Joel T Plessinger	Entergy	3	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria....” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type....”. 3. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated

Voter	Entity	Segment	Vote	Comment
				documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified" to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Kevin Querry	FirstEnergy Solutions	3	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting.
Response: **Thank you for your comments. Please see our responses to your comments from the formal comment period.**				
Lee Schuster	Florida Power Corporation	3	Negative	Implementation Plan for PRC-005-2 1. Since R2, R3, and R4 requirements would be performed after establishment of the program documentation, an additional year should be added to all implementation dates for Requirements R2, R3, and R4 as shown below: • Maintenance on components with intervals less than one year must be completed within two years after applicable regulatory approval (within one year of completion of R1 Program Documentation). • Maintenance on components with intervals between one year and two years must be completed within three years after applicable regulatory approval (within two years of completion of R1 Program Documentation). • Maintenance on components with intervals of six years must be completed within three-, five-, and seven-year milestones after

Voter	Entity	Segment	Vote	Comment
				applicable regulatory approval (within two, four, and six years of completion of R1 Program Documentation). • Maintenance on components with intervals of twelve years must be completed within five-, nine-, and thirteen-year milestones after applicable regulatory approval (within four, eight, and twelve years of completion of R1 Program Documentation). Standard PRC-005-02 1. 2. Table 1-2: Rows 1 and 2 require different intervals for the activity "Verify essential signals to and from Protection System components." Unless these inputs and outputs are monitored for Row 2, it would seem that they should be performed at the same interval for both Rows 1 and 2. Therefore, EITHER: • Row 1 should be broken into the following three activities: • 3 months - Verify communications system is functional • 6 years - Verify channel meets performance criteria • 12 years - Verify essential signals to and from other Protection System components OR: • Row 2 should be broken into the following two activities: • 12 years - Verify channel meets performance criteria • 6 years - Verify essential signals to and from other Protection System components 3. Table 1-4: Only Row 1 addresses dc supplies associated with UFLS or UVLS systems. All other rows state that UFLS or UVLS systems are excluded. What is required to "Verify dc supply voltage" for the UFLS/UVLS systems? Does it require that the overall station battery voltage be checked or just the dc voltage available to the UFLS/UVLS circuit of interest? If a voltage measurement is taken at the UFLS/UVLS circuit (e.g., in distribution breaker cabinet), can the batteries/chargers at these facilities be excluded from the PRC-005-2 scope as long as they do not also supply transmission-related protection? 4. PRC-005-2 FAQ's Document Section V.1.A, Example #2: The instrument transformer should be classified as "unmonitored" not "monitored."

Response: **Thank you for your comments.**

1. **The Implementation Plan for Requirement R1 has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.**
2. **The first and second rows differ in that the first row is for unmonitored communications systems, and the second row is for monitored communications systems. The activities in both rows are appropriate and correct.**
3. **Table 1-4 has been completely re-structured. For station dc supply for only UFLS/UVLS, the only activity is to verify the dc**

Voter	Entity	Segment	Vote	Comment
voltage. 4. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.				
Anthony L Wilson	Georgia Power Company	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. Note: We have also made various requests for clarification to the FAQ and Supplemental Reference document in our Response to Comments which we are not including here.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Michael D. Penstone	Hydro One Networks, Inc.	3	Negative	1. The added requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and as written will be subject to different interpretations by entities and compliance enforcement personnel. The addition of this new part of Requirement R1 that requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is onerous and contributes little to the reliability of the BES. 2. Changes introduced to the Implementation Plan since the last posting are not consistent with respect to jurisdictions where no regulatory approval is required. The previously posted implementation for Requirement R1 required entities to be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption. The amended implementation plan changed the three-month time to twelve months in jurisdictions with regulatory approval required but left the same six-month time for the others. For consistency, the six months timeframe should be changed to fifteen months.
Response: Thank you for your comments. 1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				

Voter	Entity	Segment	Vote	Comment
2. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.				
Garry Baker	JEA	3	Negative	JEA will be voting no on PRC-005-2 because of the following: 1. In Table 1-1 for electromechanical trip or auxiliary devices requires verification of operation as opposed to verify ability to operate that was specified on trip coils. I believe it should be ability to operate in each case. 2. Between Table 1-1 and Tables 1-5 essentially would require full functional test of each station every 12 years.
Response: Thank you for your comments. **1. The distinction in Table 1-5 is correct and as intended by the SDT.** **2. A full functional test is one means of completing the required activities, but other methods are also acceptable. See Sections 8 and 15.3 of the Supplementary Reference Document for additional discussion.**				
Mace Hunter	Lakeland Electric	3	Negative	1. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the "baseline" values ought to be if an entity recently began performing this test (assuming it's several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design? 2. Lakeland feels that the SDT should have taken into consideration numerous comments previously made regarding general concerns with testing Control Circuitry in energized substations. We agree that this can negatively impact reliability and would like to emphasize the following: • Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) • Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel

Voter	Entity	Segment	Vote	Comment
				wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. 3. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 4. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 5. the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.**

2. **A) Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.**

   B) The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.

3. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.**

4. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

Voter	Entity	Segment	Vote	Comment
5. **The SDT disagrees; the Tables establish the intervals and activities, and R1 addresses the establishment of an entities' individual PSMP.**				
Bruce Merrill	Lincoln Electric System	3	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it. Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: **Thank you for your comments.** 1. **Table 1-1 has been modified as you suggest.** 2. **This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.** 3. **Table 1-4 does not specify specific gravity testing.**				
Charles A. Freibert	Louisville Gas and Electric Co.	3	Negative	LG&E and KU Energy LLC appreciate the hard work and efforts of the Standards Drafting Team in reaching this point in the standards development process. The basis for the negative vote is the addition of Requirement R1.5 (calibration tolerances) and R4.2 to the standard. This requirement will provide the opportunity for auditors to decide if the testing criteria for whether a relay passes a test or not is acceptable. LG&E and KU Energy recommend that Requirement R1.5 be deleted from the standard.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Greg C. Parent	Manitoba Hydro	3	Negative	1. -Implementation Plan (Timeline) for R1: In areas not requiring regulatory approval, the 6 month time frame proposed for R1 is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval.

Voter	Entity	Segment	Vote	Comment
				2. - VSLs: The high VSL for R1 "Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5" may be interpreted in different ways and should be further clarified. 3. -Table 1-4: The requirements for batteries listed in Table 1-4 do not appear to be consistent with the comments in the FAQ Section (V 1A Example 1). Please see comments submitted during the formal comment period for further detail. 4. -Table 1-4: The requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience.
Response: **Thank you for your comments.** **1. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.** **2. The SDT does not understand your concern; further details are needed.** **3. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.** **4. The SDT believes that the 3-month interval specified in the Standard is appropriate.**				
Don Horsley	Mississippi Power	3	Negative	Reference the new Requirements R.1.5 and R.4.2 which are new to this posting: R.1.5 requires the Owners to "identify calibration tolerances or other equivalent parameters for each Protection System component type" is too intrusive and divisive for what it brings to the reliability of the BES. The entire SDT needs to thoroughly discuss these new requirements and modify or delete them. The SDT considered your comments during this activity.**				
Jeffrey Mueller	Public Service Electric and Gas Co.	3	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in our formal Comment Form.
Response: **Thank you for your comments. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**				
Anthony Schacher	Salem Electric	3	Negative	Battery testing methodologies are too specific and don't allow for different substation battery configurations.
Response: **Thank you for your comments. The SDT disagrees; the requirements within Table 1-4 establish the minimum maintenance activities required to assure that station dc supply of various technologies and configurations will perform as intended without unnecessarily prescribing specific methodologies.**				
Dana Wheelock	Seattle City Light	3	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical

Voter	Entity	Segment	Vote	Comment
				relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2) Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function

Voter	Entity	Segment	Vote	Comment
				electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence". Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic.** **2. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
James R. Keller	Wisconsin Electric Power Marketing	3	Negative	Q4: Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: **Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.**				
Michael Ibold	Xcel Energy, Inc.	3	Negative	See comments under the Transmission segment.
Response: **Thank you for your comments. Please see our responses to your comments from the Transmission segment.**				
Kenneth Goldsmith	Alliant Energy Corp. Services, Inc.	4	Negative	We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS. i. Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is "applied

Voter	Entity	Segment	Vote	Comment
				on" or "designed to provide protection". According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of 'protecting" the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES.
Response: **Thank you for your comments. Applicability 4.2.1 has been revised to remove "applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to 4.2.1. The Supplementary Reference Documentation has been revised to clarify.**				
David Frank Ronk	Consumers Energy	4	Negative	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this

Voter	Entity	Segment	Vote	Comment
				activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the “verify the battery terminal connection resistance” activity?
Response: **Thank you for your comments.** 1. **The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** 2. **This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.** 3. **The Implementation Plan for Requirement R1 has been modified from “six” months to “twelve” months. The standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all Individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** 4. **IEEE 450, 1188, and 1106 all recommend this activity at a 12-month interval. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** 5. **Re-torqueing the battery terminals would not meeting this requirement.**				
Frank Gaffney	Florida Municipal Power Agency	4	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to

Voter	Entity	Segment	Vote	Comment
				ensure that the regionsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**

2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.**

3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

Voter	Entity	Segment	Vote	Comment
Thomas W. Richards	Fort Pierce Utilities Authority	4	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Battery manufacturers typically do not provide this value

Voter	Entity	Segment	Vote	Comment
				and one manufacturer states that the baseline test are to be performed after the battery has been in regular float service for 90 days. It is unclear how to comply with the requirement for the initial 90 days. Additionally, we would recommend that this requirement be modified to permit an entity to establish a "baseline" value based on statistical analysis of multiple test results specific to a given battery manufacturer/model. Several commenters previously expressed their concerns with performing capacity tests. While this may just be an entity's preference, allowing an entity to establish a baseline at some point beyond the initial installation period would give entities the option of using the internal resistance test in lieu of a capacity test. 5. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to accidentally leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter- and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. The interconnected nature of tripping circuits will make it difficult to count the number of circuits consistently for the purpose of calculating a VSL.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**
2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1 in consideration of your comments.**

Voter	Entity	Segment	Vote	Comment
3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap. 4. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending. 5. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach. 6. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for detailed discussion.				
Bob C. Thomas	Illinois Municipal Electric Agency	4	Negative	It is IMEA's understanding from interaction with other entities that Draft 3 provides significant improvement, but that key concerns raised by many entities on Draft 2 were not addressed. IMEA supports comments submitted by Florida Municipal Power Agency.
Response: Thank you for your comments. Please see our responses to your comments submitted during the Formal Comment period..				
Christopher Plante	Integrys Energy Group, Inc.	4	Negative	Reason for No Vote: 1. Implementation plan is too aggressive given the drastic changes from PRC-005-1 to PRC-005-2 2. The drastic changes don't appear to provide an incremental increase in the reliability of the BES 3. We support the MRO NSRS comments
Response: Thank you for your comments. 1. The SDT has carefully considered the changes that entities will be expected to make to their program in response to PRC-005-2 and provided an Implementation Plan that should be sufficient and provided a phase-in approach to permit entities to systemically implement the revised standard. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates. 2. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance. 3. Please see our responses to MRO's NSRS comments on the Standard Comments.				
Joseph G. DePoorter	Madison Gas and Electric Co.	4	Negative	The SDT has made great improvements with this Standard but please consider the following items. 1. Replace "affecting" with "protecting" in the purpose statement.

Voter	Entity	Segment	Vote	Comment
				2. 4.2.1 under Facilities, The description is vague and open for different interpretations for what is "applied on" or "designed to provide protection". According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of 'protecting" the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. Clarification is needed by the SDT that this does not include distribution assets (notwithstanding UFLS and UVLS). 3. Upon review, R1.4, R1.5, and R4.2 were added since the last posting. These are not needed and must of been added to the Standard from an outside sorce. The SDT was on the proper track to finalize this Standard. These requirements need to be left to the individual entities to determine the depth and breath of thier PMSP.
Response: **Thank you for your comments.** **1. The "Purpose" is defined by the SAR.** **2. Applicability 4.2.1 has been revised to remove "applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to Applicability 4.2.1. The Supplementary Reference Documentation has been revised to clarify.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Douglas Hohlbaugh	Ohio Edison Company	4	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting.
Response: **Thank you for your comments. Please see our responses to your comments submitted during the Formal Comment period.**				
John D. Martinsen	Public Utility District No. 1 of Snohomish	4	Affirmative	The overly prescriptive nature of the PRC-005-2 provides greater implementation clarity. However it may be too onerous for Local Network that have demonstrated through studies that delayed clearing (that could be attributed to protection

Voter	Entity	Segment	Vote	Comment
	County			system maintenance and testing) events do not create reliability or cascading concerns.
Response: **Thank you for your comments. PRC-005-2 is applicable to Protection Systems that are designed to provide protection for BES elements, and uses the Compliance Registry to determine applicable entities. Contributions of BES elements to cascading, etc, are immaterial in this Applicability.**				
Hao Li	Seattle City Light	4	Negative	Comment: The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at

Voter	Entity	Segment	Vote	Comment
				risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2) Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 "PRC-005 R2 Pre-June 18 Evidence". Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic.** **2. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
James A Ziebarth	Y-W Electric Association, Inc.	4	Negative	Y-WEA appreciates the significant amount of work that the SDT has put into this revision of the standard. It is clear that the SDT is making a sincere effort to address comments and concerns from previous revisions of this standard, and that is a good thing. While Y-WEA thanks the SDT for the straightforward honesty of disagreeing with our previous comments on the battery testing interval of 3 months for VRLA batteries, we still feel that this mandatory maximum testing interval is unreasonably short, based on IEEE 1188-2005.

Voter	Entity	Segment	Vote	Comment
				The recommended testing intervals contained in that IEEE standard should be targeted as reasonable testing intervals, with some degree of leeway allowed before any mandatory maximum interval is defined. A mandatory maximum interval of four calendar months would be much more appropriate here. This would allow a reasonable testing and maintenance program to define a standard testing interval of three months (in line with the IEEE standard) and still be able to allow a one month buffer or grace period to account for unexpected delays in testing due to extreme storms or other unanticipated heavy workloads. With the draft standard as written, a company must use an unreasonably short preferred maintenance interval if any grace period is to be built in and still remain under the mandatory maximum interval of the NERC standard. In particular, this could have a substantial impact on small companies that are distributed over a large area but have limited resources to deal with such stringent testing requirements. Because this standard will ultimately have to comply with the Regulatory Flexibility Act, it would be worthwhile for the SDT to consider the potential impacts of essentially forcing entities into much more stringent testing programs than recommended by current technically-derived and peer reviewed and approved standards such as IEEE 1188-2005. Other than that, Y-WEA sincerely appreciates the clarity that has been added to this standard over that contained in previous versions of the testing and maintenance standards. This will give registered entities much more guidance as to what NERC's and the regional entities' expectations are when it comes to protection system testing and maintenance programs.
Response: **Thank you for your comments. The SDT has revised the 3-month interval specified for VRLA batteries for some activities to 6 months.**				
Francis J. Halpin	Bonneville Power Administration	5	Negative	Please see BPA's comments submitted seperately
Response: **Thank you for your comments. Please see our responses to your comments submitted during the Formal Comment period.**				
Wilket (Jack) Ng	Consolidated Edison Co. of New York	5	Negative	The Tables – 1. The wording “Component Type” is not necessary in each title. Just the equipment category should be listed--what is now shown as “Component Type - Protective Relay”, should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read

Voter	Entity	Segment	Vote	Comment
				Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. 2. The “Note” included in the heading is also not necessary. “Attributes” is also not necessary in the column heading, “Component” suffices. Other Comments - In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 3. Why are “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)...” not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 4. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled “Unmonitored Control circuitry associated with protective functions”, which would include trip coils, has a “Maximum Maintenance Interval” of “12 Calendar Years”. Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a “stuck” breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 5. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 6. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be

Voter	Entity	Segment	Vote	Comment
				used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 7. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 8. A control circuit is not a component, it is made up of components. 9. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters..." means, and may be subject to different interpretations by entities and compliance enforcement personnel. 10. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 11. The 'box' for "Monitored Station dc supply..." in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 12. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. **The SDT believes that the table headings are appropriate as reflected in the draft standard.**

2. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.**

Voter	Entity	Segment	Vote	Comment
				3. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available. **4. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire.** **5. With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference document. Your comments have been considered within that activity.** **6. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard.** **7. As used in the “Maximum Maintenance Interval” column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition.** **8. For purposes of this standard, the control circuit is defined as one component type.** **9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **10. In consideration of your comment, “six” has been modified to “twelve” in the Implementation Plan for Requirement R1,making it consistent with the remainder of the Implementation Plan.** **11. Table 1-4 has been further modified for clarity.** **12. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**
Amir Y Hammad	Constellation Power Source Generation, Inc.	5	Negative	Constellation Power Generation is voting against this standard for the following reasons: 1. The applicability has included more generation protective components. The current PRC-005 guidance states that only Station Service transformers for plants 75 MVA and up should be included. The proposed

Voter	Entity	Segment	Vote	Comment
				standard includes all station service transformers, regardless of plant size or connection (via generator or system). Constellation Power Generation does not see the reliability benefits of this increased scope. 2. R1.4 states that all monitoring attributes of all components must be listed and identified. For most generation facilities, it is more efficient to calibrate/check the entire protective system while the plant is in an outage, regardless of a component's monitoring capabilities. This requirement would require those facilities to maintain a list of attributes that won't ever be used, and would not alter their testing frequency. What if an entity were found non-compliant in the situation that was just described? It does not affect the reliability of the BES and therefore R1.4 should be removed. 3. M1 doesn't include a measure for R1.4. It just implies that a facility must maintain a list. 4. The battery listing in the attached table is still too prescriptive. If unmonitored, there should be a quarterly and yearly check, which is implied, but it is then broken out by battery type to be more prescriptive. 5. PTs and CTs are mentioned, but it seems as though the drafting team wants a facility to only test the outputs to ensure they are working properly. To clarify this, Constellation Power Generation suggests rewording the testing verbiage for PTs and CTs.
Response: **1. Section 4.2.5 of "Applicability" specifies that only Generation Facilities that are part of the BES are included.** **2. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the SDT has revised Requirement R1, Part 1.4 and has also removed Requirement R2 because of redundancy to Requirement R1, Part 1.4.** **3. Measure M1 has been revised in consideration of your comment.** **4. The activities for different battery types are addressed separately because the relevant activities differ.** **5. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2.**				
James B Lewis	Consumers Energy	5	Negative	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without tripping customers. The standard

Voter	Entity	Segment	Vote	Comment
				must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the "verify the battery terminal connection resistance" activity?
Response: **Thank you for your comments.** **1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** **2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.** **3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** **5. Re-torqueing the battery terminals would not meet this requirement.**				
Mike Garton	Dominion Resources, Inc.	5	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

Stanley M Jaskot	Entergy Corporation	5	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters…” whereas the associated VSL references “failure to establish calibration criteria….” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to the severity level(s) of a “failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? 3. R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type….”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how

Voter	Entity	Segment	Vote	Comment
				broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don’t believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, “When alarm producing Protection System component is verified” to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Kenneth Dresner	FirstEnergy Solutions	5	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting
Response: **Thank you for your comments. Please see our responses to your comments submitted during the formal comment period.**				
David Schumann	Florida Municipal Power Agency	5	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either.

Voter	Entity	Segment	Vote	Comment
				Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.**

2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made modifications to Applicability 4.2.1.**

3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the**

Voter	Entity	Segment	Vote	Comment
degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.				
Rex A Roehl	Indeck Energy Services, Inc.	5	Negative	The level of detail for every conceivable component of every conceivable protective system does not relate to improving reliability. For some protective systems on some equipment, following these requirements, which is undoubtedly already done, will result in good reliability, but probably not improve reliability. Applying those same requirements to the thousands, if not millions, of other protective systems with generate significant costs, generate significant numbers of violations and not have any significant impact on reliability. The costs of this type of program cannot be justified unless there is an NRC mandate or a pass through to ratepayers. Most of the industry will take the cost of this program directly from the bottom line. For minimal reliability improvement, that is not appropriate under the FPA Section 215.
Response: Thank you for your comments. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance.				
Dennis Florom	Lincoln Electric System	5	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it. Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: Thank you for your comments. 1. Table 1-1 has been modified as you suggest. 2. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements. 3. Table 1-4 does not specify specific gravity testing.				
Mike Laney	Luminant Generation	5	Negative	Luminant commends the PRC-005-2 Standard Drafting Team for its quality efforts in producing this version of the Standard however; Luminant must cast a negative

Voter	Entity	Segment	Vote	Comment
	Company LLC			ballot vote for this present version of the Standard. The negative vote against the present version of PRC-005-2 is solely based on the addition of Requirement R1 Part 1.5 with its associated reference to it in Requirement R4 Part 4.2 and the VSL table. It is Luminant's opinion that this new Requirement as written subjects all Transmission Owners, Generation Owners and Distribution Providers to vague interpretations of a requirement that cannot be complied with because it is impossible for any of them to draft the necessary documentation to be compliant with the Standard. As stated in the High VSL associated with Part 1.5 of Requirement R1 all owners will fail "to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters." It is Luminant's opinion that the measurement of acceptable performance during maintenance and testing activities can be accomplished with a Pass/Fail type of documentation on a test form. No company can effectively establish calibration tolerance parameters for an entire "component type" of the Protection System. Doing so could be detrimental to the reliability of the grid. Parameters are dependent on the location, application and situation specific to each Protection System device. The inclusion of Part 1.5 of Requirement R1 is a significant addition to the standard, and by NERC Rules of Procedure requires the input and consideration of the full Standard Drafting Team.
Response: **Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Wayne Lewis	Progress Energy Carolinas	5	Negative	1. Implementation Plan for PRC-005-2 Since R2, R3, and R4 requirements would be performed after establishment of the program documentation, an additional year should be added to all implementation dates for Requirements R2, R3, and R4 as shown below: • Maintenance on components with intervals less than one year must be completed within two years after applicable regulatory approval (within one year of completion of R1 Program Documentation). • Maintenance on components with intervals between one year and two years must be completed within three years after applicable regulatory approval (within two years of completion of R1 Program

Voter	Entity	Segment	Vote	Comment
				Documentation). • Maintenance on components with intervals of six years must be completed within three-, five-, and seven-year milestones after applicable regulatory approval (within two, four, and six years of completion of R1 Program Documentation). • Maintenance on components with intervals of twelve years must be completed within five-, nine-, and thirteen-year milestones after applicable regulatory approval (within four, eight, and twelve years of completion of R1 Program Documentation). 2. Standard PRC-005-02 1. Table 1-2: Rows 1 and 2 require different intervals for the activity "Verify essential signals to and from Protection System components." Unless these inputs and outputs are monitored for Row 2, it would seem that they should be performed at the same interval for both Rows 1 and 2. Therefore, EITHER: 1. Row 1 should be broken into the following three activities: • 3 months - Verify communications system is functional • 6 years - Verify channel meets performance criteria • 12 years - Verify essential signals to and from other Protection System components OR: 2. Row 2 should be broken into the following two activities: 1. 12 years - Verify channel meets performance criteria 2. 6 years - Verify essential signals to and from other Protection System components 2. 3. Table 1-4: Only Row 1 addresses dc supplies associated with UFLS or UVLS systems. All other rows state that UFLS or UVLS systems are excluded. What is required to "Verify dc supply voltage" for the UFLS/UVLS systems? Does it require that the overall station battery voltage be checked or just the dc voltage available to the UFLS/UVLS circuit of interest? If a voltage measurement is taken at the UFLS/UVLS circuit (e.g., in distribution breaker cabinet), can the batteries/chargers at these facilities be excluded from the PRC-005-2 scope as long as they do not also supply transmission-related protection? 4. PRC-005-2 FAQ's Document Section V.1.A, Example #2: The instrument transformer should be classified as "unmonitored" not "monitored."

Response: **Thank you for your comments.**

1. **The Implementation Plan for Requirement R1 has been changed from 12 months to 15 months in consideration of your comment. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.**
2. **The first and second rows differ in that the first row is for unmonitored communications systems, and the second row is for monitored communications systems. The activities in both rows are appropriate and correct.**

Voter	Entity	Segment	Vote	Comment
3. **Table 1-4 has been completely re-structured. For station dc supply for only UFLS/UVLS, the only activity is to verify the dc voltage.** 4. **The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**				
Jerzy A Slusarz	PSEG Power LLC	5	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: Thank you for your comments. Please see our response to your detailed comments from the formal comment period.				
Steven Grega	Public Utility District No. 1 of Lewis County	5	Negative	Do not like the word "all" in the proposed standard. Does all components mean each piece of wire is included? Engineers are conservative in their protection system designs and have redundant relays and protection paths. Even with half the relays out of service, protection is normally retained. Would want to have 80% a compliance level with a year to test & maintenance any component testing founded to be non-compliant. This proposed standard will ensure many more violations.
Response: Thank you for your comments. The approved PRC-005-1 already requires that entities have a program to maintain their Protection System and implement that program. This already implies, "all", therefore PRC-005-2 should not have the impact suggested by your comment.				
Michael J. Haynes	Seattle City Light	5	Negative	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1. the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called "bookend" issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require

Voter	Entity	Segment	Vote	Comment
				that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxilary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechnical compenents, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proporational to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasability exceptions.

