Tacoma Public Utilities	Yes	
Dominion	Yes	1. Dominion understands R3 to mean that the time-based maintenance interval can be less that but not exceed the maximum maintenance intervals in the tables. But that compliance will be based upon the maximum interval. Please confirm that our understanding is correct. 2. Dominion believes the intent of the footnote in Table 1-1 is to 'start the interval' on either the 1st day of a calendar year or calendar month. We also believe this will require any entity whose current intervals are based on annual or monthly will have to adjust their intervals to calendar as they

Organization	Yes or No	Question 2 Comment
		transition to PRC-005-2. Please confirm our understanding is correct. 3. We also believe this transition could result in the compliance interval measurement being shorter or longer than it would have been if PRC-005-2 had not been approved. If this is incorrect, please provide examples to provide clarity.
Response: Thank you for your comment. 1. Yes, your understanding of Requirement R3 is correct. 2. No, your understanding of Footnote 1 at the bottom of the page where Table 1-1 appears in the standard is not correct. The intent of Footnote 1 is to clarify, or define the terms “calendar year” and “calendar month” as they relate to the period in which the next maintenance activity for a particular interval must occur. For example, if an entity performed electromechanical relay testing at Substation A in April of 2010, in accordance with the maximum maintenance interval of six-calendar-years established in Table 1-1, the entity must perform the next round of electromechanical relay testing at Substation A sometime during the calendar-year period beginning January 1, 2016. Please see Section 7.1 of the Supplementary Reference and FAQ document for a more detailed discussion of this issue. 3. If an entity’s maintenance program specifies a maintenance activity occur “30 days” from the previous activity’s performance, it would be possible that a transition to a “calendar month” interval would allow the first performance of the activity after the transition to occur sooner or later than the 30 days previously specified. However, many existing maintenance programs that establish performance of an activity “annually” or “monthly” should not require more than adjusting the language in the program. For instance, if an entity’s current program is to inspect substations “monthly,” they are likely performing those inspections sometime during each calendar month. This practice would be no different with the interval redefined as: “once each calendar month.”		
PNGC Comment Group	Yes	The PNGC comment group agrees with this change. Removing the jeopardy associated with more stringent intervals will make it less risky for entities to tighten intervals in their PSMP.
Response: Thank you for your comment and support.		

Organization	Yes or No	Question 2 Comment
ACES Power Marketing Standards Collaborators	Yes	1. We agree the changes will benefit reliability by allowing a registered entity to have shorter maintenance cycles without the potential for compliance violations associated with missing their shorter maintenance cycle. 2. Requirement R5 should be modified to focus on what is to be accomplished. As it is written now, the requirement is essentially focused on compliance by using “shall demonstrate efforts”. Compliance is about demonstrating or presenting evidence that the requirement has been met. The purpose of the requirement is to correct Unresolved Maintenance issues. We suggest changing the wording to: “shall initiate resolution of Unresolved Maintenance Issues.”
Response: 1. Thank you for your comment and support of this change. **2.** Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “unresolved maintenance issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”		
Liberty Electric Power LLC	Yes	Thank you for the change in Requirement 3. This standard now gives clear direction to entities, removes the burden of "created paperwork" intended only for the use of auditors, and removes the compliance jeopardy for holding a program to a higher standard than required.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comment and support.		
TransAlta Centralia Generation LLC	Yes	More detail explanation or examples of Efforts on R5 is required
Response: Thank you for your comment. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "unresolved maintenance issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." See the Supplementary Reference and FAQ document Section 4.1 for additional discussion.		
Central Lincoln		1. We thank the SDT for removing the extra compliance jeopardy associated with stringent intervals. The extra jeopardy never made sense to us, since it could result in sanctions to one entity and no sanctions to another entity when both followed the same interval with no BES risk presented by either. 2. We are concerned regarding the language of R5. We understand that maintenance without resolution is worthless, but the language here is subjective allowing different auditors to reach differing conclusions whether a sufficiently documented effort has been made. We also note that entities are expected to be continually in compliance with applicable standards, and are expected to self report when they are not. Strictly interpreted, an entity is out of compliance with R5 if there is any time lag between the moment the problem is identified in the field and documentation is produced of an effort taken to resolve it. We suggest the inclusion of a reasonable time limit.

Organization	Yes or No	Question 2 Comment
Response: 1. Thank you for your comment and support. 2. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval," which allows the entity until the end of the maintenance interval to develop an approach for correcting the problem. See the Supplementary Reference and FAQ document Section 4.1 for additional discussion.

3. **The Supplemental Reference and FAQ document was revised to reflect changes made to the draft standard and to address additional issues raised. Do you agree with the changes? If you do not agree, please provide specific suggestions for improvement.**

Summary Consideration: Several comments were submitted that were unrelated to this question.

Many commenters offered questions and suggestions related to the content of the Supplementary Reference and FAQ document, which resulted in assorted changes throughout the document.

Organization	Yes or No	Question 3 Comment
Fort Pierce Utilities Authority	Negative	1. The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).” Most network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters

Organization	Yes or No	Question 3 Comment
		worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. FPUA recommends the SDT should adopt the FERC approved interpretation. 2. Another concern is regarding the sudden pressure relays. These had been out of the scope in all previous draft versions of PRC-005-2 because these do not measure electrical quantities. However, the SDT just added a requirement to test the trip path from the sudden pressure device, arguing that it is captured by the definition of Protection Systems. This inconsistency does not make sense and could create “grey areas” for other devices that can trip for low oil level or high temperature, among others. By their nature, sudden pressure devices are far less reliable than their associated control circuitry. I know of at least one large entity that disables sudden pressure relays on smaller transformers to cut down on nuisance alarms. If it is expected that non-electrically initiated devices may become part of some maintenance standard in the future, I think it would be premature for the SDT to address sudden pressure relays in PRC-005-2. 3. And lastly, page 77 of the Supplementary Reference has some text clarifying the requirement for establishing a baseline test: “For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above

Organization	Yes or No	Question 3 Comment
		should be followed at the time of installation to insure the most accurate trending of the cell/unit." This guidance does not recognize the fact that some battery manufacturers recommend the baseline tests to be performed at some point in time after the install to allow the cell chemistry to stabilize after the initial freshening charge. The manual from a battery manufacturer (Enersys Powersafe) states that "The initial records are those readings taken after the battery has been in regular float service for 3 months (90 days). These should include the battery terminal float voltage and specific gravity reading of each cell corrected to 77F (25C), all cell voltages, the electrolyte level, temperature of one cell on each row of each rack, and cell-to-cell and terminal connection detail resistance readings. It is important that these readings be retained for future comparison". If an entity follows the manufacturer's recommendation, the above statements would lead an auditor to a finding of non-compliance because internal ohmic tests were not performed prior to placing a new battery string in service. A simple modification to the wording would eliminate the conflict.

Response: Thank you for your comments.

1. **The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.**

   To address your concern, the distribution protective devices and functions provided as examples in this comment, as pointed out by the commenter, are not "installed for the purpose of detecting Faults on BES Elements," and would, therefore, not be subject to PRC-005-2. A relay used primarily for "safety and distribution voltage control reasons" is clearly not "installed for the purpose of detecting Faults on BES Elements." The reverse power relay application described is also not "installed for

Organization	Yes or No	Question 3 Comment
		the purpose of detecting Faults on BES Elements" (the relays react to changes in power flow direction, which may or may not be due to a Fault), but for the purpose of preventing feedback from the distribution system to the transmission system. Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue. 2. **DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the "Control circuitry" portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. Activities associated with the schedule submitted in the filing will be included in a final SAR to further develop PRC-005. A draft SAR has been posted on the project page for information only.** 3. **The Drafting Team has revised the Supplemental Reference and FAQ document based on your recommendations.**
DTE Energy	No	
MRO NSRF	No	1. Section 5.1 (second paragraph, under the first bullet) states: "TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components." If this "actual event" can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. 2. Section 2.4.1 - Sudden Pressure Relays - This question should be clarified that circuits from only EHV transformers should be considered in scope. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical.

Organization	Yes or No	Question 3 Comment
		3. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.
Response: Thank you for your comments. 1. **Measure M3 lists possible types of evidence, and states, "is not limited to." Therefore, in-service operations can be provided as evidence.** 2. **This standard applies to the BES and certain transformers less than 345kV are, therefore, included.** 3. **Table 5 Component Type states, "Control Circuitry associated with protective functions…" and, therefore, the circuits you reference are not included.**		
FirstEnergy	No	Please see our comments and suggested changes to the Supplemental Reference and FAQ document in Question 4.
Western Area Power Administration	No	Western Area Power Administration does not agree that the trip path from a sudden pressure device is a part of the protection system control circuitry as stated in the revised Supplementary document. FAQ should be used as guidance and not for compliance.
Response: Thank you for your comment. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1B, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff. The Supplementary Reference and FAQ document provides supporting discussion, but is not part of the Standard. The SDT intends that it be posted as a Reference Document, accompanying the standard. As established in SDT Guidelines, the standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and FAQ document.		
Nebraska Public Power District	No	1. Section D 1.3 Evidence Retention - Do not agree with requirement to keep the two most recent performances of each distinct maintenance activity. Should

Organization	Yes or No	Question 3 Comment
		not require records previous to last audit. What is the point of keeping records up to twenty years? 2. FAQ page 7 and 77 now include discussion about how sudden pressure relays are "presently" excluded because they do not meet the definition of a protection system and a method of component verification does not exist. This part I agree with. The problem is that they go on to explain that the DC control circuitry from the Sudden Pressure relay is part of a protection system. This I disagree with. It's clear that the Standards Drafting Team is attempting a compromise to address direction from FERC Docket No. RM10-5-000. This approach however, sets a bad precedence. A trip path from a non-protection system component should not be classified as a protection system trip path. 3. The removal of grace periods and the comments in the FAQ that it will be up to the Auditor to determine if a test was not done due to extraordinary circumstances (example: Communications can't be tested due to the line out from a storm and under repair) is not acceptable. The SDT needs to come up with guidelines for these situations and not leave it up to each auditor to determine what is acceptable.
Response: Thank you for your comments. 1. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities. 2. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing		

Organization	Yes or No	Question 3 Comment
elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff. 3. FERC Order 693 directs NERC to establish maximum allowable intervals. Grace periods would not satisfy this directive.		
PPL Supply NERC Registered Organizations	No	We recommend that the final sentence of M3 and M4 be changed to, "Any of the following constitutes sufficient evidence: dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, dated work orders, or other equivalent documentation," and that the slightly different final sentence of M5 be similarly changed.
Response: Thank you for your comment. The SDT believes the measures should not mandate evidence, but provide examples of evidence.		
MRO NSRF	No	1. Section 5.1 (second paragraph, under the first bullet) states: "TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components." If this "actual event" can be used as proof that the Protection System operated correctly, then this should be added to M3 in the Measures section of PRC-005-2. 2. Section 2.4.1 - Sudden Pressure Relays - This question should be clarified that circuits from only EHV transformers should be considered in scope. 3. As highlighted by the NERC GMD reports EHV transformers (345, 500 & 765 kV) are critical. In addition, circuits that do not actually trip a breaker (panel lights, alarms, etc.) should not be included in the scope of components included in the maintenance and testing program.

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. 1. Measure M3 lists possible types of evidence and states "is not limited to." Therefore, 'in-service' operations can be provided as evidence. 2. This standard applies to the BES and certain transformers less than 345kV are, therefore, included. 3. Table 5 Component Type states, "Control Circuitry associated with protective functions…" and, therefore, the circuits you reference are not included.		
Arizona Public Service Company	No	Either the FAQ or the Standard should define the bases for each interval mandated. See the response to question 2 for further details.
Response: Please see the Technical Justification document associated with Project 2007-17. Please also see Section 8.3 of the Supplementary Reference and FAQ document.		
Ingleside Cogeneration LP	No	We do not agree with the assertion in the reference and FAQs that the DC supply and control circuitry for mechanical components are part of a BES Protection System. This is not an accepted norm in the existing Standard as the Project Team claims - only an expansion in scope that was not properly vetted by the industry. If the Compliance Authorities believe that electrical components which support mechanical systems are rightfully part of the BES or BPS, then this has implications far beyond Protection System maintenance. The appropriate place to begin this determination is with Project 2010-17 Definition of the BES - where it can be fully reviewed by all affected industry stakeholders.
Response: Thank you for your comment. The trip path from a sudden pressure device is a part of the Protection System control circuitry. Sudden pressure relays, as opposed to other types of mechanical components, are installed to detect an electrical **fault** condition inside a transformer. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.		

Organization	Yes or No	Question 3 Comment
American Electric Power	No	Though the guidance provided in these documents may appear to be beneficial, we are troubled that despite the time spent on them by the drafting team, and the voluminous nature of the references, that the information contained in them essentially fades away upon approval of the standard. Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might help prevent the need for future CANs and interpretation requests.
Response: Thank you for your comments. The Supplementary Reference and FAQ document provides supporting discussion, but is not part of the standard. The SDT intends that it be posted as a **Reference Document** accompanying the standard. As established in SDT Guidelines, the standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and FAQ document. The Supplementary Reference will be revised in the course of the revision process of the standard.		
Westar Energy	No	1. We believe all of the 4 month intervals can be changed to 6 month intervals and still ensure reliability. It is unclear which equipment Table 1-4(d) applies to. 2. In the heading it says “Excluding distributed UFLS and distributed UVLS”, then the line below that says “non-distributed UFLS system, or non-distributed UVLS systems is excluded”.
Response: Thank you for your comments. 1. The activity related to this interval is to verify various basic operating parameters. The SDT believes that extension of verification of these parameters beyond the interval within the standard is inappropriate. 2. These are addressing two different items; the first addresses distributed UFLS/UVLS, whether tripping at BES levels or not, and the second addresses non-distributed UFLS/UFLS/SPS that trips only non-BES interrupting devices.		
Ameren	No	We agree with the intent of the Supplement changes but believe that they are either incomplete or need clarification. Therefore, we provide the specifics as

Organization	Yes or No	Question 3 Comment
		follow : (a) Page 93, Revise Section 15.7 Distributed UFLS (i) Change Table 1-2 to 1-3.(ii) Include 'Verify operation...and/or auxiliary tripping device' to agree with Table 3. (b) Please identify BES Elements in Supplementary Reference Figure 2. (c) Remove 'Reverse power relays' from the bulleted list on the top section of page 33. They provide thermal of the steam turbine, and they may protect CTG speed reduction gear teeth, but neither of these are electrical protection of the generator. (d) Please add Interval FAQ to address a component minimum maintenance activity that is not in the present PRC-005-1 program. (i) : "How is interval proven for a component minimum maintenance activity that is not in the present PRC-005-1 program? For example, suppose the present program continuously monitors a communication system, say audio tones, and personnel respond to alarms; this approach presently have basis that is sufficient. (ii) Table 1-2 requires two maintenance activities every 12 calendar years: 1) verify channel meets performance criteria; and 2) verify essential I/O. The entity is required to perform these minimum maintenance activities one time in the first 13 years after regulatory approval. The 12 year interval is proven by the date of the PRC-005-2 maintenance activity and the date of your PRC-005-1 program applicable for the previous maintenance. After the second time the PRC-005-2 maintenance activity is performed, appropriately sometime in year 14 to 25 after regulatory approval, then interval will be proven by the dates of the two PRC-005-2 maintenance activities." (e) Page 17 We disagree with retention of maintenance records for replaced equipment as this can cause confusion. At most the last maintenance date could be retained to prove interval between it and the test date of the replacement

Organization	Yes or No	Question 3 Comment
		equipment that provides like-kind protection. (f)Page 36, FAQ 'initial date for maintenance' answer is inconsistent with CAN-0011. Though the CAN applies to PRC-005-1, it should be consistent with NERC's position on this. (g) Page 71, Please remove 'The trip path from a sudden pressure device is a part of the Protection System control circuitry...' because the actuating relay does not respond to electrical quantities. This is just one example of the many gotcha's that will no doubt arise in enforcement. (h) If a capacitor trip device is an example of a non-battery based station DC supply, then please provide a FAQ to convey it.

Response: Thank you for your comments.

a. The SDT modified the Supplementary Reference and FAQ document, as suggested.

b. The applicable facilities for a generator are listed in Section 4.2.5 of the standard. Figure 2 is a visual representation of this.

c. Reverse power relays, as discussed in your comment, do not detect Faults; but if they can trip the generator, they must be maintained per 4.2.5.

d. This issue is addressed in the Implementation Plan for Project 2007-17.

e. The records for removed/replaced equipment need to be retained to provide documentation that you were in compliance for the entire compliance monitoring period.

f. The SDT has provided guidance as it relates to PRC-005-2.

g. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b, consistent with the SAR for Project 2007-17, and understands this to be consistent with the position of FERC staff.

Organization	Yes or No	Question 3 Comment
h. If the “capacitor trip device” you reference is the stored energy device for the breaker, it would not be included in Table 1-4(d).		
Central Lincoln	No	The Supplemental Reference and FAQ apparently has not kept up with definition changes and uses uncapitalized “component” “Protection System components”. Please use capitals if defined terms are intended.
Response: Thank you for your comment. The SDT modified the Supplementary Reference and FAQ document as suggested.		
BAE Batteries USA	No	Page 20 states that every 18 months "battery ohmic values to station battery baseline (if performance tests are not opted)" should be changed to add comment that ohmic values, while permissible as a tool, should not be taken to validate the actual capacity, thus the reliability of the battery. If capacity is an issue due to questionable ohmic values shown, a decision must be made to [1] perform a capacity test following one of the three methodologies recorded in IEEE 450 or IEEE 1188; [2] make a decision to replace the battery string depending upon the number of cells with questionable ohmic values shown, the age of the battery string, and the critical nature of the station in question; or [3] accept the risk that the battery may or may not perform as intended due to the lack of a true knowledge of the battery capacity (See IEEE Letter to Al McMeekin). Every 18 calendar months verify/inspect the following: "Cell Condition of all individual battery cells (where visible) should add "or as frequently as recommended in the battery manufacturer's operating instructions."Every 6 years: perform or verify the following:"Battery Performance Test (if internal ohmic tests are not opted)" should be changed to read "Battery Performance Test (if ohmic tests are not conducted or if ohmic test values show that a degraded situation with the cells call into question whether the battery will perform to "design requirements."this should be repeated where referenced in additional examples (VLA, VRLA, Ni-Cd)
Response: Thank you for your comment. The drafting team agrees with your statement, and those of others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ document has been modified to further elaborate on these concerns.		
ExxonMobil Research and	No	: As written, the current draft of PRC-005-2 discriminates against smaller entities

Organization	Yes or No	Question 3 Comment
Engineering		that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
TransAlta Centralia Generation LLC	Yes	More detail explanation on Segment is required; the reason of sixty (60) individual components is required for one Segment. More detail explanation on Countable Event is required.
Response: Thank you for your comments. The SDT believes that Segment and Countable Events are clearly stated in the standard. Decreasing the component population below the requirements of Attachment A will result in an unsound program due to component populations that are not statistically significant.		
City of Austin dba Austin Energy	Yes	The effort expended by the SDT in creating and revising the content of the

Organization	Yes or No	Question 3 Comment
		Supplemental Reference and FAQ is admirable and most appreciated. The guide is a useful reference.
Response: Thank you for your comment and support.		
Los Angeles Department of Water and Power	Yes	LADWP notices that the terms "Unresolved Maintenance Issue" and "maintenance-correctable issue" are used in several places. We recognize that "Unresolved Maintenance Issue" is defined as a deficiency identified during a maintenance activity that causes the component to not meet the intended performance and requires follow-up corrective action. Please define "maintenance-correctable issue" and clarify the differences between the two terms.
Response: Thank you for your comments. "Unresolved Maintenance Issue" replaced the term "maintenance-correctable issue," and the SDT corrected the Supplementary Reference and FAQ document to reflect the change.		
Progress Energy		1. Table 3, Row 7: The requirement to "Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices" contradicts Section 15.7, bullet 2 of the Supplementary Reference and FAQ document. In the supplementary reference, the phrase "and/or auxiliary tripping device(s)" has been struck out.
Response: Thank you for your comments. The Supplementary Reference and FAQ document has been modified per your suggestion.

4. If you have any other comments on this Standard that you <u>have not already provided in response to the prior questions</u>, please provide them here.

Summary Consideration: Several comments were repeated from Questions 1, 2, or 3, and the summary consideration responses are not repeated here.

Numerous commenters suggested minor changes to the definition of the terms "inspect" and "Countable Event." In response, the SDT modified the description of the term, "inspect" within the definition of PSMP. Previously "inspect" was "Examine for signs of component failure, reduced performance or degradation." now "inspect" is "Examine for signs of component failure, reduced performance or degradation." The SDT also modified the definition of Countable Event from "A Component which has failed and requires repair or replacement…" to "A failure of a Component requiring repair or replacement …"

The SDT continued to receive comments regarding the Applicability of the standard. The SDT modified the Applicability Clause 4.2.5.4 to read: "Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."

Some commenters questioned the last line in Table 1-2 for Communications Systems. The SDT realized they had several errors in the table – one omitted element and one incorrect interval. The table was corrected.

Several comments were offered regarding the station battery activities in Tables 1-4 (a-f). Representatives of the IEEE Stationary Battery Committee assisted the SDT in making revisions to these tables to address concerns related to ohmic testing of the cell/units.

Several commenters questioned elements of the criteria in Attachment A for performance-based maintenance; the SDT explained the rationale for these criteria, including, where appropriate, the related statistical basis.

Several comments pointed out inconsistencies between the Standard and Supplementary Reference and FAQ. The SDT modified the Standard and Supplementary Reference and FAQ to address these inconsistencies.

A few commenters questioned portions of the standard, or suggested changes that the SDT chose not to adopt. The SDT responded with their rationale. These comments included:

- **NERC should provide a format for test reports, etc.**
- **Include batteries within a performance-based PSMP**
- **Objections to the inclusion of distribution devices that are installed for the benefit of the BES**

- **VSLs permitting entities to experience some small level of non-performance relative to the standard without incurring a violation**
- **VSLs set at inappropriate levels**
- **The inclusion of the control circuitry related to sudden pressure relays, even though sudden pressure relays themselves are not included**
- **Various facets of control circuitry maintenance**
- **Specific intervals or activities within the tables**
- **Evidence retention language**
- **Intervals for lockout relays**
- **Voltage and current sensing devices**

Organization	Yes or No	Question 4 Comment
Northern Indiana Public Service Co.	Negative	A format for maintenance reports and specific test requirements for relays are missing.
Response: Thank you for your comments. The SDT does not believe it is necessary or appropriate to prescribe a specific format for maintenance results or test requirements.		
James A Maenner	Negative	As written, the standard may require DPs to include distribution protection devices designed to isolate and protect distribution facilities from faults on monitored transmission or other BES facilities. Qualifying language should be added differentiate protective systems which control BES and distribution facilities for faults on the BES.
Response: Thank you for your comments. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements, even if they are installed on distribution facilities. UFLS and UVLS devices which are commonly installed on distribution facilities for the purposes of addressing related NERC Standards are included. Protection Systems installed on distribution facilities for the purposes of detecting Faults on distribution facilities are not included.		
SERC Reliability Corporation	Negative	FERC Order 758 includes directives that affect this project. I understand that the

Organization	Yes or No	Question 4 Comment
		SPCS/SAMS group is looking at the technical documents to support additional standards activity but as this project is presented, it does not meet the FERC directives. Otherwise, I could vote affirmatively, but I do have some concerns about how clearly and unambiguously the standards requirements are written. This standard should be a candidate for the RSAW initiative being developed by the Standards Committee.
Response: Thank you for your comments. The Standards Committee has directed the PSMTSDT to finalize PRC-005-2 and present it to the NERC Board of Trustees for adoption, and concurrent with this posting of PRC-005-2 to post for information a draft SAR for a second phase of Project 2007-17 addressing further modifications to PRC-005-2. FERC Order 758 includes directives associated with Maintenance and Testing of Auxiliary and Non-Electrical Sensing Relays, Reclosing Relays, and DC Control Circuitry. Regarding these directives in relation to PRC-005-2: 1. Testing of Auxiliary and Non-Electrical Sensing Relays – The NERC System Protection and Control Subcommittee (SPCS) recently worked with NERC staff to develop an informational filing in response to Order 758. Activities associated with the schedule submitted in the filing will be included in a final SAR to establish a future phase of Project 2007-17 for future development of PRC-005. A draft SAR is posted on the project page for information only. 2. Reclosing relays will be addressed in a second phase of this project, which will produce PRC-005-3. Development of that revision will begin after PRC-005-2 is completed and the NERC SPCS completes the technical documentation regarding reclosing relays. 3. DC Control Circuitry and Components – This draft standard PRC-005-2 includes extensive, specific maintenance activities (with maximum maintenance intervals) related to the DC control circuits.		
Southwest Transmission Cooperative, Inc.	Negative	1. For the Requirement R1's High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. 2. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.
Response: Thank you for your comments.		

Organization	Yes or No	Question 4 Comment
1. The SDT has corrected the Requirement R1 VSL, as you suggest. 2. The SDT believes that missing three components is considered a "significant percentage," and is in accordance with the VSL guidelines.		
Midwest ISO, Inc.	Negative	In the VSL for Table 4 it seems that the phrase "5% or less" should be "not more than 5%". With the original language it seems like an entity could be found to have an R4 lower VSL violation for "failure" of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive.
Response: Thank you for your comments. The VSL Guidelines, developed in accordance with FERC's VSL Order, establish the Lower VSL for stepped VSLs as "5% or less," the Medium VSL as "more than 5% but less than (or equal to) 10%," the High VSL as "more than 10% up to (and including) 15%," and the Severe VSL as "more than 15%."

Occidental Chemical	Negative	See comments submitted by Ingleside Cogeneration LP
Dairyland Power Coop.	Negative	See MRO NSRF comments.
U.S. Army Corps of Engineers	Negative	See MRO/NSRF comments
Dairyland Power Coop.	Negative	See NSRF comments.
Beaches Energy Services	Negative	The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The

Organization	Yes or No	Question 4 Comment
		interpretation states: The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)” Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.

Response: Thank you for your comments.

The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection **System**,” and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements.

To address your concern, the distribution protective devices and functions cited in this comment are not “installed for the purpose of detecting Faults on BES Elements,” and would, therefore, not be subject to PRC-005-2. A relay used primarily for “safety and distribution voltage control reasons” is clearly not “installed for the purpose of detecting Faults on BES Elements.” The reverse

Organization	Yes or No	Question 4 Comment
power relay application described is also not "installed for the purpose of detecting Faults on BES Elements" (the relays react to changes in power flow direction, which may or may not be due to a Fault) but for the purpose of preventing feedback from the distribution system to the transmission system. Please see the PRC-005-2 Supplementary Reference and FAQ, Section 2.3, for a more detailed discussion of this issue.		
U.S. Bureau of Reclamation	Negative	1. The definition for PSMP is incongruous with the use of the PSMP in Requirement R1. Requirement R1, including the Measure and VSL focus on the identification of maintenance method of the Component types and not that the PSMP is in fact being used for maintenance of the component. 2. The requirement R5 indicates the entity has to "demonstrate" efforts to correct identified unresolved maintenance issues. The measure M5 described documentation of the efforts. The requirement language should be explicit. Does the standard want a demonstration which implies active role of the entity to prove what it is doing, or to provide documentation of the activities underway to correct deficiencies? The language in the requirement should be altered to "Each Transmission Owner, Generator Owner, and Distribution Provider shall prepare a CAP for each identified Unresolved Maintenance Issue." A second requirement is needed to require that "Each Transmission Owner, Generator Owner, and Distribution Provider shall complete its CAP to correct the identified Unresolved Maintenance Issues." The measures would need to be adjusted accordingly to reflect the CAP and evidence that the entity completed the CAP. 3. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 4. Re The definition of Components: The standard defined what constitutes a

Organization	Yes or No	Question 4 Comment
		control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: Thank you for your comments. 1. The SDT believes that the definition of a PSMP is linked to Requirement R1 in that the entity's program shall include one or all of the parameters in the definition. Requirement R1 requires that the entity establish their program and is the foundation for the standard. Requirements R3-R4 address implementation of the entity's PSMP. 2. The term within Requirement R5, "… demonstrate efforts …" is intended for both – that the entities are acting to correct the deficiency and also (to prove compliance) maintaining documentation of the activities underway to correct the deficiency. The SDT elected to not require a "Corrective Action Plan," as defined in the NERC Glossary of Terms, to avoid much of the systemic, ongoing documentation attendant to that term. However, if an entity wishes to use a Corrective Action Plan as defined, that would be an acceptable method of meeting Requirement R5. 3. The standard specifies that the terms used are intended for this document only; and, therefore, there should not be any conflict with their use in any other PRC standard. 4. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing of these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
Independent Electricity System Operator	Negative	The IESO continues to disagree with the VRF assigned to the new Requirements R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The SDT team disagrees and believes the failure to implement a PSMP should be assigned a VRF of High.		
Illinois Municipal Electric Agency	Negative	The inconsistency between the proposed Protection System language in the Applicability section of PRC-005-2 and the transmission Protection System interpretation recently approved by FERC (PRC-005-1b Appendix 1) needs to be resolved.
Response: The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting Faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference Document for additional discussion.		
Central Lincoln PUD	Negative	The percentage based VSL unreasonably penalizes smaller entities, since one Component can cause them to hit the 10% cutoff for a High VSL while a large entity may miss 100s of components without exceeding the Lower VSL.
Response: Thank you for your comments. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.		
JEA	Negative	This standard greatly expands the scope of work that will be required of JEA without providing a corresponding incremental increase in reliability and may in fact cause reliability issues. Specific concerns are that JEA believes that we do continuous monitoring of a vast majority of our components and our approach has demonstrated its effectiveness but the revised standard will most likely require JEA to have to adopt a new approach with significant increases in manpower hours. Additionally, testing lockouts is of great concern because of its ability to cause reliability issues.
Response: Thank you for your comments. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. If your components are monitored according to the attributes specified in Table 1-1 through 1-5, you may be able to utilize the extended intervals/minimized		

Organization	Yes or No	Question 4 Comment
activities associated with those monitoring attributes within the tables. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same six-year interval required for electromechanical relays. The SDT recognizes the risk of 'human error' trips when testing lockout devices, but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond six years.		
City and County of San Francisco	Negative	VSL's are based upon Failure to Maintain Percentages for "a specific Protection System component type". VSL's should be based upon Failure to Maintain Percentages for total number of Protection System components, and not give greater weight in the VSL determination, to component types with few elements, like station batteries.
Response: Thank you for your comments. The SDT believes that these VSLs should address failures to maintain percentages of each Component Type. Failure to maintain quantities of low-population Component Types, such as station batteries, may have serious consequences for BES reliability, and the SDT believes that these must not be masked by larger populations of other Component Types, such as protective relays.		
Gainesville Regional Utilities	Negative	We support FMPA's position on this matter.
Response: Thank you for your comments. Please see our response to FMPA's comments.

Southwest Transmission Cooperative, Inc.	Affirmative	1. The first part of definition of a Countable Event should be modified as follows: “The failure of a Component such that it requires repair or replacement...”. As it is currently word, it is technically counting the Component as the Countable Event and not the failure of the component. Considering that the other two items that are Countable Events are conditions and misoperations, it seems appropriate to

Organization	Yes or No	Question 4 Comment
		make failure the Countable Event. 2. Application of this standard to UFLS is problematic as worded in Section 4.2.2. The UFLS are only applicable if “installed per ERO underfrequency load-shedding requirements”. Technically, no UFLS fits this description because there are no ERO requirements to have a UFLS. PRC-006-0 was never approved by the Commission and is not enforceable. The Commission considered it a “fill-in-the-blank” standard. While PRC-006-1 corrects the “fill-in-the-blank” issues and was approved by the NERC BOT November 4, 2010, the Commission has yet to act on it. 3. The data retention requirement for the Protection System Maintenance Program documentation seems excessive. The Data Retention section states that all versions since the last compliance audit must be maintained. Since TOs, GOs, and DPs are all on six year audit cycles, this would require maintaining this documentation for six years. Is this really necessary? The length could become even greater once NERC implements registered entity assessments that could shorten or lengthen the periods between compliance audits. The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C - Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of “the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date”. While it may have been intended to apply to both clauses, the “since the previous schedule audit date”

Organization	Yes or No	Question 4 Comment
		only applies to the second clause. Since some of the maintenance activities have intervals of 12 years, this would require the registered entity to retain documentation for 24 years which cannot be audited since it is outside the audit window per the Rules of Procedures. At a minimum, we suggest clarifying that the documentation must not be maintained past the day after the last audit completion date. 4. In the fourth paragraph of the Data Retention section, Component is not used consistently. It is used in both singular and plural form. It seems like it should be one or the other. 5. Requirement R1 VSLs: For the High VSL, “entities’” should be “entity’s” to be consistent with the other VSLs. 6. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

Response: Thank you for your comments.