Voter	Entity	Segment	Vote	Comment
Response: Thank you for your comments. 1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 “PRC-005 R2 Pre-June 18 Evidence”. 2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.				
William D Shultz	Southern Company Generation	5	Negative	Please see comments submitted via the electronic comment form.
Response: Thank you for your comments. Please see our responses to your comments from the formal comment period.				
George T. Ballew	Tennessee Valley Authority	5	Negative	Project 2007-17 Protection System Maintenance for Standard PRC-005-2 Draft - NERC is recommending significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting NO because of the hurried fashion it is being commented, voted, and reviewed. Official comments to the document were entered on the NERC Portal.
Response: Thank you for your comments. Please see our responses to your comments from the formal comment period.				
Melissa Kurtz	U.S. Army Corps of Engineers	5	Negative	Paragraph 4.2.5.4 - The standard should be changed to require station service transformers only if they will cause a loss of the generator tied to the BES. Also recommend a definition of station service - we have station service that if lost would not negatively effect the BES.
Response: Thank you for your comments. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.				
Martin Bauer P.E.	U.S. Bureau of Reclamation	5	Negative	1. The tables rely on a reference document which is not a part of the standard and as such may be altered without due process. Either the relevant text from the reference needs to be inserted into the standard or the reference itself incorporated into the standard. 2. The supplemental reference provides significant clarity to the intent of standard; however, in doing so, it reveals conflicts and ambiguity in the text of the standard. It is suggested that some of the clarifying language be inserted

Voter	Entity	Segment	Vote	Comment
				into the text of the standard. 3.The concept of including definitions in this standard that are not a part of the Glossary of Terms will create a conflict with other standards that choose to use the term with a different meaning. This practice should be disallowed. If a definition is be introduced it should be added to the Glossary of Terms. This concept was not provided to industry for comment when the modifications to the Definition of Protection System was introduced. Additional related to this practice are included later on. 4. The Term "Protective Relays" is overly broad as it is not limited to those devices which are used to protect the BES. In the reference provided to the standard, the SDT defined "Protective Relays" as "These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. " The Definition for "Protective Relays' as well as the components associated with the them should be associated with the protection of the BES in the definition. 5. The Section 2.4 of the attached reference and the recent FERC NOPR are in conflict with the definition of "Protective Relays" which include lockout relays and transfer trip relays "The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. 6. This Draft 2: April3: November 17, 2010 Page 5 definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices." The definition should be revised to reflect that is really intended. The SDT as created an implied definition by specifically defining DC circuits associated with the trip function of a "Protective Relay" but failing to specifically define voltage and current sensing circuits providing inputs to "Protective Relays". The team clearly intended the circuits to be included but the definition does not since it only refers the the "voltage and current sensing devices". 7.Starting with the Definitions and continuing through the end of the document, terms that have been defined are not capitalized. This leaves it ambiguous as to whether the defined term is to be applied or it is a generic reference. Only defined terms "Protection System Maintenance Program" and "Protection System" are consistently capitalized. 8. Protection System Maintenance Program (PSMP) definition: The Restore bullet should be revised to read as follows: "Return malfunctioning components to

Voter	Entity	Segment	Vote	Comment
				proper operation by repair or calibration during performance of the initial on-site activity." Add the following at the end of the PSMP definition: "NOTE: Repair or replacement of malfunctioning Components that require follow-up action fall outside of the PSMP, and are considered Maintenance Correctable Issues." 9.Protection System (modification) definition: The term "protective functions" that is used herein should be changed to "protective relay functions" or what is meant by the phrase should become a defined term, as it is being used as if it is a well known well defined, and agreed upon term. a. The first bullet text should be revised to read as follows: "Protective relays that monitor BES electrical quantities and respond when those quantities exceed established parameters," the last two bullets should be reversed in order and modified to read as follows: o control circuitry associated with protective relay functions through the trip coil(s) of the circuit breakers or other interrupting devices, and o station dc supply (including station batteries, battery chargers, and non-battery-based dc supply) associated with the preceding four bullets. 10. Statement between the Protection System (modification) definition and the Maintenance Correctable Issue definition; Is this a NERC accepted practice? There does not appear to be a location in the standard for defining terms. Having terms that are not contained in the "Glossary of Terms used in NERC Reliability Standards," and are outside of the terms of the standards, and yet are necessary to understand the terms of the Requirements is not acceptable. They would become similar to the reference documents, and could be changed without notice. 11. Maintenance Correctable Issue definition: The last sentence should be modified to read as follows: "Therefore this issue requires follow-up corrective action which is outside the scope of the Protection System Maintenance Program and the Standard PRC-005-2 defined Maximum Maintenance Intervals." The definition could also be easily clarified to read "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration; therefore requires replacement." This ensures that any action to restore the equipment, short of replacement, is still considered maintenance. Otherwise ambiguity is introduced as what "maintenance" is. 12. Countable Event definition: An explanation should be made that this is a part of the technical justification for the ongoing use of a performance-based Protection System Maintenance Program for PRC-005. 13. Insert the phrase "Standard PRC-005-2" before the term "Tables 1-1..."

Voter	Entity	Segment	Vote	Comment
				14. Applicability: 4.2. Facilities: 4.2.5.4 and 4.2.5.5: Delete these two parts of the applicability. Station service transformer protection systems are not designed to provide protection for the BES. Per PRC-005-2 Protection System Maintenance Draft Supplementary Reference, Nov. 17 2010, Section 2.3 - Applicability of New Protection System Maintenance Standards: “The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005: “...affecting the reliability of the Bulk Electric System (BES)...” To the present language: “... and that are applied on, or are designed to provide protection for the BES.” The drafting team intends that this Standard will not apply to “merely possible” parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault.” Station Service transformer protection is designed to detect a fault on equipment internal to a powerplant and not directly related to the BES. In addition, many Station Service protection ensures fail over to a second source in case of a problem. Thus station service transformer protection system is a powerplant reliability issue and not a BES reliability issue. As such station service transformer protection should not be included in PRC 005 2. In addition, the SDT appears to have targeted generation station service without regard to transmission systems. If generating station service transformers are that important, then why are substation/switchyard station service transformers not also important? 15. Requirements Should the sub requirements have the "R" prefix? 16. R4. Change the phrase "... PSMP, including identification of the resolution of all ..." to read "...PSMP including identification, but not the resolution, of all ...". 17.General comment PRC005-2 is very specific in listing the

Response: Thank you for your comments.

1. The Tables do not provide a reference to either the Supplementary Reference Document or the FAQ. An entity must comply with the standard when approved. The reference documents provide additional explanation, discussion, and rationale, but are not part of the mandatory standard. Since the reference documents are developed in accordance with the standard and will be posted with the standard, the NERC Standard Development Procedure does require that they undergo industry review before being initially posted, and upon any revision.

2. The clarifying language is exactly that – clarifying language, and is not essential to application of the Standard. He NERC Standards Development Procedure establishes that the standard shall not include explanatory text.

3. If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.

Voter	Entity	Segment	Vote	Comment
4. “Protective relay” is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2. 5. The issues raised by the FERC NOPR will be addressed as part of the response to the NOPR (and, ultimately, the Order). The extension of auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5). 6. The extension of auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5). 7. Definition from the NERC Glossary of Terms (or those intended for the Glossary) are consistently capitalized (Protection System and Protection System Maintenance Program fall within this category). As for terms defined only for use within this standard, these terms are NOT capitalized, since they are not in the Glossary of Terms. 8. The “restore” portion of PSMP specifically addresses returning malfunctioning components to your proper operation. The requirements regarding maintenance correctable issues are further addressed within that definition (for use only within PRC-005-2). 9. The SDT is currently not planning on further modifying the most recent NERC BOT-approved definition of Protection System. 10. If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2. 11. Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to repair / replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstration completion of them. 12. Since this term is used only in Attachment A, it seems unnecessary to provide the explanation requested. 13. The SDT has elected not to change the reference to the Tables throughout the Standard. 14. Thank you for your comments. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generation plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility. 15. The current style guide for NERC Standards does not preface the Parts with an “R”. 16. Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be				

Voter	Entity	Segment	Vote	Comment
necessary to repair / replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstration completion of them. 17. It appears the remainder of your comment was truncated and cannot be ascertained.				
Linda Horn	Wisconsin Electric Power Co.	5	Negative	Q4: Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.				
Leonard Rentmeester	Wisconsin Public Service Corp.	5	Negative	1. Implementation plan is too aggressive given the drastic changes from PRC-005-1 to PRC-005-2 2. The drastic changes don't appear to provide an incremental increase in the reliability of the BES 3. We support the MRO NSRS comments
Response: Thank you for your comments. 1. The SDT has carefully considered the changes that entities will be expected to make to their program in response to PRC-005-2 and provided an Implementation Plan that should be sufficient and provided a phase-in approach to permit entities to systemically implement the revised standard. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates. 2. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that benefits reliability and that may be consistently monitored for compliance. 3. Please see our responses to MRO's NSRS formal comments in the Consideration of Comments document.				
Liam Noailles	Xcel Energy, Inc.	5	Negative	We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments
Response: Thank you for your comments. Please see our response to your formal comments.				
Edward P. Cox	AEP Marketing	6	Negative	Restructured Tables: 1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a

Voter	Entity	Segment	Vote	Comment
				maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 2. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. AEP suggests repeating the heading "Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):" for the bullet points on this page. VSLs, VRFs and Time Horizons: 3. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 "High" VSL. 4. All four levels of the VSL for R2 make reference to a "condition-based PSMP." However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 5. In multiple instances, Table 1 uses the phrase "No periodic maintenance specified" for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state "No periodic maintenance required" or perhaps "Maintain per manufacturers recommendations." Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. FAQ and Supplementary Reference: 6. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. Section 5 of the Supplementary Reference, refers to "condition-based"

Voter	Entity	Segment	Vote	Comment
				maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. b. Section 15.7, page 26, appears to have a typographical error "...can all be used as the primary action is the maintenance activity..." c. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups. "Frequently-Asked Questions": 7. With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: a. The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. b. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. c. The second sentence to the response in Section I.1 appears to have a typographical error "... an entity needs to and perform ONLY time-based...". General: 8. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate.

Voter	Entity	Segment	Vote	Comment
				9. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume a knowledge of material in the Supplementary Reference or FAQ. 10. "Protective relay" should be a defined term that lists relay function for applicability. There are numerous 'relays' used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 11. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.

Response: Thank you for your comments.

1. The 6-year activities are all related to components with "moving parts", and the 12-year activities are related to the other portions of the control circuitry. The capitalized term has been corrected.
2. Table 1-4 has been modified in consideration of your comments.
3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.
4. The SDT concluded that Requirement R2 is redundant to Requirement R1, Part 1.4 and has deleted Requirement R2 (together with the Measures and & VSL).
5. If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.
6. The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard.
    a) The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed.

Voter	Entity	Segment	Vote	Comment
b) This clause has been corrected. c) A higher-quality version of Figure 2 has been substituted. 7. The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard. a) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. b) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. c) The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. 8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 9. The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used. 10. "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition with PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2. 11. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.				
Brenda S. Anderson	Bonneville Power Administration	6	Negative	Refer to BPA comments
Response: Thank you for your comments. Please see our response to the BPA comments.				
Matthew D Cripps	Cleco Power LLC	6	Negative	Cleco applies its' UFLS on the distribution grid with each UF relay individually tripping a relatively low value of load thru breakers and reclosers. Since our program is implemented via a large number of individual components, breakers, reclosers, and individual batteries, the failure of any one component will have a minimal impact on the effectiveness of the overall UFLS program within our region. Therefore, the verification of sensing devices, dc supply voltages, and the

Voter	Entity	Segment	Vote	Comment
				paths of the control circuit and trip circuits on the UFLS systems implemented on the distribution grid is unnecessary.
Response: **Thank you for your comments. The SDT disagrees; the sensing devices, control circuitry and dc supply related to UFLS has an effect on the performance of the UFLS. The SDT has, however, respected the overall impact on the control circuitry of individual UFLS on BES reliability by requiring that UFLS be subjected to a subset of the overall sensing devices, control circuitry and dc supply maintenance activities.**				
Nickesha P Carrol	Consolidated Edison Co. of New York	6	Negative	The Tables 1. The wording "Component Type" is not necessary in each title. Just the equipment category should be listed--what is now shown as "Component Type - Protective Relay", should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The "Note" included in the heading is also not necessary. 2. "Attributes" is also not necessary in the column heading, "Component" suffices. Other Comments – 3. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 4. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)…" not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 5. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in

Voter	Entity	Segment	Vote	Comment
				real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 6. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 7. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 8. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 9. A control circuit is not a component, it is made up of components. 10. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters..." means, and may be subject to different interpretations by entities and compliance enforcement personnel. 11. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 12. The 'box' for "Monitored Station dc supply..." in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. Regarding station service transformers, 13. Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs

Voter	Entity	Segment	Vote	Comment
				(III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards.

Response: **Thank you for your comments.**

1. **The SDT believes that the table headings are appropriate as reflected in the draft standard.**

2. **Please see the SDT's response to ISO New England Inc. in the formal Standard Comments**

3. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.**

4. **The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.**

5. **According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You can maintain these devices more frequently if you desire**

6. **With respect to dc supply associated only with communication systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**

7. **The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.**

8. **As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition.**

9. **For purposes of this standard, the control circuit is defined as one component type.**

Voter	Entity	Segment	Vote	Comment
10. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this. 11. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan Please see the SDT's response to NPPC in the formal Standard Comments. 12. Table 1-4 has been further modified for clarity. 13. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.				
Brenda Powell	Constellation Energy Commodities Group	6	Negative	1. The applicability has included more generation protective components. The current PRC-005 guidance states that only Station Service transformers for plants 75 MVA and up should be included. The proposed standard includes all station service transformers, regardless of plant size or connection (via generator or system). Constellation Energy Commodities Group does not see the reliability benefits of this increased scope. 2. R1.4 states that all monitoring attributes of all components must be listed and identified. For most generation facilities, it is more efficient to calibrate/check the entire protective system while the plant is in an outage, regardless of a component's monitoring capabilities. This requirement would require those facilities to maintain a list of attributes that won't ever be used, and would not alter their testing frequency. What if an entity were found non-compliant in the situation that was just described? It does not affect the reliability of the BES and therefore R1.4 should be removed. 3. M1 doesn't include a measure for R1.4. It just implies that a facility must maintain a list. 4. The battery listing in the attached table is still too prescriptive. If unmonitored, there should be a quarterly and yearly check, which is implied, but it is then broken out by battery type to be more prescriptive. 5. PTs and CTs are mentioned, but it seems as though the drafting team wants a facility to only test the outputs to ensure they are working properly. To clarify this, Constellation Energy Commodities Group suggests rewording the testing verbiage for PTs and CTs.
Response: Thank you for your comments. 1. Section 4.2.5 of "Applicability" specifies that only Generation Facilities that are part of the BES are included. 2. The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components. However, in consideration to your comment the				

Voter	Entity	Segment	Vote	Comment
SDT has revised Requirement R1, Part 1.4 and has also removed Requirement R2 because of redundancy to Requirement R1, Part 1.4. **3. Measure M1 has been revised in consideration of your comment.** **4. The activities for different battery types are addressed separately because the relevant activities differ.** **5. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2.**				
Louis S Slade	Dominion Resources, Inc.	6	Negative	Dominion is opposed to this version because Requirement R1.5 is overly prescriptive, requiring an extraordinary level of documentation, with little anticipated improvement in reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.				
Terri F Benoit	Entergy Services, Inc.	6	Negative	The restructured tables are generally much clearer and the SDT is to be commended on their efforts. 1. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an “alarm producing device” is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn’t necessarily a maximum interval established as there is for Protection System components. Also, if an entity’s alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing device of that entity. On that basis, we suggest the interval verbiage be revised to “When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable”. Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to “When alarm producing component/protection system segment is verified”. In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification? 2. R1.5 calls for “identification of calibration tolerances or equivalent parameters...” whereas the associated VSL references “failure to establish calibration criteria….” and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply “identify” or document such calibration tolerances would be analogous to

Voter	Entity	Segment	Vote	Comment
				the severity level(s) of a “failure to specify one (or Cthe severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn’t a failure to implement any necessary calibration tolerance be accounted for in R4? R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type....”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance for a component type besides protective relays. Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don’t believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: **Thank you for your comments.** **1. The Maximum Maintenance Interval column entry in Table 2 has been revised to state, “When alarm producing Protection System component is verified” to clarify this.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**				
Mark S Travaglianti	FirstEnergy Solutions	6	Negative	Please see FirstEnergy's comments submitted separately through the comment period posting.
Response: **Thank you for your comments. Please see our response to your comments submitted separately through the formal comment period.**				
Richard L. Montgomery	Florida Municipal Power Agency	6	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry.

Voter	Entity	Segment	Vote	Comment
				What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.

Response: **Thank you for your comments.**

1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically**

Voter	Entity	Segment	Vote	Comment
excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil. **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that

Voter	Entity	Segment	Vote	Comment
				excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: **Thank you for your comments.** 1. **For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities related to the interrupting device trip coil.** 2. **This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** 3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**				
Silvia P Mitchell	Florida Power & Light Co.	6	Negative	This draft standard is too perscriptive. 1. Requirement R1, Part 1.5 would be overwhelming if approved. Requirement R1, Part 1.5 should be deleted. 2. Requirement R4, Part 4.2 phrase "established in accordance with Requirement R1, Part 1.5" should be deleted. The standard without these additional requirements would be sufficient to establish that the Protection System is maintained and protects the BES. 3. Table 1-2 Component Type Communications Systems Maximum Maintenance Interval of 3 Calendar Months to verify that the communications system is functional for any unmonitored communications system is unyielding. Most communication failures are caused by power supply failures which Next Era does monitor. Based on experience and monitoring of communication power supplies, 12 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 12 calendar months. 4. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to inspect electrolyte levels on "Any unmonitored station

Voter	Entity	Segment	Vote	Comment
				dc supply not having the monitoring attributes of a category below. (Excluding UFLS and UVLS)" is too stringent. Verifying battery charger float voltage every 18 calendar months is sufficient to prevent excessive gassing and water loss of battery cells. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months. 5. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to measure the internal ohmic values on "Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)" is too stringent. With the standard's requirement to verify the float voltage every 18 calendar months, measuring the internal ohmic values every 6 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months.
Response: Thank you for your comments. 1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 2. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section 8 for a discussion of this. The associated VSL has also been revised. 3. The activity to which you refer is an inspection-based activity based on overall functionality, and addresses functionality of various communications technologies. If an entity monitors the power supply (as suggested), doing so addresses one portion of the functionality, but does not address channel integrity, etc. 4. The SDT disagrees, and believes that the specified activities, at the specified intervals, are appropriate. 5. The standard has been revised as you suggested.				
Paul Shipps	Lakeland Electric	6	Negative	Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.)
Response: Thank you for your comments. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.				
Eric Ruskamp	Lincoln Electric System	6	Affirmative	While the proposed draft of the standard is acceptable as currently written, LES would like the drafting team to consider the following comments. (1) Table 1-1 should state "Test and calibrate (if necessary)" in the first section under activities. If a relay passes the test, there is no need to calibrate it.

Voter	Entity	Segment	Vote	Comment
				Therefore, not all relays will require calibration. (2) Please explain the drafting team's reason for not checking the trip coils of breakers in the UFLS/UVLS schemes but ensuring that all others are operated every six years. It would appear that they can all be lumped into the same group one way or another. (3) In regards to Specific Gravity Testing, many people do not perform the specific gravity test routinely if they perform the individual cell internal ohmic test routinely. LES asks the drafting team to consider allowing the internal cell ohmic test as a substitute for the specific gravity test.
Response: **Thank you for your comments.** 1. **Table 1-1 has been modified as you suggest.** 2. **This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping distribution system elements.** 3. **Table 1-4 does not specify specific gravity testing.**				
Brad Jones	Luminant Energy	6	Negative	Luminant commends the PRC-005-2 Standard Drafting Team for its quality efforts in producing this version of the Standard however; Luminant must cast a negative ballot vote for this present version of the Standard. The negative vote against the present version of PRC-005-2 is solely based on the addition of Requirement R1 Part 1.5 with its associated reference to it in Requirement R4 Part 4.2 and the VSL table. It is Luminant's opinion that this new Requirement as written subjects all Transmission Owners, Generation Owners and Distribution Providers to vague interpretations of a requirement that cannot be complied with because it is impossible for any of them to draft the necessary documentation to be compliant with the Standard. As stated in the High VSL associated with Part 1.5 of Requirement R1 all owners will fail "to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters." It is Luminant's opinion that the measurement of acceptable performance during maintenance and testing activities can be accomplished with a Pass/Fail type of documentation on a test form. No company can effectively establish calibration tolerance parameters for an entire "component type" of the Protection System. Doing so could be detrimental to the reliability of the grid. Parameters are dependent on the location, application and situation specific to each Protection System device.

James D. Hebson	PSEG Energy Resources & Trade LLC	6	Negative	The PSEG Companies do not agree with the Facilities as currently described in section 4.2.5.5. Please refer to detailed comments provided in the formal Comment Form.
Response: **Thank you for your comments. Please see our response to your comments from the formal comment period.**				
Dennis Sismaet	Seattle City Light	6	Negative	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called "bookend" issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities

Voter	Entity	Segment	Vote	Comment
				in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxilary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response: **Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 “PRC-005 R2 Pre-June 18 Evidence”.** **2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**				
David F. Lemmons	Xcel Energy, Inc.	6	Negative	We feel that several improvements were made since the last draft. However, we feel that some gaps exist that should be addressed before moving this project forward. We have detailed our issues in our formal comments.
Response: **Thank you for your comments. Please see our responses to your formal comments.**				
Jim R Stanton	SPS Consulting Group Inc.	8	Negative	1. The standard as written is wildly prescriptive and violates the concept of "what and not how." The standard and its Tables seek to prescribe in detail maintenance and testing processes which should be left up to the owners and operators of the protection systems.