1. The SDT agrees with your comments on Countable Event, and has modified the definition of Countable Event to: “A failure of a Component requiring …”
2. Applicability Clause 4.2.2 applies to whatever ERO-required UFLS that may exist, either today or in the future. NERC Reliability Standard PRC-006-1 has now been approved by FERC.
3. The SDT believes that all versions of the entity’s PSMP should be retained for audit purposes. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation.
4. The SDT has corrected the fourth paragraph of the Evidence Retention section as you suggested.
5. The SDT has corrected the Requirement R1- High VSL, as you suggested.
6. The SDT believes that missing three components is considered a “significant percentage,” and is in accordance with the VSL

Organization	Yes or No	Question 4 Comment
Guidelines.		
Oncor Electric Delivery	Affirmative	The proposed consolidation of these standards (PRC-005-1, PRC-008-0, PRC-11-0 and PRC-017-0) provides more clarity and less room for varying interpretations for relay maintenance and testing.
Response: The SDT thanks you for your comment and affirmative vote.		
Southern Company Generation		For the 18 month / 6 year activities, it is technically incorrect to allow equivalency between internal ohmic measurements and performance testing. This view is not substantiated by industry experience, documentation, or standards. Additionally, it should be specified to the auditor that the intervals for the battery maintenance are relevant to the component, not the application. This means that if a battery is replaced just before a required 6 year performance test, the 6 year interval for the performance test is reset.
Response: Thank you for your comment. The drafting team agrees with your statement, and those of others concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ document will be modified to further elaborate on these concerns. The SDT agrees with your assessment that the maintenance activity is relevant to the component, not the application. Guidance to the auditors of this nature is beyond the ability of the SDT. See Section 4.1 of the Supplementary Reference and FAQ document for additional discussion on this topic.		
Ameren		(a) R3 & R4: Change VRF to “Medium” for the following reasons: (i) Consistency with existing standards that PRC-005-2 replaces. Per the VRF_Standards_Applicability_Matrix_2012-03-01, PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (ii) We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (iii) Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events are extremely rare. (iv) Either change VRF to

Organization	Yes or No	Question 4 Comment
		Medium, or double the percentage ranges applied to each component type across VSLs. We strongly believe that the SDT needs to retune these to match the experienced risk, which has been extremely low. (b) Measure M3 on page 6 should only apply to 99.5% of the components. Please revise to state: "Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated...." We believe that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. We are not asking for the VSL to be changed. The consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is "non-performance". (c) Measure M5 - add 'internal inventory / parts request, trouble investigation assignment, trouble repair report' as examples of an entity undertaking efforts with internal parts and/or labor resources. (d) Augment R3 and R4 VSL with a 'number based limit for populations up to 100 components' for comparable treatment of small entities. For example, for Lower VSL restate as '...the responsible entity failed to maintain from one to five Components if total Components is less than 100; or 5% or less of the total Components if total exceeds 99 included within a specific Protection System Component Type...'. Otherwise a small entity could unfairly incur a Severe violation for the same number of Components that a larger entity would incur a Lower VSL. (i) Similarly, Moderate numbers should be 6 to 10; High 11 to 15; and Severe 16 or more if the total Components of a certain Component Type that is less than 100. (e) Augment R5 VSL with percentage based limits for comparable treatment of larger entities. For example, for Lower VSL restate as 'The responsible entity failed to undertake efforts to correct 5 or less Unresolved Maintenance Issues if total of such issues in the audit period is less than 100; or 5% or less if total of such issues in the

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td>audit period exceeds 99.’ (i) Similarly, Moderate numbers should be >5% to 10%; High >10% to 15%; and Severe more than 15% if the total Unresolved Maintenance Issues in the audit period exceeds 99.
(f) Please number all pages of the standard. They are missing from pages with tables.
(g) Please add a title to the table following Table 3. Is it a continuation of Table 3?</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
a) The SDT disagrees, and believes a VRF of High is appropriate for Requirements R3 and R4.
b) NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.
c) The SDT agrees that the examples listed would constitute evidence of undertaking efforts to correct Unresolved Maintenance Issues; however, Measure M5, as written, includes the phrase, “… includes but is not limited to …” to emphasize that entities may use other evidence.
d) The SDT disagrees and believes a smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.
e) The SDT disagrees and believes the VSL’s for Unresolved Maintenance Issues should be a numeric quantity and not a percentage.
In response to each of the comments ‘a’ through ‘e’, the SDT recommends reviewing the “VRF/VSL Justification” that is posted with the standard. This document provides the SDT’s analysis of how the VRFs and VSLs meet FERC and NERC guidelines, as required for the standard to achieve regulatory approval.
f) The SDT numbered all the pages.
g) The SDT corrected the Table 3 header issue.</td></tr>
<tr><td>Sacramento Municipal Utility District</td><td></td><td>1) SMUD wishes to comment on the requirement to test the trip paths from relays that do not respond to electrical quantities. In two separate sections of the FAQ, the SDT included this new guidance on the trip paths. In section 2.4.1 of the FAQ, the SDT plainly asserts that the trip path from Sudden Pressure Relays (SPR) will now be covered and implies that the trip paths from non-electrically initiated devices might also be covered. In section 2.4.1, the SDT does not provide any guidance on how to determine which trip paths are included, but does provide guidance on how one might test the trip path. In section 15.3, the SDT finally provides the guidance -</td></tr>
</table>

Organization	Yes or No	Question 4 Comment
		control circuits (trip paths) are included if the relay is installed to detect faults on BES Elements. In reviewing the definition of Protection System, SMUD feels the "Control circuitry associated with protective functions..." to be in reference to the "Protective relays which respond to electrical quantities". The SDT is now applying a new interpretation in which each of the five bullets is considered separately. Furthermore, the SDT appears to be defining "...associated with protective functions..." to mean detecting faults on the BES. What basis can the SDT offer for defining this phrase to mean detecting faults on the BES? Since this same wording is not used in defining the relay, can a relay be covered under the standard, but not its control circuitry? For instance, Out of Step Tripping? Over Excitation? Frequency or Voltage Protection on a generator? These relays respond to electrical quantities, but are not applied to detect faults on BES Elements. SMUD believes this interpretation takes us down a very confusing path. SMUD respectively requests the SDT strike the new wording (as seen on the redlined version) in 2.4.1 and 15.3.

Response: Thank you for your comments.

1. DC trip circuit from a sudden pressure relay output to the trip coil of the interrupting device has always been included in the "Control circuitry" portion of a Protection System, and is discussed in Section 15.3 of the PRC-005-2 Supplementary Reference and FAQ document. In regards to including sudden pressure relays themselves, FERC, in Order 758, recently directed NERC to submit an informational filing providing a schedule for addressing sudden pressure relays in PRC-005. The NERC System Protection and Control Subcommittee (SPCS) worked with NERC staff to develop the informational filing, which was filed with FERC on April 12, 2012. The Standards Committee has directed the PSMTSDT to finalize PRC-005-2 and present it to the NERC Board of Trustees for adoption, and concurrent with this posting of PRC_005-2, to post for information a draft SAR for a second phase of Project 2007-17 addressing further modifications to PRC-005-2.

Activities associated with the schedule submitted in the filing will be included in the final SAR to further develop PRC-005. The SDT believes that Protection Systems that trip (or can trip) BES Elements due to a Fault should be included (in the case of a Sudden Pressure Scheme, the control circuitry and DC supply components would apply). The relays mentioned are already covered by the standard, in that they are "Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays."

Organization	Yes or No	Question 4 Comment
Tennessee Valley Authority		1. Regarding the functional test required every 3 months for "unmonitored communication systems" in Table 1-2 of the PRC-005-2 Draft. TVA feels that a Maximum Maintenance Interval for the Functional Test should be every 12 months until auto-checkback has been fully implemented by the utility. 2. The Implementation Plan for PRC-005-2 Step 4 on Page 2 states: "The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees adoption. This anticipates that it will take approximately twelve (12) months to achieve regulatory approvals following adoption by the NERC Board of Trustees." TVA feels that this is not sufficient time to implement full auto-checkback capability at some utilities. The time schedule of twelve (12) months should be forty-eight (48) months following applicable regulatory approvals. 3. TVA has many excitation transformers directly connected to the generator bus, configured such that a fault on the excitation transformer will cause a generator trip. Is the intent that the revised standard will include these transformers in the applicability? Would they be included by section 4.2.5.1? 4. TVA (Rusty Hardison) has forwarded a slide presentation with six questions to the PRC-005-2 Draft Team requesting consideration as input to the Frequently Asked Questions document accompanying the standard. Thank you for considering.

Response: Thank you for your comments.

1) The SDT believes the four month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status.

2) The Implementation Plan is intended to facilitate implementation of the standard, not to facilitate modifications to meet the requirements of the standard.

3) The SDT revised Applicability Clause 4.2.5.4 to include excitation transformers connected to the generator bus.

Organization	Yes or No	Question 4 Comment
4) The SDT modified the Supplementary Reference and FAQ document to address these questions.		
Tacoma Public Utilities		1. For components that are part of a time-based PSMP, if correction of Unresolved Maintenance Issues takes place before the maximum maintenance interval expires, is it mandatory to demonstrate (document) these efforts to correct identified Unresolved Maintenance Issues? Is the purpose of Requirement R5 only to avoid compliance jeopardy when an entity discovers a problem during maintenance but cannot correct the problem until after the maximum maintenance interval has expired (as discussed in the Supplemental Reference and FAQ document)? Or, is the purpose also to ensure that all Unresolved Maintenance Issues are documented even if they corrected very quickly and within the maximum maintenance intervals and just considered part of routine maintenance (i.e., Unresolved Maintenance Issues not explicitly documented) in a manner similar to recalibrating a relay? 2. Assume that a component under a time-based PSMP is not considered “monitored” per the PSMP, but in actuality it is. If an alarm comes in, indicating a component problem, would the entity have any additional documentation obligations under PRC-005-2 associated with this alarm, provided that all minimum maintenance activities and maximum maintenance intervals associated with the unmonitored component are satisfied? The concern is that, if there are additional documentation obligations; then many entities may disable monitoring in some cases in order to avoid compliance jeopardy. 3. Assume that an entity treats batteries at certain remote communication sites as if they were applicable to PRC-005-2. These sites are not substations or generating facilities but support the broad communication system, including teleprotection functions. Furthermore, these sites have limited access during some times of the year because of heavy snow or ice. It is conceivable that it may not be possible to meet all minimum maintenance activities or all maximum maintenance intervals (4 and 6 calendar months) unless the site is extensively monitored and/or field personnel expose themselves to hazard. Would any allowances be made in these cases? Would

Organization	Yes or No	Question 4 Comment
		these sites even be applicable to PRC-005-2, since they are not part of a "station" DC supply? 4. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. 5. In the Implementation Plan for Requirements R1, R2, and R5, why there is a requirement to "be 100% compliant [with R5] on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals"? The emphasis of this question is on Requirement R5, which pertains to Unresolved Maintenance Issues. 6. In the Implementation Plan for R3 and R4, to be considered "100% compliant with PRC-005-2," is it only necessary to have completed the applicable minimum maintenance activities one time for the applicable component (which is our assumption)? Or, does being considered 100% compliant under this Implementation Plan imply that two instances of the applicable minimum maintenance activities must have been completed for the applicable component?

Response: Thank you for your comments.

1. The definition of Unresolved Maintenance issue has been revised to specify that it applies to deficiencies that "…cannot be corrected during the maintenance interval..."
2. The SDT believes that as long as all minimum maintenance activities and maximum maintenance intervals associated with a component are completed and documented, no additional documentation obligations are necessary.
3. The SDT does not believe that the scope of the standard refers to communication sites. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays

Organization	Yes or No	Question 4 Comment
to alarm at the substation. At this point, the corrective actions can be initiated. 4. The SDT believes that every trip path from relay to trip coil must be verified. If a trip coil has multiple trip paths, verifying DC voltage at the actuating device would not accomplish the maintenance activity identified in Table 1-5 for unmonitored control circuitry. 5. The SDT believes that the entity be 100% compliant with Requirement R5 on the first day of the first calendar quarter because an Unresolved Maintenance Issue could arise during the first calendar quarter. 6. The Implementation Plan addresses the initial performance of the required activity within the required intervals. The entity should expect to comply with PRC-005-1B until they fully implement PRC-005-2.		
Texas Reliability Entity		1. The Implementation Plan is still overly long and complicated. Registered Entities and Regional Entities will have to track and apply multiple versions of this standard for up to 14 years. It would be preferable to have a much shorter implementation plan, so that only one version of the standard will be applicable at any given time, recognizing that for some Components no action will be required under the standard for a number of years. 2. Referring to R3, R4 and M1 (and other places), it is redundant to add "Protection System" to describe "Components "or "Component Types" based on the "local definitions" provided. Alternatively, the defined term could be changed to "Protection System Component" and used consistently. 3. In Table 1-3, the activity should include verifying that the current and voltage signal values are within tolerances, not just that signal values are present. The minimum activity should include a ratio check and/or burden check of current transformers. Suggest revising to state "Verify that current and/or voltage signal values provided to the protective relays are within the accuracy tolerance of the voltage and current sensing device". 4. In the VSL for R2, we are assuming that the "4% within three years" is a 4% failure rate based on Attachment A, but that is unclear. We suggest clarifying this language

Organization	Yes or No	Question 4 Comment
		to match Attachment A language. 5. What is the basis for the 4% failure rate limit in Attachment A? It would appear that a 4% failure rate is high for protective relays. Does the SDT have a technical justification supporting the selection of 4% as the applicable limit? 6. In Attachment A, item 4 in the "maintain the technical justification" section needs clarification. It can be assumed that the phrase "for the greater of either the last 30 Components maintained or all Components maintained in the previous year" is referring to Components within a specific Segment, but more specific language may be needed. Also, are the references to "prior year" and "previous year" intended to refer to calendar years or 365 days preceding the analysis? 7. In Attachment A, item 5 in the "maintain the technical justification" section needs clarification. We suggest adding a timeframe for the "experience 4% or more Countable Events" phrase. Does this refer to any 12-month period? Additionally, the determination of a timeframe for "4% of the Segment population" is needed. Example- If there are 100 Components in a performance-based Segment in Year 1 and I add an additional 100 Components in Year 2, is the 4% based on 100 or 200?

Response: Thank you for your comments.

1. The SDT disagrees, and believes that having a shorter implementation plan would not allow entities to complete the requirements. The Implementation Plan is designed to allow an entity to systematically implement PRC-005-2 such that an ongoing program may be facilitated.
2. Strictly speaking, you are correct. However, the SDT has elected to include the emphasis, "Protection System" in these locations to help clarify that such components are only in-scope where they are part of the "Protection System."
3. The SDT disagrees. Verify is defined as, "Determining that the component is functioning correctly." If the signals to the relay are beyond tolerance, the component is not functioning correctly.
4. The SDT agrees and has corrected the Requirement R2 VSL to indicate "…no more than…"

Organization	Yes or No	Question 4 Comment
5. The SDT chose 4% because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation (see Supplemental Reference and FAQ Section 9.1). 6. The SDT affirms that all references to "prior year"and "previous year" refer to "calendar year." 7. The time frame refers to a calendar year. The 4% failure rate is determined from those Component segments tested in the previous calendar year.		
TransAlta Centralia Generation LLC		1.3 Evidence Retention. The standard said: For Requirement R2, R3, R4 and R5, the Transmission Owner, Generator Owner and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance. How to count" the most recent performance ". Is this Standard going forward basis? For some of the protection system component, the maximum maintenance interval is 12 years (such as CT, PT or microprocessor relay) on the standard, how to count the two most recent performance?
Response: Thank you for your comments. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
PacifiCorp		1: The definition of "Protection System" in this version of PRC-005-2 includes "station dc supply associated with protective functions..." as a Protection System component. Page 83 of the FAQ document accompanying the draft standard provides further clarification that the batteries covered under PRC-005-2 are those that "supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System." This statement in the FAQ is much more limiting than the definition of Protection System and may create confusion concerning registered entities' compliance obligations. For example, a registered entity may have one

Organization	Yes or No	Question 4 Comment
		battery / charger system in a station that supplies DC voltage to communication equipment, including that utilized in transfer trip communication, while a separate battery (typically operating at a different DC voltage) is utilized for relay / trip coil operation. In this case, it is unclear whether the battery / charger system utilized for transfer trip communication is subject to the requirements of the standard. PacifiCorp recommends that NERC or the SDT reconcile this apparent inconsistency in the FAQ document. 2: In Tables 1-4(a) thru 1-4(d), the maximum maintenance interval of four calendar months includes inspection “for unintentional grounds.” PacifiCorp seeks clarification on whether this maintenance activity is intended to target the detection of unintentional grounds on the battery bank / rack itself, or a ground located anywhere on the entire DC wiring system. 3: The Violation Severity Level (“VSL”) for R5 - which ranges from a failure to correct 5 or less (“Lower” VSL) to greater than 15 (“Severe” VSL) Unresolved Maintenance Issues - fails to adequately account for the cumulative amount of equipment a registered entity is required to maintain pursuant to PRC-005-2. A better alternative approach may be to base the VSL on the cumulative percentage of Unresolved Maintenance Issues that an entity fails to address and correct. Such an approach would be more consistent with the VSLs for R3 and R4, which are based on a percentage of the total scheduled maintenance. This approach more fairly and reasonably addresses the covered maintenance activities relative to the approach in the VSLs for R5, which are based on a strict count and therefore independent of the cumulative amount of maintenance activities performed by a registered entity. PacifiCorp recommends that the SDT develop an alternative method for determining VSLs for R5 that reflects the scope of an entity’s maintenance activities and the resulting Unresolved Maintenance Issues managed by an entity.

Response: Thank you for your comments.

1. The SDT believes the term “Station dc supply” is clearly defined within the standard, and that the definition should be

Organization	Yes or No	Question 4 Comment
considered when applying the term. Your reference to Page 83 of the Supplemental Reference and FAQ Document clarifies that Table 1-4 of the standard refers to Station Batteries only, and not Communications Site Batteries. 2. The SDT believes the inspection for unintentional grounds applies to the entire DC wiring system. 3. The SDT disagrees and believes the VSL's for Unresolved Maintenance Issues should be a numeric quantity, and not a percentage.		
Essential Power, LLC		1. This DRAFT Standard is written as a prescriptive 'procedure' and not as a 'Standard'. The SDT should revise the Standard to address the goal, or intent, rather prescribing how entities should meet the Standard. 2. Inclusion of non-BES elements within the Standard falls outside of NERC's jurisdiction, as defined in the EPA 2005. The SDT should remove these elements from the Standard. 3. The inclusion of dc circuitry for equipment that is itself not covered under the Standard is not logical and does not contribute to reliability. The SDT should remove this from the Standard.
Response: Thank you for your comments. 1. The SDT believes the standard describes the desired outcomes and is not a 'prescriptive procedure'. The entity is free to determine what maintenance methods are best suited for its program. 2. FPA Section 215(a) Definitions section defines "bulk-power system as … facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power system "does not include facilities used in the local distribution of electric energy." Facilities such as those to which you refer are not solely "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if these facilities were not covered by the reliability standards, reliability gaps would exist.		

Organization	Yes or No	Question 4 Comment
3. The SDT believes that Protection Systems that trip (or can trip) for Faults on the BES should be included. This position is consistent with the SAR for Project 2007-17, and with the position of FERC staff.		
MRO NSRF		1. Article 4.2.1 - The NSRF believes that this article should be revised to say “Protection Systems installed for the purpose of protecting BES Elements only and detecting Faults on BES Elements. Protection Systems designed to protect non-BES elements that incidentally open 100 kV and greater breakers are excluded from the scope of PRC-005-2”. This makes it very clear what is included in the scope of the Testing and Maintenance program and what is not. 2. Change the text of “Standard PRC-005-2 - Protection System Maintenance” Table 1-5 on page 21, Row 1, Column 3 to:”Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years “Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).The NSRF believes that as written the testing of “each” trip coil will result in the increased amount of time that the BES is in a less reliable system configuration. The NSRF hopes that the

Organization	Yes or No	Question 4 Comment
		SDT will consider these changes. 3. The NSRF recommends the statement "Excluding distributed UFLS and distributed UVLS (see Table 3)" be added to the top of Table 1-4(f). 4. Table 3. There will be many DP's that have distributed UFLS (or UVLS) solely on the distribution system (less than 100 kV). The only item these DP's will have to verify under Table 3 "Protection System dc supply" is the Protection System dc supply voltage. Yet, the definition of Protection System, as it relates to dc supply is "Station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply)". Our interpretation of Table 3 and Section 15.7 of the Supplementary Reference & FAQ document is that a DP need only check the dc supply voltage at the terminals of the relays. If that is the SDT interpretation as well, we recommend revising Table 3 of the standard to reflect that. Table 3 contains issues that need to be addressed in a similar fashion as discussed for non-UFLS and non-UVLS systems, i.e. Table 1-1. Comparison to independent sources is only one way to check for a reliable AC measuring device. It also appears that monitoring capabilities are not being given any credit in regards to the AC sensing devices, DC supply, or control circuitry themselves. There should be no difference in the way these systems are treated compared to BES Protection Systems. 5. In Section D Compliance, Article 1.3, paragraph 4 the standard requires documentation be kept for the ". . . two most recent performances of each distinct maintenance activity. . .". This needs to clarify that it cannot go back before 06/18/07, as evidenced by the suspension of CAN-0008. Also with some of the testing intervals being 12 years that would dictate a Registered Entity maintain 24 years of records, which is unreasonable. This article should be revised to have documentation for the most current testing interval, if after

Organization	Yes or No	Question 4 Comment
		06/18/07. 6. It is understood that lockout relay testing is important as unexercised lockouts can stick and cause regional outages as experienced at Westwing. However, lockout testing by itself is risky and can lead to local outages. If Registered Entities are required to take on the additional risk of testing lockout relays, dispensation must be granted for outages caused by those tests. The following statement should be included in the standard “No enforcement actions or penalties will result from outages caused by relay testing unless a Registered Entity shows a history of 3 or more test related outages per year for 5 years.” 7. In the VSL for Table 4 it seems that the phrase “5% or less” should be “not more than 5%”. With the original language it seems like an entity could be found to have an R4 lower VSL violation for “failure” of zero meaning they had done no testing. This VSL is written in the negative and should be rewritten in the positive. 8. The drafting team needs to clarify “maintenance summaries” as stated in Measure M3. This is an ambiguous term that could be interpreted differently amongst entities. If a term such as ‘summary’ is to be utilized within the standard, a clear definition of what the term is, what it pertains to, where it is located, etc. needs to be included. The NSRF recommends that “maintenance summaries” be defined and included in the “Definition of Terms used in Standard” section. 9. Footnote 1 in the Table sections would be much improved by inserting an example similar to what was provided in Section 8.4 of the Supplemental Reference and FAQ document 10. Additional methods of verification should be allowed for AC measurement monitoring other than simply performing comparison to an independent source. For example, a sudden rate of change in calculated relay MW analog value and/or

Organization	Yes or No	Question 4 Comment
		3Io calculation would give way towards a bad CT and/or path. Loss of potential logic is available in most microprocessor relays today, which is very reliable logic for determining PT/CCVT issues. Consideration should be given to utilities that are capable of performing this type of monitoring in order to allow them to reach that next level of attributes. 11. Please clarify why input/output verification is excluded from the highest level of monitoring related to communications systems (Table 1-2). The way the monitoring attribute is listed does not provide that these will operate when needed. Recommend language be added similar to the monitoring of inputs and outputs described in the relay section (Table 1-1). Table 1-3 should take into account the same concepts mentioned above in regards to AC measurement verification in Table 1-1. There are alternative ways to verify these quantities while still ensuring reliable operation. As such, companies should be given the opportunity to implement them. Additionally, credit should be given to circuit monitoring and alarming in AC circuits with electromechanical relays. If a transducer/alarming relay is placed in the circuit and monitoring is alarmed appropriately, the health of the AC sensing device can be determined. This would essentially provide the same level assurance as mentioned with the microprocessor relays. 12. Clarification is needed on the last row of Table 1-5. Does integrity entail monitoring and alarming of every individual path, if necessary, or is overall integrity sufficient? This statement is once again open to interpretation and leaves the entity at the mercy of the auditor.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.

Organization	Yes or No	Question 4 Comment

2. The SDT sees no appreciable change or improvement in the standard with your proposed change, and respectfully declines to modify the draft.
3. The SDT believes that the suggested change would be redundant to the current text of the Table 1-4(f) header.
4. This is an intentional difference between distributed UFLS/UVLS and the remainder of the Protection Systems addressed within the standard because of the distributed nature of distributed UFLS/UVLS and because these devices are usually tripping distribution System Elements. If an entity were to install monitoring equipment for verification of Station DC supply voltage, or other facets of the reduced maintenance activities regarding distributed UFLS/UFLS, Table 1-3 describes the adjusted activities permitted relative to that monitoring.
5. The SDT believes the Implementation Plan is descriptive in that an entity will be 100% compliant with PRC-005-2 when one maintenance period has elapsed. On a continuing basis, in order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit. The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.
6. The SDT believes it is left to the entity to determine how to align the requirements of the standard with requirements of other regulations and with operational concerns.
7. The VSL Guidelines, developed in accordance with the FERC VSL Order establish the Lower VSL for stepped VSLs as “5% or less,” the Medium VSL as “more than 5% but less than (or equal to) 10%,” the High VSL as “more than 10% up to (and including) 15%,” and the Severe VSL as “more than 15%.”
8. The SDT believes defining “Maintenance Summaries” is unnecessary. The measure simply lists some types of evidence to demonstrate that an entity has maintained its Protection System in accordance with the standard.
9. The SDT believes that the footnote is adequate, but recognizes that some entities may desire the additional details that are included in Section 8.4 of the Supplementary Reference and FAQ document.
10. The SDT believes that the methods that you suggest would be useful for meeting the 12-calendar-year interval for unmonitored Components. However, for monitored systems with no physical maintenance activities, the SDT is concerned about the quality of some of the methods suggested.

Organization	Yes or No	Question 4 Comment
		11. The SDT has modified the last row of Table 1-2 to be similar to the corresponding row of Table 1-1. 12. Section 15.3 of the Supplemental Reference and FAQ provides the following guidance: "Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path."
Duke Energy		1. Duke Energy votes "Negative" because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the Successive Ballot but prior to the Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but are not intended to provide protection for the BES. FERC's September 26, 2011 Order in Docket No. RD11-5 approved NERC's interpretation of PRC-005-1 R1 and R2, stating: "The interpretation clarifies that the Requirements are "applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES." This interpretation is consistent with the Commission's understanding that a "transmission Protection System" is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices." The SDT's response to our comment directed us to Section 2.3 of the Supplementary Reference and FAQ document which states "There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard." We agree with that statement, but question why the SDT insists on changing Section 4.2.1 to include devices that detect Faults on the BES but which do not provide protection for the BES? Duke Energy's standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate

Organization	Yes or No	Question 4 Comment
		BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following definition: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)". 2. We also note that the Lower VSLs for R3 and R4 include violations for "5% or less," and R5 for "5 or less" which mandates perfection. We believe that the consequence of a very small number of components having a missed or late maintenance activity is insignificant to BES reliability." We suggest that a range of 0.5% to 5% would be more reasonable.

Response: Thank you for your comments.

1. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.
2. NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. Much

Organization	Yes or No	Question 4 Comment
of this comment appears to be related to the technical content of the standard, not on the VRFs or VSLs.		
PPL Supply NERC Registered Organizations		Although we have provided some suggested changes in these comments, PPL Generation entities voted in favor of this version. We thank the SDT for the effort on this project and believe that the SDT has developed a revision that improves on many aspects of the existing version of PRC-005.
Response: The SDT thanks you for your affirmative vote.		
ExxonMobil Research and Engineering		As written, the current draft of PRC-005-2 discriminates against smaller entities that do not have a population size of 60 for each component type. Historical records provide an accurate account of how specific components have performed in their installed environment. For a set population size, increasing the number of historical data points should improve the accuracy of an entity's calculated mean time between failures, so, if you increase the period over which the historical data must be evaluated, you can compensate for a smaller segment population size. The SDT's current draft prevents smaller entities from using a larger historical data set to make up for a smaller population size when developing a performance based protective system maintenance and testing program. The SDT should reconsider allowing smaller entities to use historical records that extend for period longer than a single year in the development of a performance based program.
Response: Thank you for your comment. Small entities are permitted to aggregate their components with similar components of other entities to meet the component populations, as long as the programs are (and remain) similar – See Section 9 of the Supplementary Reference and FAQ document and the associated footnote to Attachment A. Decreasing the Component population below the requirements of Attachment A will result in an unsound program due to Component populations that are not statistically significant. The Supplementary Reference and FAQ document states, "Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated." Historical data may be good for trending, but may not be suitable for judging current maintenance program effectiveness.		
American Transmission Company, LLC		ATC recommends that the SDT change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to:"Verify that a trip coil

Organization	Yes or No	Question 4 Comment
		is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years "Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).ATC continues to recommend a negative ballot since we believe that the testing of "each" trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comment. The SDT sees no appreciable change or improvement in the standard with your proposed change, and respectfully declines to modify the draft.		
Bonneville Power Administration		BPA believes that PRC-005-2 achieves the goal of reducing redundancy and overlap within the PRC standards by consolidating four existing standards into one. BPA's comments are focused on improving the clarity and audit-ability of the proposed standard. 1. Regarding Section D1.3 "Evidence Retention", BPA suggests that the entire first paragraph be removed because for all the instances that follow the first paragraph there is a requirement to keep evidence obtained since the last audit. Therefore, there are no instances where the evidence retention period is shorter

Organization	Yes or No	Question 4 Comment
		than the time since the last audit, and the first paragraph is not necessary. Furthermore, the first paragraph introduces the idea of "other evidence" for which there is no explanation. It is unclear what could be used for evidence other than the items described in the 2. Measures. The idea of "other evidence" should not be introduced without an explanation of what that evidence might be, so this is another reason for removing the first paragraph. 3. Regarding requirements R2 and R4, BPA believes that these two requirements should be combined into a single requirement with two parts. Since both of these requirements deal with performance-based maintenance, it would simplify the standard and improve the flow if they were to be combined. 4. Regarding Table 1-4(f), it is unclear if all of the conditions on the left side need to be met before any of the reduced maintenance activities on the right side are allowed, or if there is a one-on-one relationship between an item on the left and the adjacent item on the right. BPA suggests that the table be reconfigured to clarify the relationship between the conditions on the left and the activities on the right.

Response: Thank you for your comments and support.

1. The SDT has been advised to include this paragraph as the first paragraph in the evidence retention.
2. The list of possible evidence with the measures is not intended to provide a comprehensive list of all type of evidence that may be useful. The entity is provided the flexibility to use other evidence that they deem relevant.
3. Requirements R2 and R4 are separate, as they address two specific requirements; one to establish a performance-based PSMP according to criteria, and the other to implement that PSMP.
4. There is a one-to-one correspondence between the right and left columns, and the SDT believes that further clarification is unnecessary.

Organization	Yes or No	Question 4 Comment
CenterPoint Energy		1. CenterPoint Energy recommends retaining an option to utilize technology for monitoring trip coil continuity as an alternative to the maintenance activity in Table 1-5. The Table 1-5 requirement to "Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating devices (regardless of any monitoring of the control circuitry)" appears to address breaker maintenance, instead of Protection System Controls. In the Supplementary Reference and FAQ, monitoring is described as greatly reducing the time between a component failure and discovery of that failure. 2. For the “Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (Excludes non-BES trip coils)”, the Table 3 requirement is to “Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic)” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes this to be a commissioning task, not a preventive maintenance task. A preventive maintenance task, such as the above, is unnecessary for distributed UFLS and UVLS system components. The overriding performance, or “risk-based”, NERC Reliability Standards for UFLS are PRC-006 and PRC-007 where an entity is required to shed their obligated firm load amount. 3. For the “Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays”, the Table 1-5 requirement is to “Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices” every 12 calendar years. CenterPoint Energy recommends this requirement be revised to “No periodic maintenance specified”. CenterPoint Energy believes that verifying all tripping paths is a commissioning task, not a preventive maintenance task. Alternatively,

Organization	Yes or No	Question 4 Comment
		CenterPoint Energy recommends specifically excluding panel wiring and requiring only cabling between panels and interrupting devices be verified. Requiring trip path verification to include panel wiring complicates maintenance while focusing on a component that is not subject to age-related degradation in addition to, historically, not being a source of protection system failures. This type of testing can negatively impact BES system reliability with the outages that are required and by exposing the electric system to incorrect tripping.
Response: Thank you for your comments. 1. While trip coil monitors may demonstrate continuity, they do not fully demonstrate operability. 2. The SDT disagrees regarding UFLS and UFLS-related control circuitry maintenance, and believes that the maintenance specified is appropriate. 3. The SDT disagrees with your proposal regarding Table 1-5 for dc control circuits and auxiliary relays which may be a critical part of a tripping scheme.		
Central Lincoln		Central Lincoln appreciates the good work the SDT has done. We believe this particular team has actually listened to our comments and made changes where needed. Thanks.
Response: The SDT thanks you for your affirmative vote.		
Constellation/Exelon		Constellation/Exelon thanks the drafting team for the hard work on the PRC-005 standard. The standard language made significant progress; however, below are outstanding issues of concern: Table 1-3 1. Table 1-3 should not include current transformers (CTs). The tests mandated by this draft seeks to measure that a signal is “provided to the protective relay” however, for CT’s this test merely confirms that a signal is sent, not that it reached the correct protective relay.