Voter	Entity	Segment	Vote	Comment
				2. References to Tables 1-5 should be deleted from the standard itself and moved to a reference section.
Response: **Thank you for your comments.** 1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need to be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.** 2. **Tables 1-1 through 1-5 are considered by the SDT to be an integral part of the requirements of the standard and thus belong within the Standard.**				
Louise McCarren	Western Electricity Coordinating Council	10	Affirmative	Our affirmative vote reflects our belief that the proposed PRC-005-2 is an overall improvement to the four standards that it would replace. We also believe that it is appropriate to address maintenance and testing of all protection systems in one standard rather than in four individual standards.
Response: **Thank you for your comments and support.**				

END OF REPORT

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Consideration of Comments on Non-binding Poll of VRFs and VSLs associated with PRC-005-2 – Protection System Maintenance (Project 2007-17)

The Project 2007-17 Drafting Team thanks all commenters who submitted comments on the non-binding poll of VRFs and VSLs associated with the proposed revisions to PRC-005-2. The standard and associated VRFs and VSLs were posted for a 30-day public comment period from November 17, 2010 through December 17, 2010, with a 10-day ballot beginning on December 10, 2010 through December 21, 2010. The stakeholders were asked to provide feedback on the VRFs and VSLs. There were 28 sets of comments, including comments from more than 46 different people from approximately 26 companies representing 6 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

Comment	The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: "Entity has failed to complete scheduled program on 1% to 5% of total Protection System components." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties.
Response	**Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.**

Comment	1. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 "High" VSL. 2. All four levels of the VSL for R2 make reference to a "condition-based PSMP." However, nowhere in the standard is the term "condition-based" used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 3. In multiple instances, Table 1 uses the phrase "No periodic maintenance specified" for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state "No periodic maintenance required" or perhaps "Maintain per manufacturers recommendations." Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required. 4. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what

	those three programs entail. These programs should be described within the standard itself and not assume knowledge of material in the Supplementary Reference or FAQ.
Response	**Thank you for your comments.** 1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** 2. **The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** 3. **If the indicated monitoring attributes are present, no "hands-on" periodic maintenance is required, as the monitoring of the component is providing a continuing indication of its functionality.** 4. **The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.**
Segment	1
Organization	Beaches Energy Services

Comment	1. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 2. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. 3. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the "baseline" values ought to be if an entity recently began performing this test (assuming it's several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a given battery manufacturer and design? 4. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control

	circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 5. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 6. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response	**Thank you for your comments.** **1. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.** **2. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.** **3. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.** **4. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **5. This interpretation is not yet approved. When this interpretation is approved, the SDT will**

	incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1. **6. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them (which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

Comment	VSL/VRF Ballot Comments: The Modified VSL's and VRF's – 1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. 4. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. 5. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 6. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response	**Thank you for your comments.** **1. Consideration of the VRFs, in association with the VRF Guidelines, yields the VRFs as established within the draft Standard.** **2. The SDT has reviewed the time horizons, and believes that Requirement R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components are performed within the related time period. The SDT concluded that Requirement R2 is redundant to Requirement R1 and has deleted Requirement R2 (together with the Measure and**

	VSL). 3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** 4. **Requirement R1 'Moderate' appears to be similar to Requirement R1 'Lower' as you suggest.** 5. **The SDT believes that, if more than two Protection System component types are not addressed, the 'Severe' VSL is appropriate.** 6. **The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**

Comment	The VRFs and VSLs still do not take into account smaller generation facilities that do not have as many protection system components as other facilities. They are penalized much more heavily.
Response	**Thank you for your comments. The percentage levels within Requirement R4 are consistent with many other NERC Standards, and are also consistent with the guidance within the NERC VSL Guidelines.**

Comment	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R4 is too aggressive in that it may not

	permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the "verify the battery terminal connection resistance" activity?
Response	**Thank you for your comments.** **1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** **2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2** **3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Section 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** **5. Re-torqueing the battery terminals would not meet this requirement.**

Comment	VSL R3. How do you measure a percentage of countable events over a period of time? How are you to determine what the total population to be considered? An entity should not be penalized if they are following their program, correcting issues, and documenting all actions, even if there is a high failure rate in an instance.
Response	**Thank you for your comments. Attachment A, to which Requirement R3 refers, specifies that countable events are assessed on the basis of "for the greater of either the last 30 components maintained or all components maintained in the previous year."**

Comment	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuity, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control

	circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical the VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response	**Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **2. This interpretation is not yet approved. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** 3. **The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.**

Comment	The Violation Risk Factors should not be the same for all registered entities because the risk in a violation by a 20 MW wind farm connected at 115 kV is de minimis compared to that same violation at a 2,000 MW transmission substation or generator. The basic structure of this revision to PRC-005 is totally defective. Combining 4 standards that each have something to do with relays into one omnibus standard was wrongheaded. The Violation Severity Levels need to match the violation and four arbitrary categories cannot do so for the myriad of components, systems and varying numbers of them for one registered entity that are covered by this draft standard.
Response	**Thank you for your comments. The VRFs are not dependent on size, and must be assigned on a requirement-by-requirement basis.**

However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection,the Applicability section should. For instance,, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. the VRF of R1 should be Low since the attached tables are essentially the PSMP. 5. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Since battery manufacturers do not provide this value, it is unclear what the “baseline” values ought to be if an entity recently began performing this test (assuming it’s several years after the commissioning of the battery.) Would it be acceptable for an entity to establish baseline values based on statistical analysis of multiple test results specific to a

	given battery manufacturer and design? 6. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn't seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 7. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to unknowingly leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the circuitry where this may not be the case is in the inter and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths.
Response	**Thank you for your comments.** **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **2. This interpretation is not yet approved. When this interpretation is approved, the SDT will incorporate it within PRC-005-2. However, the SDT has made changes to Applicability 4.2.1.** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them(which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve the gap.** **4. The SDT disagrees; the Tables establish the intervals and activities and Requirement R1 addresses the establishment of an entity's individual PSMP.**

	5. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending. **6. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.** **7. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.**

Comment	1. We disagree with the VRFs for R3, R4, and R5. R3, R4, and R5 are administrative requirements and duplicate to requirements in FAC-008 and FAC-009 that already require communication of facility ratings including those limited by relays. Thus, it should be Lower. 2. We disagree with the High VRF for Requirement R6 because the criteria in attachment will identify circuits that are not critical. If the criteria is modified per our comments on the standard and in the ballot, then we would agree with a High VRF. 3. Requirement R7 should be deleted as it represents double jeopardy. Thus, we do not agree with any VRF for it.

Comment	VRF's: The definition of a Medium Risk Requirement included on page 8 of the SAR states: "A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system." 1. The PSMP does not "directly" affect the electrical state or the capability of the bulk electric system. A failure of a Protection System component is required to "directly" affect the BES. Therefore, the PSMP has only an "indirect" affect on the electrical state or the capability of the BES. Requirements R1 through R3 and their subparts are administrative in nature in that they are comprised entirely of documentation. Therefore, I recommend changing the Violation Risk Factor of Requirements R1, R2, and R3 to Lower to be consistent with the Violation Risk Factors defined in the SAR. VSL's: 2. R2: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "condition-based" to "time-based" in all four severity levels. 3. SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with

	the SAR. 4. R3: The performance-based maintenance program identified in PRC-005 Attachment A provides the requirements to establish the technical justification for the initial use of a performance-based PSMP and the requirements to maintain the technical justification for the ongoing use of a performance-based PSMP. However, it appears the VSLs for Requirement R3 only addresses the ongoing use of the technical justification. I recommend revising the VSLs for R3 to include the initial use of the technical justification. a. Item 2) of R3 Severe VSL is a duplicate of Item 2) of R3 Lower VSL. This item is administrative in nature therefore I recommend deleting Item 2) from R3 Severe VSL. b. The first and third bullets of item 4) of R3 Severe VSL are administrative in nature and should be moved to the Lower VSL c. R4: SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less compliant I recommend revising the percentages of the violation severity levels to be consistent with the SAR.
Response	**Thank you for your comments.** **1. Requirements R1, R2, and R3 are not administrative; they are foundational. Without the fundamental development of a PSMP, an entity is unlikely to actually implement a PSMP that satisfies the reliability needs of the BES.** **2. The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** **3. The guidelines within the SAR have been superseded by subsequent revisions to the VSL Guidelines. The VSLs in the draft standard adhere to the latest VSL Guidelines and to the June 19, 2008 FERC order on VSLs in Docket No RR08-04-000.** **4. Part a – The VSL for Requirement R3 has been modified in consideration of your comments.** **Part b – These requirements are not administrative; they are foundational. Without compliance with these requirements, an entity does not have an effective performance-based PSMP, and may be detrimentally affecting reliability.** **Part c – The latest VSL Guidelines also provide examples of VSLs similar to those in the draft standard.**

Organization	Seattle City Light
Member	Dennis Sismaet
Comment	The proposed Standard PRC-005-2 is an improvement over the previous draft in that it provides more consistency in maintenance and testing duration internals. Notwithstanding, two issues are of concern to Seattle City Light such that it is compelled to vote no: 1) the establishment of bookends for standard verification and 2) the implementation timelines for entities with systems where electro-mechanical relays still compose a significant number of components in their protection systems. 1. Bookends: Proposed Standard PRC-005-2 specifies long inspection and maintenance intervals, up to 12 years, which correspondingly exacerbates the so-called “bookend” issue. To demonstrate that interval-based requirements have been met, two dates are needed - bookends. Evidencing an initial date can be problematic for cases where the initial date would occur prior to the effective date of a standard. NERC has provided no guidance on this issue, and the Regions approach it differently. Some, such as Texas Regional Entity, require initial dates beginning on or after the effective date of a Standard. Compliance with intervals is assessed only once two dates are available that occur on or after a standard took effect. Other regions, such as Western Electricity Coordinating Council (WECC), require that entities evidence an initial date prior to the effective date of a standard. For WECC, compliance with intervals is assessed as soon as a standard takes effect. Such variation makes application of standards involving bookends uncertain, arbitrary, capricious, and in the case of WECC, possibly illegal. Proposed Standard PRC-005-2 will be another such standard. Indeed this Standard will involve by far the largest number of bookends of any NERC standard - many thousands for a typical entity. Furthermore, the long inspection and maintenance intervals

	introduced in the draft will require entities in WECC, for instance, to evidence initial bookend dates prior to the date original PRC-005-1 took effect. For the 12-year intervals for CTs and VTs in proposed Standard PRC-005-2, many initial dates will occur prior to the 2005 Federal Power Act that authorized Mandatory Reliability Standards and even reach back before the 2003 blackout that catalyzed the effort to pass the Federal Power Act. As a result, many entities in WECC maybe at risk of being found in violation of proposed Standard PRC-005-2 immediately upon its implementation. Seattle City Light requests that NERC address the bookends issue, either within proposed Standard PRC-005-2 or in a separate, concurrent document. 2. Legacy Systems: Many entities still have legacy protection systems that rely upon electro-mechanical relays. Effective testing approaches differ between electro-mechanical and digital relay systems. Thus, although the proposed standard rightly looks to the future of digital relays by specifying testing and maintenance focused on protection systems as a whole, the proposed implementation timelines create a level of hardship for those utilities with legacy systems. In example, auxiliary relay and trip coil testing may be essential to prove the correct operation of complex, multi-function digital protection systems. However, for legacy systems with single-function electro-mechanical components, the considerable documentation and operational testing needed to implement and track such testing is not necessarily proportional to the relative risk posed by the equipment to the bulk electric system. Performance testing of electro-mechanical systems, particularly regarding control circuits, will require extensive disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. As such, to assist entities in their implementation efforts, we believe provision of alternatives are necessary, such as additional implementation time through phasing and/or through technical feasibility exceptions.
Response	**Thank you for your comments.** **1. This issue has been addressed by NERC in Compliance Application Notice CAN-008 “PRC-005 R2 Pre-June 18 Evidence”.** **2. Please see Sections 8 and 15.3 of the Supplementary Reference Document for a discussion on this topic. FERC Order 693 directs that NERC establish requirements for the maintenance of the Protection System and control circuitry is a portion thereof. Therefore, requirements for the maintenance of the control circuitry are necessary and the SDT has developed those requirements in a fashion that affords entities with the opportunity to best meet those requirements.**
Segment	1,3, 3, 3
Organization	Southern Company Services, Inc., Alabama Power, Georgia Power, Mississippi Power
Member	Horace Stephen Williamson, Richard J. Mandes, Anthony L Wilson, Don Horsley

Comment	We disagree with the inclusion of the VSLs, VRFs, and time Horizons associated with the new Requirements 1.5 and 4.2
Response	**Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
Segment	5
Organization	U.S. Bureau of Reclamation
Member	Martin Bauer P.E.
Comment	The VSL levels are not consistent with the true impact on reliability. Severe levels are assigned for failing to document rather than failing to maintain components. Documentation requirements that are not met should not be assigned a Severe level. The concept of penalizing an entity for failed components without regard to why they failed is unreasonable. The severely levels should be based on avoidable failures or failures that could have been detected if the entity had performed maintenance.
Response	**Thank you for your comments.** **VSLs depict the level to which an entity has failed to comply with the standard; VRFs reflect the risk to the BES. Escalations within the VSLs specifically address more egregious (severe) violations of the standard in accordance with the NERC VSL Guidelines.**

Consideration of Comments on Protection System Maintenance [Project 2007-17]

The Protection System Maintenance Drafting Team thanks all commenters who submitted comments on the 3rd draft of the standard for Protection System Maintenance and Testing. These standards were posted for a 30-day public comment period from November 17, 2010 through December 17, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 44 sets of comments, including comments from more than 81 different people from approximately 82 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Extensive changes were made to Requirements R1 and R3 of the Standard, and also to the Tables referenced within the Requirements. Of particular note, Requirement R1, Part 1.5 (which required entities to define their acceptance criteria for maintenance of components), and the associated discussion within Requirement R4, Part 4.2 were removed. Requirement R2 was removed because it was duplicative of Requirement R1, Part 1.4. Also, Table 1-4, addressing maintenance of Station DC Supply, was split into six separate sub-tables addressing the various specific technologies within this component.

Some commenters continued to object to various requirements within the standard. Where the standard was not revised in response to these comments, the SDT explained their rationale within the consideration-of-comments.

Based on the level of consensus on this posting, the SDT will post the Standard and associated documents for an additional 30-day comment period with concurrent ballot in the final 10-days of that comment period.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. **The SDT has restructured the tables to improve clarity, but did not appreciably change the content. Do you agree that the restructured tables are clearer? If not, please provide specific suggestions for improvement.**

Summary Consideration: Generally, commenters indicated that the rearrangement of the Tables was beneficial. Several commenters questioned the arrangement of Table 1-4 and the SDT responded by revising this Table. A few commenters suggested further rearrangement of the Tables; the SDT observed that there are many potential ways to organize the Tables and declined to adopt these suggestions. The SDT made minor changes to Table 1-3 and Table 2 verbiage based on stakeholder comments.

Organization	Yes or No	Question 1 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	
Tennessee Valley Authority	Yes	
Northeast Power Coordinating Council	No	The wording “Component Type” is not necessary in each title. Just the equipment category should be listed--what is now shown as “Component Type - Protective Relay”, should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The “Note” included in the heading is also not necessary. “Attributes” is also not necessary in the column heading, “Component” suffices.
Response: Thank you for your comments. The SDT believes that the table headings are appropriate as reflected in the draft standard.		
Platte River Power Authority System Maintenance	Yes	
Electric Market Policy	Yes	Dominion does not feel that clarity has been added to the tables. 1. A numbering structure should be added to the table for referencing each task prescribed.

Organization	Yes or No	Question 1 Comment
		2. The tables should more clearly designate and separate time based versus performance based tasks. 3. Additionally, Table 1-4 contains, in several places, an activity to "Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline." This seems to suggest that each time the batteries are checked, the measured cell/unit internal ohmic value should agree with some baseline value. This appears to be overly prescriptive as the values reading-to-reading should fall within the tolerances established per Requirement R1.5, not equal a baseline. The activities for other component types are not this prescriptive.
Response: Thank you for your comments. **1. The SDT believes that numbering the tasks within the Tables as you suggest would make the Tables more complex and would not add clarity.** **2. Performance-based maintenance requires that the same tasks be completed, but at intervals determined per Attachment A.** **3. The station battery baseline value is up to the entity to determine. Please see Section 15.4.1 of the Supplementary Reference for a discussion of this. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that R1 part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Bonneville Power Administration	Yes	
Santee Cooper	Yes	
NERC Staff	Yes	
FirstEnergy	Yes	While we agree that the clarity of the tables has improved, there are still items that warrant further clarity. 1.In Table 1-1, references to "Verify acceptable measurement of power system input values" is made for microprocessor relays on 6 and 12 calendar year intervals. Wouldn't this also be prudent on non-microprocessor based relays as well on the 6 year interval? 2. Also, in Table 1-3, "Verify that acceptable measurement of the current and voltage signals are received by the protective relays" is shown on a 12 calendar year interval. What is the difference between this activity and the similar activity performed in Table 1-1? 3. In Table 1-4, this table is complex and the detailed maintenance activities in this particular table is puzzling when compared to the more generic detail in the other tables within this section. For example, an incorrect operation due to a deteriorated signal from a CT or VT has a higher probability than a failure of a battery bank

Organization	Yes or No	Question 1 Comment
		to perform when called upon. 4. In Table 1-5, Please provide clarity on the "Unmonitored Control circuitry associated with protective functions" component attribute. This would most likely be an FAQ item.
Response: Thank you for your comments. 1. For non-microprocessor relays, this activity is fundamentally performed as a part of the calibration process. 2. This activity is used to verify the performance of the voltage and current sensing devices, where the activity in Table 1-1 is used to verify that the protective relay is performing properly. In some cases, the activity in Table 1-1 may also serve to satisfy the requirement in Table 1-3. 3. Table 1-4 is more detailed than the other tables because of the variability in the technologies of the station dc supply. 4. The draft definition of Protection System establishes "Control circuitry" as "…control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices". Please see Section 15.3 of the Supplementary Reference for a discussion of this.		
Florida Municipal Power Agency	Yes	
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	
MRO's NERC Standards Review Subcommittee	Yes	
Western Area Power Administration	Yes	
TransAlta Centralia Generation Partnership	Yes	
NextEra Energy	Yes	
City of Austin DBA Austin Energy		
PacifiCorp	Yes	

Organization	Yes or No	Question 1 Comment
Southern Company Transmission	Yes	The Standard Drafting Team should be commended for making the tables much easier to understand
Response: Thank you for your support.		
Clark Public Utilities	No	The SDT has greatly improved the clarity of this document in the areas of relays, communication systems, voltage and current sensing devices, control circuitry, and alarming paths. The recommendations on station dc supply are still confusing. First, there are five different attribute categories for unmonitored dc supply. Are these five categories mutually exclusive? Are we supposed to follow just the category applicable to the type of battery? Are we supposed to follow the first category and any of the subsequent four battery type categories as they apply? I suspect some of the 3 month and 18 month items in the first category are considered to be necessary by the SDT regardless of battery type. The current categorization is confusing. If we are required to perform the 3 month and 18 month activities listed in the first category regardless of battery type AS WELL AS the other applicable battery type activities, please indicate this in Table 1-4. As a different option, just eliminate the first category entirely and place the appropriate 3 month and 18 month verification and inspection requirements in the four battery type specific categories. It may be repetitive but clarity is paramount in this standard. Second, the FAQ examples seem to indicate that the SDT views the performance of an internal ohmic battery test or a battery performance test as valid forms for verifying the individual battery cell states (i.e. state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance). It would be helpful if this were more obviously stated in table 1-4. Currently it could be interpreted that we need to do all of the individual cell-cell verification in addition to the ohm test or the full performance test. I don't believe this is the intent of the SDT (based on the FAQ examples) but we need to see the intent in Table 1-4.Third, does a monitored dc supply have to monitor some or all of each of the different line items listed? The FAQ examples indicate that if only some are monitored, the dc supply can still be treated as monitored as long as the unmonitored items are verified. This means that for a VLA battery with a low voltage alarm and unintentional ground alarm, all that is needed is to check electrolyte level every 3 months, check float voltage and battery rack every 18 months and perform either an internal ohm check at 18 months or a battery performance test at 6 years. Also battery alarms need to be verified at 6 years. This is not clear in Table 1-4 and it could be interpreted by some that a monitored station dc supply monitors ALL of the listed items not just SOME. The FAQs imply that partial monitoring is acceptable but Table 1-4 does not indicate this very clearly. I do wish to say once again that this proposed standard is much easier to understand and that with a little more clarification in the dc supply section I would vote in the affirmative.
Response: Thank you for your comments. Table 1-4 has been modified in consideration of your comments. Specifically, Table 1-4 has been revised to		

Organization	Yes or No	Question 1 Comment
remove "state of charge" from the activities.		
Exelon		
Manitoba Hydro	No	The maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the state of charge of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition, which are indicated as 18 month interval tasks in table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Dynegy Inc.	Yes	
Oncor Electric Delivery Company LLC	Yes	
Ingleside Cogeneration LP	Yes	The tables clearly tie to each component type in a Protection System. This is consistent with the required PSMP format, making it straight forward to incorporate the intervals and to demonstrate compliance.
Response: Thank you for your support.		
Indiana Municipal Power Agency	Yes	
South Carolina Electric and Gas	Yes	
Entergy Services	No	The tables are generally much clearer and the SDT is to be commended on their efforts. However, we believe the Alarming Point Table needs additional clarification with regard to the Maximum Maintenance Interval. If an "alarm producing device" is considered to be a device such as an SCADA RTU, individual entity intervals for such a device would differ, and there isn't necessarily a maximum interval established as there is for Protection System components. Also, if an entity's alarm producing device maintenance is performed in sections and triggered by segment or component maintenance, there would essentially be multiple maximum intervals for the alarm producing

Organization	Yes or No	Question 1 Comment
		device of that entity. On that basis, we suggest the interval verbiage be revised to "When alarm producing device or system is verified, or by sections as per the monitored component/protection system specified maximum interval as applicable". Alternately, if the intention is to establish maximum intervals as simply being no longer than the individual component maintenance intervals as we suggest for inclusion above, then the verbiage should be revised to "When alarm producing component/protection system segment is verified". In either case are we to interpret monitored components with attributes which allow for no periodic maintenance specified as not requiring periodic alarm verification?
Response: Thank you for your comments. For clarity, the 'Maximum Maintenance Interval' column entry in Table 2 has been revised to state, "When alarm producing Protection System component is verified".		
Duke Energy	Yes	
Wisconsin Electric Power Company	Yes	
Independent Electricity System Operator		
American Electric Power	No	1. Table 1.5 (Control Circuitry), row 4, indicates a maximum interval of 12 years for unmonitored control circuitry, yet other portions of control circuitry have a maximum interval of 6 years. AEP does not understand the rationale for the difference in intervals, when in most cases, one verifies the other. 2. Also, unmonitored control circuitry is capitalized in row 4 such that it infers a defined term. 3. In the first row of table 1-4 on page 16, it is difficult to determine if it is a cell that wraps from the previous page or is a unique row. This is important because the Maximum Maintenance Intervals are different (i.e. 18 months vs. 6 years). It is difficult to determine to which elements the 6 year Maximum Maintenance Interval applies. 4. AEP suggests repeating the heading "Monitored Station dc supply (excluding UFLS and UVLS) with: Monitor and alarm for variations from defined levels (See Table 2):" for the bullet points on this page.
Response: Thank you for your comments. **1. The 6-year activities are all related to components with "moving parts", and the 12-year activities are related to the other portions of the control**		

Organization	Yes or No	Question 1 Comment
circuitry. **2. The capitalized term has been corrected.** **3. Table 1-4 has been modified in consideration of your comments.** **4. Table 1-4 has been modified in consideration of your comments.**		
ITC	Yes	The following question concerns Table 1-3. 1. Our testing program includes “impedance testing” of the current transformers (CTs) along with insulation testing of the wiring and CT secondary. Impedance testing involves impressing an increasing voltage on the secondary of the CT (with primary open circuited) until 1 (one) ampere flows. This method determines the “knee” of the saturation curve that is used as a benchmark for comparison to previous testing and other CTs. This procedure has successfully identified CT problems over the past several decades. We believe this procedure to be adequate. Does the SDT agree that this method is sufficient to meet the testing requirements of Table 1-3 and that a current comparison is not needed in addition to this testing? 2. Another variation of this is for voltage device compliance. Table 1-3 indicates that we should verify the correct voltages are received by the relay. This means that the VT would need to be energized and we would measure the secondary voltages to compare with others. Power plant relay testing is normally performed during plant outages when this measurement cannot be done. Some plants do not allow any testing while the unit is on line. It would seem that the standard would be written to allow some other type of testing to be performed other than the measurement test. 3. For Table 1-1 Row 1, we believe the intent is to verify that settings are as specified for non-microprocessor relays and microprocessor relays alike. If this is the case, consider adding “Verify that settings are as specified” as a bullet under the headings for non-microprocessor relays and microprocessor relays. 4. Splitting the tables into separate sections for Protective Relays, Communication Systems, VT and CTs, and Station D.C. Supply helped the clarity.
Response: Thank you for your comments. **1. Table 1-3 has been revised in consideration of your comments. Also, please see Section 15.3 of the Supplementary Reference Document. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.** **2. Table 1-3 has been revised in consideration of your comments. Also, please see Section 15.3 of the Supplementary Reference Document. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**		

Organization	Yes or No	Question 1 Comment
3. “Verify that settings are as specified” is specified as an activity that applies to all Protective Relays, regardless of technology. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity. **4. Thank you for your support.**		
ISO New England Inc.	No	The wording “Component Type” is not necessary in each title. Just the equipment category should be listed--what is now shown as “Component Type - Protective Relay”, should be Protective Relay. However, Protective Relay is too general a category. Electromechanical relays, solid state relays, and microprocessor based relays should have their own separate tables. So instead of reading Protective Relay in the title, it should read Electromechanical Relays, etc. This will lengthen the standard, but will simplify reading and referring to the tables, and eliminate confusion when looking for information. The “Note” included in the heading is also not necessary. “Attributes” is also not necessary in the column heading, “Component” suffices.
Response: Thank you for your comments. The SDT believes that the table headings are appropriate as reflected in the draft standard.		
Nebraska Public Power District	Yes	
CenterPoint Energy	Yes	
American Transmission Company	Yes	
Consumers Energy	Yes	
Southern Company Generation	Yes	
US Bureau of Reclamation		No Comment
Alliant Energy	Yes	
LCRA Transmission Services Corporation	No	1. It would help to add a column to the left labeled Category. I.E. a relay could be classified under Category 1 attributes unmonitored or Cat 2, Cat 3. 2. Table 1-4, Station DC is very difficult to follow.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. **1. The SDT believes that the table headings are appropriate as reflected in the draft standard.** **2. Table 1-4 has been modified in consideration of your comments.**		
MidAmerican Energy	Yes	
Ameren	Yes	
Xcel Energy	Yes	

2. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Several commenters objected to the "percentage" steps in several VSLs. The SDT observes that the 'percentage' steps follow the VSL Guidelines which can be found on the NERC website in the 'Resource Documents' area of the 'Reliability Standards' section. Other commenters requested that the VSLs permit some level of non-compliance before incurring a 'Low' VSL, again the SDT notes that this is not acceptable per the VSL Guidelines.