Organization	Yes or No	Question 4 Comment
		2. The maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays should be left to the discretion of the Generator Owner. In order to meet the required activity specified in PRC-005-2 draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse affect on the reliability of the BES. Such testing is not recommended by suppliers. Battery Testing 3. The Tables describing battery testing could be consolidated into less granular breakdown and thus alleviate some of the associated compliance burden and avoid potential confusion. 4. Further to battery testing, given the quantity of batteries and the shorter interval cycles, the four calendar month requirement for batteries is too rigid as a firm four months. Similar to how a definition of annual can have a boundary such as within 9 to 16 months; battery testing intervals should allow a boundary such as “three times per year and not more than 6 months between each and average intervals not exceeding four months.” 5. Please confirm that references throughout Standard to battery/batteries relate to the entire battery bank and not to the individual battery cells unless specifically mentioned. Similarly, battery charger maintenance activity should relate to the battery charger in its entirety and not to individual parts or components. Auto Synchronizing Systems and Relays 6. The drafting team should clarify in the language that testing of auto synchronizing

Organization	Yes or No	Question 4 Comment
		systems and relays is excluded. Applicability 7. To make 4.2.5.4 under Facilities more clear, please remove the term “generator-connected”. 8. When the SDT changed the original PRC-005 applicability language from “...affecting the reliability of the BES...” to the new 4.2.1 language “...that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)”, they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read “...and trips an interrupting device that interrupts current supplied directly from the BES.” By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005.Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1

Organization	Yes or No	Question 4 Comment
		language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement:"The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion." Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1:"Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements."This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. Evidence Retention 9. It is not necessary and is undesirable to reiterate the language from the NERC Rules of Procedure (Appendix 4C 3.1.4.2) in the standard. Stating such language in two places is redundant and future changes to this section of the Rules of Procedure language will create compliance conflict. While this language may be recommended for inclusion as new boilerplate-type language for NERC standards

Organization	Yes or No	Question 4 Comment
		and may be used in other recently revised standards, the potential conflict should be taken into account and avoided for PRC-005. The first paragraph in section 1.3 should be removed. 10. Further, the standard language should dictate data retention relevant to the standard activities and not merely default to the time period in between audits. The Rules of Procedure language enables CEAs to confirm compliance for the full audit period, but the Standard retention language allow for a more reasoned obligation for evidence retention. Specific to this standard, two or three years of evidence for certain components, such as battery tests, is sufficient to demonstrate an entity's PSMP program. On a positive note, standardizing the requested evidence information is helpful.

Response: Thank you for your comments.

1. Regarding current transformers, the SDT disagrees, and notes that the table specifies that the entity verify that the signal is provided to the relay.
2. Regarding testing for currents or potentials behind a Generator Operator's electromechanical relay panel, the SDT believes that it is possible during a 12-year interval to find a reasonably low-risk opportunity to perform the required test. Please refer to Section 15.2.1 of the Supplementary Reference and FAQ document for a discussion of this topic.
3. The existing battery tables have evolved such that entities may easily locate the specific table that applies to the technology being used in order to improve clarity and avoid confusion.
4. Regarding battery testing, the SDT believes that sufficient industry expertise supports a four-month interval requirement.
5. The SDT confirms that most of the battery requirements apply to the entire battery bank, and not necessarily to each battery jar or cell; the same is true for battery chargers. Those requirements specific to individual cells are clearly indicated.
6. Automatic synchronizing relays (which generally close circuit breakers, rather than trip them) are not covered by the Applicability.
7. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator, as stated in Applicability 4.2.5.1.
8. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes

Organization	Yes or No	Question 4 Comment
that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference Document for additional discussion. 9. The SDT has been advised to include this paragraph as the first paragraph in the Evidence Retention section. 10. For the Compliance Monitoring Authority to be confident that the corrective action is being implemented, the entity should expect to demonstrate progress toward correcting the Unresolved Maintenance Issue, such as the evidence suggested in Measure M5 (with additional suggested evidence added). The SDT has specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
DTE Energy		1. DECo does not agree with the 6 year interval for the majority of the Protection System components. There are not sufficient problems found on routine maintenance based on a 10 year interval that would justify that significant of a reduction in the maintenance interval. 2. Also, with respect the station batteries specifically, station batteries, DECo recommends the elimination of the 4 month inspection as annual inspections have been sufficient for early diagnosis of potential issues. Advanced monitoring is not practical at this time as it does not appear that the technology required to forgo the 4 month inspection is readily available.
Response: Thank you for your comments. 1. The SDT believes the intervals and activities specified are technically effective, in a fashion that may be consistently monitored for compliance. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns. If the relevant components are monitored, more lengthy intervals may be utilized. Performance-based maintenance is an option to increase the intervals, if the performance of these devices supports those intervals. 2. Regarding battery testing, the SDT believes that sufficient industry expertise supports a four-month interval requirement.		
FirstEnergy		FE asks that the team clarify the intent of certain aspects of the applicability section:

Organization	Yes or No	Question 4 Comment
		1. Sec. 4.2.5.4 - For transformers supplying unit auxiliaries, protective functions that provide for transferring of auxiliaries without tripping the generating unit should not be included. Also, we believe that the term "station service transformer" is being used inaccurately. As currently written, the section includes all the protection systems for station service transformers for generators that are a part of the BES. It states, "Protection Systems for generator-connected station service transformers for generators that are part of the BES." Generating facilities may have transfer schemes on the auxiliary transformer to transfer equipment to a reserve transformer instead of tripping the unit. These protection systems should not be included in the Facilities for PRC-005-2, since the BES is not affected. But since a station service transformer, by definition (IEEE Std. 505), is "a transformer that supplies power from a station high voltage bus to the station auxiliaries and also to the unit auxiliaries during unit startup or shutdown or when the unit auxiliaries transformer is not available, or both." [Ed. note: a.k.a. Start-Up Transformer or Cranker], the terminology "generator-connected station service transformer" is confusing and easily subject to misinterpretation. 2. Also, there needs to be consistency of use of terms between the standard and its Supplementary Reference document. On pages 32 and 33 of the FAQ, the following questions and their respective answers should be consistent with use of terms and replace "station service" with "auxiliary" as follows: FAQ Question - Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected auxiliary transformer to meet the requirements of this Maintenance Standard.FAQ Question - In the case where a plant does not have a generator connected auxiliary transformer such that it is normally fed from a system connected

Organization	Yes or No	Question 4 Comment
		auxiliary transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) auxiliary transformer will result in a trip of a BES generating facility? Therefore, for consistency between the reference FAQ document and the standard, we suggest that "station service" be replaced with "auxiliary" in 4.2.5.4 and read as follows: "Protection Systems for generator-connected auxiliary transformers used on generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays."
Response: Thank you for your comments. 1. Applicability Section 4.2.5.4 specifically addresses the Protection Systems that act to trip the generator, and the "station service transformer" term seems to be the most consistently-used term for this application. 2. The SDT modified the Supplementary Reference and FAQ document for consistency with the standard.		
Kansas City Power & Light		1. For clarity, change the text of "Standard PRC-005-2 - Protection System Maintenance" Table 1-5 on page 21, Row 1, Column 3 to: "Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.". Or alternately, "Electrically operate each interrupting device every 6 years". 2. Countable Event as proposed is somewhat unclear. Recommend the following language: Countable Event - A Component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to any other reason are not included in Countable Events.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1. The SDT believes it is important that each individual trip coil be verified. 2. The SDT does not believe that the changes you suggest improve the standard.		
BAE Batteries USA		Major comments have been addressed in Question 3.
Manitoba Hydro		Manitoba Hydro is voting negative for the following reasons: 1 - Battery inspection and verification interval - Manitoba Hydro maintains that the battery inspection interval should be extended to 6 months. The 4 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. Manitoba Hydro has more than ten years of experience using its existing battery inspection intervals and Manitoba Hydro's reliability data has proven that the 6 month inspection interval is suitable for Manitoba Hydro. Manitoba Hydro's battery maintenance tasks were derived from a reliability study of Manitoba Hydro stationary batteries, and the tasks and intervals are suitable given Manitoba Hydro's installed plant, design criteria, climate, and reliability performance. A more frequent inspection interval might be more suitable to specific utilities with material differences in climate, design, installed apparatus, and performance, but it is not suitable for Manitoba Hydro and may be more than is required for many other utilities. To use a more frequent inspection interval would penalize Manitoba Hydro which has been diligently performing battery inspections for many years, with no resulting increase in reliability. It would also potentially adversely affect reliability by diverting resources away from projects that are critical to reliability to meet this maintenance interval. In addition, the 4 month time period proposed for basic battery verification and inspection interval is not aligned with the more detailed 18 month battery verification and inspection interval which will result in additional and unnecessary site visits and maintenance activities. As well, Manitoba Hydro does not feel that the SDT has provided sufficient technical basis to support a 4 month battery inspection and verification interval and requests

Organization	Yes or No	Question 4 Comment
		that further justification and external reference be provided. 2 - PBM not permitted for batteries - Manitoba Hydro disagrees with the SDT's basis for not permitting the use of PBM for batteries. The reasons provided by the SDT for disallowing them are that batteries are perishable and involve chemical reactions. However, it is our understanding that many other industries rely on performance based maintenance programs when dealing with similar equipment. We would appreciate an external reference or source which supports the claim that equipment with these characteristics cannot have a performance based maintenance system applied to them. 3 - Phased Implementation Plan - Manitoba Hydro maintains its position that prescribing how an entity must reach full compliance with PRC-005-2 will provide a negligible improvement in reliability while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets and proving compliance for the prescribed percentages of assets during the transition period creates unnecessary overhead with no added value. We suggest that the requirement to demonstrate the percentage of assets currently under PRC-005-1 vs. PRC-005-2 be removed, that entities should be given a single compliance date for each of the maintenance intervals and be allowed the flexibility to schedule and complete their maintenance as required while transitioning to the defined time intervals in PRC-005-2, and that NERC measures progress on reaching PRC-005-2 intervals using means other than Compliance measures such as industry surveys. 4 - Data Retention Requirements - The data retention requirements are too uncertain for two reasons. First, the requirement to "provide other evidence" if the evidence retention period specified is shorter than the time since the last audit introduces uncertainty because a responsible entity has no means of knowing if or when an audit may occur of the relevant standard. Secondly, it is unclear what 'other evidence', besides the specified evidence in the Measures, an entity may be asked to provide to demonstrate it was compliant for the full time period since their last audit.

Organization	Yes or No	Question 4 Comment
Response: The SDT thanks you for your comments. 1. The SDT believes that sufficient industry expertise supports a four-month interval. 2. The SDT believes that batteries cannot be a unique population segment of a Performance-based Maintenance (PBM) Program because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. 3. The SDT disagrees with your proposal for a phased implementation plan. 4. The SDT has been advised to include this paragraph as the first paragraph in the evidence retention section.		
Alber Corporation		My comment is in regard to the proposed maintenance tasks associated with ohmic testing and capacity testing of lead-acid batteries affected by PRC-005-2.The option is given to the battery use to perform either inter cell/unit ohmic tests OR battery capacity tests whichever suits the user. The two tests, while related, are not directly interchangeable with one another. Ohmic tests are intended to be used as a tool during battery maintenance inspections to determine the general state of health (condition) of the battery as a whole. Capacity tests are intended to demonstrate the actual capacity of a battery. Ohmic tests cannot be substituted for capacity tests. Alber has pioneered the development of portable and fixed internal resistance test equipment for stationary lead-acid batteries since 1972. Through years of research, testing in real-world applications and development, Alber has conclusively determined that there is a direct relationship between internal cell resistance and capacity. However, because this correlation is not linear, ohmic measurements should not be used to calculate capacity or remaining life. Ohmic measurements should be used as a supplement to capacity testing and not as a replacement. These measurements are very valuable in identifying developing problems between the capacity testing intervals and for determining whether a battery string is going to perform its intended mission. IEEE 1188-2005 for VRLA batteries agrees with this and recommends measurement of this parameter once every three months. While not specifically recommended in IEEE 450-2010 for vented lead-acid batteries, ohmic measurements can provide early warning of potential failure and should be performed at least

Organization	Yes or No	Question 4 Comment
		annually. Again, if readings result in doubt that a battery will perform as intended, follow up capacity testing is recommended. A battery discharge test completely simulates the operating environment and therefore conclusively proves that a battery can perform during an emergency. The results of these tests will help set the priority for capacity testing as the user becomes more familiar with their batteries and may assist in extending capacity test intervals. The intention of the proposed NECR PRC-005-2 standard as it relates to the DC supply, and, in particular, the station battery is to increase reliability of the bulk electric system (BES) in north America. In its current draft form, PRC-005-2 proposes the utility may perform internal ohmic measurements or perform capacity, but both tests are not required. It would appear therefore; that the Standards Drafting Team (SDT) has made the assumption that test results obtained from measuring cell internal ohmic values is the same as performing a capacity test. It is not, and to provide the option to perform one test or the other runs counter to industry recommended practices. Such maintenance practices will, in effect, ultimately reduce the reliability of the BES rather than improve it. Periodic capacity testing on a 5 year interval for VLA batteries, and a 2 year interval for VRLA batteries is consistent with IEEE 450-2010 and IEEE 1188-2005 recommended practices respectively. It should be part of a complete maintenance program designed to maximize the DC supply's availability when needed. Respectfully submitted, Richard Tressler Alber Corp.
Response: Thank you for your comment. The SDT agrees with your statement, and those of others, concerning the true capacity of the station battery and relating it to internal ohmic measurements. Tables 1-4a, 1-4b and 1-4c have been modified for clarity, and the Supplemental Reference and FAQ Document has been modified to further elaborate on these concerns.		
NIPSCO		Per NIPSCO Tech Service Dept : There is a need for NERC to provide a format for maintenance reports. Also, it would help if specific test requirements for relays were provided.
Response: Thank you for your comments. The SDT do not believe it is necessary or appropriate to prescribe a specific format for test results or test requirements.		
PNM Resources		PNM Resources appreciate the outstanding work of the SDT! We offer two comments

Organization	Yes or No	Question 4 Comment
		for consideration by the SDT. 1) We believe that the 6 Calendar Month battery cell/unit internal ohmic value measurement for VRLA Batteries may be more frequent than we believe is necessary to maintain reliability. PNM has witnessed no significant failure patterns with VRLA batteries in our system and we currently do impedance testing of all Transmission Station Batteries on a 2-year basis. 2) We also believe that system constraints could arise that will make it difficult to “verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices” as specified in Table 1-5 for “unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays”. Thank you for your consideration.
Response: Thank you for your comments. 1. The SDT believes that it is necessary to verify that the station battery can perform as manufactured by evaluating the cell/unit parameters to station battery baseline if a performance or modified performance test is not conducted. Please see Section 15.4 of the Supplementary Reference and FAQ Document for a discussion of this topic. 2. The SDT believes the intervals and activities specified are technically effective, in a fashion that may be consistently monitored for compliance. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns.		
American Electric Power		PRC-005-2 is intended to supersede the existing standard PRC-017-0 "Special Protection System Maintenance and Testing". As it is currently written, an Entity with a Special Protection System will be required by R1 to select either a time-based, performance-based or combination maintenance method for the Entity's SPS. Since Special Protection Systems are not frequently installed, it is unlikely that an Entity will be able to meet the requirement of R2 and Attachment A that the Segment population contain 60 components for all components of the SPS. This will require the Entity to utilize the time-based maintenance method for at least some

Organization	Yes or No	Question 4 Comment
		components in the SPS. Under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems by their nature may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are not included in the NERC definition of Protection System.
Response: The SDT thanks you for your comments. The SDT does not perceive the gap in maintenance requirements that you describe for SPSs.		
US Bureau of Reclamation		1. Re Terms defined for use only within PRC-005-2: The standard provides definitions which will not be incorporated into the Glossary of Terms. This would allow the definitions as used in this standard to conflict with the definition used in other standards if this practice becomes more widespread and would reduce the cohesiveness of the standard set. 2. Re The definition of Components: The standard defined what constitutes a control circuit as a component type with "Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices." The standard then modified the definition by allowing "a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry." The definition should not be dependent upon practice. This makes the definition a fill in the blank definition. Either eliminate the allowance or remove the definition of control circuit.
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 4 Comment
1. The standard specifies that the terms used are intended for this standard <u>only</u>; therefore, there should no conflict with their use in any other PRC standard. 2. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
ReliabilityFirst		1. ReliabilityFirst votes in the negative for this standard primarily due to the language in Requirement R5. The language in Requirement R5 is subjective and non-measurable in its present state. ReliabilityFirst offers the following comments for consideration. 2. Definition of "Component" a. The language stating "discrete piece of equipment" within the first sentence is unclear and open ended. ReliabilityFirst suggests the following modified language for the first sentence in the definition of "Component": "A Component is a piece of equipment that is one of the five specific element included in a Protection System, including but not limited to a protective relay or current sensing device." 3. Definition of "Unresolved Maintenance Issue" a. There may be instances when a deficiency is identified and corrected during the maintenance itself. For further clarity and to address this circumstance, ReliabilityFirst recommends the following modification for consideration: "A deficiency identified during a maintenance activity that could not be corrected and causes the component to not meet the intended performance and requires follow-up corrective action." 4. Facilities Section 4.2.1 a. This is too limited or selective in only including Protection Systems that are installed on BES Elements to strictly detect Faults. There are a number of relays

Organization	Yes or No	Question 4 Comment
		that are installed to detect non-Fault but abnormal conditions such as power swings/out of step and overvoltage that should not be excluded from a maintenance program. ReliabilityFirst recommends the following language for consideration: “Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)” 5. Facilitates Section 4.2.2 a. It is unclear what requirements the phrase “installed per ERO underfrequency load-shedding requirements.” is referring to. Is it NERC UFLS Requirements, Regional UFLS Requirements, etc.? To be consistent with section 4.2.3, ReliabilityFirst recommends the following for consideration: “Protection Systems used for underfrequency load-shedding systems installed to arrest declining frequency, for BES reliability. 6. Requirement R3 a. For time-based maintenance program(s), there is no safeguard if more than 4% Countable Events are experienced during a maintenance interval. ReliabilityFirst recommends adding an new Subpart 3.1 (similar to the language for performance-based in Attachment A): “3.1 If the Components in a Protection System Segment maintained through a time-based PSMP experience 4% or more Countable Events, develop, document, and implement a Corrective Action Plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.” 7. Requirement R5 a. Requirement R5 has language which states “...shall demonstrate efforts to correct...”. ReliabilityFirst believes this language is subjective and non-measurable. It will be difficult in determining what amount of demonstration an entity will need to provide in order to be compliant. There is also no timeframe in which the correction needs to be completed (is it 30 days or 30 years?). ReliabilityFirst believes measurable language such as “shall correct” or “shall

Organization	Yes or No	Question 4 Comment
		have and implement a Corrective Action Plan" should be incorporated within the requirement. 8. Table 1-2 a. For "Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function" ReliabilityFirst believes the maintenance interval is too short. Carrier communication failures are a major cause of Misoperations. Many have automatic checkback and are monitored but continue to fail during Fault conditions. ReliabilityFirst recommends a maintenance interval of 6 years. b. For "Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied" ReliabilityFirst believes a maintenance interval should be required. ReliabilityFirst recommends a maintenance interval of 12 years. 9. Table 1-3 a. For "Any voltage and current sensing devices not having monitoring attributes of the category below." ReliabilityFirst recommends a maintenance interval of 6 years. b. For "Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value..." ReliabilityFirst believes the concept of never having to do any testing just because you have continuous monitoring is fundamentally flawed in this table as well as 1-5 and 2. Continuous monitoring and measurement comparison cannot test everything, such as loss of ground, multiple grounds and turn-to-turn failures, and monitoring itself can fail. ReliabilityFirst recommends a maintenance interval of 12 years. 10. Table 1-5 a. ReliabilityFirst recommends adding "auxiliary tripping devices" to

Organization	Yes or No	Question 4 Comment
		Electromechanical lockout devices in row 2 of Table 1-5. If lockout relays are maintained every six years auxiliary tripping devices should be as well. ReliabilityFirst recommends the following language for considerations: “Electromechanical lockout devices and auxiliary tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).”

Response: The SDT thanks you for your comments.

1. Requirement R5 is expressly focused on allowing entities to resolve deficiencies in an effective manner, rather than performing “band-aid” fixes. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the recognition that more complex unresolved maintenance issues could require more time to resolve effectively than there is time remaining in the maintenance interval, yet the problems must eventually be resolved. The SDT believes that corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “Unresolved Maintenance Issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”
2. The SDT believes it important to distinguish between component “types” (of which there are 5) and individual components (of which there are numerous examples), and believes that you are confusing the two concepts.
3. The definition of “Unresolved Maintenance Issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.”
4. The SDT believes your proposed language for Applicability Section 4.2.1 is overly broad and could lead to unintentional application of PRC-005-2 to other as-of-yet unidentified systems.
5. The SDT intends that this refers to either NERC UFLS requirements or regional UFLS requirements.
6. Countable Events apply only to entities that utilize a performance-based PSMP (Requirements R2 and R4). For entities that use a time-based program, the establishment of maximum intervals within the standard relieves the entity from having to have any

Organization	Yes or No	Question 4 Comment
basis, etc., that the intervals used are appropriate, as long as those intervals conform to the tables. 7. Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." 8. a) The SDT believes that sufficient emphasis is placed on communication system checks and maintenance. The SDT also believes that more frequent hands-on testing will be no more effective in finding problems than the automated monitoring of these functions. b). The SDT believes that continuous monitoring requirements, as already drafted, will drastically reduce risk to the BES. 9. a) The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Entities are empowered to develop PSMPs that exceed these requirements, if they determine such a PSMP to be necessary. b). The SDT believes that continuous monitoring is equivalent to actually conducting the maintenance activities otherwise specified at a far more frequent interval than would be possible with physical hands-on maintenance; and, therefore, improves reliability. The SDT has also identified throughout the tables specific activities that they believe to not be effectively conducted via monitoring. 10. The SDT believes the intervals and activities specified for auxiliary relays are technically effective, and believes sufficient emphasis is placed on auxiliary tripping relay maintenance.		
ATCO Electric Ltd		1. Table 1-4(a) Vented Lead-Acid (VLA) Batteries: ATCO Electric has a number of

Organization	Yes or No	Question 4 Comment
		remote substations that are difficult to access frequently. The requirement for a 4 calendar month inspection for electrolyte level is too frequent. (i) Does alarm/monitor technology exist for electrolyte level in battery design today? For in-service battery systems, if battery alarm/monitor technology exists, a capital project is required to retrofit each battery system and this kind of retrofit work could be detrimental to both the battery design life as well as the battery reliability. (ii) The electrolyte level requirement would become achievable if electrolyte level inspection was moved to the 18 calendar months category, or if the 4 calendar months frequency was increased to 8 calendar months. 2. Table 1-4(b) Valve Regulated Lead Acid (VRLA) Batteries: ATCO Electric has a number of remote substations that are difficult to access frequently. The requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category. 3. Table 1-5 Control Circuitry When a breaker is opened, there is no indication on which trip coil is actually operated. How do market participants demonstrate compliance for "verify that each trip coil is able to operate..."? The verification of trip coil health is done during breaker maintenance with various maintenance durations that maybe longer than 6 years depending on breaker types. 4. The requirement of "verify electrical operation of electromechanical lockout

Organization	Yes or No	Question 4 Comment
		devices" introduces high risk of human error outages to the BES system and diminishes the reliability gain from performing this activity. The drafting team should consider lockout relay failure rates, onerous tasks of blocking each trip contacts in many BES elements' tripping circuits, imposed risk, required resources in the overall reliability benefit gained by performing the lockout relay maintenance.
Response: The SDT thanks you for your comments. 1. Devices to monitor electrolyte levels are available. The SDT believes that the four-month interval for checking electrolyte level (absent monitoring) is appropriate, as low electrolyte level may impair the ability of the battery to function properly. 2. The SDT believes that the six-month interval for evaluation of cell/unit ohmic parameters to baseline is appropriate, as degradation of these parameters may impair the ability of the battery to function properly. 3. Breaker control circuitry is typically designed with facilities, such that individual trip coils can be isolated for observation. Also, it may be possible to distinguish operation of individual trip coils by determining what devices initiate those trip coils. 4. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same six- year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices, but believes these risks can be managed. Performance-based maintenance is an option if you want to extend your intervals beyond six years.		
Florida Municipal Power Agency		The applicability of the standard should be modified to reflect the FERC approved interpretation PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: The applicability as currently stated will sweep in distribution protection: “4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)”Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue.

Organization	Yes or No	Question 4 Comment
		These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should adopt the FERC approved interpretation.
Response: Thank you for your comments. The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference and FAQ Document for additional discussion. Reverse power relays and low-set overcurrent relays, as discussed in your comment, are not installed for detecting Faults on BES elements. The SDT does not understand your concerns regarding PRC-023, but we suggest you provide those concerns to the team working on that standard.		
Ingleside Cogeneration LP		The derivation of the implementation plan apparently incorporates the "requirements" of NERC's Compliance organization, which has released several CANs on the topic. This is exactly backwards, and has led to at least one CAN which has been withdrawn due to legal overreach. However, the plan as written is very complex. We believe that diagrams of acceptable time frames should be included in the implementation plan so that industry stakeholders can better assess the impact

Organization	Yes or No	Question 4 Comment
		on their maintenance operations.
Response: The SDT thanks you for your comments. The SDT has developed the Implementation Plan such that it is clear, both to entities and to Compliance Enforcement Authorities, as to when the various requirements must be fully implemented. The Implementation Plan has been crafted to allow entities to systematically implement the standard in a manner that facilitates effective ongoing performance of a PSMP. The SDT does not believe it necessary to "diagram" the PSMP.		
EPRI		The drafting time should see the opinion of the IEEE Stationary Battery Committee before this standard is rolled out for implementation.
Response: The SDT thanks you for your comments. Several members of the NERC Task Force of the IEEE Stationary Battery Committee participated in developing modifications to the sections of Table 1-4 to be more effective and technically accurate.		
ACES Power Marketing Standards Collaborators		1. The first part of definition of a Countable Event should be modified as follows: "The failure of a Component such that it requires repair or replacement...". As it is currently worded, it is technically counting the Component as the Countable Event and not the failure of the component. Considering that the other two items that are Countable Events are conditions and misoperations, it seems appropriate to make failure the Countable Event. 2. Application of this standard to UFLS is problematic as worded in Section 4.2.2. The UFLS are only applicable if "installed per ERO underfrequency load-shedding requirements". Technically, no UFLS fits this description because there are no ERO requirements to have a UFLS. PRC-006-0 was never approved by the Commission and is not enforceable. The Commission considered it a "fill-in-the-blank" standard. While PRC-006-1 corrects the "fill-in-the-blank" issues and was approved by the NERC BOT November 4, 2010, the Commission has yet to act on it. 3. The data retention requirement for the Protection System Maintenance Program documentation seems excessive. The Data Retention section states that all versions since the last compliance audit must be maintained. Since TOs, GOs,

Organization	Yes or No	Question 4 Comment
		and DPs are all on six year audit cycles, this would require maintaining this documentation for six years. Is this really necessary? The length could become even greater once NERC implements registered entity assessments that could shorten or lengthen the periods between compliance audits. The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C - Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of "the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date". While it may have been intended to apply to both clauses, the "since the previous scheduled audit date" only applies to the second clause. Since some of the maintenance activities have intervals of 12 years, this would require the registered entity to retain documentation for 24 years which cannot be audited since it is outside the audit window per the Rules of Procedures. At a minimum, we suggest clarifying that the documentation must not be maintained past the day after the last audit completion date. In the fourth paragraph of the Data Retention section, Component is not used consistently. It is used in both singular and plural form. It seems like it should be one or the other. 4. Requirement R1 VSLs: For the High VSL, "entities'" should be "entity's" to be consistent with the other VSLs. 5. It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT agrees with your comments on Countable Event, and has modified the definition of Countable Event to: “A failure of a Component requiring …”
2. Applicability Clause 4.2.2 applies to whatever ERO-required UFLS that may exist, either today or in the future. NERC Reliability Standard PRC-006-1 has now been approved by FERC.
3. The SDT believes that all versions of the entity’s PSMP should be retained for audit purposes. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.
4. The SDT corrected the Requirement R1- High VSL, as you suggested.
5. The SDT believes that missing three components is a “significant percentage,” and is in accordance with the VSL Guidelines.</td></tr>
<tr><td>Independent Electricity System Operator</td><td></td><td>The IESO continues to disagree with the VRF assigned to the new R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our position that the VRF for R3 be changed to Medium.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
The SDT disagrees, and believes the failure to implement a PSMP should be assigned a VRF of High.</td></tr>
<tr><td>BAE Batteries USA</td><td></td><td>The NERC Standard should incorporate suggestions made in a letter provided to the NERC Drafting Team along w/ a specific Task Force Report commissioned by the IEEE Stationary Battery Committee.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comments. Several members of the NERC Task Force of the IEEE Stationary Battery</td></tr>

Organization	Yes or No	Question 4 Comment
Committee participated in developing modifications to the sections of Table 1-4 to be more effective and technically accurate.		
Nebraska Public Power District		The SDT believes that it is possible to manage the risks that you describe and that performance of these trip path verifications will be an overall benefit to the reliability of the BES 1. Please provide the basis for the requirement of functional trip checks? 2. Are there recorded instances that an "event" would have been avoided if functional trip checks had been performed? 3. Suggest for monitored microprocessor relays in Table 1-1 and 3 to verify "settings are as specified that are essential to the proper functioning of the protection system". Many settings are not essential. 4. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. All functional tests should be moved to the minimum frequency of 12 years to minimize this unknown but present risk.
Response: The SDT thanks you for your comments. 1. Please see Section 15.3 of the Supplementary Reference and FAQ document. 2. While the SDT cannot comment on any specific events that would have been avoided explicitly by performing functional trip checks, there is no doubt that the number of Misoperations will be reduced if more comprehensive maintenance is performed. It is also likely that mal-performance of control circuitry has been a factor in a number of disturbances. 3. In many microprocessor relays, various settings impact other settings, making it difficult to explicitly determine which are essential to proper functioning of the Protection System. Additionally, the SDT anticipates that this activity, for microprocessor relays, may very well be easily performed by downloading the settings from the relay and comparing them to the file of desired settings. 4. The maintenance of the overall control circuitry is already specified for a 12-year interval. Only trip coil verification and lockout		

Organization	Yes or No	Question 4 Comment
relay verification are specified for six years.		
Southwest Power Pool Standards Development Team		Under section 1.3 Evidence Retention we feel like documentation of the last two performances of each distinct maintenance activity should be limited to the last one. This is due to the amount of documentation being recorded as well as for certain a component there is a 12 year maximum interval. Would you have to store this information for 24 years? This could also violate the NERC ruling that was just made on a CAN 008 that stated you do not have to show intervals earlier than June 18th 2007. Suggested alternate language "For Requirement R2, Requirement R3, Requirement R4, and Requirement R5, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous audit date, whichever is longer, but not prior to June 18th 2007."
Response: The SDT thanks you for your comments. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.		
NextEra Energy, Inc.		1. Verifying electrolyte levels of vented lead acid (VLA) batteries every four (4) calendar months is excessive and will not promote the reliability of the bulk electric system (BES). The maximum maintenance interval should be twelve (12) calendar months. Today's lead-calcium and lead-selenium-low antimony batteries do not experience rapid water loss as compared to the legacy lead-antimony batteries and if battery cells should crack from positive plate growth, twelve (12) calendar months is more than adequate to detect electrolyte leakage before cell failure.

Organization	Yes or No	Question 4 Comment
		2. Verifying that unmonitored communication systems are functional every four (4) calendar months is excessive and will not promote the reliability of the BES. The maximum maintenance interval should be twelve (12) calendar months. Based on our operating experience, twelve (12) calendar months is sufficient to detect communication failures without affecting the reliability of the BES.
Response: The SDT thanks you for your comments. 1. The SDT believes that the four-month interval for checking electrolyte level (absent monitoring) is appropriate, as low electrolyte level may impair the ability of the battery to function properly. 2. The SDT believes that the four-month interval is proper for unmonitored communications systems. The activity related to this interval is to verify basic operating status.		
Flathead Electric Cooperative, Inc.		1. We appreciate the work of the drafting team to fulfill the SAR objectives. Flathead generally does not like some of the new definitions proposed by the revised standard, especially R5, “Unresolved Maintenance Issues” is too vague and will be left up to individual auditors to determine compliance. 2. In addition, it appears the drafting team is creating new definitions for plain English in the definition of Protection System Maintenance Program (PSMP). Surely "test, monitor, inspect, calibrate" don't need NERC definitions. Let's leave the definition as "An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored." Suggest deleting "A maintenance program for a specific component includes one or more of the following activities: o Verify- Determine that the component is functioning correctly. o Monitor - Observe the routine in-service operation of the component. o Test - Apply signals to a component to observe functional performance or output behavior, or to diagnose problems. o Inspect - Detect visible signs of component failure, reduced performance and degradation.

Organization	Yes or No	Question 4 Comment
		o Calibrate-Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement." 3. In addition, it appears the component and component type definitions alter the meaning of the NERC approved definition of a protection system. I would suggest the drafting team not try to redefine the NERC-approved definition of Protection system. 4. "Countable Event" definition seems to conflict with standards related to Misoperation of protection system.

Response: The SDT thanks you for your comments.

1. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a six-month check. In instances, such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects and therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of “Unresolved Maintenance Issue” has been modified to add a clarifying phrase that the deficiency “cannot be corrected during the maintenance interval.” The SDT believes the definition is sufficiently clear, while also allowing some flexibility for both TOs and auditors.
2. The SDT believes that the descriptions within the PSMP definition are necessary so that the definition will be clearly understood and so that entities consistently apply those terms as they implement the activities within the tables.
3. The definitions, for use within this standard, do not alter the approved definition of “Protection System,” but instead provide consistent terms for use within the standard.

Organization	Yes or No	Question 4 Comment
4. The definition, within this standard, of Countable Event has no relationship to the approved definition of Misoperation. It is used solely to describe and evaluate Protection System performance for the purpose of developing and perpetuating a performance-based PSMP.		
Entergy Services		1. We recommend the word "Protection" be deleted from the definition of Component to make the defined term Component be a generic term. If that word is not deleted then we recommend the term used in the standard "Protection System Component" be changed to "Component" since as defined a Component is a Protection System piece of equipment. Component - A Component is any individual discrete piece of equipment included in a System, including but not limited to a protective relay or current sensing device. 2. The designation of what constitutes a control circuit Component is dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed
Response: The SDT thanks you for your comments. 1. The SDT intends that the term not be generic, and that term explicitly apply within this standard. 2. The intent of the different means of identifying control circuitry was to accommodate various entities' philosophies on testing these circuits. Regardless of how an entity chooses to identify their control circuitry, the entity must meet the requirements of the standard regarding maintenance of control circuitry.		
PNGC Comment Group		We thank the SDT for their hard work and will be voting "yes" on this project. However, we have 5 specific comments independent of the questions above and we've listed them in order of priority: 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric

Organization	Yes or No	Question 4 Comment
		System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the “NERC Guidance (Below), this seems to be a contradiction given the language of “...more than one”. a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Moderate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required performance. We suggest changing the language for “Lower VSL” for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained... OrFor Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained... 2. The PNGC comment group disagrees with the “Evidence Retention” requirements for the standard. In the current version for R2-R5, entities are required to: “...keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date, whichever is longer.” The PNGC comment group believes that keeping documentation for one previous maintenance activity or since the last audit, whichever is longer, should be sufficient. Keeping the two most recent instances of an activity with a maximum maintenance interval of 12 years could mean planning for up to 35 years or so of evidence retention. With the longer of “since the last audit” or “at least one maintenance interval” as the minimum retention requirement the CEA should have sufficient basis to determine compliance. 3. The PNGC comment group believes R5, “Unresolved Maintenance Issues” is too

Organization	Yes or No	Question 4 Comment
		vague and will be left up to individual auditors to determine compliance. This requirement appears ripe for misapplication and future CANs on the topic. Good utility practice will ensure that maintenance issues are corrected as a primary function of our members is to provide the most reliable service possible. The SDT lists several possible examples of evidence in M5 but we believe that more specificity is needed for evidence requirements or the requirement should be removed. We understand the importance of “maintenance” of protection systems and that when maintenance issues cannot be immediately addressed there needs to be follow up. We believe notation of the maintenance issue during the inspection should be sufficient for compliance. By including the examples in the associated measure for the requirement, we believe the SDT has confused the issue. In our opinion M5 should indicate that evidence of notation of the issue is all that is required (meaning acknowledging of the issue on the inspection form). Further, in your response to entity comments during the last comment period on this topic, you stated, “The SDT believes that an effective PSMP must include correction of deficiencies...”. This statement implies that the standard must cover the correction of deficiencies to completion. There could be very long time frames associated with maintenance including management budget decisions, equipment purchase lead times and personnel scheduling for follow up work. Some issues could potentially require years of tracking within this standard creating an unnecessary compliance risk for the entity. We believe the SDT has met the intent of order 693 if a maintenance activity is initiated. The completion of the initiated maintenance activity should be outside the bounds of the standard and the standard should clearly state this. 4. We also find issues with the “Definitions of Terms Used in Standard “Specifically, the definition of “Component” seems to confuse the subject unnecessarily. We suggest simplifying the definition by breaking out the control circuitry and voltage and current sensing device examples. That is a lot of material to cover in what should be a simple definition of “Component”. 5. Also we believe the definitions of the 5 behaviors under the PSMP definition are

Organization	Yes or No	Question 4 Comment
		unnecessary. We believe that indicating that the PSMP involves some or all of the 5 activities without trying to define them is fine. For example, your definition of "Inspect" states: Detect visible signs of component failure, reduced performance and degradation. But what if you find no failure, reduced performance or degradation? Have you not inspected the component? Or what about "verify"? If you determine the component is not functioning correctly, have you not verified anything?

Response: The SDT thanks you for your comments.

1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.
2. For a Compliance Monitor to be assured of compliance, the SDT believes the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding maintenance to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT specified the data retention in the posted standard to establish this level of documentation, which is consistent with the current practices of several regional entities.
3. Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken. The definition of "Unresolved Maintenance Issue" has been modified to add a clarifying phrase that the deficiency "cannot be corrected during the maintenance interval." The evidence listed in the Measure is intended to be illustrative of the types potentially effective evidence, but is not all-inclusive, as demonstrated by the term, "… not limited to…"
4. The definitions of terms that are specified for use only within this standard are intended to support consistent application of the

Organization	Yes or No	Question 4 Comment
standard. 5. The SDT believes that the descriptions within the PSMP definition are necessary so that the definition will be clearly understood and so that entities consistently apply those terms as they implement the activities within the tables. The term “inspect” was modified to “Examine for …” in consideration of your comment.		
Western Area Power Administration		Western Area Power Administration - Rocky Mountain Region does not agree with changing lockout devices to 6 year intervals for testing.
Response: The SDT thanks you for your comments. The interval for lockout relays has been at six years for several drafts; this is not a change. The SDT believes that electromechanical lockout relays need periodic operation, and that six years is the appropriate interval. Performance-based maintenance is an option, if you want to extend your intervals beyond six years.		

END OF REPORT

Consideration of Comments

Protection System Maintenance and Testing - Project 2007-17

The Protection System Maintenance and Testing Drafting team thanks all commenters who submitted comments on the 3rd draft of the standard for Protection System Maintenance. These standards were posted for a 30-day public comment period from June 18, 2012 through June 27, 2012. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 51 sets of comments, including comments from approximately 170 different people from approximately 110 companies representing all 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President of Standards and Training, Herb Schrayshuen, at 404-446-2560 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Definitions:

No changes were made to the Definitions.

Applicability:

No changes were made to the Applicability.

Requirements:

No changes were made to the Requirements.

Tables

In Table 1-2, the interval for the second portion of the first row of the table was changed from 12 years to 6 years. Also, in Table 1-2, "channels" was modified to "communications systems" in two locations,

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_StandardsProcessesManual_20120131.pdf

and the Component Attributes in the last row were modified to clarify that all attributes must be present to use the associated intervals and activities.

Editorial changes were made to Tables 1-4c, 1-4d., and 1-4e. The words “Protection System” were added to the headers of Tables 1-4c and 1-4d; in Table 1-4e, a redundant “only” was removed.

No additional changes were made to the Tables.

Measures

No changes were made to the Measures.

VRFs and VSLs

No changes were made to the VRFs and VSLs.

Version History

The Version History was updated to reflect the latest approved version of PRC-005.

Implementation Plan

The Implementation Plan was revised to retire the four legacy standards upon full implementation of PRC-005-2 rather than upon the Effective Date. Clarifying language was added to address this change.

Supplementary Reference and FAQ Document

Numerous changes, both technical and editorial, were made throughout the Supplementary Reference and FAQ.

Mapping Document

Minor clarifying changes were made to the Mapping Document.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. **In response to stakeholder input, the SDT made several changes to the standard and associated definitions as detailed below:**
    - **Revised the "Inspect" element of the definition of Protection System Maintenance Program (PSMP), the definition of the term Unresolved Maintenance Issues, and the definition of the term Countable Event.**
    - **Revised Clause 4.2.5.4 of the Applicability section of the standard.**
    - **Revised Table 1-2 "Component Type - Communications Systems."**
    - **Revised Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f "Component Type - Protection System Station dc Supply…."**

    Do you agree with these changes? If not, please indicate which changes you do not agree with and provide specific suggestions in the comment area for improvements that would allow you to support the standard.

Summary Consideration:

Some commenters continued to object to various activities and/or intervals within the tables. The drafting team made several changes detailed below in response to these comments.

1. One interval was changed – the interval for the activity in Table 1-2 for unmonitored communications systems was changed from 12 years back to 6 years as it had been in all previous postings. This change promotes consistency with similar activities within Table 1-1 (Protective Relays).
2. The language in two activities in Table 1-2 was changed from "channels" to "communications systems".
3. The language in the Component Attributes in the last row of Table 1-2 was modified to read: "Any communications system with all of the following:" to clarify that all must be present to use the related intervals and activities.
4. In Table 1-4e, a redundant "only" was removed from the Component Attributes in the last row.

A few commenters continued to contrast the Applicability (4.2.1) with the Interpretation represented in PRC-005-1b. The drafting team responded, but no changes were made.

Several comments were offered on the informational posting of the draft SAR to revise PRC-005-2 to add reclosing relays. The drafting team responded, but no changes were made.

Organization	Yes or No	Question 1 Comment

Organization	Yes or No	Question 1 Comment
Bonneville Power Administration	No	1. BPA believes the term communications system and channel needs to be clarified as to whether the intent is the communications system, a channel on the telecommunication channel, the teleprotection channel, or the teleprotection function. 2. A. Minimum battery maintenance interval is to assure that the battery plant will perform as needed, and obtain a reasonable confidence that it will continue acceptable performance until the next maintenance evaluation. Typically, any utility VLA battery application, steady state float charge/long duration discharge, a Monthly or Quarterly maintenance is excessive given a proper design/maintenance program (IEEE 450, 484, 485). There is a 60 year proven history of this. BPA recognizes that there will be specific VLA battery installations that will be required beyond this minimum. BPA recommends rolling the 4 month maintenance into the 18 month maintenance schedule. B. The scientific vetted method of determining a VLA batteries current performance, and projected performance, is a capacity test. This has been scientifically verified at least 10 times since 1919, with consistent results. This approach is consistent with the IEEE 450, as well as many other standards, and is supported by the industry. If an alternate approach using measured parameters to predict current and future battery performance is to be allowed, then it must assure the same result. C. Battery monitoring does enable measurements to be made automatically with greater frequency. Additionally it provides the ability to collect, store, report, and analyze data from the battery even during an outage. It does not mitigate the necessity to perform battery maintenance. If battery monitoring is performed mandatory maintenance should also be required on the monitor.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT has modified "channel" to "communications system" in Table 1-2 in response to your comment. Discussion was also added to Section 15.5.1 of the Supplementary Reference and FAQ Document to explain "channel". 2. See below: A. The drafting team disagrees with your assertion that the 4 month interval should be extended to the 18 month maintenance schedule for performance of maintenance activities. The 18 month maximum maintenance interval for the unmonitored VLA battery used in a Protection System station dc supply is too long for verification that there is any voltage on the dc supply, that each cell of the unmonitored station battery is inspected to see that it has electrolyte in it, or that the unmonitored dc supply is inspected for unintentional dc grounds. B. The drafting team agrees with you that the performance capacity test is a well proven method to determine the capacity of a station battery and provides an indication of the health of the battery. However, there are other measurements that are indicative of battery health and performance that when trended to the station battery baseline and examined along with the other maintenance activities required in Table 1-4 of the standard can indicate that station battery can perform as manufactured. By trending periodically measured properties indicative of battery performance while serving its Protection System, the Transmission Owner, Generator Owner or Distribution Provider can develop a condition based method to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) if the station battery should be replaced without performing a capacity test, based on the analysis of the trended data. C. The drafting team agrees that, "battery monitoring does enable measurements to be made automatically with greater frequency. Additionally it provides the ability to collect, store, report, and analyze data from the battery even during an outage." Besides these positive qualities it alleviates the necessity to physically perform - in the station - most of the battery maintenance activities listed in Table 1-4 (see Table1-4 (f)). However, the inspection of the battery, its cells and the physical condition of the battery rack are mandatory maintenance activities that must be performed by the maintenance workforce at the station or via remote control. Concerning the maintenance of the monitoring system, please refer to Table 2 (Alarming Paths and Monitoring) of the standard for the mandatory maintenance that is required on the monitor.		
Imperial Irrigation District (IID)	No	IID does not agree with the proposed changes to the definition of Inspect using the word Examine and suggests using Visual Examination instead.
Response: Thank you for your comments. The SDT believes the word 'Examine' is correct.		

Organization	Yes or No	Question 1 Comment
Western Area Power Administration	No	The Standard Drafting team has made changes to the battery maintenance tables 1-4 (a-f) that does not reflect the extensive re-wording of the Supplemental Reference/FAQ document or address the posted recommendations of IEEE Battery Task Force. The industry needs clear, concise maintenance tasks, intervals and standards for their maintenance programs that are developed and tested by industry experts such as IEEE and EPRI.
Response: Thank you for your comments. The changes to maintenance tables 1-4 (a-f) were made as a result of conversations with members of the IEEE Battery Task Force and their recommendations to the drafting team. The drafting team disagrees with the assertion that the changes to the tables do “not reflect the extensive re-wording of the Supplementary Reference and FAQ document.” The drafting team considered the IEEE Battery Task Force Recommendations and revised the Standard with the assistance of several of their members (see the drafting team response posted on the NERC site). The drafting team believes that the Component Attributes, Maximum Maintenance Intervals and Maintenance Activities of Table 1-4 are clear and concise. If an owner has a question concerning how to perform any maintenance activity listed in the table, the Supplementary reference and FAQ document along with IEEE and EPRI documents provide unambiguous and succinct examples of how to perform the activity. This standard is not intended to instruct the Transmission Owners, Generator Owners or Distribution Providers on how to perform the minimum maintenance activates listed in the tables. PRC-005-2 must plainly and tersely tell the owners what they must do - not how to do it.		
American Electric Power	No	The first column, third row of Table 1-2 should be clarified to indicate whether the bulleted items are related by an “or” clause or an “and” clause. For example, must the communication system have either or both of those attributes for it to be considered?
Response: Thank you for your comment. We are requiring both bullets to be applicable and have changed the wording to better reflect our intention.		
ReliabilityFirst	No	ReliabilityFirst offers the following comments related to the bullet points in Question 1:

Organization	Yes or No	Question 1 Comment
		a. Bullet 1 - Agree with definition revisions b. Bullet 2 - Agree with clause 4.2.5.4 c. Bullet 3 - Disagree with revised Table 1-2 “Component Type - Communications Systems.” The revision increased the maximum time for unmonitored systems to 12 years. However, communication failures correspond to one of the top three causes of Misoperations. The revised last row of the Table 1-2 still permits continuous monitoring to be substituted for testing. It is not clear that the available monitoring can actually identify the health of many of the components that can fail in a power line carrier communication system. RFC believes more research is needed to substantiate the 12 calendar year maintenance interval for unmonitored communications systems. d. Bullet 4 - Disagree with revised tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f “Component Type - Protection System Station dc Supply....” The changes appear to largely ignore the recommendations of the IEEE Stationary Battery Committee.
Response: Thank you for your comments. A. Thank you. B. Thank you. C. The SDT agrees with your comment and has changed the maximum interval for this activity back to 6 calendar years. D. The changes to maintenance tables 1-4 (a-f) were made as a result of conversations with members of the IEEE Battery Task Force and their recommendations to the drafting team. The drafting team considered the IEEE Battery Task Force Recommendations and revised the standard with the assistance of several of their members (see the drafting team response posted on the NERC site).		
BAE Batteries USA	No	I agree with the basic changes, but recommend that a slight modification be made to Tables 1-4(a) and 1-4(b). In the box defining the 18 calendar Months or 6 Calendar Years, the portion in parentheses (e.g. internal ohmic values or float current) should be changed to (e.g. internal ohmic values or

Organization	Yes or No	Question 1 Comment
		float current in concert with other accepted measurements).
Response: Thank you for your comments. The drafting team disagrees and believes that examination of other accepted measurements and inspection results (indicative of battery performance) are a part of trending to the station battery baseline. This same inference applies to the interpretation of the results of a performance or modified performance capacity test for determining whether a station battery should be replaced or cells removed. Please see section 15.4 of the Supplementary Reference and FAQ document for a further discussion of this topic.		
Central Lincoln	No	Central Lincoln agrees with most of the changes except for the change from “as designed” to “as manufactured” in the Station DC supply table. The concern is not high enough to warrant a negative ballot, and we appreciate the difficulty the SDT has had on this issue with IEEE. The “as manufactured” performance may be interpreted as the battery’s capacity when new and fully charged. Of course a properly engineered system will be based on a future aged battery capacity, reduced from the brand new capacity. We prefer “as designed,” but this might lead a CEA to ask for design documentation an entity may have not retained. In the end, it is not the manufactured or design capacity that matters, it is the battery’s ability to power the protection systems and trip the breakers. We suggest “as manufactured” be changed to “as needed.”
Response: Thank you for your comment. One of the reasons that “as designed” was changed to “as manufactured” is as you discussed. If “as designed” is used it will be difficult for the owner to determine the original design for the dc system, making it difficult for an owner during an audit. Just like the term “as designed” is difficult to document, “as needed” will also be harder for the owner to document than “as manufactured.” See question “Why is it necessary to verify the battery string can perform as manufactured?” in Section 15.4 of the Supplementary Reference and FAQ document for a further explanation of this change.		
EPRI	No	1. Table 1-4a - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-and-Verify that the station battery can perform as manufactured by conducting a performance capacity test of

Organization	Yes or No	Question 1 Comment
		the entire battery bank. 2. Table 1-4b - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-or-Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank. 3. Table 1-4c - Verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values against the baseline values of each cell.-and-Verify that the station battery can perform as manufactured by conducting a performance capacity test of the entire battery bank.
Response: Thank you for your comments: 1. The standard drafting team believes the “or” of table 1-4(a) should not be replaced with the “- and -” as stated in your comment. The station battery owner of a VLA battery should be allowed to perform either of the two maintenance activities listed in table 1-4(a) to be compliant with the standard, and that “cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current)” should remain in the standard. 2. The standard drafting team agrees that the “-or-”should remain as you suggested in your comment. This will allow the owner of a VLRA battery to choose compliance by performing either of the two maintenance activities at their maximum maintenance intervals listed in table 1-4(b). 3. Because of the marked difference in the aging process of lead acid and nickel-cadmium station batteries the drafting team does not believe that trending ohmic values against the baseline values of each cell, and conducting a performance capacity test of the entire battery bank is the appropriate maintenance activity for NiCad Batteries to ‘Verify’ that the station battery can perform as manufactured. The only appropriate maintenance activity in Table 1-4(c) at the maximum maintenance interval of 6 calendar years is to “Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.”		
Illinois Municipal Electric Agency	No	Illinois Municipal Electric Agency supports comments submitted by Florida Municipal Power Agency. IMEA appreciates SDT efforts, and supports the overall refinements in PRC-005-2; however, the inconsistency between 4.2.1 and the FERC-approved interpretation of PRC-005-1b needs to be resolved

Organization	Yes or No	Question 1 Comment
		to avoid confusion. This issue has implications for smaller entities in particular.
Response: Thank you for your comments. The SDT believes that the Applicability 4.2.1 as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT believes all Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within PRC-005-2; thus the Interpretation does not apply to PRC-005-2. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.		
PPL Generation, LLC on behalf of its Supply NERC Registered Entities	No	See Question 3 Comments
Response: Thank you for your comments. Please see the response to your Question 3 comments.		
TPI	No	See IEEE Stationary Battery Committee Letter dated 23 March 2012
Response: Thank you for your comments. The drafting team considered the IEEE Battery Task Force Recommendations and revised the standard with the assistance of several of their members (see the drafting team response posted on this project's page of the NERC website).		
Tennessee Valley Authority	No	
MRO NSRF	Yes	While we agree with the changes made, we believe that table 1-4 should include in the 18 calendar month maintenance activities: 1) Setting the battery charger to equalize, and 2) Inspect battery charger components for leakage and or damage. These additional steps would verify the ability of the battery charger to operate as needed.
Response: Thank you for your comments. Because all battery chargers used in Protection Systems do not have equalize settings or have components that leak, the drafting		

Organization	Yes or No	Question 1 Comment
team does not believe your recommendation is appropriate for this standard.		
Southern Company	Yes	Related to the changes identified in the Battery Tables: 1. We do not see that the change from "as designed" to "as manufactured" really changed the meaning of the battery capability to delivery its rated capacity. We would like the SDT to consider the following language: "verify that the station battery can provide adequate power to the Protection System by conducting....." 2. For Generating Plant Batteries, we feel as though that the only way to prove that a generation battery can deliver what it is supposed to be able to deliver for "All" of its functions is by conducting a capacity test". We would like the SDT to consider adding such a Note to the battery tables and/or make the statement in the FAQ document.
Response: Thank you for your comments: 1. To "verify that the station battery can provide adequate power" for a battery serving a generating station dc supply or a station dc supply that has dc loads considerably greater than the Protection System requirements may appear to be a good choice; however, the use of "adequate power" makes it difficult for the Generator Owner to determine the original design of the dc system and show an auditor that "adequate power" can be delivered to the dc system by the battery. For this reason and others explained in the Supplementary Reference and FAQ document under the question "why is it necessary to verify the battery string can perform as manufactured?" The drafting team believes that perform as "manufactured" is the best wording for the standard. 2. Your concerns about large amp-hour batteries used in generating stations and transmission stations with large auxiliary loads was addressed in the drafting team's response to the Chair of the IEEE Stationary Battery Committee, which stated: "In contrast to the Transmission Owner battery design function, a Generator Owner's battery likely feeds other critical loads such as DC powered oil pumps, seal oil pumps, and other DC control power loads necessary to safely shutdown a power plant following a loss of AC power. In the case of nuclear plants, these DC loads could include motor operated valves and other loads related to nuclear safety. For the Generator Owner, the design load profile for the battery is a long duration, deep discharge of the battery. While a cell ohmic value trending program might be adequate to prove that the Generator Owners battery could fulfill its Protection System function, the Generator Owner might want to		

Organization	Yes or No	Question 1 Comment
validate the deep discharge capability of the battery by routine periodic capacity testing to prove the battery's adequacy at providing power to those long duration loads critical for plant shutdown. The PSMTSDT believes that this deep discharge battery capacity test approach will prove the battery can meet its function relative to the plant Protection System without also having a trending program for cell ohmic values.”		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP agrees that the changes described above make PRC-005-2 clearer and less ambiguous. We believe that this will result in far fewer violations related to administrative or documentation errors - and focus on those cases which actually may impair BES reliability.
Response: Thanks for your support.		
San Diego Gas & Electric	Yes	TABLE 1-5: Similar to the distributed under-frequency load-shedding relays, SPS control circuitry should only be regulated to verify the integrity of the control circuits from the relay to the lockout or auxiliary relay that is used to trip the circuit breakers, but not to the circuit breakers themselves. Owners of SPS control circuitry should have the option of testing these schemes using test procedures that will confirm the control circuitry through the completed trip circuit is continuous and that the circuit breaker will operate when required. Often times the operation of the circuit breaker is confirmed by operation through other protection systems and the SPS function is a parallel path that can be verified without operating the circuit breaker. This change would allow the Transmission Owner to eliminate equipment outages required to test this scheme or the risk caused by removing the SPS for energized testing.
Response: Thank you for your comments. The table only requires that the SPS control circuit path including the trip coil of the breaker be verified with a 12 year maximum interval. The testing does not have to be done all at once; the maintenance activities in the table can be performed in segments and are complete as long as the entire circuit is tested within the interval. Section 10 of the Supplementary Reference and FAQ document provides additional discussion on this.		
Alliant Energy	Yes	While we agree with the changes made, we believe that Table 1-4 should

Organization	Yes or No	Question 1 Comment
		include in the 18 month maintenance activities more checks on Battery Chargers. Based on EPRI data and vendor recommendation we believe that 1) Setting the Battery Charger to equalize, and 2) Inspect battery charger components for leakage and/or damage should be added. These additional steps would better verify the ability of the battery charger to operate as needed.
Response: Thank you for your comments. Because all battery chargers used in Protection Systems do not have equalize settings or have components that leak, the drafting team does not believe your recommendation is appropriate for this standard.		
Ameren	Yes	We believe that the SDT has improved the definitions with these changes and we fully support them. In addition, we also support the Table 1-2 Communication Systems changes based on our experience, and the Station dc Supply changes in the five Tables 1-4a, 1-4b, 1-4c, 1-4d, and 1-4f because they are realistic and consistent with our experience.
Response: Thank you for your support.		
Public Service Company of New Mexico	Yes	1. PNM seeks clarification on the revised Clause 4.2.5.4 of the Applicability section of the standard. - “Protection Systems for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.” Will Auxiliary Transformers that are directly connected to the generator bus of generators which are part of the BES and that step down to distribution level voltage & perform similar functions as that of station service transformer fall under this clause?
Response: Thank you for your comments. If the cited Protection Systems trip the generator, they are applicable to the requirements of PRC-005-2 and maintained accordingly.		
Brazos Electric Power Cooperative	Yes	Please see the formal comments submitted by ACES Power Marketing.

2. The SDT made complementary changes in the "Supplementary Reference and FAQ Document" to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for further improvements?

Summary Consideration:

Commenters suggested a variety changes to the Supplementary Reference and FAQ document. The SDT appreciated the feedback and made numerous modifications to the document ranging from correcting typographical errors to including some additional FAQ and corresponding answers, as well as presenting new and revised technical content.

Organization	Yes or No	Question 2 Comment
San Diego Gas & Electric	No	R5/M5: M5 should add "The evidence may include but is not limited to...tracking of the unresolved maintenance issue in accordance with the TO's corrective maintenance process." This alleviates the Transmission Owner from setting up a separate corrective maintenance tracking process intended solely for this regulation.
Response: Thank you for your comments. This comment is related to the standard itself and not to the Supplementary Reference and FAQ document. The Measures are intended to provide examples of evidence, and are not meant to be all-inclusive.		
Illinois Municipal Electric Agency	No	Illinois Municipal Electric Agency supports comments submitted by Florida Municipal Power Agency.
Response: Thank you for your comments. Please see the responses to Florida Municipal Power Agency's comments.		
PPL Generation, LLC on behalf of its Supply NERC Registered Entities	No	See Question 3 Comments

Bonneville Power Administration	Yes	BPA requests the drafting team to provide more detailed examples of the following for both monitoring and testing: 1. That addresses the multiple routes, and automated switching between the routes, in a typical large Telecommunications Network Cloud. This applies only if testing of the 'cloud', or a teleprotection channel through the 'cloud', is the intent of the standard. 2. That addresses the fact that many older teleprotection technologies, not only used separate test inputs/outputs, but the internal path through the equipment is unverified until the particular function is activated. I.E.: In certain technologies, a functioning 'guard' signal does not have any correlation to a functioning 'trip' signal.
Response: Thank you for your comments. 1. The intent of the standard is to verify the teleprotection channel is functional, regardless of what constitutes the channel. 2. The SDT believes that the maintenance activity in Table 1-2, "Verify operation of communication system inputs and outputs that are essential to proper functioning of the Protection System" allows the entity flexibility to maintain the various technologies that they may own. The Supplementary Reference and FAQ document addresses some of the options available, but obviously cannot provide detail on all types of equipment.		
ACES Power Marketing Standards Collaborators	Yes	Several capitalized terms in the supplementary reference document are used inconsistently with their definition or the reference to their definition is not clear. For example, "communications Systems" in the second bullet in section 2.2 uses "Systems" inconsistently with its definition. The use of "sensing Element" on page 6 is another example. We believe this is inconsistent with the definition of Element which could be a generator, transformer, circuit breaker, bus section, etc. but does not appear to be a Protection System Component. The "localized" definition of Component that is contained in the standard should also

Organization	Yes or No	Question 2 Comment
		be included in the reference document since it is not in the NERC Glossary. Use of “dc Load” on page 82 is not consistent with the definition of Load. Load is an end use customer. There are many other places in the document where there are inconsistencies with these definitions. Thus, the document needs to be further reviewed to ensure the use of the terms is consistent with their definitions.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document as you suggested.		
Dominion	Yes	The term ‘Underfrequency' is capitalized in the Supplementary Reference document yet it is not included in NERC’s Glossary of terms. We suggest a return to lower case. In fact, given this document is meant to be used for reference only, we question the need to capitalize any term.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document as you suggested. For consistency with the standard, the SDT will continue to capitalize terms when they are used in the context defined in the NERC Glossary of Terms.		
Luminant	Yes	The testing of non-BES breakers for plants should be discussed in the FAQ using the similar application for Distribution Providers. Luminant recommends a section for Generation Owners that describes what Elements (circuit breakers) should be tested. Luminant strongly believes that there is no additional benefit to the BES by requiring the GO to test the non-BES breakers (UAT low side and generator field breakers). These circuits are radial fed.
Response: Thank you for your comments. The FAQ discussion on testing of non-BES breakers for Distribution Providers pertains to those devices used as part of UFLS or UVLS schemes. Section 15.3.1 of the Supplementary Reference and FAQ document has been augmented to address this topic for Generator Owners.		
Southern Company	Yes	See comment on Generating Plant Batteries in Question #1.
Response: Thank you for your comments. Please see the response to your comments in Question 1.		
Western Area Power	Yes	Western Area Power Administration is appreciative of the hard work done by the SDT

Organization	Yes or No	Question 2 Comment
Administration		and NERC. We respectfully submit that the Supplementary Reference and FAQ Document should: 1. Offer guidance on establishing baselines for older battery banks 2. Be in agreement with IEEE standards for battery maintenance 3. Replace the existing CANS
Response: Thank you for your comments. 1. Please see Section 15.4.1 of the Supplementary Reference and FAQ document, specifically the question, "How is baseline established for cell/unit internal ohmic measurements?" which offers guidance on establishing baselines for older battery banks. 2. The IEEE documents to which you refer are "Recommended Practices" as explicitly stated in their titles and not mandatory standards. The SDT considered the IEEE Recommended Practices, as well as other documents, in developing the minimum requirements and maximum intervals within PRC-005-2. 3. The CANs are developed by NERC Compliance Staff to address specific currently-approved NERC Standards, and will be retired when the related standards are retired. The SDT has no control or influence regarding CANs.		
Alliant Energy	Yes	Section 15.4 of the FAQ document does an excellent job of describing the details of battery maintenance and testing, but there is essentially no description of battery charger maintenance and testing activities. We believe this section needs to be expanded to include a good description of battery charger maintenance activities as well.
Response: Thank you for your comments. While manufacturers' recommendations for maintenance of their equipment are quite diverse, the required maintenance activities within PRC-005-2 for battery chargers are: verification of the station dc supply voltage (maximum unmonitored maintenance interval 4 calendar months); and, verification of the battery charger float voltage (maximum unmonitored maintenance interval of 18 calendar months). If anomalies regarding the battery charger are found by performing these activities, relevant corrective actions should be taken.		
American Electric Power	Yes	Rather than voluminous supplementary references, we suggest adding this information, as necessary, to the standard itself. Not only would this prove beneficial by having less information housed outside of the standard, it might also help prevent

Organization	Yes or No	Question 2 Comment
		the need for future CANs and interpretation requests. Though the guidance provided in these documents may appear to be beneficial, we are troubled that the SDT feels it is necessary to provide such a volume of material outside the standard itself, and yet still consider such “references” as enforceable.
Response: Thank you for your comments. This document provides supporting discussion, but is not part of the standard and not enforceable. The SDT intends that it be posted as a reference document accompanying the standard. As established in the SDT Guidelines, the standard is to be a terse statement of requirements, and is not to include explanatory information like that included in the Supplementary Reference and FAQ document. The Supplementary Reference and FAQ document will be revised in conjunction with any revisions of PRC-005.		
BAE Batteries USA	Yes	1. On page 21 of 97,Question 7.1, "Please provide an example of the unmonitored versus other levels of monitoring available," "Every six calendar years, perform/verify the following: Battery performance test (if ohmic tests are not opted)" - add after ohmic tests "or other accepted battery measurement parameters." 2. pg 22 of 97, Example 2 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to station battery baseline . . ." 3. pg 23 of 97, Example 3 "Every 18 calendar months": Add the same verbiage so that the first bullet reads: "Battery ohmic values or other accepted battery measurement parameters to station battery baseline . . ." 4. pg 23 of 97, Example 3 "Every six calendar years": Add the same verbiage so that the first bullet reads: "(if internal ohmic test or other accepted battery measurement parameters to station battery baseline are not opted)" 5. pg 27 of 97, Question 8.1.2, item #4: Change the last sentence to read: "However, the methods prescribed in these recommendations cannot be specifically required because they are offered as best practice guidelines and not set as standards." 6. pg 71 of 97, Question 15.4.1, Frequently asked Questions: "How is a baseline

Organization	Yes or No	Question 2 Comment
		established for cell/unit internal ohmic measurements?" 2nd paragraph - 1st sentence, replace the word "consistent test equipment" with "the same type of test equipment." In addition, should add a final sentence at the end of this paragraph that states, "Also, in many cases, one manufacturer's 'conductance' test may not produce the same measurement results as another 'conductance' test manufacturer's equipment. Therefore, for meaningful results to an established baseline, the same instrument should always be used." 7. Page 73 of 97, Question 15.4.1, Frequently asked questions: "What conditions should be inspected for visible battery cells?" Approximately in the 7th line modify the sentence to read . . .abnormal color(which is an indicator of sulfation or possible copper contamination) . . . 8. Page 75 of 97, Question 15.4.1, Frequently asked questions: "How do I verify the battery string can perform as manufactured?" 2nd paragraph that reads "Whichever parameter is evaluated . . ." should be revised to say "Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, specific gravity, performance test, or combination thereof), the goal is to determine . . . 9. Page 75 of 97, Question 15.4.1, Frequently asked questions: "How do I verify the battery string can perform as manufactured?" 5th paragraph starts, "A detailed understanding of the characteristic of a battery is also attempting to use float current as a measure of the ability of a battery . . . and ends with "to see if a trending process is recommended for determining aging of these products." The Stationary Battery Task Force recommends deleting this whole paragraph due to inaccuracies or statements that are not relevant. If a paragraph that alludes to float current is considered critically essential, then a short paragraph could be substituted which might say," Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement devices is to establish a trending line against baseline so that a documented process establishes the validity of the judgment used to determine that the battery may

Organization	Yes or No	Question 2 Comment
		perform or not perform as manufactured." 10. Page 81 of 97, Question 15.4.1, Frequently asked questions: "Why does it appear that there are two maintenance activities in Table 1-4(b) for VRLA batteries . . . .?" 3rd paragraph: "A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to 'perform as manufactured.'" This might better be restated as follows: "Trending against the baseline of VRLA cells in a battery string is essential to determine approximate state of health of the battery. For example, using ohmic measurement testing as the mechanism for measuring the battery cells, then, if all the cells in the string show to be in a consistent trend line and that trend line has not risen above say a 25-30% deviation over baseline, then a judgment can be made that the battery is still in a reasonably good state of health. This judgment can assume that the battery is still able to 'perform as manufactured.' It would be wise to confirm the accepted deviation range with the manufacturer of the battery in question to assure good judgment in deciding on the state of health to perform as manufactured.' This is the intent of the "perform as manufactured six-month test' at Row 4 on Table 1-4(b)." 11. Page 81 of 97, Question 15.4.1, Frequently asked questions: [same as Item #10 above], following paragraph: Recommend using a range of 25-30% with the statement that "It would be wise to confirm the accepted deviation range with the manufacturer of the battery in question to assure good judgment' in deciding on the state of health to perform as manufactured.