Organization	Yes or No	Question 2 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	
Tennessee Valley Authority	No	1. There is no allowance for deferral of maintenance because of factors beyond the control of the TO, GO, or DP. These include the unavailability of customer outages, generation outages, system configuration, high risk of loss of generation or customer load or impact to power quality. Proposed Change: Provide a process for acceptable deferral of maintenance activities. 2. Table 1-4 The requirement to perform cell internal ohmic resistance measurements every 18 months for vented lead-acid batteries is excessive. Our normal battery life is 20+ years. A 3-year internal resistance test frequency is adequate to prove battery integrity. IEEE 1188 recommends verification of internal ohmic resistance to be on a quarterly basis. It appears other intervals take into account recommended inspection interval plus some grace period. Proposed Change: Change maintenance interval from 3 months to 6 months. 3. Section: R1.5 This new requirement will require significant documentation with no known improvement to the reliability of the BES. What data is being used to determine the need for this requirement? How far does this requirement go? 4. Table 1-4 requires the inspection of "physical condition of battery rack" What are "identify calibration tolerance or other equivalent parameters" for this task? You already have verified, test, inspect, and calibrate defined. Leave out R1.5 which requires more than meeting the definitions.
Response: Thank you for your comments.		

Organization	Yes or No	Question 2 Comment
1. FERC Order 693 directs NERC to establish maximum allowable intervals. A "deferral process" would not satisfy this directive. **2. The SDT disagrees, and believes that 18-months is the proper interval for this activity.** **3. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section 8 for a discussion of this. The associated VSL has also been revised.** **4. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Northeast Power Coordinating Council	No	1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 4. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response: Thank you for your comments. **1. Consideration of the VRFs, in association with the VRF Guidelines, yields the VRFs as established within the draft Standard.** **2. The SDT has reviewed the time horizons, and feels that R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components is performed within the related time period. The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).** **3. The SDT has determined that the fundamental concerns of R1 part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** **4. The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**		

Organization	Yes or No	Question 2 Comment
Platte River Power Authority System Maintenance	No	The 5%, 10%, and 15% levels for R2 & R4 exaggerate the severity levels for small companies. A small DP with only 9 relays in a protection system would only have to be missing 1 record for a severe VSL.
Response: Thank you for your comments. The percentage levels for Requirement R4 are consistent with many other NERC Standards and are also consistent with the guidance within the VSL Guidelines. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
Electric Market Policy	No	VSL R3. How do you measure a percentage of countable events over a period of time? How are you to determine what the total population to be considered? An entity should not be penalized if they are following their program, correcting issues, and documenting all actions, even if there is a high failure rate in an instance.
Response: Thank you for your comments. Attachment A, to which Requirement R3 refers, specifies that countable events are assessed on the basis of " for the greater of either the last 30 components maintained or all components maintained in the previous year."		
Bonneville Power Administration	Yes	
Santee Cooper		
NERC Staff		
FirstEnergy	No	The VSL for R2 need to be adjusted since "Condition Based Maintenance" has been removed from the standard.
Response: Thank you for your comments. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
Florida Municipal Power Agency	No	The VRF of R1 should be Low since the attached tables are essentially the PSMP.
Response: Thank you for your comments. The SDT disagrees; the Tables establish the intervals and activities, and Requirement R1 addresses the establishment of an entities' individual PSMP.		
PSEG Companies ("Public Service Enterprise Group Companies")		No comment

Organization	Yes or No	Question 2 Comment
MRO's NERC Standards Review Subcommittee	Yes	
Western Area Power Administration	Yes	
TransAlta Centralia Generation Partnership	No	Please provide acronyms list and its explanations in the standard.
Response: Thank you for your comments. In accordance with established NERC custom, acronyms are either established at the first use of the term, or are general acronyms used throughout NERC Standards.		
NextEra Energy	Yes	
City of Austin DBA Austin Energy		
PacifiCorp	Yes	
Southern Company Transmission	No	We disagree with the inclusion of the VSLs, VRFs, and time Horizons associated with the new Requirements 1.5 and 4.2
Response: Thank you for your comments. The SDT determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.		
Clark Public Utilities	Yes	
Exelon		
Manitoba Hydro	No	The high VSL for R1 “Failed to include all maintenance activities relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5” may be interpreted in different ways and should be further clarified.
Response: Thank you for your comments. The SDT does not understand your concern; further details are needed.		

Organization	Yes or No	Question 2 Comment
Dynegy Inc.	No	For R4, the VRF has been changed to high. We question the need to change to high since there are numerous elements that will still protect the system while repairs are being made.
Response: Thank you for your comments. Requirement R4 addresses implementation of the overall PSMP; that is – maintaining all devices within the program. This VRF is consistent with the "high" assigned to R2 of PRC-005-1.		
Oncor Electric Delivery Company LLC	No	Oncor strongly disagrees with the modification to the Violation Severity Levers (VSL) table under the High VSL column where it states that it is a high VSL for "Failed to establish calibration tolerance or equivalent parameters to determine if components are within acceptable parameters." Oncor feels modifying the standard by adding a requirement that requires a Transmission Owner, Generation Owner or Distribution Provider to "identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities" is too intrusive and divisive for what it brings to the reliability of the BES. The requirement (Requirement R1 part 1.5) and its associated High VSL should be removed from PRC-005-2.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.		
Ingleside Cogeneration LP		
Indiana Municipal Power Agency	No	IMPA does not agree with the percentage in the VSL table for R4. For smaller entities that have six or less of any one type of Protection System Component and they fail, for whatever reason (even if it's a matter of incomplete documentation), to complete scheduled program maintenance on that component they will be subjected to the severe VSL penalty Matrix. Consideration should be given to entities having less than say, 100 of a component. There should be some type of tiered sub table within the VSL matrix for this consideration - registered entities having a certain component in quantities greater than or equal to 100 and registered entities having quantities of that certain component of less than 100.
Response: Thank you for your comments. The percentage levels within Requirement R4 are consistent with many other NERC Standards, and are also consistent with the guidance within the VSL Guidelines. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).		
South Carolina Electric and Gas	Yes	

Organization	Yes or No	Question 2 Comment
Entergy Services	No	R1.5 calls for "identification of calibration tolerances or equivalent parameters..." whereas the associated VSL references "failure to establish calibration criteria...." and is listed as high. If R1.5 is to be included in this standard, then we suggest the severity level of a failure to simply "identify" or document such calibration tolerances would be analogous to the severity level(s) of a "failure to specify one (or the severity level should be consistent with the other elements of R1. Both cases appear to be more of a documentation issue as opposed to a failure to implement. Shouldn't a failure to implement any necessary calibration tolerance be accounted for in R4?
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised.		
Duke Energy	No	1. R1.3 appears to be missing from the VSL for R1. 2. Also, it's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. 3. R4 - More clarity must be provided on the expectation for compliance documentation. This is a High VRF requirement, and there may only be a small number of maintenance-correctable items, hence a significant exposure to an extreme penalty.
Response: Thank you for your comments. **1. The High VSL for Requirement R1 has been revised in consideration of your comment.** **2. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted R2 (together with the associated Measure and VSL).** **3. Examples of compliance documentation are included within Measure M4 and discussed within Section 15.7 of the Supplementary Reference Document.**		
Wisconsin Electric Power Company		
Independent Electricity System Operator	No	1. R1 Lower - We suggest including a second part as follows: "Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. "

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>2. R1 Moderate - We suggest similar to the Lower VSL but catering for two Protection System component types.R1 High - We suggest changing the wording of the 3rd part to match the requirement and to cater for more than two Protection System component types.
3. Editorial Comment to Severe VSL for R3: In part 3, replace “less” with “fewer”.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.
2. The ‘Moderate’ VSL for Requirement R1 appears to be similar to the ‘Lower’ VSL for Requirement R1 as you suggest. The SDT believes that, if more than two Protection System component types are not addressed, the ‘Severe’ VSL is appropriate.
3. Thank you. The SDT elected not to change the VSL for Requirement R3 as suggested.</td></tr>
<tr><td>American Electric Power</td><td>No</td><td>1. The VSL table should be revised to remove the reference to the Standard Requirement 1.5 in the R1 “High” VSL.
2. All four levels of the VSL for R2 make reference to a “condition-based PSMP.” However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The VSL for R2 should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1.
3. In multiple instances, Table 1 uses the phrase “No periodic maintenance specified” for the Maximum Maintenance Interval. Is this intended to imply that a component with the designated attributes is not required to have any periodic maintenance? If so, the wording should more clearly state “No periodic maintenance required” or perhaps “Maintain per manufacturers recommendations.” Failure to clearly state the maintenance requirement for these components leaves room for interpretation on whether a Registered Entity has a maintenance and testing program for devices where the Standard has not specified a periodic maintenance interval and the manufacturer states that no maintenance is required.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.
2. The SDT concluded that Requirement R2 is redundant with R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).
3. If the indicated monitoring attributes are present, no “hands-on” periodic maintenance is required, as the monitoring of the component is</td></tr>

providing a continuing indication of its functionality.		
ITC	Yes	
ISO New England Inc.	No	1. Because all the requirements deal with protective system maintenance and testing, violations could directly cause or contribute to bulk electric system instability, etc., the VRFs should all be "High". 2. The Time Horizons should all be "Operations Planning" because of the immediacy of a failure to meet the requirements. 3. For the R1 Lower VSL, include a second part to read: Failed to identify calibration tolerances or other equivalent parameters for one Protection System component type that establish acceptable parameters for the conclusion of maintenance activities. 4. For the R1 Moderate VSL, suggest similar wording as for the Lower VSL but specifying two Protection System component types. 5. For the R1 High VSL, suggest changing the wording of the 3rd part to be similar to the Lower VSL to match the requirement and to cater for more than two Protection System component types. 6. For the R3 Severe VSL, in part 3, replace "less" with fewer.
Response: Thank you for your comments. **1. The SDT set the VRFs in accordance with the FERC's and NERC's VRF guidance.** **2. The SDT has reviewed the time horizons, and feels that Requirement R1 is properly assigned a Long-Term Planning time horizon, as the activities to develop a program and to determine the monitoring attributes of components is performed within the related time period. The SDT concluded that Requirement R2 was redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. The associated VSL has also been revised.** **4. The 'Moderate' VSL for Requirement R1 appears to be similar to the 'Lower' VSL for Requirement R1 as you suggest.** **5. The SDT believes that, if more than two Protection System component types are not addressed, the 'Severe' VSL is appropriate.** **6. The SDT believes that your suggestion is similar to the existing text, and declines to modify the standard.**		
Nebraska Public Power District	No	VRF's: 1. The definition of a Medium Risk Requirement included on page 8 of the SAR states: "A requirement that,

Organization	Yes or No	Question 2 Comment
		if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system." The PSMP does not "directly" affect the electrical state or the capability of the bulk electric system. A failure of a Protection System component is required to "directly" affect the BES. Therefore, the PSMP has only an "indirect" affect on the electrical state or the capability of the BES. Requirements R1 through R3 and their subparts are administrative in nature in that they are comprised entirely of documentation. Therefore, I recommend changing the Violation Risk Factor of Requirements R1, R2, and R3 to Lower to be consistent with the Violation Risk Factors defined in the SAR. VSL's: 2. R2: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "condition-based" to "time-based" in all four severity levels. 3. SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less complaint recommend revising the percentages of the violation severity levels to be consistent with the SAR. 4. R3: The performance-based maintenance program identified in PRC-005 Attachment A provides the requirements to establish the technical justification for the initial use of a performance-based PSMP and the requirements to maintain the technical justification for the ongoing use of a performance-based PSMP. However, it appears the VSLs for Requirement R3 only addresses the ongoing use of the technical justification. a. I recommend revising the VSLs for R3 to include the initial use of the technical justification. Item 2) of R3 Severe VSL is a duplicate of Item 2) of R3 Lower VSL. This item is administrative in nature therefore I recommend deleting Item 2) from R3 Severe VSL. b. The first and third bullets of item 4) of R3 Severe VSL are administrative in nature and should be moved to the Lower VSL c. R4: SAR Attachment B - Reliability Standard Review Guidelines states that violation severity levels should be based on the following equivalent scores: Lower: More than 95% but less than 100% compliant Moderate: More than 85% but less than or equal to 95% compliant High: More than 70% but less than equal to 85% compliant Severe: 70% or less complaint recommend revising the percentages of the violation severity levels to be consistent with the SAR.

Organization	Yes or No	Question 2 Comment
Response: Thank you for your comments. **1. Requirements R1, R2, and R3 are not administrative; they are foundational. Without the fundamental development of a PSMP, an entity is unlikely to actually implement a PSMP that satisfies the reliability needs of the BES. The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **2. The SDT concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and deleted Requirement R2 (together with the associated Measure and VSL).** **3. The guidelines within the SAR have been superseded by subsequent revisions to the VSL Guidelines. The VSLs in the draft standard adhere to the latest VSL Guidelines and to the June 19, 2008 FERC order on VSLs in Docket No RR08-04-000.** **4. Part a – The VSL for Requirement R3 has been modified in consideration of your comments.** **Part b – These requirements are not administrative; they are foundational. Without compliance with these requirements, an entity does not have an effective performance-based PSMP, and may be detrimentally affecting reliability.** **Part c – The latest VSL Guidelines also provide examples of VSLs similar to those in the draft standard.**		
CenterPoint Energy		
American Transmission Company	Yes	
Consumers Energy	Yes	
Southern Company Generation	Yes	
US Bureau of Reclamation	Yes	The tables rely on a reference document which is not a part of the standard and as such may be altered without due process. Either the relevant text from the reference needs to be inserted into the standard or the reference itself incorporated into the standard. Specific References such as
Response: Thank you for your comments. The Tables do not provide a reference to either the Supplementary Reference Document. An entity must comply with the standard when approved. The reference documents provide additional explanation, discussion, and rationale, but are not part of the mandatory standard. Since the reference documents are being developed to accompany the standard, the NERC Standard Development Procedure requires that they be posted with the draft standard and undergo stakeholder review, both initially and with any revision of the standard.		
Alliant Energy	Yes	

Organization	Yes or No	Question 2 Comment
LCRA Transmission Services Corporation	Yes	
MidAmerican Energy	Yes	
Ameren	No	(1)The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: “Entity has failed to complete scheduled program on 1% to 5% of total Protection System components.” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties.
Response: Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation.		
Xcel Energy	Yes	

3. The SDT has provided the "Supplementary Reference" document to provide supporting discussion for the Requirements within the standard. Do you have any specific suggestions for improvements?

Summary Consideration: Some commenters questioned whether the Supplementary Reference Document was a part of the Standard and thus mandatory and enforceable; the SDT responded that this document is not a part of the standard but instead offers guidance/rationale to assist in the implementation of the standard. Various other comments were offered regarding the content of the Supplementary Reference Document, to which the SDT responded accordingly.

Electric Market Policy	Yes	The document on page 3 states that data available from EPRI (et.al) was utilized by the Standard Drafting Team; however, there are no references to EPRI documents in Section 16. Suggest including EPRI references for completeness.
Response: Thank you for your comments. Page 3 of the Supplementary Reference Document has been revised to remove reference to EPRI documents.		
Bonneville Power Administration		
Santee Cooper	No	

Organization	Yes or No	Question 3 Comment
NERC Staff	Yes	1. In section 2.3, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. 2. In Section 2.4, NERC staff recommends changing the phrase “relays that use measurements of voltage, current, frequency and/or phase angle” with “protective relays that respond to electrical quantities” for consistency with recent changes to the proposed definition of Protection System.
Response: Thank you for your comments. **1. The SDT believes that it is not advisable to reference future activities, but notes that the standard will be applicable to whatever is defined to be the BES, either today or in the future.** **2. The Supplementary Reference Document has been revised as suggested.**		
FirstEnergy	Yes	The discussions surrounding implementing the PSMP on pages 10 and 11 of the clean copy are troublesome for the following reasons. 1. On Pg. 10, under Sec. 8.1, the 4th bullet item states "If your PSMP (plan) requires more activities then you must perform and document to this higher standard". This statement's use of the word "must" implies that an entity will be audited to their documented maintenance practices, even if those practices exceed the requirements of the PRC-005 standard. The PRC-005 standard, and any standard, details the minimum requirements that must be met to achieve a certain reliability goal. For example, if an entity's program states that it will do maintenance on a relay every 4 years, but the standard only requires maintenance every 6 years, the entity shall be held compliant to the standard's 6 year interval. If the entity in this example decides that in year 4 it must delay its maintenance to year six, that should be allowable since the standard PRC-005-2 requires maintenance every 6 years. 2. Since the standard no longer discusses Condition Based Maintenance, it should be removed from the reference document for consistency.
Response: Thank you for your comments. **1. This text is in the Supplementary Reference Document as a caution to entities that they may be expected to be held accountable for their entire documented PSMP, even if it exceeds the minimum requirements of the standard.** **2. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference document to clarify the manner in which condition-based maintenance is discussed.**		

Organization	Yes or No	Question 3 Comment
Florida Municipal Power Agency	Yes	
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	Figure 2 "typical generation system" shows a typical auxiliary medium voltage bus, in addition to the color coded elements suggest that a very distinct line of demarcation (dark dotted line) be added to the figure that defines the elements associated with the MV bus protection served by the station Aux Transformer and unit aux transformer are not part of the BES- PSMP PRC5 requirements. Also see comment 5 below; we suggest that the station service transformer must be connected to BES for inclusion in standard requirements. Suggest adding an explanation note to figure 2 to clarify this.
Response: Thank you for your comments. Figure 2 is intended to provide an example to users, not to describe the entire applicability of the draft standard. As such, the SDT does not believe that this figure needs to reflect all possible arrangements, nor does it need to suffice to describe the entire applicability. As for your comment regarding the unit auxiliary transformer, please see the SDT response to your more detailed comments in Question 5.

Southern Company Transmission	Yes	1. Page 11 and 12, (Additional Notes for Table 1-1 through 1-5) Comment ->> The standard does not reference these notes. Should these notes be referenced and included in the Standard? 2. Page 12, Additional Notes for Table 1, item #7 ("performing an operational trip test")

Organization	Yes or No	Question 3 Comment
		Comment ->> Standard does not state that an operational/full functional test is required. Please clarify. 3. Page 22, 15.3, Control Circuitry Functions, paragraph 1 ("verify, with a volt-meter, the existence of proper voltage at the open contacts" Comment ->> The example of measuring the proper voltage with a volt-meter at the open contacts to verify the circuit indicates that the 12-year "full functional" trip test of control circuits is not required. Please clarify. 4. Page 22, 15.3, Control Circuitry Functions, paragraph 3 ("UVLS or UFLS scheme are excluded from the tripping requirement, but not from the circuit test requirements") Comment ->> This indicates to me that measuring the proper voltage with a volt-meter at the open contacts will verify the circuit. Please confirm. Please clarify - If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be "extended beyond 12 years". Standard indicates that no periodic maintenance is required. Consider changing "extended beyond 12 years" to "eliminated". 5. Page 23, 15.3, Control Circuitry Functions, paragraph 5 ("When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly.") Comment ->> This indicates that we must verify that trip and auxiliary device contacts change state. Please confirm. The standard does not state that the contacts must be verified to change states. If this is required, please add to the standard.

Response: Thank you for your comments.

1. **These notes are provided as application guidance relative to the Tables, which as you note, does not reference them.**
2. **This note has been revised within the Supplementary Reference Document in consideration of your comment.**
3. **This example is stated within the Supplementary Reference Document as an example method of testing the dc control circuitry. The draft standard no longer requires a "functional trip test", although it does require that lockout relays and auxiliary relays be operated at least once every 6 years to verify that they function properly.**
4. **The Supplementary Reference Document has been revised as suggested.**
5. **The draft standard specifies "Verify electrical operation" of these components every 6 years. This seems implicitly to require a change of state of the contacts. However, it may be possible to verify electrical operation without having to check the change of state of the individual contacts, but the contacts will have to be checked as part of the 12-year full test. The cited clause/paragraph Supplementary Reference Document has been revised to clarify.**

Clark Public Utilities	No	
Exelon		
Manitoba Hydro	No	
Dynegy Inc.	No	
Oncor Electric Delivery Company LLC	No	
Ingleside Cogeneration LP	Yes	Ingleside Cogeneration, LP, believes that the Section 15.5 of the Supplementary Reference “Associated communications equipment (Table 1-2)” properly reflects the intent of the validation of relay-to-relay communications. It states that any “evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates can fulfill the requirements.” However, Table 1-2 - which will be the ultimate reference used by audit teams - only clearly allows for the measurement of channel parameters. Although the newer technology relays provide read-outs of signal level or data-error rates that do not require intrusive testing, older relays do not. The tools required to perform such testing are not easily available - and may leave the communications channel in worse shape after testing than it was prior to testing. We believe that Table 1-2 should be updated to clearly state that an operational test is sufficient for the testing of relay-to-relay communication - consistent with the Supplementary Reference.
Response: Thank you for your comments. The standard does not explicitly require measurement of channel parameters, but instead specifies that they may be verified. The Supplementary Reference Document has been revised to remove the discussion of operational testing of the communications channel.		
Indiana Municipal Power Agency	No	
South Carolina Electric and Gas	No	
Entergy Services	Yes	R1.5 calls for “identification of calibration tolerances or equivalent parameters for each Protection System Component Type....”. We believe the Supplementary Reference document should provide additional information and examples of calibration tolerances or equivalent parameters which would be expected for the various component types. Especially for any “equivalent” parameters which would be required for compliance

Organization	Yes or No	Question 3 Comment
		for a component type besides protective relays.
Response: Thank you for your comments. The SDT determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed.

Independent Electricity System Operator	No	
American Electric Power	Yes	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications: 1. Section 5 of the Supplementary Reference, refers to “condition-based” maintenance programs. However, no where in the standard is the term “condition-based” used in reference to defining ones PSMP. The Supplementary Reference should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term “condition-based” within the Standard Requirements and Table 1. 2. Section 15.7, page 26, appears to have a typographical error “...can all be used as the primary action is the maintenance activity...” 3. Figure 2 is difficult to read. The figure is grainy and the colors representing the groups are similar enough that it is hard to distinguish between groups.
Response: Thank you for your comments. The discussion within the Supplementary Reference Document and FAQ are informative, not normative, and thus do not belong as part of the standard. **1. The Supplementary Reference Document discusses condition-based maintenance in a conceptual manner, as a generally-recognized term. The SDT did make some changes within the Supplementary Reference Document to clarify the manner in which condition-based maintenance is discussed.** **2. This clause has been corrected.**		

Organization	Yes or No	Question 3 Comment
3. A higher-quality version of Figure 2 has been substituted.		
ITC	Yes	1. Auxiliary Relay Testing: We repeat our objection to the 6 year requirement for testing of auxiliary relays. The STD response to our previous objection was: Please see new Table 1-5. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. Auxiliary relays are, of course, electromechanical relays, but much less complicated than impedance, differential or even time-overcurrent electromechanical relays. It has been our experience that trip failures are rare and that our present 10 year control, trip tests, and other related testing are sufficient in verifying the integrity of the scheme. Section 8.3 of the Supplementary Reference notes statistical surveys were done to determine the maintenance intervals. Were auxiliary relays included in these surveys in a such a way to verify that they indeed require a 6 year maintenance interval? We recommend they be considered part of the control circuitry, with a 12 year test cycle. 2. High Speed Ground Switch Testing: We repeat our recommendation that the standard state that a high speed ground switch is an interrupting device. We also recommend that testing requirements for High-Speed ground switches be clearly stated in the standard. Section 15.3 of the Supplementary Reference contains the following: It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "...applied on, or designed to provide protection for the BES..." then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade. We disagree that a high-speed ground switch can be adequately tested by disconnecting the solenoid triggering unit. The ability of the trip coil to "operate the circuit breaker" must be verified per Table 1-5 Row 1. The ability of the "solenoid triggering unit" to operate the ground switch should be required also. A high-speed ground switch is a unique device. Its maintenance requirements should be specifically included in the standard itself. Based on Draft 3 of the standard, this is a electromechanically operated device and would have to be tested every 6 years. A logical location would be in Table 1-5. Is there test

Organization	Yes or No	Question 3 Comment
		data to support the test method of disconnecting the solenoid triggering unit?
Response: Thank you for your comments. **1. The SDT believes that the appropriate interval for electromechanical devices such as aux or lockout relays should remain at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.** **2. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems". There is currently an unapproved interpretation response (project 2009-17) addressing what is a "transmission protection system." When this interpretation is approved, the SDT will incorporate it within PRC-005-2. Section 15.3 of the Supplementary Reference Document will be revised to clarify the discussion of testing of the ground-switch trip coil.**		
ISO New England Inc.	No	
Nebraska Public Power District	Yes	The Supplementary Reference Documents identified are unapproved and in draft form. I believe that only approved documents should be referenced in the Standard. Therefore, I recommend updating the Supplementary Reference Documents section with approved versions of the documents.
Response: Thank you for your comments. The SDT revised the Supplementary Reference Document section of the draft Standard.		
CenterPoint Energy		
American Transmission Company	No	
Consumers Energy	No	
Southern Company Generation	Yes	1. On Page 4, Paragraph 2.2 is no longer proposed - the paragraphs just before 2.2 need to be revised. 2. On Page 12, item 7, the phrase "operational trip test" is not used in the standard. Please consider using this phrase in the standard. 3. On Pages 14-15, several paragraphs describing the contents of Sections 9, 10, 11, & 13 are given – these appear to be out of place and don't seem to belong here (just before "9. Performance-Based Maintenance Process). 4. On Page 24, correct the bulleted Protection System Definition to match the most recent definition.