Response: Thank you for your comments.

2. The SDT modified the Supplementary Reference and FAQ document on page 22 as you suggested.
3. The SDT modified the Supplementary Reference and FAQ document on page 23 as you suggested.
4. The SDT modified the Supplementary Reference and FAQ document on page 23 as you suggested.
5. The drafting team agrees with your comment concerning all of the best practices of the IEEE guidelines not being requirements of the standard and incorporated your comments into the Supplementary Reference and FAQ document on page 27.

Organization	Yes or No	Question 2 Comment
6. The drafting team incorporated your comments concerning same type test equipment replacing consistent type test equipment on pages 71 & 72 of the Supplementary Reference and FAQ document. 7. The drafting team added a comment regarding color observation on page 74 of the Supplementary Reference and FAQ document. 8. The SDT modified the Supplementary Reference and FAQ document on page 75 as you suggested. 9. The SDT modified the paragraph on float current on page 75 of the Supplementary Reference and FAQ document as you suggested. 10. The SDT modified the Supplementary Reference and FAQ document based on your comment. 11. The SDT revised the Supplementary Reference and FAQ document as you suggested.		
Georgia Transmission Corporation	Yes	Recommend adding further comments on data retention. We prefer the interpretation for the maintenance cycles equaling 12 calendar years, example microprocessor protective relays. This proves the extreme of data retention. We interpret the retention period to be 24 years. Previous test record to current test record equals 12 years, and 12 more years (next maintenance cycle) before removing previous records from storage (24 years).
Response: Thank you for your comments. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05.		
Ameren	Yes	(1) Capitalizing in some cases is inappropriate (e.g., Systems; Glossary defines System as 'A combination of generation, transmission, and distribution components.' So 'communication System' incorrectly capitalizes 'system'). (2) Page 15, we disagree with retention of maintenance records for replaced equipment as this can cause confusion. We believe that at the most the last maintenance date could be retained to prove interval between it and the test date of the replacement equipment that provides like-kind protection. (3) We request the SDT to provide a few examples of 'non-battery-based dc supply'. The SDT has previously responded that this does not include 'capacitor trip devices'.

Organization	Yes or No	Question 2 Comment
		Does the SDT mean to include M-G sets, flywheels, and / or rectifiers? Also, Emerging Technologies on page 73 is vague please clarify.
Response: Thank you for your comments. 1. The SDT revised the Supplementary Reference and FAQ document to address your comment. 2. The records for removed/replaced equipment need to be retained to provide documented evidence that the entity was in compliance for the entire compliance monitoring period. This documentation includes maintenance activities as well as maintenance intervals. 3. As noted, the drafting team previously stated that the "capacitor trip devices" on circuit breakers and reclosers are not examples of station dc supply devices using emerging technology. Some of the non-battery based energy storage devices with demonstrated prototypes for use in Protection System dc supplies are the flywheel and the fuel cell. One non-battery based dc supply commercially available in the United States and Canada uses compressed air and a capacitor to replace the electrochemical process of a station battery for supplying the dc power required for operating Protection System elements and for supplying normal dc power to the station in the event of loss of ac power.		
Public Service Company of New Mexico	Yes	The Supplementary Reference and FAQ Document has served as a valuable resource and PNM commends the drafting team's efforts in writing a comprehensive document. Section 13. Self Monitoring Capabilities and Limitations - Last but one bullet on Page 59 of the Supplementary Reference and FAQ Document is confusing and needs possible rewording and clarification. "With this information in hand, the user can document monitoring for some or all sections by extending the monitoring to include..." appears confusing.
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document to address your comment.		
EPRI	Yes	Why consider the ability of the station battery to perform as manufactured? The reason the term "perform as manufactured" was used is because there is not much data available to verify actual sizing of the cells for their application. The only battery values for typical Protection systems that have a verifiable basis are the battery manufacturer's data. The only way to know when a battery needs to be replaced is to

Organization	Yes or No	Question 2 Comment
		compare measured values against manufacturer's data or other established values. To verify that the station battery can perform as manufactured is the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. Inspections alone do not provide trending information that indicates the state of aging of a station battery. The maintenance activities listed in Table 1-4 to "verify that a station battery can perform as manufactured" are intended to provide information about the aging process of a station battery. A Transmission Owner, Generator Owner or Distribution Provider can then use the information provided by the maintenance activity to determine if testing of a station battery is required or if timely replacement or removal of the station battery or its components (cell/unit) should be accomplished. Capacity discharge testing is the only industry approved method of determining the true capacity of lead acid and nickel-cadmium station batteries. The performance capacity test of the entire battery bank listed as maintenance activities of table 1-4 provides a mechanism for trending battery discharge characteristics based on manufacturers published data. Trending discharge test results is the basis for determining the aging of a station battery serving a Protection System. Based on these results, decisions concerning replacement of a battery serving a Protection System and its components can be made by the Transmission Owner, Generator Owner or Distribution Provider. There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of the two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. However, the primary failure of nickel - cadmium batteries is because of the gradual linear aging of the active materials in the plates. The electrolyte of a nickel - cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued

Organization	Yes or No	Question 2 Comment
		corrosion of the positive plate and grid structure throughout its operational life while a nickel - cadmium battery does not. Changes to the periodic measured properties of a lead acid battery when trended to a baseline can provide an indication of aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate. Since aging in nickel-cadmium cells is linear, periodic measured properties of nickel-cadmium cells when trended to a baseline can provide an indication of aging of the active material in the positive plates. By trending periodic measured properties of a station battery serving its Protection System the Transmission Owner, Generator Owner or Distribution Provider can develop a condition based method to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test. There is a clear difference in the aging process of lead acid and nickel-cadmium batteries. The measurable properties of a nickel - cadmium battery will change more gradually than VRLA cells; therefore, periodic interval and trending to determine aging has very little industry experience, but the user should work with the battery manufacturer to determine if internal ohmic measurements can be applied to their product. While it has been proven that there is a relationship between internal ohmic measurements and cell capacity of lead acid batteries, an accurate determination of a battery's exact capacity cannot be attained by measuring its cell's internal ohmic values. However, trending internal ohmic measurement of VRLA battery cells to establish a base line is a method of trending measured properties by Transmission Owners, Generator Owners and Distribution Providers to evaluate their station battery cells for health and aging. Evaluating internal ohmic cell/unit measurements against the battery cell baseline values is an acceptable Maintenance Activity listed in tables 4-1(a) and 4-1(b) 4-1(c) to verify that the station battery can perform as manufactured as long as it is measured and trended to the baseline values at an interval less than or equal to the published Maximum Maintenance Interval of tables. Why was the term "manufactured" used instead of "designed" in the maintenance activities of tables 1-

Organization	Yes or No	Question 2 Comment
		4(a), 1-4(b), 1-4(c), 1-4(d) and 1-4(f)?The phrase “as designed” always raises the question of “who made the design requirements that are being tested to or evaluated, the manufacturer of the battery or the engineer sizing the battery? The use of the term designed when discussing a battery’s ability to perform was incorrect because we did not differentiate between a performance test and a service test. The phrase “meets the design requirements” is used when discussing a service test which is a discharge test that measures a battery’s capability to meet a duty cycle which was designed by the person sizing the battery. However, when talking about a performance capacity test, the test is a measure of the currents or amp-hour discharge rates based on the battery manufacturer data for the station battery being tested. The term “manufactured” used in the tables avoids the confusion caused by the term “designed” and its application to service testing. Also, when discussing internal ohmic measurement trending, “manufactured” applies to establishing a set of base line values when compared to a battery of known capacity based on the manufacturer’s published data. When trending other measurable properties that assist in establishing aging, the battery manufacturer’s data are used as a basis for establishment of baseline values and therefore the use of “manufactured” avoids any ambiguity that might be caused by use of the term “designed”.

Response: Thank you for your comments.

The drafting team recognizes that the majority of your comments support and amplify the information contained in the Supplementary Reference and FAQ document. However, the drafting team does not agree with some of the information contained in your comments.

1. While the drafting team agrees that part of the process of determining when to replace a battery should be “to compare measured values against manufacturer’s data or other established values,” we disagree with the statement “the only way to know when a battery needs to be replaced is by using this maintenance activity” because it does not give credit to the role visual inspections play in the replacement process.
2. The drafting team has a broader interpretation of the term “manufactured” than that implied in your comment concerning ohmic measurement trending (“manufacturer’s published data”). We believe the term “manufactured” as used in the maintenance activities of the standard also includes as you stated earlier in your comment “other established values.” Just as

Organization	Yes or No	Question 2 Comment
battery manufacturers establish tolerances that when exceeded constitute further examination of the battery for replacement, test equipment manufacturers, battery owners and others have established tolerances for specific batteries that are considered valid to determine if the particular battery can perform as "manufactured." 3. As implied in your comment and by over a decade of industry experience, it has been proven that there is a relationship between internal ohmic measurements and the aging process of lead-acid batteries. No such relationship has been established for nickel-cadmium batteries. Also at this time - with the exception of the results of a capacity test - the drafting team is unaware of any published data for nickel-cadmium battery properties that can be measured and trended against the station battery baseline. The drafting team believes that either of the two maintenance activities listed in table 1-4(a) and 1-4(b) for lead-acid batteries are acceptable to verify that the station battery can perform as manufactured when conducted at the maximum maintenance intervals of the tables. However, the drafting team disagrees with your inference that table 1-4(c) for Nickel Cadmium batteries should have any other maintenance activity besides the performance or modified performance capacity test of the entire bank to verify that the station battery can perform as manufactured.		
US Bureau of Reclamation	Yes	The FAQ should clarify why the requirement for a "Summary of maintenance and testing procedures" developed by an entity is considered prescribing a methodology to meet those requirements. The entity is developing the methodology for meeting the requirements that the elements be maintained.
Response: Thank you for your comment. "Summary of maintenance and testing procedures" is terminology used in Requirement R1.2 of the existing standard PRC-005-1.1b and is not applicable to version PRC-005-2.		
Oncor Electric Delivery	Yes	On Page 81 of the Supplementary reference and FAQ Draft it appears that the drafting team changed the term "designed" to "manufactured" and then used the quotation from the previous standard's Table 1-4(b). Oncor recommends that the two statements on page 81 of the Supplementary Reference and FAQ - Draft be changed from the present version "...verify that the station battery can perform as manufactured by evaluating the measured cell/unit internal ohmic values to station battery baseline." "Verify that the station battery can perform as manufactured by conducting a performance, service, or modified performance capacity test of the entire battery bank." to a new version of the quotes based on the new version of Table 1-4(b). The new quotes should be stated as follows:"...verify that the station

Organization	Yes or No	Question 2 Comment
		battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline.” ”Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.”
Response: Thank you for your comments. The SDT modified the Supplementary Reference and FAQ document based on your comments.		
Brazos Electric Power Cooperative	Yes	Please see the formal comments submitted by ACES Power Marketing.
Response: Thank you for your comment. Please see the responses to the ACES Power Marketing comments.		
Xcel Energy	Yes	The following paragraph from the top of page 71 in the FAQ should be retained. When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment. Keep in mind that one manufacturer’s “Conductance” test equipment does not produce similar results as another manufacturer’s “Impedance” test equipment, even though both manufacturers have produced “Ohmic” test equipment. This paragraph from page 78 (second full paragraph) should be stricken or re written. Consistency is the key when measuring and evaluating ohmic readings. Consistent testing methods by trained personnel are essential. Moreover, it is absolutely critical that personnel use the same make/model of test instrument every time readings are taken if the values are going to be compared. The type of probe, the location of the reading (post, connector, etc.) and the room temperature during the test needs to be carefully recorded when the readings are taken. For every subsequent time the readings are taken, the same make/model of the test instrument must be used, the same type of probes must be used, and the location of the reading must be the same. The first paragraph explain the consistency issue and the second then removes the ability to

Organization	Yes or No	Question 2 Comment
		use consistent equipment and rather demands that identical equipment be used. This is not a feasible position as manufacturers can and do leave the testing space and therefore the entity should be cognizant of using the appropriate compatible test equipment but to spell out that particular make/models be maintained is not acceptable and brushes against anti-trust complications by inhibiting new players in this testing space.
Response: Thank you for your comments. The SDT revised the Supplementary Reference and FAQ document to address your concerns.		
TPI	Yes	Page 81...this statement is incorrect and should be changed: "A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life." "can be used" has to be changed to "may be used". This should refer to the other FAQ to fully explain how to use ohmic measurements. Page 81...25% is not a universally accepted value. This value has to be determined by experience for a particular type/model of battery. This part of the FAQ contradicts other FAQs.
Response: Thank you for your comments. 1. The SDT revised the Supplementary Reference and FAQ document based on your comment. 2. The SDT used 25% as an example, and revised the Supplementary Reference and FAQ document for clarity. Since there are no universally accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured. This is the most difficult and important part of the entire process. The paragraph on page 81 of the Supplementary Reference and FAQ document has been modified based on your comments.		
HHWP		no comment

Central Lincoln	Yes	
American Transmission Company, LLC	Yes	

3. **If you have any other comments that you have NOT provided in response to the above questions, please provide them here. (Please do not repeat comments that you provided elsewhere.)**

Summary Consideration:

Some commenters continued to object to various activities and/or intervals within the tables. The drafting team made several changes detailed below in response to these comments.

1. One interval was changed – the interval for the activity in Table 1-2 for unmonitored communications systems was changed from 12 years back to 6 years as it had been in all previous postings. This change promotes consistency with similar activities within Table 1-1 (Protective Relays).
2. The language in two activities in Table 1-2 was changed from “channels” to “communications systems”.
3. The language in the Component Attributes in the last row of Table 1-2 was modified to read: “Any communications system with all of the following:” to clarify that all must be present to use the related intervals and activities.
4. In Table 1-4e, a redundant “only” was removed from the Component Attributes in the last row.

A few commenters objected to the prescribed VRFs and/or VSLs. The SDT responded that these VRFs and VSLs are in accordance with guidance from FERC and NERC.

A few comments were offered regarding Data Retention, generally objecting to retaining the maintenance records for two complete maintenance intervals. The SDT responded that the data retention specifications are consistent with auditors’ expectations and with Compliance Process Bulletins 2011-001 and 2009-05.

Several comments were made (some expressed as the reason for a Negative Ballot) in response to the informational posting of the draft SAR to modify PRC-005-2 to add reclosing relays. No changes were made as a result of these comments.

Organization	Yes or No	Question 3 Comment
Ameren		(1) Remove Table 1-4 batteries from the Countable Event definition. (2) Please change Table 1-4(d) title to “Component Type - Protection System Non Battery Based Station dc Supply” [delete: Using Non Battery Based Energy Storage] to be consistent with the definition.

Organization	Yes or No	Question 3 Comment
		(3) R3 & R4: Change VRF to “Medium” for the following reasons: (a) Guideline (3) - Consistency among Reliability Standards is not satisfied. The VRF_Standards_Applicability_Matrix_2012-03-01 clearly shows that comparable requirements in the standards that PRC-005-2 replaces are Medium or Lower, specifically PRC-005-1b R2 VRF is Lower, PRC-008-0 R2 VRF is Medium, PRC-011-0 R2 VRF is Lower, and PRC-017-0 R2 VRF is Lower. (b) The High Risk Requirement is not met. We are not aware that lack of Protection System maintenance alone has directly caused or contributed to bulk electric system instability, separation, or a cascading sequence of failures. (c) Guideline (4) Consistency with NERC’s Definition of the Violation Risk Factor Level is not met. Many entities do not presently perform several of the proposed minimum maintenance activities, and/or perform maintenance activities at greater than the PRC-005-2 maximum interval. Yet BES system instability, separation, or cascading sequence of failure events continues to be extremely rare. (4) Measure M3 on page 6 should only apply to 99.5% of the components. We strongly advocate the SDT to revise and state: “Each ... shall have evidence that it has implemented the Protection System Maintenance Program for 99.5% of its components and initiated....” We believe l that PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability by distracting valuable resources from higher priority duties concerning the Protection System. Note that we are not suggesting for the VSL to be changed. Our proposed reasonable tolerance sets an appropriate level of performance expectation. We disagree with the notion that this is “non-performance”.

Response: Thank you for your comments.

1. The SDT believes that R1.1 is very explicit (All batteries associated with the station dc supply Component Type of a Protection System shall be included in a time-based program) and has precedence over the Countable Event definition. However, the

Organization	Yes or No	Question 3 Comment
		drafting team does not agree that Table 1-4 should be removed from the Countable Event definition; Table 1-4(d) addresses non-battery-based energy storage devices, which can use a performance based program. 2. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard. The drafting team believes the words “Energy Storage” in the title of Table 1-4(d) better conveys the role or circumstance of not having a battery in the dc supply, more so than using the wording from the latest version of the definition of Protection System (non-battery-based dc supply). 3. The SDT believes that the assigned VRFs are correct, as explained below: a. The SDT believes the requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement – to – requirement comparison of VRFs is irrelevant. b. The SDT believes that failure to implement and follow its PSMP could cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures. c. The SDT believes that failure to implement and follow its PSMP could cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures. **4.** VSLs define the degree to which compliance with a requirement was not achieved. Anything less than 100% constitutes a violation.
ACES Power Marketing Standards Collaborators		-1- The data retention requirements for Requirements R2, R3, R4, and R5 are not consistent with NERC Rules of Procedure. Section 3.1.4.2 of Appendix 4C – Compliance Monitoring and Enforcement Program states that the compliance audit will cover the period from the day after the last compliance audit to the end date of the current compliance audit. The data retention requirements compel the registered entity to retain documentation for the longer of “the two most recent performances of each distinct maintenance activity for Protection System Components, or all performances of each distinct maintenance activity for the Protection System Component since the previous scheduled audit date”. Given that many of the maximum maintenance intervals exceed audit periods for responsible entities, an entity could be required to retain data previous to its last audit, which is not consistent with the Rules of Procedure. We suggest changing this such that the data only needs to be maintained since the last audit. -2- Under the “Definitions” section, for the definition of “Protection System” it is

Organization	Yes or No	Question 3 Comment
		unclear whether the bullets constitute items that are considered to be Protection Systems, elements that may be included within a Protection System, or elements which all must be included to constitute a Protection System. A statement preceding the bullets that explains their relationship to the term “Protection System” would be helpful. This clarification should at least be made within the supplementary reference document, if it cannot be made to the actual definition. -3- Requirement R1 VSLs: It is not clear why missing three component types jumps to a Severe VSL. Missing two is a Moderate VSL. Missing three should be a High VSL.
Response: Thank you for your comments. 1. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT’s experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. 2. The definition of Protection System is expressed in the manner that FERC approved on February 3, 2012. 3. The SDT believes that missing three component types is a “significant percentage” and is in accordance with the VSL Guidelines.		
Exelon Corporation and its affiliates		1. In the response to Exelon’s previous comment regarding current transformers, the SDT disagreed that test mandated by the current Standard draft seeks to measure a signal is “provided to the protective relay”; however, the test referenced in Table 1-3 merely confirms that the signal is sent and not that it reached the correct protective relay. Generation sites are built in phases, and these requirements do not ensure that the wiring of the protection system matches the prints and the intent of the engineers who designed it. Please provide a technical explanation of how this type of test for a CT will verify that the signal reaches the relay. 2. In the response to Exelon’s previous comment related to the maintenance activity in Table 1-3 for PTs and CTs as they relate to electro mechanical relays the SDT disagreed that the maintenance program should be left to the discretion of the Generator Owner. Exelon further explained that In order to meet the required activity specified in PRC-005-2 draft 2 Table 1-3, the generating unit would be required to take readings with meters while the unit is operating. This practice

Organization	Yes or No	Question 3 Comment
		introduces a risk of tripping the unit inadvertently. The risk of tripping the unit while performing this maintenance activity is contrary to the intended purpose of PRC-005 and introduces a potentially adverse effect on the reliability of the BES. In its response the SDT has not provided the justification as to why performing such a high risk activity increases the reliability of the BES and justification for testing that refutes existing manufacturers recommendations. 3. In the last round of comments, the SDT did not specifically address Exelon's comments regarding the omission of "...and trips an interrupting device that interrupts current supplied directly from the BES" from the revised applicability language in Section 4.2.1. We are concerned that the SDT may not fully appreciate our concern. Without the qualification that comes from the "and..." phrase above, Exelon feels that section 4.2.1 will bring reverse-looking relays on radial transformers into scope, which are not interpreted as BES Protection Systems. By doing so, it creates a perverse incentive to disable these protection functions, even though they provide a reliability benefit, for the sake of limiting compliance exposure. Please offer a direct response to why the phrase, "...and trips an interrupting device that interrupts current supplied directly from the BES" is no longer included in 4.2.1 and clarify that non-BES relays are not considered within scope. Comments and SDT Response from last comment period (for reference):Exelon Comment: When the SDT changed the original PRC-005 applicability language from "...affecting the reliability of the BES..." to the new 4.2.1 language "...that are installed for the purpose of detecting faults on BES elements (lines, buses, transformers, etc.)", they opted to exclude the second half of this sentence taken from the PRC-005-1a Interpretation, which read "...and trips an interrupting device that interrupts current supplied directly from the BES." By doing so, the SDT failed to recognize that some Protection Systems can be responsive to faults on the BES, but still have no effect on the reliability of the BES. The change in 4.2.1 may unintentionally expand the scope of PRC-005.Depending on how Section 4.2.1 is interpreted, it could create a perverse incentive to disable, or not apply, reverse directional protection on the secondary (at voltages less than 100kV) of radially connected load-serving transformers. Such

Organization	Yes or No	Question 3 Comment
		relaying typically uses available units in a multifunction device, and while not critically necessary for fault clearing, it is applied because it adds a benefit at no incremental cost with minimal security risk, and it will not interrupt a BES element if it operates insecurely. It also improves reliability to connected distribution load, in the event a BES transmission line faults during abnormal switching, by coordinating with non-directional overcurrent relays that would otherwise interrupt the entire load. Furthermore such directional relaying would only operate after the faulted BES line is already removed from any connection at BES voltages via its high voltage (>100kV) circuit breakers. Viewed in an expansive way, the proposed 4.2.1 language could bring into scope these relays as well as tripping circuits of distribution voltage circuit breakers that are normally operated in a radial configuration. It would be reasonable for a TO to disable this relaying, rather than accept these consequences. In the previous comment period (Sept 2011), industry raised similar concerns and to most of the commenters, the SDT responded with the following statement: ” The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.” Unfortunately, this response fails to address the concerns raised above. Entergy previously suggested the following language for 4.2.1:”Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.) and trips an interrupting device that interrupts current supplied directly from the BES Elements.” This language is appropriate and addresses industry concerns. We ask that the SDT adopt this language as Section 4.2.1. SDT Response: The SDT believes that the Applicability, as stated in PRC-005-2, is correct and supports the reliability of the BES. The SDT observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the

Organization	Yes or No	Question 3 Comment
		interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses "Protection Systems that are installed for the purpose of detecting Faults on BES Elements." Please see Section 2.3 of the Supplementary Reference Document for additional discussion. Thank you for the opportunity to comment.
Response: Thank you for your comments. 1. Section 15.2 of the Supplementary Reference and FAQ document provides a technical explanation of how this type of test for a CT will verify the signal reaches the relay. 2. The SDT believes it is possible during a 12-year interval to find a reasonably low-risk opportunity to perform the required test and that performing the test satisfies FERC Order 693 "…that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System." Please see Section 15.2.1 of the Supplementary Reference and FAQ document for examples of off-line tests that can minimize the risk you describe. **3.** Reverse-looking relays (in the cited application) are not installed for the purpose of detecting faults on the BES and would not be subject to this standard. The SDT believes that the Applicability as stated in PRC-005-2 is correct and that it supports the reliability of the BES.		
Southern Company		1. We would like the SDT to consider rewording M5 as follows: The evidence may include any form of evidence indicating an entity is demonstrating efforts to correct identified Unresolved Maintenance Issues. Additionally: All of the examples of evidence should be moved to the Supp Ref doc and be there only for reference. 2. Page numbers should be visible on all pages.
Response: Thank you for your comments. 1. The SDT does not believe that the changes you suggest improve the standard. Regarding "demonstrate efforts to correct…," the SDT's intent is to allow an entity to furnish a way of addressing Unresolved Maintenance Issues without the formality and burden of a full-fledged Corrective Action Plan. 2. The SDT agrees and has referred the concern to NERC Staff for their consideration when preparing the documents for posting.		
Ingleside Cogeneration LP		Although Ingleside Cogeneration LP does not want to derail the improvements that the SDT has obviously made to PRC-005-1, we remain concerned that expansions in

Organization	Yes or No	Question 3 Comment
		scope of a BES Protection System will automatically roll over to other standards. For example, if the loss of a low voltage auxiliary transformer can trip a generator, its Protection System will be in-scope for PRC-005-2. It is not a big leap in logic to assume that the auxiliary transformer itself should be a BES Element - and subject to the whole body of CIP, MOD, IRO, and TOP standards. Our experience has been that Compliance authorities will make these assumptions, even if that was never the intent of the SDT. The effort to develop and maintain procedures, test results, and communications concerning every BES Element is not trivial - and a single instance of a missed requirement may lead to fines in the thousands of dollars. Ingleside Cogeneration is committed to take any action required to assure BES reliability, but NERC and the project teams must have evidence of its own that it is worth the cost.
Response: Thank you for your comments. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
American Electric Power		1. As stated in our previous comments for R3, Table 1-5 notes a “mitigating device” as part of component attributes. The meaning of this phrase is open to interpretation and needs to be clearly defined. Is it a discrete device? A protection scheme? Either? The team’s response, by stating its intentions regarding this phrase, actually illustrates the need to provide clarity for this term within the standard. 2. As stated previously, under the time-based maintenance method and R3, the Entity will be required to utilize the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3. Special Protection Systems, by their nature, may physically include components that are not listed in the NERC definition of Protection System and therefore are not included in the tables of PRC-005-2. The standard, as currently drafted, does not clearly provide a means for an Entity with a Special Protection System to establish both minimum maintenance activities and maximum maintenance intervals for components that have been declared by their Region as part of a Special Protection System but that are *not* included in the NERC definition of Protection System. For example, consider a Special Protection

Organization	Yes or No	Question 3 Comment
		System that is comprised of the following elements: Generating Unit Distributed Control System (DCS) - Qty 1Protective Relays - Qty 4 - Provide digital inputs to DCS Boiler Pressure Transmitters - Qty 2 - Provide analog inputs to DCS For a predetermined set of system events, the protective relays operate, indicating to the DCS that the event has occurred. If the pressure transmitters indicate that the boiler pressure exceeds a predefined threshold, the DCS responds by adjusting the analog output signals to the turbine valves. For compliance with the existing version of PRC-017-0, the owner of the above system has written a Maintenance and Testing Program that thoroughly tests the protective relays, DCS logic and analog inputs and outputs. However, under PRC-005-2, the owner of the system would not be able to use the proposed performance based method because the system does not have the required Segment population of 60 components. This leaves the owner no other option than the time based method. However, only the protective relays meet the NERC definition of Protection System and they are the only elements of this hypothetical SPS described in Tables 1-1 through 1-5. The existing PRC-005-2 draft does not contain time based activities that would be applicable to the DCS logic, analog inputs and analog outputs. Therefore, whereas the existing NERC standards demand the testing of these devices, NERC standards would no longer require their testing upon the implementation of PRC-005-2.
Response: Thank you for your comments. 1. A mitigating device is one that acts to respond as directed by a Special Protection System (SPS). It may be a breaker, valve, distributed control system, or any variety of other devices. 2. The SDT notes that the definition of a Special Protection System states “An automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability.” If the SPS you described meets this definition and contains Protection System components, then PRC-005-2 applies to those Protection System components.		
American Transmission Company, LLC		ATC recommends that the SDT change the text of “Standard PRC-005-2 - Protection System Maintenance” Table 1-5 on page 24, Row 1, Column 3” to: “Verify that a trip

Organization	Yes or No	Question 3 Comment
		coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years." Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. In addition, many utilities purchase breakers with dual redundant trip coils to mitigate the possibility of a failure. It is well recognized that the most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice to mitigate the most prevalent cause of breaker failure. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).ATC continues to recommend a negative ballot since we believe that the testing of "each" trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comments. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to make the modification.		
Colorado Springs Utilities		Colorado Springs Utilities votes "negative" based on the document "Draft SAR for Phase 2 of Project 2007-17" under the section titled Brief Description of Proposed Standard Modifications/Actions, which states " The Standard Drafting team shall modify NERC Standard PRC-005-2 to add reclosing relays to the standard. In order to do so, the definition of Protection System shall be revised to include reclosing relays, the Facilities portion of the Applicability of the Standard shall be revised to describe

Organization	Yes or No	Question 3 Comment
		those reclosing relays that are included within the standard, and appropriate minimum maintenance intervals (with maximum allowable intervals) shall be added to the standard. The Standard Drafting team shall also make any other changes that are necessary to explicitly address reclosing relays, but shall not make general revisions to the standard, either in content or arrangement." Colorado Springs Utilities position is reclosing relays are used as part of the system restoration process, and should not be associated with the protection or reliability of the system. Reclosing relays should be grouped with SCADA controls of breakers and manual controls of breakers, and should be tested with the same frequency. Breaker reclosing is not used on many lines, and is disabled on many lines. Automatic Breaker Reclosing is a system enhancement, not a system requirement.
Response: Thank you for your comments. The SDT notes that the draft SAR for Phase 2 of Project 2007-17 is not applicable to the current successive ballot and was posted for informational purposes only. In Order 758, FERC directed NERC to include reclosing relays in a future version of PRC-005; the SDT developed this draft SAR to address FERC's directive.		
Duke Energy		Duke Energy votes "Negative" because we strongly object to the wording in the Applicability section 4.2.1. We believe that the wording change to PRC-005-2 draft 4 after the previous Successive Ballot but prior to the associated Recirculation Ballot expanded the reach of the standard to relaying schemes that detect faults on the BES but which are not intended to provide protection for the BES. The SDT's response to our comment directs us to Section 2.3 of the Supplementary Reference And FAQ Document which states "There should be no ambiguity: if the element is a BES element then the Protection System protecting that element should be included within this Standard." We agree with that statement, but point out that Section 4.2.1 is inconsistent with that statement, and has a much broader reach because it includes devices that detect Faults on the BES but which do NOT provide protection for the BES. Compliance audits will be driven by the words in the standard, not the explanations in the Supplementary Reference And FAQ Document. We would appreciate a response to our concern that explains the reliability benefit associated

Organization	Yes or No	Question 3 Comment
		with this expansion of scope, and which specifically addresses the following Duke Energy situation: Duke Energy's standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. In the most recent draft, the relays, current transformers, potential transformers, trip paths, auxiliary relays, batteries, and communication equipment associated with the dispersed generation protection scheme would be subject to the requirements in PRC-005-2. Previous drafts of the standard would not have required Duke Energy to maintain the protection system components associated with dispersed generation schemes at retail stations in accordance to the requirements in PRC-005-2. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. Duke Energy does not believe it was the intent of the standard to include elements that did not have an impact on the reliability of the BES. Duke Energy would prefer the following wording for Section 4.2.1: Protection Systems that are installed for the purpose of protecting BES Elements (lines, buses, transformers, etc.)".FERC's September 26, 2011 Order in Docket No. RD11-5 approved NERC's interpretation of PRC-005-1 R1 and R2, stating: "The interpretation clarifies that the Requirements are "applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES." This interpretation is consistent with the Commission's understanding that a "transmission Protection System" is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices."
Response: Thank you for your comments. The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. All Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The SDT observes that the approved Interpretation addresses the term, "transmission Protection System", and notes that this term is not used within		

Organization	Yes or No	Question 3 Comment
PRC-005-2; thus the Interpretation does not apply to PRC-005-2. Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.		
Entergy Services		Entergy provides the following comments to achieve consistency in the written standards: • Numbers indicating measurable quantities should be numbers: 95%, 5%, etc. and not spelled out. • Words indicating a specific document or entity should be capitalized: this Standard • Words indicating generic devices should not be capitalized: components, faults, monitors, misoperation • 4. If two words go together with a singular meaning they should both be either capitalized or not: Communication Systems
Response: Thank you for your comments. The SDT followed NERC's style guide for the various issues you point out.		
FirstEnergy		FirstEnergy supports the standard and thanks the drafting team for all their hard work.
Response: Thank you for your comments.		
Luminant		In addition to the revised Supplemental Reference and FAQ guide revision requested in question 2, Luminant recommends that Table 1-5; Line 1 and 4 be revised to specifically state that only BES elements (circuit breakers/interrupting devices) are to be tested. There is no benefit to the BES system for testing the non-BES breakers and some locations, trip testing of the breakers would cause a unit black-out due to unit design. Some units do not have start-up transformers. By performing these tests, there is a risk of causing unit damage while the unit is off-line. Therefore Luminant recommends that Table 1-5 be revised to only require BES breakers be tested for compliance purposes. This would be consistent with the requirements covered in Table 3 for UFLS Systems.
Response: Thank you for your comments.		

Organization	Yes or No	Question 3 Comment
The SDT revised Section 15.3.1 of the Supplementary Reference and FAQ document to address this concern, and does not believe that further revision of the standard is necessary.		
Public Utility District No. 1 of Okanogan County		In tables 1-4 with regards to station batteries. 1. DC Supply voltage. Is this reading taken off the batteries or out of the charger? Which read needs to be documented? 2. Unintentional grounds. If the charger has the ability to detect and alarm on unintentional grounds, do we need to manually check this as well? 3. In the 18 month section there is a reference to Float voltage of charger. How do we document in our procedure? Can we use SCADA? 4. In the NICAD battery section. Why can't we do impedance testing? Why only load testing? 5. In table 1-5 there is mention of "Lockout Devices" does this mean that 86 relays are being brought into scope? 6. In table 2 there is discussion with regard to Alarm paths and alarm path monitoring. Table 1-5 item 4 discusses Auxiliary Relays in the control circuit path. Typically, Auxiliary relays in this scenario are closed contacts and open when in an alarmed state. For example, a low SF6 alarm contacts on a breaker interrupts the trip circuit and prevents the breaker from operating. Does this type of auxiliary relay need to be tested every 12 years? 7. For monitoring transmission PTs- Can we measure low side voltage (13kv) PTs multiplied by the power transformer ratio to verify transmission PT accuracy? 8. Table 1-3 describes independent "measurements continuously verified by comparison" Does separate AC measurement need to be connected to same relay? or can it be connected to separate relay with comparison done in SCADA?
Response: Thank you for your comments. 1. The verification of dc voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not		

Organization	Yes or No	Question 3 Comment
malfunctioning, and the standard is indifferent as to where the voltage is actually measured. However, Section 15.4.1 of the Supplementary Reference and FAQ document suggests that this voltage be optimally measured at the battery's main terminals. 2. Per Table 1-4(f) and Table 2, if your charger has the ability to detect and alarm on unintentional grounds and meets the Table 2 requirements, no periodic inspection of unintentional dc grounds is required. 3. As explained in Section 15.4.1 of the Supplementary Reference and FAQ document, the maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltage on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. Per Table 1-4(f) and Table 2, if your charger has the ability to monitor and alarm to ensure correct float voltage is being applied on the station dc supply and meets the Table 2 requirements, no periodic verification of float voltage of battery charger is required. The standard is proscribed from describing "how". It is left to the entity to determine what methods best address their program. 4. At this time - with the exception of the results of a capacity test - the drafting team is unaware of any published data for nickel-cadmium battery properties that can be measured and trended against the station battery baseline. 5. As explained in Section 15.3 of the Supplementary Reference and FAQ document, if the lock-out relays (86) are electromechanical type components, then they must be trip tested per Table 1-5. 6. As explained in Section 15.3 of the Supplementary Reference and FAQ document, contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 6 or 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. 7. There are multiple methods to verify the current and voltage signal values as explained in Section 15.2 of the Supplementary Reference and FAQ document. 8. It is left to the entity to determine what methods best address their program. Section 15.2 of the Supplementary Reference and FAQ document discusses various methods of conducting this comparison.		
Manitoba Hydro		Manitoba Hydro is maintaining our negative vote based on our previously submitted comments (see comments submitted in the comment period ending on March 28th, 2012).
Response: Thank you for your comment. The SDT has also not changed its position from that expressed in response to the earlier comments.		
Oncor Electric Delivery		On Page 89 of the Supplementary reference and FAQ Draft document on the References page (reference #12) the correct number of the standard should read "Std

Organization	Yes or No	Question 3 Comment
		450-2010" instead of "Std 45-2010."
Response: Thank you for comment. The Supplementary Reference and FAQ document has been corrected.		
Dominion		On the Redline version of the standard, page 11 Version History; Version 2 Action, should PRC-005-1a be listed as PRC-005-1b and PRC-017 listed as PRC-017-0. Additionally, it does not appear that the Version History has captured a complete record of all revisions to this standard.
Response: Thank you for your comments. The references to the approved standards and the Version History have been corrected.		
Brazos Electric Power Cooperative		Please see the formal comments submitted by ACES Power Marketing.
Response: Thank you for your comment. Please see our responses to the comments submitted by ACES Power Marketing.		
PPL Generation, LLC on behalf of its Supply NERC Registered Entities		PPL Generation, LLC thanks the SDT for their effort on this latest version of the standard and has voted affirmatively. We offer the following comments/suggestions: 1.) PPL Generation, LLC would like more direction on how the Tables 1-3 are to be interpreted. Under the left column "Component Attributes," it is not completely clear as to which situation is applicable in order to know what "Maintenance Activity" applies. Either the table's "Component attributes" or the statement "Include the applicable monitored Component attributes applied to each Protection System Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System Components" could be more prescriptive on the specific component attributes to provide entities direction as to when exactly each table is to be followed. 2.) In regards to Unresolved Maintenance Issues, PPL Generation, LLC is concerned with the use of the word "efforts" in regards to the use in "shall demonstrate efforts" in Requirement 5. We suggest that either a formal definition of "effort" is provided or more clarity is added in the Requirement 5, shown below, that gives a quantitative

Organization	Yes or No	Question 3 Comment
		scale of what constitutes an effort. "Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues." In its current form, "efforts" can be broadly interpreted by auditors as any number of different required actions of an entity and could potentially lead to inconsistencies in applying the term throughout the regions.
Response: Thank you for your comments. 1. The left column of the Tables describes the monitoring attributes (if any) that are available on the particular components. The center and right columns describe the related maximum maintenance intervals and minimum maintenance activities. **2.** The SDT believes there is sufficient understanding in the industry for the term "efforts" and the risk of compliance jeopardy is minimal.		
Progress Energy		1. R3 and the VSL for R3 seem to imply that an entity would not be in violation of this standard if they exceed their PSMP intervals (including any program grace) as long as the maintenance is performed within the maximum intervals prescribed within the tables. This interpretation was further supported in the previous draft of the Supplemental Reference (Section 8.2.1, page 35), which stated: "According to R3, a strictly time-based maintenance program would only be in violation if the maximum time interval of the Tables is exceeded." However, this statement has been removed from the supplemental document under the latest draft revision. Would the entity be noncompliant if they exceed their PSMP interval but not the maximum table interval? 2. Table 1-4(e): Typo. "Any Protection System dc supply used only for tripping only...." 3. Page 51, 4th paragraph, 5th line: Typo "thre" should be "three."
Response: Thank you for your comments. 1. The standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Requirement R3 was revised recently to establish that entities must maintain their Protection System components, at a minimum, in accordance with the relevant tables. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP is necessary; however, according to Requirement R3, the entity will not be held to their more-aggressive (than the tables) PSMP for compliance monitoring purposes.		

Organization	Yes or No	Question 3 Comment
2. The SDT made the suggested editorial change to Table 1-4(e). **3.** The Supplementary Reference and FAQ document has been corrected as suggested.		
ReliabilityFirst		ReliabilityFirst offers the following comments for considerations: 1. General Comment a. ReliabilityFirst believes not only should there be testing required for individual components (as required Protection System Maintenance Program), ReliabilityFirst believes that the entire Protection System (consisting of all Protective relays, communications systems, Voltage and current sensing devices, etc.) should be tested as a whole. Individually each component may test successfully but while tested as a complete Protection System (through interaction between all the interdependent components), deficiencies in settings along with logic and wiring errors could be discovered. 2. Requirement R5 a. ReliabilityFirst believes the language in Requirement R5 ("...shall demonstrate efforts to correct...") is subjective and non-measurable. It will be difficult in determining what amount of "demonstration" an entity will need to provide in order to be compliant along with lack of timeframe in which the correction needs to be completed. While RFC understands it is hard to prescribe a specific timeframe/deadline (it can depend on various number of supply, process and management problems), RFC believes at a minimum, the applicable entity should be required to develop a Corrective Action Plan to address the Unresolved Maintenance Issue. ReliabilityFirst offers the following modification for consideration: "Each Transmission Owner, Generator Owner, and Distribution Provider shall put in place a corrective action plan to remedy all identified Unresolved Maintenance Issues."
Response: Thank you for your comments. 1. The SDT does not believe it feasible to craft requirements for testing an entire Protection System as a whole that would simultaneously prove performance of every component and believes such invasive testing would jeopardize BES reliability. 2. The SDT's intent is to furnish a way for an entity to address Unresolved Maintenance Issues without the formality and burden of a		

Organization	Yes or No	Question 3 Comment
full-fledged Corrective Action Plan.		
Seattle City Light Operations		SCL supports the position of WECC PNGC with regard to the position paper VRF/VSL recommendation. Specifically, it is the contention of PMGC and members that small entities with maybe 2 or 3 components within a Component Type that sustain a violation will unnecessarily be subjected to a “severe” or “high” VSL assignment due to the % based parameter. We feel the SDT did not adequately address our concerns during the last ballot/comment period. While this is a non-issue for larger entities with hundreds or thousands of individual components, we believe this exposes smaller entities to unnecessary compliance risk. 1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given NERC Guidance (following), this seems to be a contradiction given the language of “...more than one” [NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance. ii. MODERATE: Missing at least one significant element (or a moderate percentage) of the required performance. iii. HIGH: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. SEVERE: Missing most or all of the significant elements (or a significant percentage) of the required performance.] Thus we support the WECC PNGC suggestion to change the language for “Lower VSL” for R3 to: 'For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained...' OR 'For Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained...'

Organization	Yes or No	Question 3 Comment
Response: Thank you for your comments. The SDT respectfully disagrees and believes that the Standard appropriately incorporates and accounts for the system risks and burdens of maintenance for both large and small entities. The VSLs were developed in accordance with the "FERC VSL Order" and the NERC criteria; for stepped VSLs - Lower VSL is "5% or less", Medium VSL is "more than 5% up to (and including) 10%", High VSL is "more than 10% up to (and including) 15%", and Severe VSL is "more than 15%".		
Public Service Company of New Mexico		Table 1-1 Component Type - Protective Relay and Table 1-2 Component Type - Communications Systems refer to Table 2 Alarm Paths and Monitoring for monitoring related attributes. However, the maximum maintenance interval in rows referring to Table 2 in both Tables 1-1 and 1-2 is 12 calendar years whereas there is a row in Table 2 that if there is an Alarm Path with monitoring (row 2 of Table 2), no periodic maintenance is required. Does this mean that even if there is an Alarm Path with monitoring for which no periodic maintenance is required, the component type - Protective Relay or Communications Systems will still be required to be maintained within the maximum 12 calendar years interval? This appears to be contradictory especially since rows in Tables 1-3, 1-4(f), and 1-5 that refer to Table 2 have "no periodic maintenance specified" under maximum maintenance interval. This also appears to be contradictory to the text provided under bullet 1 of Section 5.2 Extending Time-Based Maintenance which states that - If continuous indication of the functional condition of the Component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated." Rows referring to Table 2 in Tables 1-1 and 1-2 do not suggest that manual testing will be eliminated as it is requiring a 12 calendar year maintenance time interval even if it meets the requirements under table 2 for alarm path with monitoring. PNM recommends adding the following under Maximum Maintenance Interval to be consistent with other tables 1-3, 1-4(f), and 1-5 - "12 calendar years OR no periodic maintenance specified".
Response: Thank you for your comments. For protective relays and communications systems, the only maintenance activity in the last line of the related table is to verify those unmonitored inputs and outputs that are essential to the proper functioning of the Protection System. The SDT sees no appreciable		

Organization	Yes or No	Question 3 Comment
improvement in the standard with your proposed change and respectfully declines to modify the standard.		
Bonneville Power Administration		1. Table 1-2: Communication Systems: BPA believes that the entire section of Table 1-2 needs clarity. A channel, channel performance criteria, & communication system all have very precise definitions in the communications world. (Please refer to Supplemental Frequency AQ - Figure 1 - Typical Transmission System Diagram, Telecommunications Network Cloud)When referring to the terms in Table 1-2, if the drafting team is referring to the 'telecommunications cloud', this section is unclear. BPA believes it is clearer if the drafting team is referring to the two telecommunications equipment panels and requests documented clarification. The traditional term for this would be teleprotection channel or teleprotection function. BPA assumes the intention was teleprotection channel. BPA recognizes that the teleprotection equipment panels, in many modern cases, are built into the relay. For background information, the Telecommunications Network is composed of multiple Communication Systems (40 to 50 is not uncommon) that contain multiple thousand (5-6K) pieces of equipment. These systems and equipment are tied together with hundreds of thousands of Communication Channels and Tributaries. Most of the Channels and Tributaires have, at least a primary and backup (WECC Guideline: Design of Critical Communications Circuits), and some have multiple primary's and backups. All of these are needed to create the circuit connections, as indicated on the diagram from one teleprotection panel to another teleprotection panel. Given the above scenario - the confusion is possible. As an example, for the component attribute: 'Any unmonitored communication system necessary for the correct operation of the protective functions, and not having all the monitoring attributes of a category below.' The 4 calendar month maintenance activity is to: 'Verify that the communications system is functional.' The questions that arise are which systems, the drop system or the transport system? The whole system or just the part carrying the protective signals? What about the channels interconnecting the various systems and so on? BPA suggests clarifying: Any unmonitored teleprotection function necessary for the correct operation of the protective

Organization	Yes or No	Question 3 Comment
		functions, and not having all the monitoring attributes of a category below. The 4 calendar month maintenance activity is to: ‘Verify that the teleprotection function is functional’ BPA believes this is a much better approach as it identifies only that the teleprotection panels must get inputs and outputs to the relays between them. BPA believes more clarity is still needed. A simple example of an old tone based FSK transfer Trip System over a single point to point analog MW radio channel; the teleprotection panel will normally transmit a guard tone in a particular spectrum over a single radio channel to the teleprotection panel at the far end. BPA understands that one way to verify that the teleprotection function is serviceable in a 4 month maintenance activity is if the guard signal arrives at the opposing end, correct? BPA infers that this is efficient as entities can now monitor loss of guard and have a continuously monitored system which will result in performing just a12 year maintenance. Is this correct? This raises the question of the trip function. Until the trip function is energized from the relay, the circuitry sending the trip by initiating a FSK in not functioning. Does this function needs to be check in addition to the guard function? This raises the question of the MW radio channel. BPA recognizes that the FSK trip signal travels over different spectrum in the analog MW radio. Even if the radio will transmit a Guard FSK signal to the far end, it will not necessarily transmit a Trip FSK signal to the far end (a common hidden failure mode in many MW systems). Do entities need to check for guard at the far end and test that a FSK Trip signal propagates through the radio system and is received at the teleprotection panel? BPA requests clarification in the followings scenario: Using testing inputs as opposed to operating inputs that trips and guards may be initiated from a different set of inputs of the teleprotection panel, and monitored from a different set of outputs on the teleprotection panel (very common on teleprotection equipment). The test might work, but an actual Trip signal would not work (a common hidden failure mode on current available equipment). If one were to say ‘good enough’ for a 4 month test (and hope any auditors agree if there is ever a false operation). How about the 12 calendar year test? For a point to point analog MW radio,

Organization	Yes or No	Question 3 Comment
		there is only a single channel that can be tested for passage of guard and trip tones. If the radio is redundant, which it most likely is (WECC Guideline: Design of Critical Communications Circuits) then this has to be done twice, once for each path. Can the drafting team clarify this scenario? In a more typical real-world case, the circuit connection, between the two teleprotection panels, will transverse multiple redundant communications systems. If it crosses 4 redundant systems in the communications cloud, then there are a total of 4^2 or 16 possible communication channels, each with different test criteria, that need to be tested. Additionally, the channels are rerouted manually and automatically much faster than a 12 year cycle (daily is not uncommon). Do all these combinations need to be tested? This discussion illustrates the confusion of the current wording. BPA recommends that: If the intention is to test in the 'cloud' or the performance of the 'cloud', BPA believes there needs to be a new standard, or set of standards created to deal with the intricacies of the telecommunication cloud. If the intention was to test the teleprotection channel, BPA believes additional clarity needs to be provided to address the dynamic redundancies and rerouting of the communications system. If the intention was to test the teleprotection function BPA believes additional clarity needs to be provided to test/monitor the functions (inputs and outputs) between the teleprotection panels. 2. Table 1-4(a):VLA Battery: 4 Months/Inspect/Electrolyte Level BPA believes that for a properly designed and installed steady state float charge/long duration discharge type battery plant this is not needed. The inspection at 4 Month intervals will unearth catastrophic failures (Split cells, severe overcharging, etc...). These types of failures can happen anytime, and need to be designed around. Unless the battery plant is under high cyclic load, water usage can be handled in a 12/18 month maintenance cycle. Severe overcharging needs to be dealt with by design/maintenance practices (for example: an Appropriate high voltage alarmed with an immediate call out) since 4 months is too long to wait to detect the condition. Minor overcharging will not be detectable in a 4 month interval (and one wants to very slightly overcharge a battery verse any individual cell being

Organization	Yes or No	Question 3 Comment
		undercharged, but that is a whole different technical discussion). IEEE484 specifies ventilation should be provided for the worst-case hydrogen generation due to overcharging. Other than an inherent manufactures defect that can happen anytime 24/7, splitting cells due to sulfation build up is a slow know process that can be handled in a 12/18 month maintenance cycle with a good visual inspection. Although this is in line with IEEE450, given the specific type of battery configuration in the utility world, this is excessive. Should there be a unique battery plant design, then it is incumbent on that utility to have appropriate shorter intervals. BPA is in support of "For unintentional grounds" and recognizes that it does not apply to intentionally grounded battery systems (teleprotection systems run off of communication batteries in sites where there is no station battery {i.e.: Grand Coulee/Lower Snake}).In general there are two types of batteries used by utilities, outside of their control centers, which will be supplying protective systems. The vast majority is the station battery, which is described very well in the IEEE standards: Switchgear control battery applications typically require output current levels that vary over a relatively long period of time. The battery operates on a float charge during steady state conditions. The battery charger powers relays, indicating lights, and peripheral devices during normal conditions. Instantaneous operation of the circuit breaker and switches require battery output current. Initially, this current may be relatively high for a short duration and then reduce for an extended period of time, followed by another high operating current demand. If the charger output is lost, these low-level currents are supplied by the battery for a specified period. The second is a telecommunications battery supplying the teleprotection equipment (excluding the telecommunications batteries supplying only the communication cloud), which are described very well in the IEEE standards: Telecommunication systems are typically of high reliability, with a minimum uptime of 99.99% is often required. Although the batteries are sized for long duration discharge, short duration discharges are usually the case. Excess charging capacity is often available because of redundant charger configurations and engineered

Organization	Yes or No	Question 3 Comment
		overcapacity. The reserve battery time is usually of long duration.
Response: Thank you for your comments. 1. The SDT does not necessarily agree that the term "teleprotection" is universally used or interpreted consistently in the utility protection industry and believes its use in the standard would not improve the standard. Your comments in the complexity and intricacy of the telecommunications "cloud" are well-taken; however, it was the SDT's intent to require an overall functional test of the "cloud"-based path, but not an exhaustive test of each and every individual channel that could be involved. Yes, there is some risk in a FSK-based guard/trip scheme that the trip function may not perform even if the guard function does, but the SDT sees this risk as manageable and in line with other risks inherent in interval-based maintenance. **2.** This standard is applicable to station batteries. Please see Section 15.4.1 of the Supplementary Reference and FAQ document for more discussion. The scope of this standard does not include communication site batteries. The SDT believes that PRC-005-2 strikes an appropriate balance between maintenance burden, failure modes, manufacturer recommendations and IEEE battery guidelines.		
Independent Electricity System Operator		The IESO continues to disagree with the VRF assigned to the new Requirements R3 and R4. R3 and R4 ask for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3/R4 not executable. Hence, we reiterate our request to change R3's VRF to Medium.
Response: Thank you for your comments. The SDT respectfully disagrees and contends that the consequences of failing to maintain Protection Systems in the required time frames merit a High VRF.		
PNGC Small Entity Comment Group		The PNGC Small Entity Comment Group appreciates the hard work of the Standards Development Team on this difficult and complex project. However we are disappointed with the response to our concerns over the VSL matrix and although we believe on balance this should not be the sole reason for voting "no", we find it difficult to re-cast a "yes" vote and will therefore vote "abstain" to maintain the integrity of the quorum and reflect our position. Your response to our comment;"1.

Organization	Yes or No	Question 3 Comment
		A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate." reflects a position that indicates are cursory and dismissive review of our concern. We would counter that because a smaller entity has less to maintain, a solely percentage violation measure is therefore inappropriate. We've appended our original comment below in addition to the SDT response. PNGC Comment:1. The PNGC Comment Group takes issue with the associated VSLs for R3. For a small entity using a time based maintenance program, even one missed interval could be enough to elevate them to a high VSL despite the limited impact on the Bulk Electric System. Consider an entity with 9 total components within a specific Protection System Component Type. One violation would mean an 11% violation rate, enough to catapult them into a High VSL. Given the "NERC Guidance (Below), this seems to be a contradiction given the language of "...more than one". a. NERC Guidance on VSL assignment: i. LOWER: Missing a minor element (or a small percentage) of the required performance ii. Moderate: Missing at least one significant element (or a moderate percentage) of the required performance. iii. High: Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. iv. Severe: Missing most or all of the significant elements (or a significant percentage) of the required performance. We suggest changing the language for "Lower VSL" for R3 to: For Responsible Entities with more than a total of 20 Components within a specific Protection System Component Type in Requirement R3, 5% or fewer have not been maintained... Or for Responsible Entities with a total of 20 or fewer Components within a specific Protection System Component Type, 2 or fewer Components in Requirement R3 have not been maintained... SDT response: 1. A smaller entity will have less to maintain in accordance with the standard; and, thus, the percentages are still appropriate.
Response: Thank you for your comments. The SDT respectfully disagrees and believes that the Standard appropriately incorporates and accounts for the system risks and burdens of maintenance for both large and small entities. The VSLs were developed in accordance with the "FERC VSL Order" and the NERC criteria; for stepped VSLs - Lower VSL is "5% or less", Medium VSL is "more than 5% up to (and including) 10%", High VSL is		

Organization	Yes or No	Question 3 Comment
"more than 10% up to (and including) 15%", and Severe VSL is "more than 15%".		
US Bureau of Reclamation		The reliability level for protection systems has been lowered by eliminating the requirement for entity defined maintenance and testing procedures. Currently the draft only prescribes that the elements are identified as to when they will be maintained. The FAQ suggested that the PRC-005 did not have sufficient specificity with regard to the PSMP requirement. The entity no longer must be able to document that they were maintained in accordance with any prescribed method, jus that they were maintained in accordance within an acceptable interval. Second, the measure for R1 does not specific what evidence is considered acceptable. This makes the standard hard to enforce.
Response: Thank you for your comments. The standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP to be necessary. Measure M1 offers examples of documentation that should ease compliance and enforcement.		
Seminole Electric Cooperative, Inc		1. The SDT has provided ONE Protection System Component with two differing maintenance periods, the lockout (86) device. Six years is used for the lockout operation and twelve years is used for contact testing of the lockouts. Earlier the SDT had a similar arrangement with microprocessor relays, the microprocessor relay would be tested on a twelve year cycle but the microprocessor's electro-mechanical trip outputs were to be tested on a six year cycle. The SDT then made a decision that the single microprocessor asset would have a common testing cycle of twelve years, reasonably considering it a single asset with a single maintenance cycle of 12 years. To eliminate confusion with lockout relays, it is recommended that a similar decision be made by the SDT to make a single lockout relay asset have a common maintenance cycle of twelve years. The lockout relay twelve year cycle would include both the lockout operational test and the lockout relay tripping contact tests. This twelve year cycle would also be in direct maintenance alignment with other microprocessor relays and auxiliary relay testing cycles.

Organization	Yes or No	Question 3 Comment
		2. In addition, the sudden pressure relays and their integral control circuit should either be included or excluded. This is a compliance trap and will lead to many findings of non-compliance, based on sudden pressure relays not being included in many prior versions and currently not included in this version, except for their DC control circuit.
Response: Thank you for your comments. 1. The SDT believes that electromechanical lockout relays need periodic operation. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. The SDT recognizes the risk of human error trips when working with testing of lockout devices but believes these risks can be managed. Performance based maintenance is an option if you want to extend the intervals beyond 6 years. However, the SDT modified Table 1-5 to remove other auxiliary relays, etc, from this activity, and clarified that the verification of such devices is included within the 12-year unmonitored control circuitry verification. **2.** The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the SDT is unaware of industry recognized testing protocol for the sensing elements. The SDT believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently approved PRC-005-1 and with the SAR for Project 2007-17.		
Florida Municipal Power Agency		1. The SDT is still not agreeing with the applicability as interpreted and approved by FERC PRC-005-1b Appendix 1 that basically says that applicable Protection Systems are those that protect a BES Element AND trip a BES Element. The interpretation states: In these two standards, use of the phrase transmission Protection System indicates that the requirements using this phrase are applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES. The SDT continues to ignore this FERC approved interpretation, and this omission causes us to vote Negative again. The basic issue is that some distribution protection will be swept in with the applicability of the standard, which states: 4.2.1 Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines,

Organization	Yes or No	Question 3 Comment
		buses, transformers, etc.) 2. Many (most) network distribution systems that have more than one source into a distribution network will have reverse power relays to detect faults on the BES and trip the step-down transformer to prevent feedback from the distribution to the fault on the BES. This is not a BES reliability issue, but more of a safety issue and distribution voltage issue. These relays would be subject to the standard as the applicability is currently written, but, should not be and they are currently not within the scope of PRC-005-1b Appendix 1 because the step-down transformer (non-BES) is tripped and not a BES Element (hence, the "and" condition of the interpretation is not met). There are many other related examples of distribution that might be networked or have distributed generation on a distribution circuit where such reverse power relays, or overcurrent relays with low pick-ups, are used for safety and distribution voltage control reasons and are not there for BES Reliability. To make matters worse, for these Reverse Power relays, it is pretty much impossible to meet PRC-023 because the intent of the relay is to make current flow unidirectional (e.g., only towards the distribution system) without regard for the rating of the elements feeding the distribution network. So, if these relays are swept in, and if they are on elements > 200 kV, then the entity would not be able to meet PRC-023 as that standard is currently written. So, the SDT should have adopted the FERC approved interpretation. We have made this recommendation several times before.

Response: Thank you for your comments.

1. The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT observes that the approved interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion.
2. In the case you cite, the transformer is likely not a BES element; thus reverse power relays, even if installed to detect a fault in the transformer rather than actually to detect transformer energizing current, would not be included (as they are not installed for the purpose of detecting a fault on the BES). Please note that reverse power relays respond to real power (watts) instead of

Organization	Yes or No	Question 3 Comment
reactive power, and fault current is highly reactive.		
Tennessee Valley Authority		This comment is regarding the Implementation Plan for Requirements R3 and R4, 1. (Page 3 of 5) of The Implementation Plan for Project 2007-17 Protection Systems Maintenance and Testing PRC-005-02. Number 1. states: For Protection System component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5: o The entity shall be 100% compliant with PRC-005-2 on the first day of the first calendar quarter eighteen (18) months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter thirty (30) months following NERC Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities. TVA Comment: Even though TVA has already started a plan to address this issue, it will take several years to implement automatic checkback on 541 carrier blocking sets on the TVA system. TVA performed quarterly testing from 2000 through 2007, then after data showed failures not attributed to signal margin, the test was changed to twice a year in 2008. TVA carrier failure rate has not increased since the frequency was changed in January 2008 from 4 tests/year to 2 tests/year. We suggest a graduated implementation plan for this effort similar to number 3 (being compliant 30% in 24 months, 60% in 36 months, and 100% in 48 months) on Pages 3 and 4 of 5.
Response: Thank you for your comments. If an entity's experience is that these components require less-frequent maintenance, a performance-based program in accordance with Requirement R2 and Attachment A is an option. Your comments on your failure rates seems to indicate that you are performing a failure rate analysis similar to what is required under Attachment A for performance maintenance. While it is unfortunate that you feel you cannot meet the implementation requirements, the SDT believes that the existing plan is judicious in its time frame relative to the maximum intervals required by the standard.		
Tacoma Power		1. This is a follow-up question/comment from the previous round of balloting; please see the part in all capitals. It is still unclear whether Section 15.3 permits periodically verifying DC voltage at the actuating device trip terminals as an

Organization	Yes or No	Question 3 Comment
		acceptable method of accomplishing the maintenance activity identified in Table 1-5 for unmonitored control circuitry associated with protective functions IF DC VOLTAGE IS VERIFIED AT EACH APPLICABLE SET OF ACTUATING DEVICE TRIP TERMINALS SO THAT EVERY TRIP PATH IS ADDRESSED. It is recommended that this approach be considered acceptable, provided that auxiliary relays are operated within the maximum maintenance interval. 2. In Table 1-2, does the 'channel' include the communication interface/driver that is part of the end device?
Response: Thank you for your comments. 1. The method chosen for verification is left to the entity. The second to last paragraph of Section 15.3 of the Supplementary Reference and FAQ document states: "Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control Systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker." If your suggested activity verifies each and every individual path to the trip coil, it may be an effective method of addressing this requirement; simply checking for voltage at the trip coil may not verify all individual paths. 2. Please see Section 15.5.1 of the Supplementary Reference and FAQ document. The maintenance activities in Table 1-2 related to "channel" have been revised to "communications systems"		
BAE Batteries USA		This revision is a major improvement over the previous draft. Hopefully, the comments above are seen in the light of ensuring basic accuracy of the revised statements. They are not intended to materially change the intent of the position agreed upon at the last drafting team meeting.
Response: Thank you for your comments.		
HHWP		VSL should not be a function of "specific Protection System Component Type". VSL should look at percentage of TOTAL Protection System Components that were not tested within scheduled test date. Consider the entity with 400 Protection System Components, including 2 station battery systems. If that entity completed 399 of 400 tests within schedule and missed 1 battery test, the VSL would be high or severe.

Organization	Yes or No	Question 3 Comment
		Alternatively, if the entity completed 399 of 400 tests, but the missed test was one of 200 protective relays, the VSL would be low. There is no assurance though that the missed battery test resulted in higher risk for the BES than the missed protective relay test. As a result the relationship between VSL and the degree of violation severity lacks predictability.
Response: Thank you for your comments. The SDT disagrees because a battery supplies control power to numerous protective schemes, failure to ensure that the battery is fit for duty is more egregious than missing one component of numerous schemes.		
Consumers Energy		1. We agree with the purpose in section 3 of the Standard. However, section 4.2.1 expands the scope from "affecting the reliability of the Bulk Electric System" to "detecting Faults on BES Elements". In our opinion, the Applicability should be limited to the stated Purpose. Expanding the scope as is done in 4.2.1 greatly increases the number of Protection Systems covered without an increase in reliability of the BES. We prefer the applicability as expressed in Appendix 1 of PRC-005-1b. 2. We suggest changing "Component Type" in R1.2 to something similar to "Segment" as defined within the Standard. A "Component Type" limits to one of five categories, whereas a "Segment" must share similar attributes. 3. In item 2 of the second section of Attachment A, it is only necessary to use 5%, as 5% of a Segment (minimum of 60) is always 3 or more.
Response: Thank you for your comments. 1. The SDT believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT observes that the approved interpretation addresses the term, “transmission Protection System”, and notes that this term is not used within PRC-005-2; thus the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses “Protection Systems that are installed for the purpose of detecting faults on BES Elements.” Please see Section 2.3 of the Supplementary Reference and FAQ document for additional discussion. 2. In the documentation to support Requirement R1.2, an entity can list different technologies within a Component Type along with their respective monitoring attributes. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard.		