Organization	Yes or No	Question 3 Comment
		5. On Page 29, please improve the clarity of Figure 2. 6. On Page 31, please revise the flowchart references to R4.4.1 and R4.4.2. 7. Please correct the following formatting: Page 2, Table of Contents; Page 18, the bulleted item list; Page 23, add a space before the last paragraph.
Response: Thank you for your comments. **1. This Section of the Supplementary Reference Document has been corrected.** **2. This Section of the Supplementary Reference Document has been revised.** **3. The Supplementary Reference Document has been revised to address your comment.** **4. The Supplementary Reference Document has been revised to address your comment.** **5. The Supplementary Reference Document has been revised to address your comment.** **6. The Supplementary Reference Document has been revised to address your comment.** **7. The Supplementary Reference Document has been revised to address your comment.**		
US Bureau of Reclamation	Yes	The Supplementary reference provides significant clarity to the intent and application of standard; however, in doing so, it reveals conflicts and ambiguity in the text of the standard. It is suggested that some of the clarifying language be inserted into the text of the standard.
Response: Thank you for your comments. To the extent possible, the clarifying language of the Supplementary Reference Document will be incorporated into the next version of PRC-005 when the standard is drafted in the Results-based format.		
Alliant Energy	No	
LCRA Transmission Services Corporation	Yes	Well written and helpful document. In Section 8.1, the document states that if your PSMP requires activities more often than the Tables maximum, then you must perform to that higher standard. While it is understandable that an entity may desire to maintain their PRS at a higher level, they should not be fined or penalized for achieving less than their standard but within the intervals stated in the Tables. This point should be clarified, preferably within the standard itself.
Response: Thank you for your comments. Requirement R1, Part 1.3 and Requirement R4 within the Standard has been revised in a manner which addresses your comment. However, the SDT re-emphasizes that entities may be expected to be held to their PSMP developed in accordance to		

Organization	Yes or No	Question 3 Comment
Requirement R1, whether it minimally addresses the remainder of the requirements in the standard or exceeds those requirements.		
MidAmerican Energy	Yes	The Supplementary Reference should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Response: Thank you for your comments. NERC establishes that only the Standard is mandatory and enforceable, and Section F of the standard introduces the Supplementary Reference Document as presenting supporting discussion. The introductory area of the Supplementary Reference Document will be revised to clarify this.		
Ameren	No	
Xcel Energy	Yes	1. Requirement R1 of the standard has been changed and no longer states that only relays which sense current, voltage, and phase angle to detect anomalies are in scope. However, it is noted that the new definition of Protection System states “Protective Relays which respond to electrical parameters.” Does Section 2.4 of the Supplementary Reference and, in particular, the last sentence of this section, still align with the standard such that sudden pressure devices are not classified as a relay requiring calibration per Table 1-1? Is the tripping path through the Sudden Pressure Device included as DC Control Circuitry per Table 1-5? FAQ II.4.F would indicate testing of trips from 63 devices are also not required. If so, perhaps this should be restated in Section 2.4 of the Supplementary reference. 2. Section 2.4 could be read to imply that “applicable relays” includes IEEE device #86, lockout relays and IEEE device #94, tripping or trip free relays. However, it is apparent from Table 1-1 “Component Type – Protective Relays” that there are no maintenance activities applicable to 86 or 94 devices. On the other hand, Table 1-5 “Component Type - Control Circuitry” does include maintenance activities for electromechanical trip or auxiliary devices. Thus the tables of the standard imply that 86 and 94 devices would be more accurately classified as DC control circuitry rather than relays. We suggest that Section 2.4 be written to clarify the SDT’s intent for the component type classification of devices 86 and 94. Note that auditors of PRC-005-1 frequently ask for a list of in scope relays and it would nice to have a definite rationale for excluding 86 and 94 devices from these relay lists.
Response: Thank you for your comments. **1. The Supplementary Reference Document has been revised to clarify this point.** **2. The SDT re-emphasizes that auxiliary and lockout relays are included within the standard as mechanical-operating devices that must be verified to operate within a 6-year interval, and also as devices which must be verified within the verification of all paths of the trip circuits on a 12-year interval. It is left to the entity to determine how to best demonstrate compliance with that requirement to the compliance monitor. The**		

Organization	Yes or No	Question 3 Comment
Supplementary Reference Document has been revised to clarify this point.		

4. The SDT has provided the "Frequently-Asked Questions" (FAQ) document to address anticipated questions relative to the standard. Do you have any specific suggestions for improvements?

Summary Consideration: Commenters suggested corrective language and requested additional discussions within the FAQ document. The SDT decided to eliminate the FAQ document and incorporate its contents into the Supplementary Reference Document as appropriate. The SDT considered all commenters' suggestions during that activity.

Organization	Yes or No	Question 4 Comment
Pepco Holding Inc & Affiliates	Yes	
Pacific Northwest Small Public Power Utility Comment Group	Yes	WECC does not use the definition of the BES that NERC supplied to FERC via http://www.nerc.com/docs/docs/ferc/RM06-16-6-14-07CompFilingPar77ofOrder693FINAL.pdf,so the answer to III.1.3 (page 19-20) is not accurate.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Tennessee Valley Authority	No	
Northeast Power Coordinating Council	Yes	See response to Question 5 below.
Response: Thank you for your comments. Please see our response to your comments in Question 5.		
Platte River Power Authority System Maintenance	No	
Electric Market Policy	Yes	The FAQ's do not appear to have kept up with the current draft Standard. 1. For example, Question B under Section 2 for Protective Relays, refers to the use of the word "Restoration" in the definition of a Protection System Maintenance Program. The current definition uses the word "Restore." 2. Additionally, Answers B, I, and J under Section 2 for Protective Relays each refer to Requirement R4.3,

Organization	Yes or No	Question 4 Comment
		which in not in the current Standard. Suggest a final edit of the FAQ's to clean-up these type of issues.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Bonneville Power Administration		
Santee Cooper	No	
NERC Staff	Yes	1. At a minimum, the response to Question II.1.A should be revised to reflect the present revision of Requirement R1. In the current proposed response to the FAQ, the answer refers to text that was deleted from Requirement R1 in the current posting of the standard; i.e., this standard covers protective relays "that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES." The removal of this text from Requirement R1 makes it less clear whether the standard applies to reclosing functions and protective functions used to supervise automatic or manual closing of a circuit breaker to ensure the voltage magnitude and phase angle difference are within specified tolerances. The drafting team also should consider whether additional specificity is required to ensure applicability is clearly defined within the standard. 2. In the response to Question II.2.H, NERC staff notes that the word "than" should be changed to "then" in the phrase "If the component no longer performs Protection System functions than..." 3. In the response to Question II.2.I, NERC staff recommends noting that "When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s)." The recommended text is included in the Supplementary Reference Document and inclusion in the FAQ response provides consistency and highlights obligations in other standards necessary for BES reliability. 4. In the response to Question III.1.A, NERC staff recommends noting that the present NERC Glossary definition of Bulk Electric System will be revised in response to FERC Order No. 743. 5. In the response to Question III.3.A, NERC staff recommends a more generic reference to NERC UFLS requirements in place of the reference to PRC-007-0, as PRC-007 will be retired pending FERC approval of PRC-006-1.In the response to Question IV.1.A (third paragraph), NERC staff recommends changing the phrase "that are certainly coming to the industry" to "may be coming to the industry" for consistency with the change to the response to Question V.4.A. Both questions appear to address the same or similar concerns.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
FirstEnergy	No	
Florida Municipal Power Agency	Yes	
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	Suggest that the section 5 - station DC supply have some specific examples added that would be acceptable methods for verifying the "state of charge" as required by standard table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
MRO's NERC Standards Review Subcommittee	No	
Western Area Power Administration	No	
TransAlta Centralia Generation Partnership	No	
NextEra Energy	No	
City of Austin DBA Austin Energy		
PacifiCorp		
Southern Company Transmission	Yes	1. Page 7, L. ("verify operation of the relay inputs ...") Comment ->> Clarification needed. Standard states that each input should be "picked up" or "turned on and off". Do you have to change states of the input contact(s) or can you just jumper positive to the input(s) to verify that the microprocessor relay verifies this change of state?

Organization	Yes or No	Question 4 Comment
		2. Page 10, 4.E ("What does functional (or operational) trip test include?") Comment ->> The words "functional (or operational) trip test" are not in the Standard. Is this required? If so, please clarify this in Standard. If not, please remove. (Reference comment regarding "verify all paths of the control and trip circuits" on page 17 of standard.) 3. Page 18, 7. (Distributed UVLS and UFLS system.) and Page 19 8. (Centralized UVLS and UFLS system.) Comment ->> Standard does not specify "distributed" or "centralized" UVLS and UFLS systems. Please consider combining section 7 & 8, omitting items 7.C., 8.E., and omitting "distributed" and "centralized" references on pages 18 and 19.
Response: Thank you for your comments. **The standard does explicitly require that auxiliary relays, lockout, and trip coils of interrupting devices be verified to have electrically operated every 6 years, and this is the only place in the standard that currently requires this sort of activity.** **The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**		
Clark Public Utilities	Yes	Provide answers to the following questions. Does the completion of a battery ohm test or a battery performance test satisfy the verification requirements for state of charge of the individual battery cells/units, battery continuity, battery terminal connection resistance, and battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)?
Response: Thank you for your comments. The activities described do not satisfy all of the requirements (at the established intervals) listed in your comment. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Exelon	Yes	1. Clarify what kind of testing is required on lockout relays/86 devices. Specifically, whether functional testing is adequate or if simple calibration, similar to protective relays, is all that is are required. 2. Clarify if protective relays that trip equipment (e.g., a condensate pump that would in turn cause a main generator trip) are also included in the scope of this Standard. 3. Clarify if relays which result in generator run back, but do not trip the generator, are included in the scope of this Standard.
Response: Thank you for your comments.		

Organization	Yes or No	Question 4 Comment
1. For lockout relays, the standard requires that they be electrically operated every 6 years, and that the trip path be verified every 12 year. No calibration/etc is specified. **2. As described in FAQ III.2.A, protective relays which trip equipment within the plant which may eventually result in tripping of the generator, but do not trip the generator (either directly or via a generator lockout relay) , are not included.** **3. If the generator run back scheme is characterized as a Special Protection System within your region, these relays would be included as part of that system (Section 4.2.6- Applicability of the draft Standard).** **The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**		
Manitoba Hydro	Yes	As previously stated, the maintenance requirements for batteries listed in Table 1-4 do not appear to be consistent with example 1 in Section V, 1A of the FAQ. Specifically the FAQ does not mention the of the individual battery cells/units, the battery continuity, the battery terminal connection resistance, the battery internal cell-to-cell or unit-to-unit connection resistance, or the cell condition which are indicated as 18 month interval tasks in table 1-4.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Dynegy Inc.	No	
Oncor Electric Delivery Company LLC	Yes	There is still confusion in Table 1-4 concerning the "Monitored Station dc supply." The uncertainty is over whither an Owner must have all seven (7) monitoring activities (Station dc supply voltage, State of charge of the individual battery cell/units, Battery continuity of station battery, Cell-to-cell and battery terminal resistance, Electrolyte level of all cells in station battery, Unintentional dc grounds, and Cell/unit internal ohmic values of station battery) listed in the table or just one of them to take advantage of forgoing the maximum maintenance interval for an activity and going to the 6 year maximum maintenance interval to verify that the monitoring device is calibrated. A FAQ concerning this question would be beneficial to those who are concerned that they must monitor all seven activities in order to take advantage of condition based maintenance for the station dc supply. Also an explanation of how each of the 7 monitoring activities relates to a specific station dc supply maintenance activity might be beneficial.
Response: Thank you for your comments. Table 1-4 has been further revised to address your concern (see Table 1-4(f)). The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.

Ingleside Cogeneration LP		
Indiana Municipal Power Agency	No	
South Carolina Electric and Gas	No	
Entergy Services	Yes	Section II.2.B references R4.3 which has been revised to R4.2.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Duke Energy	Yes	There are typographical errors on the FAQ Requirements Flowchart (should be R4.1.1 and R4.1.2 instead of R4.4.1 and R4.4.2).
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
Wisconsin Electric Power Company	Yes	Table 1-4 requires an activity to verify the state of charge of battery cells. There are no possible options for meeting this requirement listed in the FAQ document. Unlike other terms used in the standard, this term is not mentioned or defined in the FAQ. To comply with this standard, the SDT needs to provide more guidance. For example, for VLA batteries the measured specific gravity could indicate state of charge. For VRLA batteries, it is not as clear how to determine state of charge, but possibly this can be determined by monitoring the float current.
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity. Table 1-4 has been revised to remove "state of charge" from the activities.		
Independent Electricity System Operator	No	
American Electric Power	Yes	With such a complex standard as this, the FAQ and Supplementary Reference documents do aid the Protection System owner in demystifying the requirements. But AEP holds strong doubt on how much weight the documents carry during audits. It would be better to include them as an appendix in the actual standard, but in a more compact version with the following modifications:

Organization	Yes or No	Question 4 Comment
		1. The section "Terms Used in PRC-005-2" is blank and should be removed as it adds no value. 2. Section I.1 and Section IV.3.G reference "condition-based" maintenance programs. However, no where in the standard is the term "condition-based" used in reference to defining ones PSMP. The FAQ should be revised to remove reference to a condition-based PSMP; alternatively the Standard could be revised to include the term "condition-based" within the Standard Requirements and Table 1. 3. The second sentence to the response in Section I.1 appears to have a typographical error "... an entity needs to and perform ONLY time-based...".
Response: Thank you for your comments. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
ITC	No	
ISO New England Inc.	Yes	See response to Question 5 below.
Response: Thank you for your comments. Please see our response to your comments in Question 5.		
Nebraska Public Power District	No	
CenterPoint Energy	Yes	The need for an FAQ document, in addition to an extensive Supplementary Reference document, illustrates the complexity and impracticality of the proposed Standard. CenterPoint Energy does not support the development of an additional type of document, that is, the FAQ document. CenterPoint Energy recommends eliminating the FAQ document and using only a Supplementary Reference" document. This would also provide the benefit of not having contradictory information in the two documents.
Response: Thank you for your comments. The SDT believes that entities should be able to implement the standard without either the FAQ or Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion/rationale useful, particularly to assist them in implementing the standard in an efficient manner. The SDT decided to eliminate the FAQ document and incorporate the FAQ's contents into the Supplementary Reference Document as appropriate.		
American Transmission Company	Yes	1. FAQ Protective Relays 2.D: The last sentence is not consistent with the discussions at the "March 2010, Standard Drafting Team Meeting, Project 2007-17". The understanding from that meeting was that the relay settings would be verified that the "as left" settings were the same as the "as found" settings and that the intent was not to verify the settings against a Master Record. Therefore the intent is that the tester will

Organization	Yes or No	Question 4 Comment
		verify that no setting changes were made as part of the testing process. Please include this clarification with the language in the standard. 2. FAQ Group by Type of Maintenance Program 2.B: We agree with the use of either the in-service date or the commissioning date to start the initial due date calculation for maintenance. Please include this clarification with the language in the standard.
Response: **1. The intent is that the settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have “drifted” since the prior maintenance or whether changes were made as part of the testing process.** **2. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.**		
Consumers Energy	No	
Southern Company Generation	Yes	1. On Page 3, please revise the flow chart references to R4.4.1 and R4.4.2. Also, add (Attachment A) to the “Performance Based” label. 2. On Page 7, Section I, correct the reference of R4.3 to R4.2. 3. Also, revise the last paragraph in Section I to the following: The entity should assure that the component performance is acceptable at the conclusion of the maintenance activities or initiate resolution of any indentified maintenance correctable issues. 4. On Page 7, Section J, correct the reference of R4.3 to R4.2. 5. On Page 10, Section D, a reference is made to “trip test” Table 1. Should this be Table 1-5? The exact phrase “trip test” is not used in the standard. Should it be? 6. On Page 10, Section e, the phrase “functional (or operational) trip test” is not used in the standard – should it be? 7. On Page 11, Section 5A, correct the reference of Table 1 to Table 1-4 in the Station Battery and Emerging Technologies paragraph. 8. On Page 12, Section B, correct the reference of Table 1 to Table 1-4. (2X)

Organization	Yes or No	Question 4 Comment
		9. On Page 13, Section F, correct the reference of Table 1 to Table 1-4. (1X) 10. On Page 14, Section G, correct the reference of Table 1 to Table 1-4. (3X) 11. On Page 14, Section G, change the text “The first maintenance activity” to The capacity testing activity”. 12. On Page 14, Section G, change the text “The second maintenance activity”, to The internal ohmic measurement activity”. 13. On Page 14, Section H, correct the reference of Table 1 to Table 1-4. (1X) 14. On Page 17, Section C, correct the reference of Table 1 to Table 1-5. (1X) 15. Please address what is meant by “Battery terminal connection resistance” on Page 14, Table 1-4 of the standard.
Response: Thank you for your comments. The discussion within the Supplementary Reference and FAQ are informative, not normative, and thus do not belong as part of the standard. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		
US Bureau of Reclamation		No Comment
Alliant Energy	No	
LCRA Transmission Services Corporation	Yes	
MidAmerican Energy	Yes	The Frequently Asked Questions should have clear disclaimers indicating that nothing in the reference is mandatory and enforceable.
Response: Thank you for your comments. NERC establishes that only the Standard is mandatory and enforceable, and Section F of the standard introduces this (and the Supplementary Reference Document) as presenting supporting discussion. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The introductory area of the Supplementary Reference Document will be revised to address your concern.		
Ameren	No	This document is helpful.
Xcel Energy	Yes	The changes in the standard and edit attempts on the FAQ have created some problems and confusion. Examples; The new FAQ I.1 answer does not make sense “An entity needs to and perform ONLY time-based

Organization	Yes or No	Question 4 Comment
		. . .” FAQ II.1.A: Requirement R1 no longer contains the statement that “use voltage, current, or phase angle to detect anomalies” so the answer to this FAQ is now out of synch with the standard. FAQ II.2.B – “Restoration” is no longer in the PMSP and has been changed to “Restore” and R4.3 no longer exists. FAQ II.2.I and II.2.J answers also references non-existent requirement R4.3. These are just some examples of fidelity issues that have been created by the most recent edit of PRC-005-2 – we did not perform a review of the entire document. The SDT should be commended for its efforts on the FAQ document as it is exceedingly helpful and well written. However, it needs to be brought back into alignment with the Standard. It is apparent that this fidelity check between the standard and the FAQ was not done prior to this posting. Finally, it seems some FAQs would be warranted to help explain the intent of new requirements R1.5 and R4.2 especially in regards to non-quantifiable maintenance results such as battery visual inspection as well as to provide examples of “other equivalent parameters” acceptance criteria for the various component types included in the Protection System definition
Response: Thank you for your comments. The SDT decided to eliminate the FAQ document and incorporate the FAQ’s contents into the Supplementary Reference Document as appropriate. The SDT considered your comments during this activity.		

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Many commenters disagreed with Requirement R1, Part 1.5 which was added in the previous draft; in response, the SDT removed Requirement R1, Part 1.5 from the standard. Commenters also observed that Requirement R1, Part 1.4 was redundant with Requirement R2, and the SDT removed R2 in response to these comments. Many commenters objected to 4.2.5.5 in the Applicability Section; the SDT removed this clause.

Organization	Yes or No	Question 5 Comment
Pepco Holding Inc & Affiliates	Yes	1. What "specific statistical data" was used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays? Comments were previously submitted that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." The 3 month interval is very burdensome and our experience does not appear to justify. A longer interval should be reconsidered.
Response: Thank you for your comments. The SDT reasserts that the 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays. If an entity's experience is that these components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.		
Pacific Northwest Small Public Power Utility Comment Group	No	
Tennessee Valley Authority	Yes	1R4 - "Identification of the resolution" and "Initiation of the resolution" are very distinct activities. In other places in this standard the requirement is for the resolution to be initiated, that is identified in a corrective maintenance work order, "identification of a resolution" requires technical expertise and can be difficult to track and might change over time for a particular problem. Proposed Change: Change "identification" to "initiation" in phrase "including identification of the resolution...". Overall: NERC is making significant changes to this sizeable standard and only allowing minimum comment period. While this is a good standard that has clearly taken many hours to develop, we are primarily voting

Organization	Yes or No	Question 5 Comment
		"NO" because of the hurried fashion it is being commented, voted, and reviewed.
Response: Thank you for your comments. Requirement R4 has been revised.		
Northeast Power Coordinating Council	Yes	1. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 2. Why are "Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)..." not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 3. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled "Unmonitored Control circuitry associated with protective functions", which would include trip coils, has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 4. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 5. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 6. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 7. A control circuit is not a component, it is made up of components.

Organization	Yes or No	Question 5 Comment
		8. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters..." means, and may be subject to different interpretations by entities and compliance enforcement personnel. 9. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 10. The 'box' for "Monitored Station dc supply..." in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation. 11. Regarding station service transformers, Item 4.2.5.5 under Applicability should be deleted. The purpose of this standard is to protect the BES by clearing generator, generator bus faults (or other electrical anomalies associated with the generator) from the BES. Having this standard apply to generator station service transformers, that have no direct connection to the BES, does meet this criteria. The FAQs (III.2.A) discuss how the loss of a station service transformer could cause the loss of a generating unit, but this is not the purpose of PRC-005. Using this logic than any system or device in the power plant that could cause a loss of generation should also be included. This is beyond the scope of the NERC standards. 12. The Drafting Team must respond to the following concerns raised in the FERC NOPR, Docket No. RM10-5-000, Interpretation of Protection System Reliability Standard, December 16, 2010) to "prevent a gap in reliability". a. Any component that detects any quantity needed to take an action, or that initiates any control action (initial tripping, reclosing, lockout, etc.) affecting the reliability of the Bulk-Power System should be included as a component of a Protection System, as well as any component or device that is designed to detect defective lines or apparatuses or other power system conditions of an abnormal or dangerous nature and to initiate appropriate control circuit actions. b. The exclusion of auxiliary relays will result in a gap in the maintenance and testing of Protection Systems affecting the reliability of the Bulk-Power System. c. Excluding the maintenance and testing of reclosing relays will result in a gap in the maintenance and testing of relays affecting the reliability of the Bulk-Power System. d. Not establishing the specific requirements relative to the scope and/or methods for a maintenance and testing program for the DC control circuitry that is necessary to ensure proper

Organization	Yes or No	Question 5 Comment
		operation of the Protection System, including voltage and continuity.

Response: Thank you for your comments.

1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need be prescribed. If an entity's experience is that components require less-frequent maintenance, a performance-based program in accordance with Requirement R3 and Attachment A is an option.**
2. **The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.**
3. **According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. As a regional entity, you can specify Supplementary regional requirements to maintain these devices more frequently if you desire.**
4. **With respect to dc supply associated only with communications systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**
5. **The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms as used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.**
6. **As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition**
7. **For purposes of this standard, the control circuit IS defined as one component type.**
8. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary. Therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
9. **In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.**
10. **Table 1-4 has been further modified for clarity**
11. **In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.**

Organization	Yes or No	Question 5 Comment
12. The FERC NOPR is a notice-of-proposed-rulemaking and is not yet a directive. At such a time as a directive is published, NERC will take the necessary actions to address it.		
Platte River Power Authority System Maintenance	Yes	1. Please clarify what is required by R1.5: Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities required. Is the intent a brief summary for each component type in the PSMP that would cover all equipment within that component type, or is it a detailed list of each piece of equipment within each component type? 2. The inclusion of dated check-off lists in M4 provides much needed clarity to the list of evidence.
Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. Thank you for your support.**		
Electric Market Policy	Yes	1. The draft to PRC-005-2 contains defined terms that upon approval will remain with the standard rather than being moved to the Glossary of Terms. These terms when used in the Requirements are not designated in any way (e.g., capitalization, bold, etc.) to point the reader back to the in-standard definition. 2. Need to explicitly state the intent of the SDT to either (1) use the newly defined term “Protection System (modification)” only in this standard (PRC-005-2) or (2) replace the existing definition of the existing term in the “Glossary of Terms Used in NERC Reliability Standards” with the proposed definition for the existing term. 3. The language used in Footnote 1 on Attachment A does not agree with the definition of Countable events provided elsewhere in the draft standard. Suggest footnote be removed. 4. Requirement R1.5 uses the phrase “or other equivalent parameters” which is confusing. Suggest replacing with “or acceptance criteria.” Requirement R1.5 should read as follows: “Identify calibration program.” The currently proposed language focuses on specific calibration tolerances and acceptance parameters. These tolerances are developed on a per device, per location basis and would be captured at a procedural level, not a program level. To add this at a program level would only complicate the program and would not lend any improvement to the reliability of the bulk electric system. We recommend maintaining a general calibration requirement, similar to what is stated above, for an entity to develop their calibration program. 5. Requirement 2 Component should be replaced with Component Type. Creating a program to monitor the

Organization	Yes or No	Question 5 Comment
		equipment at this level of equipment would not add any value to the bulk electric system as all components should already be included in component type maintenance tasks. Recommend removing the definition of Component. 6. The requirement to address “monitoring attributes” in Requirement 2 for time based maintenance program is unclear, onerous and unnecessary for a reliable protection system program. 7. Requirement (R4) should identify correctible maintenance issues not the resolution of these issues. The language in R4.2 should strike correcting maintenance issues related to R1.5 and instead state: Any maintenance correctible issues found during the maintenance activity should be identified” 8. Table 1.2 change time frame from 3 months to 3 years.
Response: Thank you for your comments. **1. The standard capitalizes defined terms only when they refer to terms which are (or will be) in the NERC Glossary of Terms. Terms will generically be capitalized when appearing at the beginning of a sentence or within a title, in accordance with common editorial practice.** **2. The statement of the definition has been revised in the standard as “NERC Board of Trustees Approved Definition”, but will remain in the posted draft standard until it is successfully balloted for the convenience of stakeholders.** **3. The footnote has been removed.** **4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **5. The SDT disagrees; monitoring attributes must be present on the individual components as actually installed, not to the overall component type.** **6. The SDT believes that the verifiable presence of the monitoring attributes on the individual components as installed is a necessary element of using the extended maintenance intervals that result from the monitoring. If you consistently use specific monitoring attributes on all components within a group, they may be able to address these attributes on a global basis. If an entity does not wish to document these attributes, they are free to apply the maintenance intervals and activities specified for the unmonitored components.** **7. Requirement R4 has been revised. The SDT believes it important that the entity initiate resolution of maintenance correctable issues, in addition to simply identifying them.** **8. The SDT believes that the 3-month interval is proper for verification of the functionality of unmonitored communications systems.**		
Bonneville Power Administration	Yes	Some of the maintenance tasks need to be defined: 1. The state of charge of each individual cell may need to be better defined. There are means to verify the

Organization	Yes or No	Question 5 Comment
		state of charge of the entire bank, but not each individual cell. 2. Battery continuity needs to be defined.- There is no mention to what the limits are for the "other equivalent parameters" when performing maintenance activities, just that they need to be identified. There are a large number of battery models which creates a large contrast of parameters, which cannot be grouped together. It is also difficult to get baseline values for older battery models which could result in moving baselines until they become more accurate as the database is populated. 3. If corrective actions are required, is there a maximum allowable duration for when they need to be resolved? 4. The maximum allowable maintenance for station batteries (impedance testing and performance/service testing) is too frequent and suggest an extension or alternative testing methods to stay in compliance. The frequency with which BPA performs the 18 month maintenance tasks as prescribed in the standard are on a 24 month interval along with visual inspections and voltage measurements monthly.BPA has seen success with this maintenance program with the ability to identify suspect cells or entire banks with adequate time to perform corrective actions such as repairs or replacements. 5. BPA also does not perform routine capacity testing, this is an as required maintenance task to confirm/validate our other test results if needed. BPA would like to see clarification for these issues before we can fully support this standard.
Response: Thank you for your comments. **1. Table 1-4 has been revised to remove "state of charge" from the activities.** **2. This is thoroughly discussed in Section 15.4 of the Supplementary Reference Document.** **3. No. The SDT appreciates that some corrective actions for maintenance correctable issues may take an extended period of time to complete, and has therefore not included completion of the corrective actions within PRC-005-2.** **4. The SDT believes that the 18-month interval is proper for these activities.** **5. For vented lead-acid and valve-regulated lead batteries, alternative activities are specified if desired instead of capacity tests. If Ni-Cad batteries are used, capacity tests are required.**		
Santee Cooper	No	We do not agree with the addition of Requirements 1.5 and 4.2 without work on or review by the Power System Maintenance and Testing Drafting Team. While some maintenance activities on some component types (such as calibration testing of electromechanical relays) translate inherently well into these requirements, the requirements of tolerances and documentation do not fit as well to all maintenance activities on other types of equipment considered part of the protective system. These requirements need to

Organization	Yes or No	Question 5 Comment
		be worked on through the drafting team to make them viable and effective for all protective system component types.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
NERC Staff	Yes	1. Commissioning (Initial) Testing: During development of PRC-005-2, NERC staff has observed a trend in system disturbances involving Protection System problems that should have been identified and corrected during commissioning (initial) testing. While NERC staff recognizes that the addition of commissioning testing may be unrealistic at this stage in the standard drafting process, we want to emphasize its importance. If the SDT chooses to leave commissioning testing out at this juncture, we plan to pursue other avenues to ensure its eventual inclusion through a separate standards project. NERC staff agrees with the SDT’s opinion that without commissioning testing, a registered entity responsible for compliance with this standard cannot provide proof of its interval testing period as required by the standard. As soon as the entity puts the protective scheme into service, time “0” for interval testing begins. The next testing interval would be some specific number of years in the future from time “0. ”An entity’s failure to properly commission new protection system equipment has caused or exacerbated several recent events, greatly impacting BPS reliability. The following are examples of errors that were not detected during commissioning. These undetected errors were observed by NERC staff during event analysis and investigation activities: oFailure to apply correct relay settings. This has occurred repeatedly and has been due to improper procedures, poor document control, misapplication or miscalibration of the relay, or a combination of the above. oFailure to install the proper CT or PT ratio occurred due to poor document control practices and resulted in an undesired protection system response after the equipment was placed in service. oFailure to conduct a functional test of new control circuits to the schematic diagram resulted in an undesired protection system response after equipment was placed in service. oAn incorrect CT ratio was not detected during commissioning, and the equipment was subsequently placed in service. Because in-service testing was not performed, the error remained undetected until the relay misoperated during a fault. Many of the above conditions can remain undetected for extended periods, until they are revealed by a

Organization	Yes or No	Question 5 Comment
		relay misoperation during fault or heavy load conditions. The affects resulting from these cases could have been prevented with proper commissioning testing. We believe that by requiring commissioning testing for new protection system equipment, the reliability of BPS would be improved. 2. Requirement 2:In Requirement 2, it is unclear what is meant by “shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5 in its PSMP” because the use of terms in the Requirement is not consistent with the column headings used in Tables 1-1 through 1-5. It also is not clear that components need not possess all attributes; rather, they must possess all attributes consistent with the Maximum Maintenance Interval specified in an entity’s PSMP. NERC staff recommends revising R2 to provide additional clarity as follows:”Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems described in Tables 1-1 through 1-5, shall verify those components possess the monitoring attributes Component Attributes identified in the first column of Tables 1-1 through 1-5 consistent with the Maximum Maintenance Interval specified in its PSMP.”
Response: Thank you for your comments. **1. Thank you for your comments.** **2. Requirement R2 of the standard has been modified as you suggested.**		
FirstEnergy	Yes	REQUIREMENTS 1. Requirement R1 - Subpart 1.5 - We do not support this subpart for the following reasons and offer the following suggestions: To satisfy R1.5, a calibration tolerance or other equivalent parameter would have to be established for each item included in the definition. Many devices which may have similar functionality may also have different performance criteria that would preclude the use of a "one size fits all" calibration tolerance. Many of these criteria are provided by the manufacturer and often vary by manufacturer for a similar device. It would be very difficult to specify in your program all of the calibration tolerances or other equivalent parameters associated with the protection system components. Therefore, we suggest the team delete Subpart 1.5 of Req. R1, and revise Subpart 4.2 of Req. R4 to read: "Initiate resolution of any identified maintenance correctable issues at the conclusion of maintenance activities for Protection System components." IMPLEMENTATION PLAN 2. On pg. 2 of the implementation plan, under "Retirement of Existing Standards", the statement "The existing standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2" is not accurate. Since the new PRC-005-2 standard allows for at least 12 months

Organization	Yes or No	Question 5 Comment
		to become compliant with Requirement R1 - establish a Protection System Maintenance Program (PSMP) -the existing standards are still effective during this time. Additionally, we have concerns with the "General Considerations" describing protocols for compliance audits conducted during the allowed 12 month development period of the PSMP and that entities could specify for "each component type" whether maintenance of that component is being performed according to its maintenance program under the "retired" PRC maintenance standards or the new PRC-005-2 standard. In our view, this creates a level of compliance complexity for both the Registered Entity and Regional Entity that should be avoided in the transition to PRC-005-2. FirstEnergy proposes that the Implementation Plan state that the existing standards remain in effect for one year past applicable approval (NERC Board or Regulatory) and that they are retired coincident with the one-year transition to Requirement R1 of PRC-005-2 which would establish all Registered Entities having a new PSMP per the expectations of PRC-005-2. At that time all entities would be required to be under the new PRC-005-2 standard and begin implementing their PSMP per the phased-in Implementation Plan for the remaining requirements. To summarize, per our above discussion we propose the team perform the following:1. Revise the Implementation Plan section titled "Retirement of Existing Standards" section to read as follows: "The existing Standards PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired on the first day of the first calendar quarter twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following the Board of Trustees adoption"2. Remove the entire "General Considerations" section from the Implementation Plan. 3. The bulleted item under the section titled "Implementation plan for R1" has a discrepancy in the time allowed to implement R1 between entities applicable to regulatory approval of the standard versus those in jurisdictions where no regulatory approval is needed and base their adherence per the Board of Trustee adoption. Please revise to reflect a 12 month transition period for each. DEFINITIONS 4. Maintenance Correctable Issue - This is a maintenance standard and this concept gets into the long term repair activities. Is this really appropriate in this standard? If NERC feels repairing is critical to BES reliability, then they should probably initiate a standard in that area. 5. Component - Regarding the phrase "local zone of protection", why is this in quotes? Is there a narrow definition for this? If so, this term should be defined also. DATA RETENTION SECTION 6. 1.3 Regarding the data retention for Req. R3 and R4, it is not practical to keep potentially 24 years of data for components that are maintained every 12 years. We suggest rewording this to "For R3 and R4, Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performances of each distinct maintenance activity for the Protection System components, or to the

Organization	Yes or No	Question 5 Comment
		previous scheduled audit date, whichever is longer". 7. ATTACHMENT A - FOOTNOTE 1This footnote regarding countable events needs to be revised to match the definition of countable events found at the beginning of the standard.
Response: Thank you for your comments. 1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** 2. **The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).** 3. **The Implementation Plan for Requirement R1 has been modified as you suggest.** 4. **The SDT believes that the activities necessary to restore a Protection System component to proper service is an essential part of the PSMP. Please note that the related requirements only address initiation of the corrective actions, not completion, in deference to the extended period of time that some of these activities may take.** 5. **The quotes have been removed from the definition of component. However, the SDT believes that this term is a commonly-understood term within the industry.** 6. **In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.** 7. **This footnote has been removed.**		
Florida Municipal Power Agency	Yes	1. UFLS and UVLS maintenance and testing is greatly expanded, e.g., we interpreted PRC-008/011 as being only the UFLS/UVLS equipment. The new PRC-005 sweeps in other protection system components, e.g., communications (probably not applicable), voltage and current sensing devices (e.g., instrument transformers), Station DC supply, control circuitry. What's key about this is that these components are all part of distribution system protection, so, these activities would not be covered by other BES protection system maintenance and testing. I'm sure we are testing batteries and the like, but, we are probably not testing battery chargers and control circuitry, and, in many cases distribution circuits are such that it is very difficult, if not impossible, to test control circuitry to the trip coil of the breaker without causing an outage of the customers on that distribution circuit. There is no real reliability need for this either. Unlike Transmission and Generation Protection Systems which are needed to clear a fault and

Organization	Yes or No	Question 5 Comment
		may only have one or two back-up systems, there are thousands and thousands of UFLS relays and if one fails to operate, it will not be noticeable to the event. It does make sense to test the relays themselves in part to ensure that the regio0nsl UFLS program is being met, but, to test the other protection system components is not worthwhile. Note that DC Supplies and most of the control circuitry of distribution lines are "tested" frequently by distribution circuits clearing faults such as animals, vegetation blow-ins, lightning, etc., on distribution circuits, reducing the value of testing to just about null. However, this version is better than prior versions because it essentially requires the entity to determine it's own period of maintenance and testing for UFLS/UVLS for DC Supply and control circuitry. 2. Applicability, 4.2.1, should reflect the Y&W and Tri-State interpretation (Project 2009-17) of "transmission Protection System" and should state: "Protection Systems applied on, or designed to provide protection for a BES Facility and that trips a BES Facility" 3. Applicability, 4.2. - does not reflect the interpretation of Project 20009-10 that excludes non-electrical protection (e.g., sudden pressure relays) and auxiliary relays. Because the definition of Protection System (recently approved) does not clearly exclude "non-electrical" protection, the Applicability section should. For instance, a vibration monitor, steam pressure, etc. protection of generators, sudden pressure protection of transformers, etc. should not be included in the standard. An alternative is to change the definition of Protection System to make sure it only includes electrical 4. Table 1-4 requires a comparison of measured battery internal ohmic value to battery baseline. Battery manufacturers typically do not provide this value and one manufacturer states that the baseline test are to be performed after the battery has been in regular float service for 90 days. It is unclear how to comply with the requirement for the initial 90 days. Additionally, we would recommend that this requirement be modified to permit an entity to establish a “baseline” value based on statistical analysis of multiple test results specific to a given battery manufacturer/model. Several commenters previously expressed their concerns with performing capacity tests. While this may just be an entity’s preference, allowing an entity to establish a baseline at some point beyond the initial installation period would give entities the option of using the internal resistance test in lieu of a capacity test. 5. Small entities with only one or two BES substations may not have enough components to take advantage of the expanded maintenance intervals afforded by a performance-based maintenance program. Aggregating these components across different entities doesn’t seem too logical considering the variations at the sub-component level (wire gauge, installation conditions, etc.) 6. Trip circuits are interconnected to perform various functions. Testing a trip path may involve disabling other features (i.e. breaker failure or reclosing) not directly a part of the test being performed. Temporary modifications made for testing introduce a chance to accidentally leave functions disabled, contacts shorted, jumpers lifted, etc. after testing has been completed. Trip coils and cable runs from panels to breaker can be made to meet the requirements for monitored components. The only portions of the

Organization	Yes or No	Question 5 Comment
		circuitry where this may not be the case is in the inter- and intra-panel wiring. Because such portions of the circuitry have no moving parts and are located inside a control house, the exposure is negligible and should not be covered by the requirements. Entities will be at increased compliance risk as they struggle to properly document the testing of all parallel tripping paths. The interconnected nature of tripping circuits will make it difficult to count the number of circuits consistently for the purpose of calculating a VSL.
Response: Thank you for your comments. **1. For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general. Regardless, without proper functioning of these component types, UFLS and UVLS will not respond as expected, and will therefore degrade BES system reliability, particularly during the stressed system conditions for which UFLS and UVLS are installed. Relative to control circuitry, Table 1-5 specifically excludes UFLS and UVLS from maintenance activities relate to the interrupting device trip coil.** **2. This interpretation is not yet approved by FERC. When this interpretation is approved, the SDT will incorporate it within PRC-005-2** **3. The recently-balloted revision of the definition of Protection System, which has been approved by the NERC Board of Trustees and will soon be filed with FERC for approval, clearly includes only protective relays that respond to electrical quantities. As for auxiliary relays, the interpretation to which you refer states that they are not explicitly included, but are included to the degree that an entity's Protection System control circuitry addresses them (which has been identified as a reliability gap), and are being added to PRC-005-2 to resolve that gap.** **4. Typical baseline values for various types of lead-acid batteries can be obtained from the test equipment manufacturer, perhaps the battery vendor, and perhaps other sources for batteries that are already in service. For new batteries, the initial battery baseline ohmic values should be measured upon installation and used for trending.** **5. Entities are not required to use performance-based maintenance programs. Requirement R3 and Attachment A are provided for the use of entities that can (and desire to) avail themselves of this approach.** **6. The requirement relative to control circuitry does not explicitly require trip or functional testing of the entire path; it requires that entities verify all paths without specifying the method of doing so. Please see Section 15.5 of the Supplementary Reference Document for a detailed discussion.**		
PSEG Companies ("Public Service Enterprise Group Companies")	Yes	1. The facilities listed in 4.2.5.5 include protection systems for "system connected" station service transformers associated with generators that are part of the BES. If a station service transformer is connected to a non BES bus then it would still fall under the PRC5 applicability requirements as written. The FAQs discuss relays associated with station auxiliary loads as not included in the program requirements. The non BES connected transformers should be included in that same category of equipment. 2. From the FAQ's - "Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could

Organization	Yes or No	Question 5 Comment
		result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit." Suggest the following added details be considered to be consistent with intent of BES connected facilities. Revise Description 4.2.5.5 as follows: "Protection systems for BES system connected station service transformers connected for generators that are part of the BES". 3. With respect to DC supply systems (batteries, chargers),the implementation plan is too aggressive. Some battery checks will have to be done on a 3 month interval, and entities will be required to be compliant with this new frequency in 1 Calendar year. This timeframe is unreasonable and needs to be pushed back to at least 2 years. 4. PSEG is also asking for clarification to the Supplementary reference document: On page 4, section 2.3 it states that the standard is designed to ONLY include "relays that detect a fault on the BES and take action in response to that fault". If PSEG is interpreting this correctly, this is a massive shift from the existing PRC-005-1 standard. The existing PRC-005-1 includes all distribution relays that trip a BES breaker to be part of the scope. In this revision, PRC-005-2 would exclude those distribution relays if they are designed to act for faults on the distribution system. PSEG would fully support this interpretation. PSEG would like this clarified and confirmed. This is very important.
Response: Thank you for your comments. **1. The Applicability of the draft Standard had been revised to remove "system-connected station service transformers".** **2. The FAQs have been merged into the Supplementary Reference Document; this discussion has been revised.** **3. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. Section 2.3 of the Supplementary Reference Document has been extensively revised, and the sentence to which you refer is no longer present. As for your comment, "The existing PRC-005-1 includes all distribution relays that trip a BES breaker to be part of the scope," the SDT believes that this is an element of a Regional practice regarding PRC-005-1, and entities should expect to comply with PRC-005 as established within the NERC Standard and further defined by Regional practice.**		
MRO's NERC Standards Review Subcommittee	Yes	1. In the Purpose statement delete "affecting" and replace it with "protecting". The purpose of the standard deals with systems that protect the BES. 2. In sections R1 and R4.2.1 delete "applied on" as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES.

Organization	Yes or No	Question 5 Comment
		3. The NSRS believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves not purpose. 4. The NSRS believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. 5. The NSRS believes that Article 4.2 needs to be deleted from the standard. There is no need for this article if Article 1.5 is deleted. 6. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS.4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. 7. Section F Supplementary Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. 8. Table 1-4 Component Type Station dc Supply: o “Any dc supply for a UFLS or UVLS system” - This should not tied to the same testing interval as control circuits. The dc supply system is significantly different from control circuits and should have a maximum maintenance period as other dc supplies do. 9. Replace the words “perform as designed” on page 14 of Table 1-4 with “operate within defined tolerances.” 10. Table 1-5 Component Type Control Circuitry: a. This table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. “Unmonitored control circuitry associated with protective functions” should also have an exclusion for UFLS and UVLS circuitry that would allow for “no periodic maintenance”. b. There is a concern that requiring the electrical testing and maintenance of Electromechanical trip or Auxiliary devices will force entire bus outages to be scheduled, which will compromise the BES

Organization	Yes or No	Question 5 Comment
		reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned" and therefore such testing will result in more outages than actual failures.

Response: Thank you for your comments.

1. **The "Purpose" is defined by the SAR.**
2. **Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.**
3. **The SDT disagrees; Requirement R1, Part 1.4 supports Requirement R1, Part 1.2, and seems necessary to assure that entities have appropriately applied the longer intervals associated with monitored components.**
4. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. Please see Supplementary Reference Document, Section for a discussion of this. The associated VSL has also been revised.**
5. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
6. **Applicability 4.2.1 has been revised to remove 'applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to Applicability 4.2.1. The Supplementary Reference Document has been revised to clarify.**
7. **The date in Clause F of the standard related to the Supplementary Reference Document has been revised.**
8. **The SDT disagrees. Station dc supply for UFLS/UFLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits.**
9. **"Tolerances" does not fully describe the parameters for maintenance of station dc supply; "perform as designed" is far more inclusive.**
10. **a. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document.**

    b. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals

Organization	Yes or No	Question 5 Comment
Western Area Power Administration	No	
TransAlta Centralia Generation Partnership	No	
NextEra Energy	Yes	The draft standard is too prescriptive. 1. Requirement R1, Part 1.5 would be overwhelming if approved. Requirement R1, Part 1.5 should be deleted. 2. Requirement R4, Part 4.2 phrase "established in accordance with Requirement R1, Part 1.5" should be deleted. The standard without these additional requirements would be sufficient to establish that the Protection System is maintained and protects the BES. 3. Table 1-2 Component Type Communications Systems Maximum Maintenance Interval of 3 Calendar Months to verify that the communications system is functional for any unmonitored communications system is unyielding. Most communication failures are caused by power supply failures which Next Era does monitor. Based on experience and monitoring of communication power supplies, 12 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 12 calendar months. 4. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to inspect electrolyte levels on “Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. Verifying battery charger float voltage every 18 calendar months is sufficient to prevent excessive gassing and water loss of battery cells. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months. 5. Table 1-4, Component Type Station dc Supply Maximum Maintenance Interval of 3 Calendar Months to measure the internal ohmic values on “Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)” is too stringent. With the standard’s requirement to verify the float voltage every 18 calendar months, measuring the internal ohmic values every 6 calendar months would be adequate. The maximum maintenance interval should be changed from 3 calendar months to 6 calendar months.

Response: Thank you for your comments.