Organization	Yes or No	Question 3 Comment
3. The SDT agrees with your observation but sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard.		
Alliant Energy		We appreciate the work done by the SDT and believe it is an excellent product.
Response: Thank you for your comments.		
Georgia Transmission Corporation		We cast our ballot as an affirmative vote and agree with the nature of the standard. We raise concerns on the measures that are very prescriptive on documentation. We prefer a standard based on the program and measures that track the application and performance of the groups program. Maintaining the documentation for individual elements becomes a group's prime directive along with maintaining the equipment; this develops a process more controlled by documentation than results. This also adds a level of complexity for data retention, the drafting team tried to resolve by reducing the load of data. We contend the retention levels to be extreme considering some of the 12 calendar year cycles, interpret the data for compliance to be 24 years. One cannot remove previous documents until new maintenance performed 12 years after the current recorded date. We recommend reducing the data retention to list or check sheets and not the extreme of each individual component. Another important factor in managing the data is the capability of retrieval after 12 or 24 years. Some systems and formats are not available for 12 or 24 years and add a burden on companies to maintain legacy systems or convert massive amounts of data.
Response: Thank you for your comments. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The SDT has specified the data retention in the posted standard to establish this level of documentation. The entity is urged to assure that data is retained as specified within the standard.		
Nebraska Public Power District		1. We recommend removing requirement 5. This is adding the requirement for a

Organization	Yes or No	Question 3 Comment
		corrective action program to the standard. Performance metrics should be utilized to measure if a registered entity is correcting maintenance deficiencies in a timely manner. Examples of performance metrics include: o A Countable event has already been defined in the definition of terms, which would cover the need to replace equipment. o The quantity and causes of Misoperations are a direct correlation to good or poor maintenance practices and corrective actions by a utility. o TADS records events which are initiated by failed protection system equipment and would identify utilities with poor corrective action processes. 2. Can you show us a study or references justifying why records need to be kept for longer than the end of the current audit period. We are concerned that the complexities and costs of tracking and maintaining records, along with the corresponding maintenance program and PRC-005 revision that old tests would fall under will be an undue cost to small utilities. We suggest requiring entities to retain the last maintenance record or any records created during the current audit period. 3. The comment from the previous consideration of comments, "The SDT believes that Protection Systems that trip (or can trip) the BES should be included" seems to include any device that can affect the BES. This sets a precedence to include any device that can trigger trip coils into the maintenance system. These devices are meant to protect equipment and not the BES. 4. Based on the IEEE device numbers, please indicate which devices are part of the BES protection system and should be included in a maintenance program. 5. Why do functional trip checks need to be done on any interval if checks are done upon commissioning, maintenance and modification? We suggest eliminating any interval and making the requirement to check upon commissioning, maintenance and modification. 6. Comments on SAR for 2007-17 Very few reclosing relays protect the BES. Most reclosing relays actually would have a negative impact on the reliability of the bulk electric system. It is imperative that the SDT clearly define what types of reclosing relays are referred to here, and if it pertains to ANY reclosing relay that

Organization	Yes or No	Question 3 Comment
		can affect the BES. 7. There is a difference between components designed to protect the BES and components which can affect the BES. 8. For R5 if the maintenance interval is 6 years does the maintenance issue become an “unresolved” item immediately or does the next maintenance interval 6 years later need to be reached before it takes on an unresolved status to be auditable under R5? 9. Comments: Suggest for monitored microprocessor relays in Table 1-1 and 3 to change wording to verify “settings are as specified that are essential to the proper functioning of the protection system”. Many settings are not essential. 10. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. I suggest there be consideration that the interval for functional tests be moved to the minimum frequency of 12 years to minimize this unknown but present risk.

Response: Thank you for your comments.

1. The SDT disagrees:
   NERC has demonstrated its belief that returning Protection System devices to good working order exists currently as a required element of a sound maintenance program subject to the existing Protection System maintenance and testing standard, PRC-005-1. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to “…look for relay test results or field records with annotations such as “as-found” readings or pass/fail results; <u>if failed, then adjustments made. The maintenance record for adjustments may be requested”</u>.
   Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase “demonstrate efforts to correct” (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a “closed-end process”). For example, a problem might be identified on a VRLA battery during a 6 month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the 6 calendar month requirement for this maintenance activity. The SDT does believe corrective actions should be timely but concludes it would be impossible to postulate all possible

Organization	Yes or No	Question 3 Comment
		remediation projects and therefore impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues, or what documentation might be sufficient to provide proof that effective corrective actions are being undertaken. 2. To be assured of compliance, the SDT believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. This seems to be consistent with what auditors are expecting (per the SDT's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The SDT has specified the data retention in the posted standard to establish this level of documentation. The entity is urged to assure that data is retained as specified within the standard. 3. The response cited from a previous consideration of comments was specifically related to sudden pressure relays. The Applicability 4.2.1 of the standard, specifically states, "…installed for the purpose of detecting Faults on BES Elements". 4. It is left to the entity to determine which devices and their complementary IEEE device numbers are installed for the purpose of detecting Faults on BES Elements. 5. The standard does not specify "functional trip tests", but instead requires that various elements of the dc control circuit be verified at various intervals. Also, FERC Order 693 directs NERC to establish maximum allowable maintenance intervals for Protection System components. Please see Section 15.3 of the Supplementary Reference and FAQ Document. 6. Reclosing relays are not covered in PRC-005-2. In Order 758, FERC directed NERC to include reclosing relays in a future version of PRC-005; the SDT developed the draft SAR to address FERC's directive 7. The SDT agrees; the standard explicitly covers "Protection Systems that are installed for the purpose of detecting Faults on BES elements (lines, buses, transformers, etc.)". 8. The item does not become an "Unresolved Maintenance Issue" unless it is not corrected before the current maintenance interval expires. 9. The SDT sees no appreciable improvement in the standard with your proposed change and respectfully declines to modify the standard. 10. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES. The standard does not specify "functional trip tests", but instead requires that various elements of the dc control circuit be verified at various intervals.
Western Area Power Administration		Western Area Power Administration is appreciative of the hard work done by the SDT and NERC. 1. We respectfully submit our professional opinion that the increased relay testing

Organization	Yes or No	Question 3 Comment
		required by the PRC-005-2 will result in a net degradation to the reliability of the BES due to human hands disturbing working systems. 2. We propose that auxiliary relays be tested at commissioning and anytime the circuits are rewired or redesigned. If there is evidence that the relay has functioned properly in its current configuration then the best practice for insuring reliability is to leave it alone. 3. The maintenance interval of 6 years for lock-out relay testing is not consistent with 12 year interval of auxiliary relay testing or control circuit testing. No justification is provided for this increased testing interval of lock-out relays versus other electro-mechanical devices. These inconsistent testing intervals, within the same protection control schemes and protective devices, will complicate the industry's Protection System Maintenance Program and cause an increase in maintenance costs. 4. Condition Based Monitoring or Performance Based Monitoring are not allowed on trip coil circuits or lock-out relays. This is inconsistent with current or future technology. Deviation from the 6 year testing interval should be allowed, using CBM or PBM. The Standard should not present a barrier to technology advancements or industry initiatives. The continuous, frequent testing of these devices is detrimental to system reliability. 5. Disagree with testing of the dc control portion of the sudden pressure device as defined by the FAQ. We feel that this device and its wiring were deemed out of scope previously.

Response: Thank you for your comments.

1. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES.
2. The SDT believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES. Also, FERC Order 693 directs NERC to establish maximum allowable maintenance intervals for Protection System components.
3. The SDT believes that electromechanical lockout relays need periodic operation to remain reliable. As such, these devices are required to be exercised at the same 6 year interval required for electromechanical relays. Performance based maintenance is an option if you want to extend the intervals beyond 6 years.
4. Performance-based maintenance per Attachment A of the standard may be applied to both trip coil circuits and lockout relays.

Organization	Yes or No	Question 3 Comment
5. The trip path from a sudden pressure device is a part of the Protection System control circuitry. The sensing element is omitted from the definition of Protection System because the SDT is unaware of industry recognized testing protocol for the sensing elements. This position is consistent with the currently-approved PRC-005-1 and the SAR for Project 2007-17.

END OF REPORT

Consideration of Comments

Project 2007-17 Protection System Maintenance and Testing

The Protection System Maintenance and Testing Drafting Team would like to thank all commenters who submitted comments on the 4th draft of the standard for Protection System Maintenance. These standards were posted for a 30-day public comment period from July 27, 2012 through August 27, 2012. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 36 sets of comments, including comments from approximately 102 different people and from approximately 65 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Mark Lauby, at 404-446-2560 or at mark.lauby@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

The only edit to the standard was to add an "s" to "communication" in several locations within Table 1-2 for consistency. The term is now "communications system" throughout the table.

Definitions: No changes made.

Applicability: No changes made.

Requirements: No changes made.

Tables: In Table 1-2, added an "s" to "communication" in several locations for consistency. The term is now "communications system" throughout the table.

Measures: No changes made.

VSLs: In the VSLs for Requirement R5, the word "identify" was added to each VSL to be consistent with the requirement.

Supplementary Reference and FAQ Document: Various spelling and punctuation errors were corrected, and additional content was added to improve the reference document.

Implementation Plan: No changes made.

[1] The appeals process is in the Standard Processes Manual: http://www.nerc.com/files/Appendix_3A_StandardsProcessesManual_20120131.pdf

Unresolved Minority Views:

- A few commenters questioned the inclusion of breaker trip coil verification, auxiliary relay verification, and/or lockout relay verification. The drafting team responded that each of these devices needs to be maintained at the prescribed intervals to assure reliability.
- Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.
- Several commenters continued to object to inclusion of UFLS and UVLS relays, in that they may not be installed on BES equipment. The drafting team responded that these devices, while not on BES equipment, are installed for the reliability of the BES, and are therefore included. The drafting team further noted that these devices are currently addressed in PRC-008-0 and PRC-011-0.
- A few commenters questioned the inclusion of the dc control circuitry for sudden pressure relays even though the relays themselves are excluded from the definition of "Protection System"; the SDT reiterated its position that this dc control circuitry is included because the dc control circuitry is associated with protective functions.
- Several commenters expressed concerns regarding Requirement R5 and Unresolved Maintenance Issues. The SDT explained its rationale for the requirement as drafted.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

9 — Federal, State, Provincial Regulatory or other Government Entities

10 — Regional Reliability Organizations, Regional Entities

1. **In response to stakeholder input, the SDT made several changes to Table 1-2 of the standard, as detailed below:**
    - **The interval for the second portion of the first row of the table was changed from 12 years to 6 years.**
    - **The term "channels" was modified to "communications system" in two locations.**
    - **The Component Attributes in the last row were modified to clarify that all attributes must be present to use the associated intervals and activities.**

    Do you agree with these changes? If not, please provide specific suggestions for changes to Table 1-2 in the comment area.

Summary Consideration: In general, the industry was supportive of the changes to the table. More clarification on the scope of the "communications systems" was provided in Section 15.5.1 of the Supplementary Reference and FAQ document, and the term, "communication system" was corrected to "communications system."

Organization	Yes or No	Question 1 Comment
Bonneville Power Administration	No	BPA believes that changing the language from "channels" to "communications systems" does not clarify the intent since "communications systems" is not defined in the standard. The term "communications systems" which is referenced in the Supplementary Reference and FAQ document remains ambiguous. BPA recommends one of these two definitions be included in the standard:1) If the intent is to cover only the Communications Equipment and "channel" as defined above:"Communications System" - The Communications System as defined for the purposes of PRC-005-02 consists of a Component's signaling inputs and outputs and the communications channel that these signals traverse. The intervening carrier communications devices that transport this channel are explicitly excluded from the definition of Communications System.2) If the intent is to cover the Communications Equipment, "channel" and the cloud functionally:"Communications System" - The Communications System as defined for the purposes of PRC-005-02 consists of a Component's

Organization	Yes or No	Question 1 Comment
		signaling inputs and outputs and the communications channel that these signals traverse. The Communications System includes the simple end-to-end functionality of the intervening carrier communications devices that transport this channel but explicitly excludes intermediate switching, redundant paths, packet routing, digital cross-connections and other “cloud” carrier elements from the definition of Communications System.
Response: Thank you for your comments. It is the drafting team’s intent to require the entity to perform maintenance on the protective system communications part of the scheme to verify that it is performing as required. Both the communications equipment and the channel are part of that. If that channel is a third-party leased circuit, then the entity can only verify performance of the channel and not maintain any of its equipment. If the channel is a power line carrier and owned by the entity, the performance can be verified and the equipment can be maintained, if necessary. This standard is proscribed from describing “how” to perform an overall functional test of a communications system; it is left to the entity to determine what methods best address their program. **Also, Section 15.5.1 of the Supplementary Reference and FAQ document was revised to further discuss communications systems.**		
Southern Company	No	Suggestion - Change the interval back to 12 years instead of 6 years. The 12 year interval is reasonable considering that un-monitored communications systems will be functionally tested every 4 months
Response: Thank you for your comments. The drafting team respectfully disagrees. Although an entity functionally tests an unmonitored communications system every four months, there is no requirement to have the pertinent performance criteria verified as part of this functional test. Testing the communications system's performance criteria involves additional tests, such as those described in Section 15.5.1 of the Supplementary Reference and FAQ document. Of course, an entity can always perform both types of tests on a four-month interval, but at this time we see no reason to have the performance criteria verification at a four-month interval. An entity has the latitude to perform maintenance more frequently than specified, if it feels that such maintenance is needed.		
Tacoma Power	Yes	In Table 1-2, for unmonitored communications systems, under Maintenance Activities, ‘communication system’ is used, but in the next row,

Organization	Yes or No	Question 1 Comment
		'communications system' is used. These terms should be consistent.
Response: Thank you for your comment. The drafting team has revised the Table 1-2 to consistently use "communications systems."		
Ameren	Yes	Ameren supports these changes in the interest of BES reliability.
Response: Thank you for your support.		
Ingelside Cogeneration LP	Yes	Ingleside Cogeneration LP was prepared to support a six year maintenance interval - which was specified in all other drafts of PRC-005-2. We agree that the project team's modification is necessary to correct a mistake that crept into the last version.
Response: Thank you for your support.

2. **The SDT modified the Implementation Plan as follows:**

- **Within "Retirement of Existing Standards," the legacy standards will be retired upon full implementation of PRC-005-2, rather than upon PRC-005-2 becoming effective.**
- **Within "General Considerations," each entity shall be responsible for maintaining each of their Protection System components according to their maintenance program already in place for the legacy standards (PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0) or according to their maintenance program for PRC-005-2, but not both.**

Do you agree with these changes? If not, please provide specific suggestions for changes to the Implementation Plan in the comment area.

Summary Consideration: The commenters largely supported the Implementation Plan, including the changes made at this revision. Several commenters questioned whether the added text within "General Considerations" is necessary, in that it essentially duplicates statements made elsewhere in the Implementation Plan; the drafting team believes that the additional emphasis is useful. No changes were made to the Implementation Plan in response to comments.

Organization	Yes or No	Question 2 Comment
Southern Company	No	The "General Consideration" sentence in question above is superfluous and therefore unnecessary. The instruction provided in the sentence is (repeated and) more clearly stated in the first sentence of the "Retirement of Existing Standards:" section.
Response: Thank you for your comment. The drafting team believes that the modification to the "General Considerations" section of the Implementation Plan adds clarity.		
Western Area Power Administration	No	The logistics of these statements are confusing and need further clarification as to intent and implementation.
Response: Thank you for your comment. The drafting team believes that the implementation plan is clear. The entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the		

Organization	Yes or No	Question 2 Comment
transition is occurring, the entity should adjust its maintenance and testing schedule so that they are able to demonstrate that the required percentage of components meet the maintenance intervals given in the PRC-005-2 tables at each of the percent compliant milestones given in this Implementation Plan.		
Tennessee Valley Authority		The intent of this modification is not clear. It could be interpreted as allowing an entity, for any given Protection System component identified in Table 1-1 through Table 1-5, to choose to maintain those components under an existing maintenance program that is compliant with the legacy standards until PRC-005-2 completely retires PRC-005-1b, PRC-008-0, PRC-011-0 and PRC-017-0 (first calendar quarter one hundred fifty-six (156) months following regulatory approval of PRC-005-2). For example, if an entity elects to maintain unmonitored communications system components described in Table 1-2 using its program that is compliant with the legacy standards, when would it have to meet the intervals defined in Table 1-2? The use of “or” under “General Considerations” indicates that compliance with the legacy standards is acceptable until such time that all of the legacy standards are retired.
Response: Thank you for your comment. The drafting team believes that the Implementation Plan is clear. **The entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the transition is occurring, the entity should adjust its maintenance and testing schedule so that they are able to demonstrate that the required percentage of components meet the maintenance intervals given in the PRC-005-2 tables at each of the percent compliant milestones given in this Implementation Plan.** **If an entity elects to maintain unmonitored communications system components described in Table 1-2 using its program that is compliant with the legacy standards, it would have to meet the intervals defined in Table 1-2 according to the Implementation Plan for Requirements R3 and R4.**		
ACES Standards Collaborators	Yes	We thank the drafting team for this consideration that will allow early compliance with the new version of the standard. This plan should avoid many of the transitional issues that have occurred with other new versions of standards.
Response: Thank you for your comment.		

Organization	Yes or No	Question 2 Comment
American Electric Power	Yes	We believe the text "Once an entity has designated PRC-005-2 as its maintenance program for specific Protection System components, they cannot revert to the original program for those components" does improve the clarity of the standard.
Response: Thank you for your comment.		
Ameren	Yes	Ameren supports this practical reality.
Response: Thank you for your comment.		
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration LP sees the modifications to the implementation plan as a clarification-only. We had anticipated that auditors will look for evidence that a legacy program remains in place until a specifically-identified transition date. In fact, the project team should consider adding an allowance for entities to adopt PRC-005-2 immediately upon FERC's approval. This may mean in rare cases that maintenance activities and intervals managed in accordance with PRC-005-1b will drop out of the program; but if the industry and regulatory bodies agree that the new program is superior, there is no reliability purpose served by waiting. Furthermore, the maintenance activities will continue anyways - they will just not be subject to auditor review. Unfortunately, NERC Compliance has taken the opposite position for the implementation of the CIP version 4 "bright-line criteria" - which we believe is counter-productive to our shared commitment to reliability. Just as with PRC-005-2, a thorough evaluation showed that the elimination of ambiguity reduces risk to the greater system. It is disingenuous to require outdated standards to remain in place simply to avoid a possibility that a borderline facility remain on the regulatory books.
Response: Thank you for your comments. The drafting team suggests that, in the event that an entity fully implements PRC-005-2 for all components (i.e., has maintained everything according to PRC-005-2) upon regulatory approvals, the entity will have retired PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-17-0 from their program at that time. However, the drafting team believes that the		

Organization	Yes or No	Question 2 Comment
phased Implementation Plan is necessary to avoid any gaps in applicability throughout the maintenance intervals currently in use. Further, to demonstrate continuing compliance, an entity will need evidence that they have been in full compliance with whichever version of the standard was in effect.

Organization	Yes or No	Question 3 Comment
American Transmission Company	No	
Idaho Power Company	No	
CenterPoint Energy	No	
KCP&L/ KCPL-GMO	No	
Primax Technologies Inc.		In 15.4.1 Frequently Asked Questions, to the question: What did the PSMT SDT mean by “continuity” of the dc supply? One of the proposed methods for ensuring continuity is the following: Specific gravity tests can infer continuity because, without continuity, there could be no charging occurring; and if there is no charging, then specific gravity will go down below acceptable levels. Comment: I agree that the uncharged cell's specific gravity would drop but it would take weeks or months to show. Should power be needed from the battery during this period of time the battery would not be able to perform as it should. To me this an unacceptable risk
Response: Thank you for your comments. The drafting team agrees with you that some methods of detecting continuity are better than others, but the Supplementary Reference and FAQ Document is intended as a general aid to understanding the standard, and not as a strict recommendation of particular maintenance methods. An entity can always do more, or more frequent maintenance if they wish.		
Southwest Power Pool Reliability Standards Development Team	Yes	1. On page 70 of the document we noticed that the word “reakers” was used and would suggest this was intended to be “breakers”. 2. Also on page 81 of the document under the section of “My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?” We would suggest that the wording be changed on “in

Organization	Yes or No	Question 3 Comment
		accessible" to remove the space to give you "Inaccessible".
Response: Thank you for your comments. Punctuation, spelling and content changes have been made to the Supplementary Reference and FAQ Document.		
Chris Searles	Yes	1. In Section 7.1-Frequently Asked Questions, pg 24 - add "or" before "other measurements" inadvertently left out. 2. In Section 8.1.2.4 - 4th & 5th sentences. Consider changing the verbiage: "....The Protection System owner may want to follow the guidelines in the applicable IEEE recommended practices for battery maintenance and testing, especially if the battery in question is used for application requirements in addition to the strict protection and control demands covered under this standard." 3. In section 15.4.1 - (pg 74) "What is the State of Charge...." In the first paragraph on page 74, the first complete sentence, I think the intent is to say "For these two types of batteries, and also for VRLA batteries," . . .
Response: Thank you for your comments. Punctuation, spelling and content changes have been made to the Supplementary Reference and FAQ Document.		
ACES Standards Collaborators	Yes	We suggest that the document should clarify Table 1-4(f). We understand from conversations with drafting team members that not all component attributes have to be met for the exclusion to apply. Rather each component attribute only has to be met individually for the exclusion to apply. We appreciate the drafting team including the localized definitions in the supplementary reference document. However, we believe there is still confusion with the use of component. Component is capitalized within the definition but it is not capitalized throughout the document. We believe the term should be capitalized throughout the document to be clear the localized definition applies. Capitalization of most instances of "system" has been correctly removed since the NERC definition was not consistent with the use. However, there are a few instances where it was removed and should not have been. One example occurs in the second paragraph on page 5 in the red-line document

Organization	Yes or No	Question 3 Comment
		where "system collapse" should be "System Collapse". In the third paragraph on page 5 in the red-line document, "transmission" should be capitalized since the NERC definition would be applicable.

Response: Thank you for your comments. Punctuation, spelling and content changes including your suggestions for capitalization have been made to the Supplementary Reference and FAQ Document. Based on your comment regarding Table 1-4(f), an additional FAQ has been added to Section 15.4.1 of the Supplementary Reference and FAQ Document.

Organization	Yes or No	Question 3 Comment
O&M Group	Yes	(1) We do not agree with no maintenance on the battery monitoring system (2) Also, we do not agree with replacing a battery capacity test by evaluating cell/unit measurements indicative of battery performance against station battery baseline.

Response: Thank you for your comments.

1. Thank you for your comment concerning maintenance on the battery monitoring system. Based on comments concerning the battery Component Attributes in table 1-4(f) a new Frequently Asked Question was added to the Supplementary Reference and FAQ Document. As a part of that FAQ the drafting team gave rational why no maintenance on the battery monitoring system is required by stating "the basis of the exclusions granted in the table is that the monitoring devices must incorporate the monitoring capability of microprocessor based components which perform continuous self-monitoring. For failure of the microprocessor device used in dc supply monitoring, the self-checking routine in the microprocessor must generate an alarm which will be reported within 24 hours of device failure to a location where corrective action can be initiated."

2. Thank you for your comment concerning battery capacity testing. The drafting team agrees that a performance or modified performance capacity test is the only industry recognized method for determining the actual capacity of a battery. However, the maintenance activity required in the tables of PRC-005-2 is to "Verify that the station battery can perform as manufactured" not to determine the capacity of the battery. For many of the lead acid batteries used in BES Protection Systems, the drafting team believes that evaluating cell/unit measurements indicative of battery performance against a station battery baseline is as a valid method of verifying "that the station battery can perform as manufactured." That is why in Tables 1-4(a) and Tables 1-4(b) owners are allowed to do either of the two listed maintenance activities in their appropriate maximum maintenance intervals to "Verify that the station battery can perform as manufactured."

Organization	Yes or No	Question 3 Comment
Western Area Power Administration	Yes	Yes. The standard itself should be more clearly written so that a 100+ page Supplementary Reference and FAQ Document is not needed. This document is also not enforceable, nor is it a standard, so verbiage which interprets the standard and forces requirements should be removed.
Response: Thank you for your comments. This document provides supporting discussion, but is not part of the standard. The drafting team intends that it be posted as a reference document, as expressed in Section F of the standard. The standard is to be a terse statement of requirements, etc., and is not to include explanatory information like that included in the Supplementary Reference and FAQ Document.		
American Electric Power	Yes	On page 82, the text “in accessible” should be correct as “inaccessible”.
Response: Thank you for your comments. Punctuation, spelling and content changes have been made to the Supplementary Reference and FAQ Document.		
Manitoba Hydro	Yes	1. Table of Contents - The drawing should be removed from the Table of Contents. 2. Introduction and Summary: [Page 1] - Should include “Canada”. The sentence should read “The standards are mandatory and enforceable in the United States and Canada”. 3. Protection Systems Product Generations: [page 8] - We suggest changing "control Systems" to "control systems".[Page 28]: “Voltage & Current Sensing Device ...” should be “Voltage and current sensing device ...”[Page 29] "Control Circuit" should not be capitalized.[Page 44] A space is missing: “performance formal-performing segments” should be “performance for mal-performing segments”.[Page 45] "Other problems ..." ascribed to batteries may also apply to other Protection System Components, and therefore does not require special mention for batteries. This paragraph should be removed. 4. [Page 67]: Normally-open contacts of relays 94 & 86 should be treated the same as the current-carrying contacts if they are in use.
Response: Thank you for your comments. Punctuation, spelling and content changes have been made to the Supplementary		

Organization	Yes or No	Question 3 Comment
Reference and FAQ Document. Based on your comment, "Canada" was added to the introductory sentence on page 1 of the Supplementary Reference and FAQ Document. In the case of the normally-open contacts of the 94 and 86, entities may perform more maintenance than is listed within the standard.		
Tacoma Power	Yes	1. On page 88, third bullet, change "auxiliary communications equipment" to "associated communications equipment" for consistency. 2. In Figure A-1, what is meant by "Also verify wiring and test switches"? The emphasis of this question is on 'test switches'.
Response: Thank you for your comments. **1. Punctuation, spelling and content changes have been made to the Supplementary Reference and FAQ Document.** **2. The object of any test in any circuit that has test switches is the same as those tests in similar circuits without test switches. There is no specific mandated test in the standard for "Test Switches," but a test switch might well be a point of failure that one needs to be aware of when performing the mandated routine tests.**		
Illinois Municipal Electric Agency	Yes	Please see response to Question 4.
Response: Thank you for your comments.		
Midtronics Inc	Yes	The paragraphs below are from page 83 of the document (page 89 of the pdf). The first paragraph below contains the words, "risen above" and "over" a baseline. For conductance trending would be going below a baseline. Since this is a technical standard I think there should be a comment noting the difference in trending of conductance as compared to resistance and impedance like it is in the next paragraph. For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. Trending against the baseline of VRLA cells in a battery string is essential to determine the approximate state of health of the battery. Ohmic measurement testing may be used as the mechanism for measuring

Organization	Yes or No	Question 3 Comment
		the battery cells. If all the cells in the string exhibit a consistent trend line and that trend line has not risen above a specific deviation (e.g. 30%) over baseline, then a judgment can be made that the battery is still in a reasonably good state of health and able to 'perform as manufactured.' It is essential that the specific deviation mentioned above is based on data (test or otherwise) that correlates the ohmic readings for a specific battery/tester combination to the health of the battery. This is the intent of the "perform as manufactured six-month test" at Row 4 on Table 1-4b. The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not necessarily have a formal trending program. When a single cell/unit changes significantly or significantly varies from the other cells (e.g. a doubling of resistance/impedance or a 50% decrease in conductance), there is a high probability that the cell/unit/string needs to be replaced as soon as possible. In other words, if the battery is 10 years old and all the cells have approached a significant change in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.
Response: Thank you for your comments. Punctuation, spelling and content changes have been made to the Supplementary Reference and FAQ Document. Based on your comment, the sentence was rewritten as follow: "If all the cells in the string exhibit a consistent trend line and that trend line has not risen above a specific deviation (e.g. 30%) over baseline for impedance tests or below baseline for conductance tests, then a judgment can be made that the battery is still in a reasonably good state of health and able to 'perform as manufactured.'"		
Luminant	Yes	
Southern Company	Yes	

4. If you have any other comments that you have NOT provided in response to the above questions, please provide them here. (Please do not repeat comments that you provided elsewhere.)

Summary Consideration: Other than as noted below, no changes were made to the standard in response to comments in Question 4.

Commenters continued to object to Applicability 4.2.1 in contrast to the interpretation in PRC-005-1b. The drafting team explained their position relative to this objection, and added discussion in Section 2.3.1 of the Supplementary Reference and FAQ Document to further explain their position.

Several commenters objected to various VSLs, particularly as it relates to the Lower VSL for Requirement R3. The drafting team explained that the VSLs are established in accordance with the VSL Guidelines. However, a minor editorial change was made to all levels of VSL for Requirement R5.

Several commenters continued to object to inclusion of UFLS and UVLS relays, in that they may not be installed on BES equipment. The drafting team responded that these devices, while not on BES equipment, are installed for the reliability of the BES, and are therefore included. The drafting team further noted that these devices are currently addressed in PRC-008-0 and PRC-011-0.

Several commenters questioned the inclusion of breaker trip coil verification, auxiliary relay verification, and/or lockout relay verification. The drafting team responded that each of these devices needs to be maintained at the prescribed intervals to assure reliability.

A few comments were offered on unresolved maintenance issues, various aspects of battery maintenance, communications system batteries, performance-based maintenance program criteria, and sudden pressure relay dc circuit testing. The drafting team provided responses to each of these comments, explaining the importance of the requirements within the standard.