1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to**

Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted Requirement R2 (together with the associated Measure and VSL).**		
PacifiCorp		
Southern Company Transmission	Yes	1. Page 5, 4.2. ("or initiate resolution") Comment ->> Standard does not specify to "follow through" to completion. Is record of completion required? 2. Page 5, 1.5. (1.5. Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance

Organization	Yes or No	Question 5 Comment
		activities.) Comment ->> This is too vague, broad, general and all encompassing. For example, what is the calibration tolerance for "control circuitry" which is made up of many things such as wiring, auxiliary relays, trip coils, etc. We currently have calibration tolerances on electromechanical relays but not on all components of a protection system (communications systems, voltage and current sensing devices, station dc supply, control circuitry). To try to identify calibration tolerances or other equivalent parameters for each of these components would be extremely difficult and time consuming. Clarification is needed on what components or parts of components require calibration tolerances. Another option is to remove this requirement. 3. Page 5, 4.5. (4.2. Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any identified maintenance correctable issues.)Comment ->> See comments above on 1.5. Clarification is needed on what is required to verify that the components are within acceptable parameters. We feel it should be adequate to provide a simple way to verify this requirement such as to include this in our maintenance procedure (equipment is to be left within tolerance), provide closed work order, show "checked" check box, provide a simple statement that this was completed, or etc. We feel that having to provide detailed data such as "as found" / "as left" values is too complicated and time consuming. Please clarify or consider removing this requirement. 4. Page 6, M.4. ("and initiated resolution") Comment ->> Standard does not specify to "follow through" to completion. Is record of completion required? 5. Page 10, F.1 (July 2009) & F.2 (DRAFT 1.0 - June 2009) Comment ->> Need new dates and draft number. 6. Page 11 (For microprocessor relays, verify operation of the relay inputs and outputs that are essential ...) Comment ->> Does this require changing the state of the input contacts or can you just jumper voltage to the inputs and verify that the microprocessor relays acknowledged the change? 7. Page 17 ("Verify electrical operation(1)of EM trip and auxiliary devices(2).") Comment ->> (1) Is it required to verify that trip and auxiliary device contacts change state? If so, please state as a requirement.(2) We recommend that this requirement only includes EM aux LO / tripping relays that trip interrupting devices directly. Other EM aux relays such as BFI aux. relays should be excluded. Please state this clearly in the Standard. Note that these aux relays such as BFI aux relays are included

Organization	Yes or No	Question 5 Comment
		in the "unmonitored control circuitry associated with protective functions" requirement and will be verified on a 12 year interval. (3) Please consider including an elementary diagram to show what is included. 8. Page 17 (Verify all paths of the control and trip circuits.) Comment ->> Clarification needed. Is it required to perform a full functional test, i.e. trip breakers? Or is reading DC across trip contacts all that is required? 9. Page 14 (Table 1.4) Change the maintenance interval for unmonitored station dc supply from "3 Calendar Months" to "4 times annually". This facilitates compliance to the standard by creating completion milestones for batteries at the end of each quarter of the year. 10. Page 15 (Table 1.4The standard requires the establishment of a battery baseline for cell/unit internal ohmic values and the comparison of impedance readings every 18 calendar months to that baseline. Due to the lack of original impedance readings at the time of installation of the battery. Since in many cases no such data is available; it needs to be made clear that establishing a baseline from , from manufacturer's data, the most recent impedance test, or the first impedance test completed after the adoption of the new standard is acceptable

Response: Thank you for your comments.

1. **No. Full resolution of maintenance correctable issues may require extensive work; the SDT intends that INITIATION of the resolution is all that is required per PRC-005-2.**
2. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. 4. **No. Full resolution of maintenance correctable issues may require extensive work; the SDT intends that INITIATION of the resolution is all that is required per PRC-005-2.**
5. **The date has been revised.**
6. **The SDT believes that it would be sufficient to apply voltage to the input and observe that the relay responds accordingly.**
7. **1 – "Verify" means "Determine that the component is functioning correctly". The SDT intends that the device be electrically operated, but not that**

Organization	Yes or No	Question 5 Comment
additional verification be conducted during the electrical operation. However, the 12-year activity for unmonitored control circuitry would require verification of full functionality, including all of the related contacts. 2- The standard has been modified in consideration of your comment. 3 – An elementary diagram would be inappropriate in the standard. Additionally, the design of the control circuitry varies so widely from one application to another that it seems (to the SDT) that it would not be effective to include such an example in the Supplementary Reference Document. **8. The control circuitry can be tested in overlapping segments. It seems to the SDT that it is not necessary to trip the breakers with the functional test, as long as the entity performs the activities necessary to demonstrate that all overlapping segments will function properly.** **9. The SDT believes that your suggestion would not be effective in assuring periodic maintenance of the dc supply.** **10. The station battery baseline value is up to the entity to determine. Please see Clause 15.4.1 of the Supplementary Reference Document for a discussion of this.**		
Clark Public Utilities	No	
Exelon	Yes	1. In response to Exelon's comments provided to drafts 1 and 2 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. 2. In addition, although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant's routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity

Organization	Yes or No	Question 5 Comment
		or a self report of non-compliance. To ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. 3. In addition, Exelon has the following technical comments a. Sections 4.2.5.4 and 4.2.5.5 need to clearly state that only protection which affects the BES is within the scope of the PRC-005. b. There is not enough clarity in the statement “each protection system component type” for one to stay at the component level vs. dropping to sub-component level. If sub-components reviews are required, the effort becomes unmanageable. Therefore the Standard should identify calibration tolerances or other equivalent parameters. Suggest rewording to "each protection system major component type”
Response: Thank you for your comments. **1. If several different regulatory agencies have differing requirements for similar equipment, it seems that the entity must be compliant with the most stringent of the varying requirements. In the cited case, an entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant.** **2. The 18-month (and shorter) interval activities are activities that can be completed without outages – primarily inspection-related activities. An entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant.** **3. a. Applicability 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.** **b.The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Manitoba Hydro	Yes	1) We disagree with the requirements for battery maintenance outlined in table 1-4. In particular the requirement for a 3 month check on electrolyte level seems too frequent based on our experience. We would like to point out that although IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals it also states that users should evaluate these recommendations against their own operating experience. 2) Also, the Implementation Plan is not consistent for areas requiring regulatory approval and areas requiring regulatory approval. The 6 month time frame proposed for R1 for areas not requiring regulatory approval is not achievable and is not consistent with areas requiring regulatory approval. To be consistent, the effective

Organization	Yes or No	Question 5 Comment
		date for R1 in jurisdictions where no regulatory approval is required should be the first day of the first calendar quarter 12 months after BOT approval.
Response: Thank you for your comments. **1. The SDT believes that the 3-month interval specified in the standard is appropriate.** **2. In consideration of your comment, "6" has been modified to "12" in the Implementation Plan for Requiremnet R1.**		
Dynegy Inc.	Yes	For R1.5, we feel to much is being asked for since this information is not easilly controlled and the tolerances vary over time.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Oncor Electric Delivery Company LLC	Yes	Comment A: Oncor believes that Requirement R1 Part 1.5 of this Standard should be removed. It is too vague, intrusive, and divisive for what it brings to the reliability of the BES. Specifically it burdens all Transmission Owners, Generation Owners or Distribution Providers with the impossible task of having to "identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities." By definition a Protection System component type is "any one of the five specific elements of the Protection System definition" and "a component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device." What Requirement R1 part 1.5 with its associated High VSL in the Standard would decree is that all Transmission Owners, Generation Owners and Distribution Providers who "failed to establish calibration tolerance or equivalent parameters to determine if every individual discrete piece of equipment in a Protection System is within acceptable parameters" would be in violation of the Standard - with a High VSL. Oncor with over 98 years of Protection System maintenance experience feels that most Owners including itself would be non-compliant with this unclear, meddling and disruptive requirement no matter how long the implementation plan for the Standard is. Comment B: Oncor believes that in light of Comment "A" above Requirement R4 Part 4.2 must be modified to remove all references to Requirement R1 Part 1.5 of the Standard. The new requirement should be modified to read "Either verify that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct maintenance correctable issues." Also in order to assist both the owners and the compliance authorities who may question how one verifies that the components are within acceptable parameters the FAQ document should be modified to discuss how many

Organization	Yes or No	Question 5 Comment
		utilities are doing this with results that indicate either a pass or fail certified by the qualified persons performing maintenance. Comment C: Oncor feels that the wording "no less frequently than" found in Requirement R4 Parts 4.1.1 and 4.1.2 should be chanced back to the wording in the previous version of the Standard "not to exceed." Comment D: Oncor recommends that in light of Comment "A" above Measure M1 be modified to remove all reference to Requirement R1 Part 1.5. Comment E: Oncor, as stated in Comment "B" above, recommends that the FAQ document be modified to provide more information on what could be used for evidence that the Transmission Owner, Generation Owner or Distribution Provider has "initiated resolution of identified maintenance correctable issues." This will assist both the owners and the compliance authorities in answering the question of what constitutes proof that a maintenance correctable issue was identified. Comment F: The second and third paragraphs added under Compliance 1.3 Data Retention provide more information as to what data is required to be retained. Oncor feels that these two paragraphs will help the compliance authorities, the Transmission Owners, Generation Owners and Distribution Providers needed guidance of what is required for data retention.

Response: Thank you for your comments.

A. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

B. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

C. **"No less frequently than" was adopted on recommendation of NERC Staff as the preferred method of addressing this requirement.**

D. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

E. **The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.**

Organization	Yes or No	Question 5 Comment
F. Thank you for your comment.		
Ingleside Cogeneration LP		The latest version of PRC-005-2 includes a new requirement (R1.5) to identify calibration tolerances or equivalent parameters that must be verified before a maintenance activity is considered complete. Although we understand the project team's intent, Ingleside Cogeneration LP is concerned that this requirement will lead to multiple interpretations of which tolerances or parameters are the most important. In addition, audit teams may expect to see certain values based upon their own sense of reliability. This is exactly the ambiguity that PRC-005-2 is trying to eliminate. In addition, calibration tolerances and reliability parameters may vary by equipment manufacturer or by configuration. It is not clear that documenting every scenario to demonstrate regulatory compliance is a benefit to BES reliability.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Indiana Municipal Power Agency	Yes	Standard PRC-005-2 Draft 3 contains a section of "Definitions of Terms Used in Standard" that includes newly defined or revised terms uses in this proposed standard. There are a number of references made to these Terms in the Standard that are not capitalized. IMPA would propose that anywhere that the terms included in the "Definition of Terms Used" are used in the standard that they be capitalized. When any word is not capitalized in a standard then the common practice is to use the Webster Dictionary meaning. IMPA does not know why the SDT is reluctant to put these terms in the NERC Glossary of Terms, but by putting the terms in the glossary it would eliminate any confusion. When these terms are capitalized all registered entities will know that these are defined terms and will be able to consistently apply the definition without confusion. For example: 1.1 Address all Protection System component types would become1.1 Address all Protection System Component Types. If these terms are not capitalized in the standard (meaning they are not referring to the defined term) then the meaning of these terms could vary not only from utility to utility but also from Region to Region.
Response: Thank you for your comments. The standard capitalizes defined terms only when they refer to terms which are (or will be) in the NERC Glossary of Terms. Terms will generically be capitalized when appearing at the beginning of a sentence or within a title, in accordance with common editorial practice. If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.		

Organization	Yes or No	Question 5 Comment
South Carolina Electric and Gas		
Entergy Services	Yes	Adding Requirement 1.5 is a significant revision and raises questions as to how broadly an accuracy or equivalent parameter requirement and associated documentation would need to be addressed by entities and/or will be measured for compliance. Discussion on this new requirement does not seem to be addressed anywhere in the FAQ or Supplementary Reference documents. Additionally, to the best of our knowledge, the need for such a requirement was not brought up as a concern or comment on the prior draft version of this standard, and in the context of a requirement need, we don't believe it has been attributed to or actually poses any significant reliability risk. We do not believe this requirement is justified.
Response: Thank you for your comments. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.		
Duke Energy	Yes	1. We have previously commented that the FAQ and Supplementary Reference documents should be made part of this standard. If that cannot be done, then more of the information in those documents needs to be included in the requirements in the standard to provide clarity. Compliance will only be measured against what is in the standard, and we need more clarity. 2. R1.4 and R1.5 need more information to provide clarity for compliance. It's unclear to us what the expectation is for compliance documentation for "monitoring attributes and related maintenance activities" in R1.4 and "calibration tolerances or other equivalent parameters" in R1.5. This is fairly straightforward for relays, but not for other component types. Either provide clarity or delete these requirements. 3. R4.2 - it is critical that more clarity be provided for R1.5 so that we can also understand what the compliance expectation is for R4.2 4. M4 - Need to clarify that these pieces of evidence are all "or", not "and" (i.e. any of the listed examples are sufficient for compliance). We reiterate the need for additional clarity on R1.5 and R4.2 such that compliance can be demonstrated for all component types. 5. Table 2 - We are fairly clear on the expectation for relays, but need more clarity on the expectation for other component types. Also, need to change the phrase "corrective action can be taken" to "corrective action can be initiated", consistent with the Supplementary Reference document.
Response: Thank you for your comments.		

Organization	Yes or No	Question 5 Comment
1. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. The SDT believes that entities should be able to implement the standard without the Supplementary Reference. However, the SDT is also convinced that many entities may find the supporting discussion/rationale/etc useful, particularly to assist them in implementing the standard in an efficient manner. **2. Requirement R1, Part 1.4 has been modified for clarity. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **3. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **4. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point.** **5. Table 2 has been modified to be clearer. "Taken" has been replaced with "initiated" in consideration of your comment.**		
Wisconsin Electric Power Company		
Independent Electricity System Operator	Yes	1. Requirement R1, Part 1.5 is vague and needs clarification. It is not clear what "Identify calibration tolerances or other equivalent parameters" means and this may be subject to different interpretations by entities and compliance enforcement personnel. 2. Additionally, in the Implementation plan for Requirement R1, we recommend changing "six" to "fifteen" to restore the 3-month time difference between the durations of the implementation periods for jurisdictions that do and don't require regulatory approval, which existed in the previous draft. This change will ensure equity for those entities located in jurisdictions that do not require regulatory approval as is the case here in Ontario. More importantly it supports the IESO's strong belief in the principle that reliability standards should be implemented in an orderly and coordinated fashion across regions to ensure system reliability is not compromised.
Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Document, Section 8 for a discussion of this. **2. In consideration of your comment, "6" has been modified to "12" in the Implementation Plan for Requirement R1.**		
American Electric Power		1. Standards Requirement 1.5 and the reference to R1.5 in Requirement 4.2 should be removed. Specifying calibration tolerances for every protection system component type, while a seemingly good idea, represents a substantial change in the direction of the standard. It would be very onerous for companies to maintain a list of calibration tolerances for every protection system component type and show evidence of such at an audit. AEP believes entities need the flexibility to determine what acceptance criteria is warranted and need discretion to apply real-time engineering/technician judgment where appropriate. 2. Three different types of maintenance programs (time-based, performance-based and condition-based) are referenced in the standard or VSLs, yet the time-based and condition-based programs are neither defined nor described. Certain terms defined within the definition section (such as Countable Event or Segment) only make sense knowing what those three programs entail. These programs should be described within the standard itself and not assume knowledge of material in the Supplementary Reference or FAQ. 3. "Protective relay" should be a defined term that lists relay function for applicability. There are numerous 'relays' used in protection and control schemes that could be lumped in and be erroneously included as part of a Protection System. For example, reclosing or synchronizing relays respond to voltage and hence could be viewed by an auditor as protective relays, but they in fact perform traditional control functions versus traditional protective functions. 4. The Data Retention requirement of keeping maintenance records for the two most recent maintenance performances is a significant hurdle for any owners to abide by during the initial implementation period. The implementation plan needs to account for this such that Registered Entities do not have to provide retroactive testing information that was not explicitly required in the past.
Response: Response: Thank you for your comments. **1. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **2. The term, "condition-based" has been removed from the draft standard. The other terms are used, but are clear in the context in which they are used.** **3. "Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition within PRC-005. Further,**		

Organization	Yes or No	Question 5 Comment
the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2. 4. In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.		
ITC	Yes	1. We would like some further clarification on PRC-005-2 Draft 3, specifically on the statement in Table 1-4 for unmonitored station DC supply with VLA batteries. In the table it is mentioned that we are to perform either a capacity test every six years or verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline, the latter statement is a little vague and needs further clarification with regards to the expectations from the standard. Please describe an acceptable method of establishing a baseline “measured cell/unit internal ohmic value” We would like to know what exactly is required. We measure the cell internal ohmic value on an annual basis every 12 months, is that enough? What are the comparison parameters with regards to battery baseline? At what percent should we look to replace the cell? 2. Is a battery system that only supplies the SCADA RTU considered part of the protective system if alarms for the monitored protective systems utilize that SCADA RTU?
Response: Response: Thank you for your comments. **1. The station battery baseline value is up to the entity to determine. Please see Section 15.4.1 of the Supplementary Reference for a discussion of this.** **2. No. The Applicability of the standard limits the standard to only those devices within the Protection.**		
ISO New England Inc.		1. In general, the standard is overly prescriptive and complex. It should not be necessary for a standard at this level to be as detailed and complex as this standard is. Entities working with manufacturers, and knowledge gained from experience can develop adequate maintenance and testing programs. 2. Why are “Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation)...” not included? The output contacts from these devices are oftentimes connected in tripping or control circuits to isolate problem equipment. 3. Due to the critical nature of the trip coil, it must be maintained more frequently if it is not monitored. Trip coils are also considered in the standard as being part of the control circuitry. Table 1-5 has a row labeled “Unmonitored Control circuitry associated with protective functions”, which would include trip coils,

Organization	Yes or No	Question 5 Comment
		has a "Maximum Maintenance Interval" of "12 Calendar Years". Any control circuit could fail at any time, but an unmonitored control circuit could fail, and remain undetected for years with the times specified in the Table (it might only be 6 years if I understand that as being the trip test interval specified in the table). Regardless, if a breaker is unable to trip because of control circuit failure, then the system must be operated in real time assuming that that breaker will not trip for a fault or an event, and backup facilities would be called upon to operate. Thus, for a line fault with a "stuck" breaker (a breaker unable to trip), instead of one line tripping, you might have many more lines deloaded or tripped because of a bus having to be cleared because of a breaker failure initiation. The bulk electric system would have to be operated to handle this contingency. 4. In reference to the FAQ document, Section 5 on Station dc Supply, Question K, clarification is needed with respect to dc supplies for communication within the substation. For example, if the communication systems were run off a separate battery in separate area in a substation, would the standard apply to these batteries or not? 5. To define terms only as they are used in PRC-005-2 is inviting confusion. Although they may be unique to PRC-005-2, some or all of them may be used in future standards, some already may be used in existing standards, and may or may not be deliberately defined. Consistency must be maintained, not only for administrative purposes, but for effective technical communications as well. 6. What is the definition of "Maintenance" as used in the table column "Maximum Maintenance Interval"? Maintenance can range from cleaning a relay cover to a full calibration of a relay. 7. A control circuit is not a component, it is made up of components. 8. Sub-requirement 1.5 needs to be clarified. It is not clear what "Identify calibration tolerances or other equivalent parameters..." means, and may be subject to different interpretations by entities and compliance enforcement personnel. 9. In the Implementation plan for Requirement R1, recommend changing "six" to fifteen. This change would restore the 3-month time difference that existed in the previous draft, between the durations of the implementation periods for jurisdictions that do and do not require regulatory approval. It will ensure equity for those entities located in jurisdictions that do not require regulatory approval, as is the case in Ontario. 10. The 'box' for "Monitored Station dc supply..." in Table 1-4 is not clear. It seems to continue to the next page to a new box. There are multiple activities without clear delineation.

Response: Thank you for your comments.

1. **The intervals and activities specified are believed by the SDT to be technically effective, in a fashion that may be consistently monitored for**

Organization	Yes or No	Question 5 Comment
compliance. Further, FERC Order 693 directs NERC to establish maximum allowable intervals, which implies that minimum activities also need be prescribed. If an entities' experience is that components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option. **2. The SDT concentrated their efforts on protective relays which use the entire group of component types within the Protection System definition. Also, there is currently no technical basis for the maintenance of the devices which respond to non-electrical quantities on which to base mandatory standards related either to activities or intervals. Absent such a technical basis, we are currently unable to establish mandatory requirements, but may do so in the future if such a technical basis becomes available.** **3. According to Table 1-5, trip coils of interrupting devices must be verified to operate every 6 years, rather than the 12-year interval. You are free to maintain these devices more frequently if you desire.** **4. With respect to dc supply associated only with communications systems, we prescribe, within Table 1-2, that the communications system must be verified as functional every 3 months, unless the functionality is verified by monitoring. The specific station dc supply requirements (Table 1-4) do not apply to the dc supply associated only with communications systems. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity.** **5. The SDT has proposed these terms for use only within PRC-005-2 because we are concerned that other uses of these terms, either now or in the future, may not be consistent with the terms as used here. They are defined only for clarify within this standard. The SDT will confirm with NERC staff that this approach is acceptable.** **6. As used in the "Maximum Maintenance Interval" column title of the table, maintenance refers to whatever activities are specified in the Activities column. The term is capitalized in the column title in conformance with normal editorial practice as a title, rather than as a definition** **7. For purposes of this standard, the control circuit IS defined as one component type.** **8. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **9. In consideration of your comment, "six" has been modified to "twelve" in the Implementation Plan for Requirement R1, making it consistent with the remainder of the Implementation Plan.** **10. Table 1-4 has been further modified for clarity**		
Nebraska Public Power District	Yes	Definitions: 1. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was

Organization	Yes or No	Question 5 Comment
		directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "and proper operation of malfunctioning components is restored." from the first sentence of the PSMP definition. I believe that failure to do so exceeds the scope of the SAR. 2. The definition of a Countable Event should clearly state whether or not multiple conditions on a single component will count as a single Countable Event or as multiple Countable Events. For example, a single relay fails its undervoltage setting and its under frequency setting. Is this one Countable Event or two Countable Events? 3. Applicability Part 4.2.2:The ERO does not establish underfrequency load-shedding requirements. Those requirements will be established by Reliability Standard PRC-006-1 when it is approved by FERC. I recommend changing Accountability Part 4.2.2. to "...installed to provide last resort system preservation measures." (Note this wording is consistent with the Purpose of PRC-006-0.)Applicability Part 4.2.5.4 and 4.2.5.5: 4. Station Service transformers provide energy to plant loads and not the BES. If these plant transformers are included, why not include the rest of the plant systems? I recommend deleting Applicability Part 4.2.5.4 and 4.2.5.5. 5. Requirement R1 Part 1.2: The wording of the first sentence is unclear about what information is required. For example, I could state in my PSMP that: "All Protection System component types are addressed through time-based, performance-based, or a combination of these maintenance methods" and be compliant with the Requirement. I recommend re-wording the first sentence to state: "Identify which maintenance method is used to address each Protection System component type. Options include time-based, performance-based (per PRC-005 Attachment A), or a combination of time-based and performance-based (per PRC-005 Attachment A)." Note that PRC-005 Attachment A does not address a combination of maintenance methods and therefore the second reference in the first sentence should be removed if the original wording is retained. 6. Requirement R1 Part 1.4: The column titles in Tables 1-1 through 1-5 have been revised to “Component Attributes” and “Activities”. I recommend changing "monitoring attributes" to "component attributes" and "maintenance activities" to "activities" to be consistent with the Tables. 7. Requirement R1 Part 1.5: Maintenance acceptance criteria for a given Protection System component type may very depending on the manufacturer, model, etc.. Including all acceptance criteria in the PSMP

Organization	Yes or No	Question 5 Comment
		document will over-complicate the program document. I recommend clarifying Part 1.5 to allow the incorporation of device-specific acceptance criteria in the applicable evidentiary documentation. One possible option is to add a second sentence as follows: "The calibration tolerances or other equivalent parameters may be included with the maintenance records." Note that a personal preference would be to use the phrase “acceptance criteria” instead of “calibration tolerances or other equivalent parameters”. 8. Requirement R4:The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words "including identification of the resolution of all maintenance correctable issues" from the first sentence of the Requirement. I believe that failure to do so exceeds the scope of the SAR. 9. Requirement R4 Part 4.2: What is considered sufficient verification of parameters? Does this require an engineer or technician signature or simply an indication of pass/fail? The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend re-wording Requirement 4, Part 4.2 to state: "Verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities." I believe that failure to do so exceeds the scope of the SAR. 10. Measurement M2: Can a single specification document suffice for similar relay types such as one document for SEL relays? For trip circuit monitoring can a standard document be used for a group of

Organization	Yes or No	Question 5 Comment
		similar schemes ? 11. Measurement M4:I assume this is not an all inclusive list of potential forms of evidence. Please clarify what is meant by "such as". Does this mean that: 1) Any one item is sufficient?; 2) Certain combinations of evidence are necessary? If so, what combinations?; 3) Are other items that are not identified here acceptable? 12. Measurement M4 repeatedly refers to "dated" evidence. However, current audit expectations include either performer signatures or initials on the evidence in addition to the dates. Please revise Measurement M4 to clearly state the expectations regarding performer signatures or initials on the evidence documents. 13. The PSMP definition inappropriately extends the maintenance program to include corrective maintenance. The first bullet of the Detailed Description section of the SAR specifically states: "Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The comment in the SAR was directed toward the Purpose of PRC-017 since it is the only one of the applicable PRC standards that included corrective measures in its Purpose. However, the concept of not including corrective maintenance in a maintenance standard should apply to all of the applicable PRC standards. The same statement from the SAR identified above was also included in the NERC SPCTF Assessment of Standards referenced in the SAR. Neither the SAR nor the NERC SPCTF Assessment of the Standards identified the need to expand the maintenance and testing program to include corrective maintenance. I recommend deleting the words: "and initiated resolution of identified maintenance correctable issues" from the last sentence of Measurement M4. I believe that failure to do so exceeds the scope of the SAR 14. .Compliance Part 1.3: Tables 1-1 through 1-5 refers to time-based maintenance programs. I recommend changing "performance-based" to "time-based" in the last sentence of the third paragraph. 15. The last paragraph of Part 1.3 of the Compliance Section states: "The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records." This appears to be a requirement of the Compliance Enforcement Authority however they are not identified in Section 4 Applicability of the Standard. It is also in conflict with the SAR Attachment B - Reliability Standard Review Guidelines which states on page SAR-10: "Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity." I recommend deleting the last paragraph of Part 1.3 of the Compliance Section to avoid conflict with the SAR. 16. Table 1-1: The Activity of row 1 states: “Verify operation of the relay inputs and outputs that are essential to ...” Please clarify what is meant by “operation of” the relay inputs and outputs. What is the criteria to determine if something is “essential”? The first line of row 2 has a double colon. Please delete one of

Organization	Yes or No	Question 5 Comment
		them. 17. For the second bullet of row 2 column 1, please clarify what is meant by the last part of this sentence "that are also performing self monitoring and alarming" and how it relates to the voltage and current sampling required. It appears the self monitoring is required in the first bullet. 18. For the first bullet of row 2 column 3, many relay settings may not be essential to the protective function of the relay. I recommend revising the first bullet to: “Settings that are essential to the proper function of the protection system are as specified.” 19. The format of the Activities column for all three rows is different. Please reformat them to be consistent. My preference is the second row. 20. Table 1-2: Row 1 Column 2, verifying the functionality of communications systems on a 3 calendar months basis is excessive and unnecessary. Suggest changing the Maximum Maintenance Interval to either 6 calendar months or semi-annual. 21. Row 2 Column 1, please provide examples of typical communications systems that fit into this category, e.g. Mirror Bit or Guard systems? 22. The words “such as” are used repeatedly. Please clarify what is meant by "such as". Is this left up to the Utility to define in their PSMP? 23. Table 1-5: The Activity for row 1 requires verification that each trip coil is able to operate the device. If a control circuitry contains multiple trip coils, it is not always possible to determine which trip coil energized to trip the device. I recommend changing "each trip coil" to "at least one trip coil". 24. Please clarify what is meant by an "Electromechanical trip" device in row 3. 25. Row 3 column 3, does this mean verify the trip contact on the device operates properly but not verify the trip circuit wiring from this contact to the trip coil since the trip circuit is tested in the row below? It is difficult to separate the meaning in these two rows. 26. Row 4 column 3 requires verification of all paths of the control and trip circuits. Please clarify if this includes the control circuitry of Protection Systems located at the other end of a line if the device utilizes a remote trip scheme?