Organization	Yes or No	Question 4 Comment
Consumers Energy		1. We agree with the purpose in section 3 of the Standard. However, section 4.2.1 expands the scope from "affecting the reliability of the Bulk Electric System" to "detecting Faults on BES Elements". In our opinion, the Applicability should be limited to the stated Purpose. Expanding the scope as is done in 4.2.1 greatly

Organization	Yes or No	Question 4 Comment
		increases the number of Protection Systems covered without an increase in reliability of the BES. We prefer the applicability as expressed in Appendix 1 of PRC-005-1b. 2. We suggest changing "Component Type" in R1.2 to something similar to "Segment" as defined within the Standard. A "Component Type" limits to one of five categories, whereas a "Segment" must share similar attributes.
Response: Thank you for your comments. **1. The drafting team believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The SDT observes that the approved interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses: "Protection Systems that are installed for the purpose of detecting faults on BES Elements." The drafting team has added a discussion to Section 2.3.1 of the Supplementary Reference and FAQ Document explaining their intent regarding the Applicability.** **2. In the documentation to support Requirement R1.2, an entity can list different technologies within a Component Type along with their respective monitoring attributes. The drafting team sees no appreciable improvement in the standard with your proposed change, and respectfully declines to modify the standard.**		
Ameren		Ameren supports PRC-005-2 in the interest of BES reliability. We also appreciates the SDT's overall high quality product and looks forward to its implementation; however, we still assert that 1) the zero tolerance approach, in this case involving significantly large number (thousands) of devices, is an impractical requirement, 2) the VRF for R3 should be Medium, and 3) maintenance records for replaced equipment should not be retained. We' have raised these concerns and justified our position repeatedly but yet not convinced the SDT to change their position.
Response: Thank you for your comments. **1. The NERC VSL Guidelines do not allow some level of non-performance without being in violation.**		

Organization	Yes or No	Question 4 Comment
2. The drafting team believes that the assigned VRF is correct, in that that failure to implement and follow its PSMP could cause or contribute to Bulk Electric System instability, separation, or a Cascading sequence of failures. **3. The drafting team believes the Compliance Monitor will need the data for the most recent performance of the maintenance, as well as the data for the preceding maintenance period, to determine compliance. This seems to be consistent with what auditors are expecting (per the drafting team's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05.**		
Florida Municipal Power Agency		1. Applicability does not align with previously approved interpretation of "transmission Protection System", Appendix 1 of the current V1 standard, that basically says that protection systems applicable to the standard are those that both "detect faults" and "trip" BES equipment. Applicability 4.2.1 says: "Protection Systems that are installed for the purpose of detecting Faults on BES Elements", which does not match "and" relationship of the interpretation. Eliminating this "and" relationship will cause distribution protection to be swept into the standards, such as reverse power relays designed to "detect" faults on the transmission system but "trip" distribution breakers. Distribution is expressly excluded in Section 215 and these types of relays have no impact on BES reliability. 2. Zero defect approach, should move to what CIP v5 is moving towards of internal controls rather than strict 100% compliance, or even better, a Total Quality Management approach. 3. UFLS and UVLS testing - broaches on distribution which is expressly excluded from Section 215 jurisdiction - when discussing control circuit testing, instrument transformer testing, etc.. We believe the requirement should be relay-only testing. We also believe that the incremental benefit is not worth the increased costs, e.g., one UFLS relay not operating has insignificant impact on a UFLS event; whereas one relay not operating to clear a fault has significant impact.
Response: Thank you for your comments. **1. The drafting team believes the Applicability as stated in PRC-005-2 is correct and supports the reliability of the BES. The**		

Organization	Yes or No	Question 4 Comment
drafting team observes that the approved interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the interpretation does not apply to PRC-005-2. PRC-005-2 specifically addresses: "Protection Systems that are installed for the purpose of detecting faults on BES Elements." The drafting team has added a discussion to Section 2.3.1 of the Supplementary Reference and FAQ Document explaining their intent regarding the Applicability. 2. The NERC VSL guidelines do not allow some level of non-performance without being in violation. 3. FPA Section 215(a) definitions section defines bulk-power system as: "(A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition then is limited by a later statement which adds the term bulk-power System: "… does not include facilities used in the local distribution of electric energy." Also, Section 215 also covers users, owners, and operators of bulk-power facilities. UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if UFLS/UVLS facilities were not covered by the Reliability Standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that load would have to be shed at the transmission bus to ensure the load-generation balance and voltage stability is maintained on the BES.		
Beaches Energy Services		1. Applicability does not align with previously approved interpretation of "Transmission Protection System", Appendix 1 of the current V1 standard, that basically says that protection systems applicable to the standard are those that both "detect faults" and "trip" BES equipment. Applicability 4.2.1 says: "Protection Systems that are installed for the purpose of detecting Faults on BES Elements", which does not match "and" relationship of the interpretation. Eliminating this "and" relationship will cause distribution protection to be swept into the standards, such as reverse power relays designed to "detect" faults on the transmission system but "trip" distribution breakers. Distribution is expressly excluded in Section 215 and these types of relays have no impact on BES reliability. 2. Illinois Municipal Electric Agency		As indicated in previous comments, Illinois Municipal Electric Agency (IMEA) appreciates SDT efforts, and supports the overall refinements in PRC-005-2. However, IMEA respectfully disagrees with the SDT's decision to not resolve the

Organization	Yes or No	Question 4 Comment
		inconsistency between 4.2.1 and the FERC-approved interpretation in PRC-005-1b. Whether the term “transmission Protection System” is used in PRC-005-2, as indicated in the SDT response to our comments, is not the point. The interpretation in PRC-005-1b provides clarity to smaller entities in particular regarding which protective devices need to be factored into compliance with PRC-005 (and other PRC standards). This inconsistency should have been more clearly vetted within the industry given the fact that this was a recently NERC- and FERC-approved Protection System interpretation which was being compromised by the proposed language in 4.2.1. Once again, we find ourselves aiming at a constantly moving compliance target. This issue has the potential to require more DPs to comply with PRC-005, and draw more small entities into registration, which of course would require increased resource expenditures associated with compliance. This issue does not appear to be consistent with NERC and FERC efforts to minimize the impact on smaller entities that have minimal or no potential to impact the BES. If the 4.2.1 language was carefully considered so as not to unnecessarily impact small entities, it would be appreciated that these provisions be more clearly addressed in the "Supplementary Reference and FAQ". Thank you for this opportunity to comment. This issue is significant enough that IMEA felt a Negative vote was unfortunately necessary on an otherwise significant improvement to PRC-005.
Response: Thank you for your comments. **The drafting team believes that the Applicability 4.2.1 as stated in PRC-005-2 is correct and supports the reliability of the BES. The drafting team believes all Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The drafting team observes that the approved Interpretation addresses the term, “transmission Protection System,” and notes that this term is not used within PRC-005-2; thus, the Interpretation does not apply to PRC-005-2. The drafting team has added a discussion to Section 2.3.1 of the Supplementary Reference and FAQ Document explaining their intent regarding the Applicability.**		
American Transmission Company		ATC recommends that the SDT change the text of “Standard PRC-005-2 - Protection System Maintenance” Table 1-5 on page 24, Row 1, Column 3 to:”Verify that a trip

Organization	Yes or No	Question 4 Comment
		coil is able to operate the circuit breaker, interrupting device, or mitigating device." Or alternately, "Electrically operate each interrupting device every 6 years". Basis for the change: Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. In addition, many utilities purchase breakers with dual redundant trip coils to mitigate the possibility of a failure. Interrupting devices with multiple trip coils operate the same mechanism. Therefore, by requiring testing of each trip coil in a redundant system you double the amount of times the system is out of its desired state without increasing the performance of the device. It is well recognized that the most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice to mitigate the most prevalent cause of breaker failure. ATC would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language, as currently written in Table 1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle).ATC continues to recommend a negative ballot since we believe that the testing of "each" trip coil will result in the increased amount of time the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comments. The definition of Protection System includes trip coils within the dc control circuitry component, and it is necessary to perform maintenance on all of these devices to assure proper performance. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
Bonneville Power		BPA appreciates that the Standards Development Team does not believe that communications batteries are included in PRC-005-2 standard. While BPA believes

Organization	Yes or No	Question 4 Comment
Administration		the SDT did not intend to include communications batteries in the standard, this intention is neither captured by the language of the standard nor explicit in the Supplementary Reference and FAQ document. Ambiguity on regulation of communications batteries provides no benefit and comprises a concrete regulatory risk to BPA during an audit. BPA strongly believes that the standard should articulate exactly what types and applications of batteries it means to regulate and which batteries it does not.
Response: Thank you for your comments. The drafting team believes this issue is addressed in the response to FAQ: "Does this standard refer to Station batteries or all batteries; for example, Communications Site Batteries?" in the Supplementary Reference and FAQ Document.		
CenterPoint Energy		CenterPoint Energy recommends that PRC-005-2 include a built-in tolerance and move away from a zero-defect enforcement model. Achieving one-hundred percent schedule and documentation compliance is negatively impacting resources on an industry-wide basis for the sake of the "last one percent" and is not needed to provide an adequate level of BES reliability. Entities should be allowed the opportunity to correct minor deficiencies discovered in the program via customary mitigation activities as part of an internal controls policy and good utility practice instead of via the enforcement channel. One possible avenue for incorporating such a tolerance into the Standard is to establish a threshold for the Lower VSL. For example, the Lower VSL for requirement R3 could state: "For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 1% but 5% or less of the total Components included within a specific Protection System Component type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.".
Response: Thank you for your comments. The drafting team believes that the assigned VSLs are correct. The SDT believes that failure to implement and follow a PSMP could cause or contribute to Bulk Electric System instability, separation, or a Cascading		

Organization	Yes or No	Question 4 Comment
sequence of failures. Anything less than 100% should be a violation.		
NIPSCO		Comment: Test and maintenance data requirements need to be specific and not open to interpretation. Examples: 1. The number of data points required on an impedance circle graph for a relay calibration versus maximum torque angle only.2. Verification of inputs into microprocessor relay records to include magnitude or is a check box sufficient.
Response: Thank you for your comments. The drafting team believes it has struck the appropriate balance in affording some freedom in applying the standard by Transmission Owners, while minimizing the possibility of adverse auditing interpretations.		
Duke Energy		Duke Energy votes “Negative” because we strongly object to the wording in the Applicability section 4.2.1 which expands the reach of the standard to relaying schemes that detect faults on the BES but which are not intended to provide protection for the BES. Duke Energy’s standard protection scheme for dispersed generation at retail stations would become subject to the standard due to the changes in section 4.2.1. These protection schemes are designed to detect faults on the BES, but do not operate BES elements nor do they interrupt network current flow from the BES. The new wording in section 4.2.1 would add significant O&M costs and resource constraints due to the inclusion of protection system devices at retail stations without increasing the reliability of the BES. FERC’s September 26, 2011 Order in Docket No. RD11-5 approved NERC’s interpretation of PRC-005-1 R1 and R2, stating: “The interpretation clarifies that the Requirements are “applicable to any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the [BES] and trips an interrupting device that interrupts current supplied directly from the BES.” This interpretation is consistent with the Commission’s understanding that a “transmission Protection System” is installed for the purpose of detecting and isolating faults affecting the reliability of the bulk electric system through the use of current interrupting devices.” Duke Energy proposes the following wording for Section 4.2.1: “Protection Systems that are installed for the purpose of protecting BES

Organization	Yes or No	Question 4 Comment
		Elements (lines, buses, transformers, etc.)".
Response: Thank you for your comments. The drafting team still believes that the Applicability as stated in PRC-005-2 is correct, that it supports the reliability of the BES, and that all Protection Systems installed for the purpose of detecting faults on the BES need to be maintained per the requirements of PRC-005-2. The drafting team observes that the approved Interpretation addresses the term, "transmission Protection System," and notes that this term is not used within PRC-005-2; thus, the Interpretation does not apply to PRC-005-2. Please see Section 2.3 of the Supplementary Reference and FAQ Document for additional discussion.		
Nebraska Public Power District		1. Keeping records after the end of the audit period does not increase the current reliability of the electric grid. Requiring records to be kept for longer time periods will increase the risk to utilities of making a mistake in their record keeping and receiving a fine due to the zero tolerance policy drafted in the standard. Records beyond the audit period, up to 24 years old, don't have any effect on the reliability of the current bulk electric system. 2. A key concern is will the reliability of the bulk electric system be affected negatively due to increased risk from human element initiated events as a result of the more frequent functional trip checks that will be required. I suggest there be consideration that the interval for functional tests be moved to the minimum frequency of 12 years to minimize this unknown but present risk. 3. We recommend removing requirement 5. This is adding the requirement for a corrective action program to the standard. Performance metrics should be utilized to measure if a registered entity is correcting maintenance deficiencies in a timely manner. Examples of performance metrics include:-A Countable event has already been defined in the definition of terms, which would cover the need to replace equipment. -The quantity and causes of Misoperations are a direct correlation to good or poor maintenance practices and corrective actions by a utility. -TADS records events which are initiated by failed protection system equipment and would identify utilities with poor corrective action processes.

Organization	Yes or No	Question 4 Comment

Response: Thank you for your comments.

1. **In order that a Compliance Monitor can be assured of compliance, the drafting team believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The drafting team has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with what auditors are expecting (per the drafting team's experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The entity is urged to assure that data is retained as specified within the standard.**
2. **The drafting team believes that performing these maintenance activities at the specified intervals will benefit the reliability of the BES. The standard does not specify "functional trip tests," but instead requires that various elements of the dc control circuit be verified at various intervals.**
3. **The drafting team respectfully disagrees:**

it's the drafting team believes that returning Protection System devices to good working order exists currently as a required element of a sound maintenance program subject to the existing Protection System maintenance and testing standard, PRC-005-1. For reference, NERC Compliance Application Notice CAN-0043 (Posted Final 12/30/2011) directs Compliance Enforcement Authorities (CEAs) to "…look for relay test results or field records with annotations such as "as-found" readings or pass/fail results; <u>if failed, then adjustments made. The maintenance record for adjustments may be requested"</u>.

Management of completion of the identified unresolved maintenance issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The drafting team specifically chose the phrase: "… demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex unresolved maintenance issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requires battery replacement as part of the long term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The drafting team does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible unresolved maintenance issues or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

Organization	Yes or No	Question 4 Comment
Manitoba Hydro		1. Manitoba Hydro is maintaining our negative vote based on our previously submitted comments (see comments submitted in the comment period ending on March 28th, 2012. 2. Additionally, Standard PRC-005-2:R3: "minimum maintenance activities" is not specified in the Tables. We suggest removing the word "minimum". 3. R5: It is not clearly stated that the Unresolved Maintenance issues must be identified. As written, only "identified Unresolved Maintenance Issues" are applicable in R5. 4. Measure M1: “responsible entity(s)” is not defined in the standard. The format of examples is inconsistent with the other measures. We suggest replacing "... (such as ... drawings) ..." with "The evidence may include, but is not limited to, manufacturer's specifications or engineering drawings. ...". 5. Evidence Retention: There is no statement in either the requirements or the measures regarding a "dated" PSMP. 6. VSL: a. R3 - "minimum maintenance activities" is not specified in the Tables. We suggest removing the word "minimum". b. R5 - We suggest "identified Unresolved Maintenance Issues" to agree with the wording in R5. 7. Table 1.1: The Maintenance Activities statement "For all unmonitored relays:" is redundant since it is specified in the Component Attributes. 8. Table 3: Voltage and current sensing devices for UFLS or UVLS should be excluded from periodic maintenance if they are connected to microprocessors relays with AC measurements continuously verified with alarming, as provided for voltage and current sensing devices in Table 1-3. 9. The wording "Protection System dc supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system" is unclear. It is unclear if "used only for a UFLS or UVLS system" applies to the "Protection System dc supply" or to the "non-BES interrupting devices". Exclusions in Table 1-4(f) which pertain to verifying dc supply voltage should also apply to the dc supply in Table 3.

Organization	Yes or No	Question 4 Comment
		10. Attachment A a. To maintain the technical justification Item 5: for consistency with Item 4 and the VSL, we suggest changing the wording to “If the Components in a Protection System Segment maintained through a performance-based PSMP experience more than 4% Countable Events, develop, document, and implement an action plan to reduce the Countable Events to no more than 4% of the Segment population within 3 years. b. "Technical Justification: "Other problems ..." [page 7] ascribed to batteries may also apply to other Components, and therefore does not require special mention for batteries. This paragraph should be removed. c. Pages 12 to 13 - The numbering should agree with the standard. d. Item 10 [page 13] - For consistency with the previous item and the VSL, we suggest changing the wording to "If the Components in a Protection System Segment maintained through a performance-based PSMP experience more than 4% Countable Events, develop, document, and implement an action plan to reduce the Countable Events to no more than 4% of the Segment population within 3 years." 11. The bullet “All of the relevant communication system tests still apply” was added in examples 1 and 2 on pages 68 and 69 of the Supplementary Reference and FAQ - Draft PRC0005-2 Protection System Maintenance (JULY 2012) document (SRFAQ). This makes reference to Table 3 (page 26) of the Standard, but Table 3 does not identify communication systems as a Component Attribute. Table 1-2 (Communications Systems) on page 14 of the standard also excludes the UFLS and UVLS equipment on Table 3. Section 15.7, page 91, of the SRFAQ document also states “No maintenance activity is required for associated communication systems for distributed UFLS and distributed UVLS schemes”. I believe that since no communications systems has been identified in Table 3, this bullet cannot be added to the examples identified above in the SRFAQ document. 12. Implementation Plan: Should entities be given a single compliance date for each of the maintenance intervals, and be allowed the flexibility to schedule and

Organization	Yes or No	Question 4 Comment
		complete their maintenance as required while transitioning to the defined time intervals in PRC-002-2. For example, if a maximum maintenance interval is 6 calendar years, should the implementation plan only require that “The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.”? The existing standard PRC-005-1 already requires protection systems to be maintained as part of a program. Prescribing how an entity must reach full compliance may provide a negligible improvement in reliability, while significantly increasing the compliance burden. PRC-005-2 affects a large number of assets, and proving compliance for prescribed percentages of assets during the transition period may create unnecessary overhead with little added value.

Response: Thank you for your comments.

1. **The drafting team has not changed its position from that expressed in response to the earlier comments.**
2. **Requirement R3 establishes that the maintenance activities specified in the Table are minimum maintenance activities.**
3. **The drafting team believes it is implicit that Unresolved Maintenance issues must be identified.**
4. **The term, “responsible entities” is used throughout NERC standards, and pertains to the applicable entities specified in a particular requirement. The drafting team suggests that the evidence for Measure M1 is sufficiently variable that the term “may include but is not limited to” would not be appropriate.**
5. **The drafting team believes it is self-evident that compliance documents must be dated in order that the time period to which they apply is clear.**
6. **Requirement R3 establishes that the maintenance activities specified in the Table are minimum maintenance activities, and therefore apply to the related VSL. The drafting team has added “identified” to the Requirement R5 VSL table.**
7. **The drafting team believes that the word “unmonitored” is still required for clarity in Table 1-1.**
8. **The drafting team observes that the third row of Table 3 (protective relays) addresses your suggestion.**

Organization	Yes or No	Question 4 Comment
9. The drafting team believes that the wording in Table 3, third row of component attributes is clear and is applicable only to dc supplies used for distributed UFLS and distributed UVLS systems. **10. The drafting team does not believe that your suggested changes improve the standard and declines to make the changes.** **11. The drafting team has modified the Supplementary Reference and FAQ Document to remove the reference to the communication system in these two locations.** **12. The drafting team believes that implementation of the standard according to the milestones established within the Implementation Plan is necessary to establish an effective ongoing Protection System Maintenance Program and to demonstrate a commitment to implementing the new standard.**		
Dominion		Page 11 of the PRC-005-2 redline standard, Version History; Previous versions (i.e. 0, 1, 1a, 1b) need to be included here.
Response: Thank you for your comments. The Version History is intended to capture changes between the last-approved version of the standard and the new standard being proposed.		
ReliabilityFirst		ReliabilityFirst thanks the SDT for changing the maximum time for unmonitored systems within Table 1-2 back to six years. However, RFC continues to believe the language in Requirement R5 ("...shall demonstrate efforts to correct...") is subjective and will be hard to measure. RFC believes at a minimum, the applicable entity should be required to develop a Corrective Action Plan to address the Unresolved Maintenance Issue. Without the formality and burden of a full-fledged Corrective Action Plan, ReliabilityFirst is concerned the identified Unresolved Maintenance Issues may not get resolved or resolved in a timely manner. ReliabilityFirst offers the following modification for consideration: "Each Transmission Owner, Generator Owner, and Distribution Provider shall put in place a Corrective Action Plan to remedy all identified Unresolved Maintenance Issues."
Response: Thank you for your comments. As to demonstrating efforts to address Unresolved Maintenance Issues, the drafting team's intent is to furnish a way for an entity to address Unresolved Maintenance Issues without the formality and burden of a		

Organization	Yes or No	Question 4 Comment
full-fledged Corrective Action Plan.		
Puget Sound Energy		1. Sealed Battery Maintenance: The requirement of impedance testing the batteries every 6 months seems excessive based on our experience. We have been successfully maintaining our sealed cells with impedance testing at 36 months. 2. CT testing on Neutrals: The requirement to verify operation is not possible on the Neutral CT as they don't normally carry current. There should be a clarification that verification of readings can only occur (and is only required) on phase CT's and the neutral CT is excluded. 3. Dual Trip Coil Check: In our experience the requirement to verify operation of both trip coils through a trip is overly burdensome and does not improve the reliability of the system. Testing to verify operation of the output relays, proper tripping of the breaker, and verification of trip coil continuity is sufficient to verify the protective system will operate appropriately. 4. Breaker Failure Relay Testing: In our experience testing of the breaker failure relay up to the relay outputs is sufficient to ensure proper operation. The tripping of the breakers through the coils is maintained through the individual relay maintenance. Requiring clearing of the main bus during maintenance is not practical and may negatively impact the reliability of the Bulk Electric System.
Response: Thank you for your comments. **1. The drafting team believes that the six-month interval is proper for VRLA batteries.** **2. See discussion in Section 8.1.3 of the Supplementary Reference and FAQ Document.** **3. The definition of Protection System includes trip coils within the dc control circuitry component, and it is necessary to perform maintenance on all of these devices to assure proper performance. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.** **4. The standard does not require that the bus be cleared for breaker failure relay testing, but does require that the circuitry from the output of breaker failure relays be verified to the intended target (trip coil, lockout relay coil, input to another relay, etc). The use of test switches or trip cutout switches may be used to break the control circuit into manageable portions so the circuitry can be verified using overlapping zones without necessitating that all associated breakers be tripped for each**		

Organization	Yes or No	Question 4 Comment
maintenance activity.		
ACES Standards Collaborators		The drafting team has done an outstanding job refining the standard. Because no standard will ever be perfect, we believe industry and reliability would be best served to move the standard to recirculation ballot at this point. Regarding Requirement R1 VSLs, we continue to believe that missing three component types should not jump to a Severe VSL when missing two is a Moderate VSL. Missing three should be a High VSL.
Response: Thank you for your response. **The drafting team believes that missing three Protection System component types (out of five) meets the definition of a Severe VLS in the VSL Guidelines.**		
City of Palo Alto		These comments supercede the comments submitted earlier by Tom Finch by mistake. Attachment A "Criteria for a Performance-Based Protection System Maintenance Program" requires a minimum segment population of 60 Components in order to justify a PSMP. We feel the 60 component requirement is arbitrary and discriminates against small entities such as Palo Alto which do not have 60 components and may wish to implement a performance-based PSMP. We feel the decision on whether to use a time-based or performance-based PSMP should be made by the Entity and not NERC.
Response: Thank you for your comment. The minimum population of 60 components, as described in Section 9.1 of the Supplemental Reference and FAQ Document, is a statistically-significant sample size to meet the performance goals of the performance-based maintenance program. Section 9.2 of the Supplemental Reference and FAQ Document suggests that small entities may be able to pool their component populations with other small entities to establish a common performance-based maintenance program.		
Tennessee Valley Authority		TVA appreciates the work that the standard drafting team has done on PRC-005-2.

Organization	Yes or No	Question 4 Comment
		As stated in our comments on Draft 3, TVA is concerned with the maximum maintenance interval of 4 calendar months specified for unmonitored communications systems in Table 1-2, and for that reason has voted negative. A longer implementation timeframe is needed for replacement of the unmonitored units.
Response: Thank you for your comments. The drafting team suggests that performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. If an entity's experience is that these components require less-frequent maintenance, a performance-based program in accordance with Requirement R2 and Attachment A is an option.		
Southwest Power Pool Reliability Standards Development Team		We have a concern that the RE would have difficulty in implementation of the phased in approach. We would suggest extensive training for the auditors for this standard and others which have these multi phased approaches to implementation. With this training it would also be beneficial if NERC would hold a webinar to fill in the industry on the training provided to keep everyone on the same page. We would like to also suggest that NERC compliance staff work with the Drafting Team to develop the RSAWs for this standard.
Response: Thank you for your comments. The drafting team believes that implementation of the standard according to the milestones established within the Implementation Plan is necessary to establish an effective ongoing Protection System Maintenance Program and to demonstrate a commitment to implementing the new standard. The drafting team will pass your suggestion for auditor training and webinar on to NERC Compliance staff. The current NERC RSAW development process encourages that NERC staff involve drafting team representatives when developing RSAWs.		
Southern Company		We strongly suggest that the SDT modify the Applicability section to clarify that Sections 4.2.1 thru 4.2.4 apply to transmission and distribution facilities, and that Section 4.2.5 defines the generator owner applicability by making changes similar to these proposed below. Without this distinctive change, there exists an ability to mis-interpret Section 4.2.1 such that auditors may apply this standard to a generation scope wider than is specified in the NERC Statement of Registry Criteria (Rev 5). We

Organization	Yes or No	Question 4 Comment
		propose the following changes to 4.2.1 thru 4.2.4:1) Replace the existing 4.2.1 with "Protection Systems for transmission and distribution Facilities, including:"2) Move the existing 4.2.1 thru 4.2.4 to subparts of the new 4.2.1 as 4.2.1.1, 4.2.1.2, 4.2.1.3, 4.2.1.4.
Response: Thank you for your comments. **Protection Systems that are installed in non-BES facilities for the purpose of detecting faults on the BES are included in this standard. The drafting team intends that Applicability 4.2.1 address non- generator BES elements. The drafting team has added a discussion to Section 2.3.1 of the Supplementary Reference and FAQ Document explaining their intent regarding the Applicability.**		
Western Area Power Administration		Western feels that our comments and concerns as provided on the previous comment form were not adequately addressed. Those comments are repeated below: 1. Western Area Power Administration is appreciative of the hard work done by the SDT and NERC. We respectfully submit our professional opinion that the increased relay testing required by the PRC-005-2 will result in a net degradation to the reliability of the BES due to human hands disturbing working systems. We propose that auxiliary relays be tested at commissioning and anytime the circuits are rewired or redesigned. If there is evidence that the relay has functioned properly in its current configuration then the best practice for ensuring reliability is to leave it alone. 2. The maintenance interval of 6 years for lock-out relay testing is not consistent with 12 year interval of auxiliary relay testing or control circuit testing. No justification is provided for this increased testing interval of lock-out relays versus other electro-mechanical devices. These inconsistent testing intervals, within the same protection control schemes and protective devices, will complicate the industry's Protection System Maintenance Program and cause an increase in maintenance costs. Condition Based Monitoring or Performance Based Monitoring are not allowed on trip coil circuits or lock-out relays. This is inconsistent with current or future technology. Deviation from the 6 year testing

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 4 Comment</th></tr>
<tr><td></td><td></td><td>interval should be allowed, using CBM or PBM. The Standard should not present a barrier to technology advancements or industry initiatives. The continuous, frequent testing of these devices is detrimental to system reliability.
3. Disagree with testing of the dc control portion of the sudden pressure device as defined by the FAQ. We feel that this device and its wiring were deemed out of scope previously. Do not use the FAQ to modify the standard. The FAQ should strictly be used for clarification only. A standard that relies on a lengthy FAQ and multiple CAN's needs to be re-written concisely and clearly.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments
1. The drafting team recognizes the risk of human error trips when performing maintenance but believes these risks can be managed. Auxiliary relays must be maintained every 12 years, and may be included within the 12-year unmonitored control circuitry verification. Performance-based maintenance is an option if you want to extend your intervals beyond 12 years.
2. The drafting team believes that electromechanical lockout relays need periodic operation and that they need to be exercised at the same six-year interval required for electromechanical relays. Performance-based maintenance is an option if you want to extend your intervals beyond six years.
3. The need to verify the path from the sudden pressure relay trip contact through the auxiliary seal in and through to the lockout relay coil is clearly within the scope of PRC-005-2 as part of the Protection System control circuitry. The sensing element is omitted from PRC-005-2 testing requirements because the drafting team is unaware of industry-recognized activities or intervals for the sensing elements. The drafting team believes that Protection Systems that trip (or can trip) the BES should be included. This position is consistent with the currently-approved PRC-005-1b and consistent with the SAR for Project 2007-17. However, a future revision of PRC-005 will likely add sudden pressure relays in response to directives from FERC Order 758. The Supplementary Reference and FAQ Document provides supporting discussion and clarification but does not modify the standard in any way. The standard is drafted such that the requirements are fully stated; however, the entire field of maintenance of Protection Systems is sufficiently complex that that the drafting team has provided the Supplementary Reference and FAQ Document to share effective methods of meeting the requirements (as anticipated by the drafting team) and to share the drafting team’s rationale in establishing the required maximum intervals and minimum activities.</td></tr>

END OF REPORT

Exhibit I

Discussion of Assignments of VRFs and VSLs

Project 2007-17 – PRC-005-2 Protection System Maintenance

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-2 — Protection System Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria - Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC Violation Risk Factor Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report
The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.
In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

Emergency operations

Vegetation management

Operator personnel training

Protection systems and their coordination

Operating tools and backup facilities

Reactive power and voltage control

System modeling and data exchange

Communication protocol and facilities

Requirements to determine equipment ratings

Synchronized data recorders

Clearer criteria for operationally critical facilities

Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard
The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

Guideline (3) — Consistency among Reliability Standards
The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005-2 Protection System Maintenance is a revision of PRC-005-1a Transmission and Generation Protection System Maintenance and Testing with the stated purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order. PRC-008-0 Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 Undervoltage Load Shedding System Maintenance and Testing and PRC-017-0 Special Protection System Maintenance and Testing are also being replaced by merging them into PRC-005-2 in accordance with suggestions from FERC Order 693. PRC-005-2 also establishes maximum allowable maintenance intervals as directed by FERC in Order 693 in their discussion of the legacy standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

PRC-005-2 has five (5) requirements that incorporate and enhance the intent of the requirements of PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. Several Tables of minimum maintenance activities and maximum maintenance intervals are also included to addresses FERC's directives from Order 693. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Protection System Components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005-2 do not map, one-to-one, with the requirements of the legacy standards, each of which comingle various attributes addressed within the new standard; thus, a requirement-to-requirement comparison of VRFs is irrelevant. When developing VRFs for the

requirements of PRC-005-2, the Standard Drafting Team carefully considered the NERC criteria for developing VRFs, as well as the FERC VRF guidelines. Therefore, PRC-005-2 Requirements R3 and R4 are assigned a VRF of High, while Requirements R1, R2, and R5 are assigned VRFs of Medium.

PRC-005-2 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-2 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-2 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a Component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - Violation Severity Levels

Violation Severity Levels (VSLs) define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

Violation severity levels should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on Violation Severity Levels

In its June 19, 2008 Order on Violation Severity Levels, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-2 Requirement R1.

VRF and VSL Justifications – PRC-005-2, R1	
Proposed VRF	**Medium**
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF..
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL – PRC-005-2, R1

(Part 1.1).

VRF and VSL Justifications – PRC-005-2, R1	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R1	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R2	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-2 Requirement R1.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for .

VRF and VSL Justifications – PRC-005-2, R2			
Proposed VRF	**Medium**		
	Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.		
Proposed VSL – PRC-005-2, R2			
Lower	**Moderate**	**High**	**Severe**
The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	N/A	The responsible entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but: 1)Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP

Proposed VSL – PRC-005-2, R2			
Lower	**Moderate**	**High**	**Severe**
			OR 2) Failed to reduce countable events to no more than 4% within five years OR 3) Maintained a segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR • Annually perform maintenance on the greater of 5% of the segment population or 3 Components, OR • Annually analyze the program activities and results for each segment.

VRF and VSL Justifications – PRC-005-2, R2	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R2	
Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R3	
Proposed VRF	**High**
NERC VRF Discussion	Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only Reliability Standards with similar goals are those being replaced by this standard, and the High VRF assignment for this requirement is consistent with the assigned VRFs for companion requirements in those existing standards.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL – PRC-005-2, R3			
Lower	**Moderate**	**High**	**Severe**
For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain 5% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.	For Protection System Components included within a time-based maintenance program, the responsible entity failed to maintain more than 15% of the total Components included within a specific Protection System Component Type, in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, and Table 3.

VRF and VSL Justificati3ons – PRC-005-2, R3	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R3	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R4	
Proposed VRF	**High**
NERC VRF Discussion	Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only Reliability Standards with similar goals are those being replaced by this standard, and the High VRF assignment for this requirement is consistent with the assigned VRFs for companion requirements in those existing standards.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to implement and follow its Protection System Maintenance Program (PSMP) could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition. Thus, this requirement meets the criteria for a High VRF.
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL – PRC-005-2, R4			
Lower	**Moderate**	**High**	**Severe**
For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.	For Protection System Components included within a performance-based maintenance program, the responsible entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Protection System Component Type in accordance with their performance-based PSMP.

VRF and VSL Justifications – PRC-005-2, R4	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-2, R4	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-2, R5	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only requirement within approved Standards, PRC-004-2a Requirements R1 and R2 contain a similar requirement and is assigned a HIGH VRF. However, these requirements contain several subparts, and the VRF must address the most egregious risk related to these subparts, and a comparison to these requirements may be irrelevant. PRC-022-1 Requirement R1.5 contains only a similar requirement, and is assigned a MEDIUM VRF. FAC-003-2 Requirement R5 contains only a similar requirement, and is assigned a MEDIUM VRF.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system.

VRF and VSL Justifications – PRC-005-2, R5			
Proposed VRF	**Medium**		
	However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

Exhibit J

Record of Development of Proposed Reliability Standard PRC-005-2

Project 2007-17
Protection System Maintenance and Testing

Related Files

Status:
PRC-005-2 will be presented to the NERC Board of Trustees for adoption in November 2012 and if adopted, filed with regulators for approval.

Purpose/Industry Need:
The purpose of standard PRC-005 should remain "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

In Order 693, the Federal Energy Regulatory Commission directed that changes be made to these standards.

These standards should be consolidated into a single standard to reduce the costs of compliance and a number of technical short comings in these standards should be corrected to provide reliable performance when responding to abnormal system conditions.

Standard Authorization Request Form

Title of Proposed Standard: Project 2007-17 — Transmission and Generation Protection System Maintenance and Testing	
Request Date:	May 7, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: System Protection and Controls Task Force (Attachment A)	☐	New Standard
Primary Contact Charles Rogers	X	Revision to existing Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs PRC-011-0 — UVLS System Maintenance and Testing PRC-017-0 — Special Protection System Maintenance and Testing
Telephone (517) 788-0027 Fax (517) 788-0917	X	Withdrawal of existing Standard
E-mail cwrogers@cmsenergy.com	☐	Urgent Action

Purpose (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of standard PRC-005 should remain "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

Industry Need (Provide a detailed statement justifying the need for the proposed standard, along with any supporting documentation.)

In Order 693, the Federal Energy Regulatory Commission directed that changes be made to these standards.

These standards should be consolidated into a single standard to reduce the costs of compliance and a number of technical short comings in these standards should be corrected to provide reliable performance when responding to abnormal system conditions.

Brief Description (Describe the proposed standard in sufficient detail to clearly define the scope in a manner that can be easily understood by others.)

Revise PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, to consolidate PRC-005-1, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs; PRC-011-0 — UVLS System Maintenance and Testing; and PRC-017-0 — Special Protection System Maintenance and Testing into a single maintenance and testing standard. Standards PRC-008-0, PRC-011-0, and PRC-017-0 would then be withdrawn.

The revised PRC-005 standard should address the issues raised in the FERC Order 693 and the issues addressed in the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" – Attachment A to this SAR The revised standard should also address the comments submitted by stakeholders during the development of Version 0, and Phase III & IV and should reflect improvements identified in the Reliability Standards Review Guidelines – Attachment B to this SAR.

Detailed Description:

The PRC-005, 008, 011, and 017 reliability standards are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."

- Applicable to PRC-017 — Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between various protection system technologies.
- Applicable to all four standards — The terms "maintenance programs" and "testing programs" should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.
- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor.

The revised standard should also include the general improvements identified in the attached Reliability Standard Review Guidelines.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the End-use customer.
☒	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☒	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☒	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☒	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replace existing 'levels of non-compliance.') The violation severity levels must be applied for each requirement and may be combined to cover multiple requirements, as long as it is clear which requirements are included and that all requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: more than 95% but less than 100% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: more than 85% but less than or equal to 95% compliant.
- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: more than 70% but less than or equal to 85% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: 70% or less compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan. The effective date should be linked to the NERC BOT adoption date.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

NERC SPCTF Assessment of Standards:

- **PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing**
- **PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs**
- **PRC-011-0 — UVLS System Maintenance and Testing**
- **PRC-017-0 — Special Protection System Maintenance and Testing**

DRAFT 1.0

March 8, 2007

A Technical Review of Standards

Prepared by the
System Protection and Controls Task Force
of the
NERC Planning Committee

Table of Contents

This report and its attendant Standards Authorization Request were approved by the Planning Committee on March 21, 2007, for forwarding to the Standards Committee.

Introduction

When the original scope for the System Protection and Control Task Force was developed, one of the assigned items was to review all of the existing PRC-series Reliability Standards, to advise the Planning Committee of our assessment, and to develop Standards Authorization Requests, as appropriate, to address any perceived deficiencies.

This report presents the SPCTF's assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing. The report includes the SPCTF's understanding of the intent of this standard and contains specific observations relative to the existing standard.