Response: Response: Thank you for your comments.

1. **Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.**

Organization	Yes or No	Question 5 Comment

2. The example cited would be one countable event. The definition has been modified to clarify.
3. Underfrequency load shedding requirements, whether established by Regional Entities (current practice) or by NERC, are ERO requirements.
4. Clause 4.2.5.5 has been removed. Generator-connected station service transformers are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.
5. Requirement R1, Part 1.2 has been modified essentially as you suggest.
6. "Monitoring attributes" are used within the respective tables; "Component attributes" can include monitoring or not. The Tables have been revised to specify "Maintenance Activities".
7. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.
8. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.
9. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.
10. Yes. However, the degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. The Measure has been modified to clarify this point. The Measure M2 to which you refer has been deleted in conjunction with the deletion of the accompanying requirement.
11. Yes. The SDT has provided examples of the sort of evidence that may serve to demonstrate compliance. The degree to which any single evidence type is sufficient is dependent on the completeness of the evidence itself. "Such as" was not intended to be an all-inclusive list; additional examples are provided in Section 15.7 of the Supplementary Reference Document. The Measure has been modified to clarify this point.
12. Signatures, initials, etc, may not apply to all forms of evidence. "Dated" is more universal.
13. Corrective maintenance is included within PRC-005-2 only in that the initiation of resolution of maintenance-correctable issues (discovered during maintenance activities) is included. The SDT considers this inclusion to be appropriate and necessary as part of the maintenance program.
14. The portion of "Compliance" that referred to the Tables has been deleted.
15. The text to which you refer is part of the standard language for NERC Standards and reflects a general responsibility of the Compliance Enforcement Authority. The Compliance Enforcement Authority does not need to be indentified as an Applicable Entity.
16. If proper operation of an input or output is required such that the Protection System operate properly, it is "essential". "Verify operation …" means

Organization	Yes or No	Question 5 Comment
to determine that the component functions properly. The typo has been corrected. **17. The text to which you refer has been deleted in consideration of your comment.** **18. The SDT disagrees; settings beyond those "essential for proper function of the relay" may be essential to proper functioning of the monitoring, etc, which is used to extend the maximum maintenance interval of the relay.** **19. The SDT has arranged the format of each of the cells within the Maintenance Activities column for the best clarity within each individual cell.** **20. The SDT believes that the 3-month interval is proper for unmonitored communications systems.** **21. Examples such as you suggest may violate the NERC Anti-Trust Guidelines by appearing to favor specific proprietary technologies. Some examples may be found in Section 15.5 of the Supplementary Reference Document.** **22. "Such as" refers to examples pertinent to various equipment technologies, and thus are equipment-dependent, as opposed to entity-selectable. Some examples may be found in Section 15.5 of the Supplementary Reference Document.** **23. The SDT believes that each individual trip coil needs to be verified as required within PRC-005-2.** **24. "Electromechanical" refers to any device which has moving parts that respond to electrical signals, such as lockout relays and auxiliary relays. This row in Table 1-5 has been modified.** **25. Yes. The verification of the entire control circuitry is performed according to the following row in the Table, on a less-frequent interval.** **26. The testing of the "remote trip scheme" seems best characterized as testing of a "Communications System". Accordingly, testing of the remote station control circuitry is an independent activity.**		
CenterPoint Energy	Yes	(a) CenterPoint Energy cannot support this proposed Standard. Any standard that requires a 35 page Supplementary Reference document and a 37 page FAQ - Practical Compliance and Implementation document, in addition to extensive tables in the Standard, is much too prescriptive and complex to be practically implemented. (b) CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would "fix" non-existent problems. To clarify this last point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. (c) CenterPoint Energy is very concerned that a large increase in the amount of documentation will be required in order to demonstrate compliance - with no resulting reliability benefit. CenterPoint Energy

Organization	Yes or No	Question 5 Comment
		believes this Standard could actually result in decreasing system reliability, as the Standard proposes excessive maintenance requirements. The following is included in the Supplementary Reference document (page 8): "Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it." System reliability can be even further reduced by the number of transmission line and autotransformer outages required to perform maintenance. (d) The following is included in the FAQ - Practical Compliance and Implementation document: "PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life." CenterPoint Energy believes some proposed requirements, such as wire checking a relay panel, do not conform to this statement. CenterPoint Energy's experience has been that panel wiring does not degrade with age and service and that problems with panel wiring, after thorough commissioning, is not a systemic issue.
Response: Response: Thank you for your comments. **a. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document.** **b. FERC Order 633 directed that NERC establish maximum maintenance intervals. Additionally, the SDT is directed to develop a measurable, effective continent-wide standard. Entities may continue their current practices as long as those practices meet the minimum requirements of this standard.** **c. FERC Order 633 directed that NERC establish maximum maintenance intervals. The documentation required should not expand dramatically from the documentation currently required to demonstrate compliance. An entity may minimize hands-on maintenance by utilizing monitoring to extend the intervals.** **d. The standard does not require "wire-checking", but instead generically specifies "verification" – however an entity chooses to do so.**		
American Transmission Company	Yes	ATC recognizes the substantial efforts that the SDT has made on PRC-005 and appreciate the SDT's modifications to this Standard based on previous comments made. ATC looks forward to continuing to have a positive influence on this process via the comment process, ballots and interaction with the SDT. ATC was very close to an affirmative vote on this Standard prior to the unanticipated changes that appeared in this most recent posting. These changes introduce a significant negative impact from ATC's perspective. Therefore, ATC is recommending a negative ballot in the hope that our concerns regarding R 1.5 and R 4.2 and other clarifications will be included with the standard The two items within the proposed Standard that we take exception to are not directly related to implementing FERC Order 693. Rather, it is the overly

Organization	Yes or No	Question 5 Comment
		prescriptive nature with respect to the "how" as outlined in the proposed Standard that ATC takes exception... To improve and find the proposed Standard acceptable, ATC would like to see the following modifications: 1. Change the text to require the actuation of a single trip coil (row 1 of table 1.5). This would satisfy the intent to exercise the mechanism on a regular schedule, given that the mechanism binding is a much more likely source of a coil failure. The balance of trip coils could then be tested as part of routine breaker maintenance. 2. Eliminate the additional requirements introduced by the addition of R1.5 and the associated modifications to R4.2. The additional documentation required for the range of each element is typically incorporated into the pass/fail mechanism of the existing test equipment (which is reflective of the manufacturer recommendations) used to conduct these tests. Therefore, requiring the assembly of this additional documentation from each entity would: a. Be duplicative and voluminous as it would require us to track thousands of additional data points due to the variability in element ranges by relay manufacturer, model number and vintage. b. Not add to the reliability of the system as this function is already being performed on a collective basis.
Response: Response: Thank you for your comments. **1. The SDT believes that each individual trip coil needs to be verified as required within PRC-005-2.** **2. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**		
Consumers Energy	Yes	1. Table 1-3 states, "are received by the protective relays". Does this require that the inputs to each individual relay must be checked, or is it sufficient to verify that acceptable signals are received at the relay panel, etc? 2. Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. If the changes to the BES definition (per the FERC Order) causes system elements such as 138 kV connected distribution transformers to be considered as BES, these components can not be removed from service for maintenance without outaging customers. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers. 3. For the component types addressed in Tables 1-3 and 1-5, the requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete.

Organization	Yes or No	Question 5 Comment
		The Implementation Plan for R1 and R4 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar years for R1 and 12 calendar years after that for R4. 4. As for the interval in Table 1-4 regarding the battery terminal connection resistance, we believe that an 18-month interval is excessively frequent for this activity, and suggest that it be moved to the 6-calendar-year interval. 5. In Table 1-4, we currently re-torque all of the battery terminal connections every 4-years, rather than measuring the terminal connection resistance to determine if the connections are sound. Disregarding the interval, would this activity satisfy the “verify the battery terminal connection resistance” activity?
Response: Response: Thank you for your comments. **1. The SDT intends that the voltage and current signals properly reach each individual relay, but there may be several methods of accomplishing this activity.** **2. This concern seems more properly to be one to be addressed during the activities to develop the new BES definition, rather than within PRC-005-2.** **3. The Implementation Plan for Requirement R1 has been modified from 6 months to 12 months. The Standard has also been modified (Requirement R1, Part 1.1) to not specifically require identification of all individual Protection System components. The Implementation Plan for Requirement R4 has been revised to add one year to all established dates.** **4. IEEE 450, 1188, 1106 all recommend this activity at a 12-month interval. Please see Section 15.4.1 of the Supplementary Reference Document for a discussion of this activity.** **5. Re-torqueing the battery terminals would not meet this requirement.**		
Southern Company Generation	Yes	1. Please consider retaining the definitions stated to be moved to the NERC Glossary - they would be valuable to entities in the standard. 2. On Page 5, Section 1.2, please consider changing “or a combination of these maintenance methods (per PRC-005-Attachment A).” to “or a combination of these two maintenance methods.” 3. On Page 5, Section 1.5: recommend deleting this section - the subjectivity of what is an acceptable value for component testing makes this requirement un-valuable. 4. On Page 5, Section 4.2, it is recommended that the requirement be the following: Either verify that the component performance is acceptable at the conclusion of the maintenance activities or initiate resolution of any identified maintenance correctable issue.

Organization	Yes or No	Question 5 Comment
		5. On Page 5, Measure M1, replace 1.5 with 1.4 (after eliminating Requirement 1.5) 6. On Page 6, Section 1.3, replace the existing Data Retention text with the following: The TO, GO, and DP shall each retain documentation for the longer of the these time periods: 1) the two most recent performances of each distinct maintenance activity for the Protection System component, or (2) all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date. The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records. 7. On Page 10, Section F, please correct the revision information for the documents listed. 8. On Pages 14 & 15, Table 1-4, move the bottom row to the next page so that it is easier to see that the maintenance activities are an “either/or” option. 9. On Page 17, Table 1-5, it seems that the 12 calendar year interval activities would automatically be included in the 6 calendar year activity for verifying the electrical operation of electromechanical trip and auxiliary devices. Is the 12 year requirement superfluous? 10. On Page 19, Attachment A, it is recommended to delete the footnote #1 since the definition is given already on Page 2.

Response: Response: Thank you for your comments.

1. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
2. **Requirement R1, Part 1.2 has been modified.**
3. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
4. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
5. **Measure M1 has been modified as you suggest.**
6. **The Data Retention section has been modified essentially as you suggest.**

Organization	Yes or No	Question 5 Comment
7. The Reference information has been corrected. 8. Table 1-4 has been revised. 9. The 12-year interval activities are more extensive than the 6-year interval activities. 10. Footnote #1 has been removed.		
US Bureau of Reclamation	Yes	1. The concept of including definitions in this standard that are not a part of the Glossary of Terms will create a conflict with other standards that choose to use the term with a different meaning. This practice should be disallowed. If a definition is be introduced it should be added to the Glossary of Terms. This concept was not provided to industry for comment when the modifications to the Definition of Protection System were introduced. Additional related to this practice are included later on. 2. The Term "Protective Relays" is overly broad as it is not limited to those devices which are used to protect the BES. In the reference provided to the standard, the SDT defined "Protective Relays" as "These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. " The Definition for "Protective Relays" as well as the components associated with the them should be associated with the protection of the BES in the definition. 3. The Section 2.4 of the attached reference and the recent FERC NOPR are in conflict with the definition of "Protective Relays" which include lockout relays and transfer trip relays "The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. 4. This Draft 2: April3: November 17, 2010 Page 5 definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices." The definition should be revised to reflect that is really intended. The SDT as created an implied definition by specifically defining DC circuits associated with the trip function of a "Protective Relay" but failing to specifically define voltage and current sensing circuits providing inputs to "Protective Relays". The team clearly intended the circuits to be included but the definition does not since it only refers the "voltage and current sensing devices". 5. Starting with the Definitions and continuing through the end of the document, terms that have been defined are not capitalized. This leaves it ambiguous as to whether the defined term is to be applied or it is a generic reference. Only defined terms "Protection System Maintenance Program" and "Protection System" are consistently capitalized. 6. Protection System Maintenance Program (PSMP) definition: The Restore bullet should be revised to read

Organization	Yes or No	Question 5 Comment
		as follows: "Return malfunctioning components to proper operation by repair or calibration during performance of the initial on-site activity."Add the following at the end of the PSMP definition: "NOTE: Repair or replacement of malfunctioning Components that require follow-up action fall outside of the PSMP, and are considered Maintenance Correctable Issues." 7. Protection System (modification) definition: The term "protective functions" that is used herein should be changed to "protective relay functions" or what is meant by the phrase should become a defined term, as it is being used as if it is a well known well defined, and agreed upon term. The first bullet text should be revised to read as follows: "Protective relays that monitor BES electrical quantities and respond when those quantities exceed established parameters," the last two bullets should be reversed in order and modified to read as follows: o control circuitry associated with protective relay functions through the trip coil(s) of the circuit breakers or other interrupting devices, and o station dc supply (including station batteries, battery chargers, and non-battery-based dc supply) associated with the preceding four bullets. 8. Statement between the Protection System (modification) definition and the Maintenance Correctable Issue definition; Is this a NERC accepted practice? There does not appear to be a location in the standard for defining terms. Having terms that are not contained in the "Glossary of Terms used in NERC Reliability Standards," and are outside of the terms of the standards, and yet are necessary to understand the terms of the Requirements is not acceptable. They would become similar to the reference documents, and could be changed without notice. 9. Maintenance Correctable Issue definition: The last sentence should be modified to read as follows: "Therefore this issue requires follow-up corrective action which is outside the scope of the Protection System Maintenance Program and the Standard PRC-005-2 defined Maximum Maintenance Intervals." The definition could also be easily clarified to read "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration; therefore requires replacement." This ensures that any action to restore the equipment, short of replacement, is still considered maintenance. Otherwise ambiguity is introduced as what "maintenance" is. 10. Countable Event definition: An explanation should be made that this is a part of the technical justification for the ongoing use of a performance-based Protection System Maintenance Program for PRC-005. 11. Insert the phrase "Standard PRC-005-2" before the term "Tables 1-1..." 12. Applicability: 4.2. Facilities: 4.2.5.4 and 4.2.5.5: Delete these two parts of the applicability. Station service transformer protection systems are not designed to provide protection for the BES. Per PRC-005-2 Protection System Maintenance Draft Supplementary Reference, Nov. 17 2010, Section 2.3 - Applicability of New Protection System Maintenance Standards: "The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005: "...affecting the reliability of the Bulk

Organization	Yes or No	Question 5 Comment
		Electric System (BES)...”To the present language:”... and that are applied on, or are designed to provide protection for the BES.”The drafting team intends that this Standard will not apply to “merely possible” parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault.”Station Service transformer protection is designed to detect a fault on equipment internal to a power plant and not directly related to the BES. In addition, many Station Service protection ensures fail over to a second source in case of a problem. Thus station service transformer protection system is a power plant reliability issue and not a BES reliability issue. As such station service transformer protection should not be included in PRC 005 2.In addition; the SDT appears to have targeted generation station service without regard to transmission systems. If generating station service transformers are that important, then why are substation/switchyard station service transformers not also important? 13. B. Requirements Should the sub requirements have the "R" prefix? 14. R4.Change the phrase "... PSMP, including identification of the resolution of all ..." to read "...PSMP including identification, but not the resolution, of all ...". 15. General comment PRC005-2 is very specific in listing the maximum maintenance interval but is still very vague in listing the specific components to test. Suggest adding the following to the standard. a. A sample list of devices or systems that must be verified in a generator to meet the requirements of this Maintenance Standard: b. Examples of typical devices and relay systems that respond to electrical quantities and may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to: Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions Loss-of-field relays Volts-per-hertz relays Negative sequence overcurrent relays Over voltage and under voltage protection relays Stator-ground relays Communications-based protection systems such as transfer-trip systems Generator differential relays

Organization	Yes or No	Question 5 Comment
		Reverse power relays Frequency relays Out-of-step relays Inadvertent energization protection Breaker failure protection o lockout or tripping relays c. For generator step up transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program: Transformer differential relays o Neutral overcurrent relay Phase overcurrent relays 16. In the Lower, Moderate and Severe VSL descriptions, in addition to not being capitalized, the defined term Maintenance Correctable Issues should not be hyphenated. 17. In Attachment A Section 2 Page 51 should be modified as follows: 2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 until results of maintenance activities for the segment are available for a minimum of either 30 individual components of the segment or a significant statistical population of the individual components of a segment." Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number of components supports it. In Attachment A Section 5 Page 51 should be modified as follows: 5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population of the individual components of a segment maintained in the previous year. Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number components supports it. 18. In Attachment A Section 5 Page 52 should be modified as follows: 5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or a significant statistical population

Organization	Yes or No	Question 5 Comment
		of the individual components of a segment components maintained in the previous year. Without the modification the requirement unfairly target smaller entities. This will allow smaller entities to determine adjust its time based intervals if its experience with an appropriate number of components supports it.

Response: Thank you for your comments.

1. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
2. **"Protective relay" is defined by IEEE, and the SDT sees no need to either change the definition or to repeat the definition within PRC-005. Further, the applicability of generically-described protective relays is defined by the Applicability clause of PRC-005-2.**
3. **The issues raised by the FERC NOPR will be addressed as part of the response to the NOPR (and ultimately the Order). The extension to auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).**
4. **The extension to auxiliary and lockout relays is not part of the protective relay (addressed within Table 1-1), but instead as part of the control circuitry (Table 1-5).**
5. **Definitions from the NERC Glossary of Terms (or those intended for the Glossary) are consistently capitalized (Protection System and Protection System Maintenance Program fall within this category). As for terms defined only for use within this standard, these terms are NOT capitalized, since they are not in the Glossary of Terms.**
6. **The "restore" portion of PSMP specifically addresses returning malfunctioning components to proper operation. The requirements regarding maintenance correctable issues are further addressed within that definition (for use only within PRC-005-2).**
7. **The SDT is currently not planning on further modifying the most recent NERC BOT-approved definition of Protection System.**
8. **If the terms were placed in the Glossary of Terms, the SDT is concerned that some future SDT, in order to utilize these terms, may change them in a fashion inconsistent with the intended usage within PRC-005-2.**
9. **Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to repair/replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstrate completion of them.**
10. **Since this term is used only in Attachment A, it seems unnecessary to provide the explanation requested.**
11. **The SDT has elected not to change the reference to the Tables throughout the standard.**
12. **Applicability 4.2.5.5 has been removed. Generator-connected station service transformers (4.2.5.4) are essential to the continuing operation of the generating plant; therefore, protection on these system components is included within PRC-005-2 if the generation plant is a BES facility.**
13. **The current style guide for NERC Standards does not preface the subparts with an "R".**
14. **Identifying problems, but not fixing them, does not constitute an effective program. In deference to the time that may be necessary to**

Organization	Yes or No	Question 5 Comment
repair/replace defective components, the SDT has decided to require only initiation of resolution of maintenance correctable issues, not to demonstrate completion of them. 15. The various specific components you suggest are addressed within the Facilities portion of the Applicability 4.2.5, as well as other components that satisfy the attributes within 4.2.5. These examples are in the Supplementary Reference Document (Section 8.1.3). 16. Within the VSLs, the hyphenated term has been corrected. 17. The SDT has determined that 30 individual components is the minimum acceptable statistically-significant population for use to establish performance-based intervals. Multiple entities may aggregate component populations to establish this component population, provided that the programs are sufficiently similar to make the aggregation valid. See Supplementary Reference Document Section 9 for a discussion. 18. The SDT has determined that 30 individual components is the minimum acceptable statistically-significant population for use to establish performance-based intervals. Multiple entities may aggregate component populations to establish this component population, provided that the programs are sufficiently similar to make the aggregation valid. See Supplementary Reference Document Section 9 for a discussion.		
Alliant Energy	Yes	1. In the Purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. 2. In sections R1 and R4.2.1 delete “applied on” as unneeded and potentially confusing. The goal is to cover Protection Systems designed to protect the BES. 3. Alliant Energy believes that Article 1.4 needs to be deleted from the standard. It is redundant and serves no purpose. 4. Alliant Energy believes that Article 1.5 needs to be deleted from the standard. There is a major concern on what an “acceptable parameter” is and how it would be interpreted by the Regional Entities. 5. Section 4.2 Applicable Facilities: We are concerned with this paragraph being interpreted differently by the various regions and thereby causing a large increase in scope for Distribution Provider protection systems beyond the reach of UFLS or UVLS.4.2.1 Protection Systems applied on, or designed to provide protection for, the BES. The description is vague and open for different interpretations for what is “applied on” or “designed to provide protection”. According to the November 17, 2010 Draft Supplementary Reference page 4, the Standard will not apply to sub-transmission and distribution circuits, but will apply to any Protection System that is designed to detect a fault on the BES and take action in response to the fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional Entity interpretations of ‘protecting” the BES. Most distribution protection systems will not react to a fault on the BES, but are caught up in the interpretation due to tripping a breaker(s) on the BES. We request clarification that the examples listed below do not constitute components of a BES Protection

Organization	Yes or No	Question 5 Comment
		System: 1. Older distribution substations that lack a transformer high side interrupting device and therefore trip a transmission breaker or a portion of the transmission system or bus, or 2. Newer distribution substations that contain a transformer high side interrupting device but also incorporate breaker failure protection that will trip a transmission breaker or a portion of the transmission system or bus. 6. Since distribution provider systems are typically radial and do not contain the level of redundancy of transmission or generation protection systems, it is not cheap, safe, maintaining BES reliability, or easy to coordinate companies to test these protection systems to the level of PRC-005-2 draft recommendations. 7. Section F Supplementary Reference Documents: The references listed in this section refer to 2009 dates and do not match with the 2010 reference documents supplied for comment. 8. Table 1-4 Component Type Station dc Supply: a. "Any dc supply for a UFLS or UVLS system" - This should not have the same testing interval as control circuits, but should have a maximum maintenance period as other dc supplies do. b. Replace the words "perform as designed" on page 14 of Table 1-4 with "operate within defined tolerances."Table 1-5 Component Type Control Circuitry: c. This table allows for unmonitored trip coils for UFLS or UVLS breakers to have "no periodic maintenance". The PRC-005-2 Supplementary Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components. d. Alliant Energy is concerned that the addition of mandatory 86 and 94 auxiliary lockout relays (Electromechanical trip or Auxiliary devices) will force entire bus outages that will compromise the BES reliability more by forcing utilities across the US to unnecessarily take multiple non-faulted BES elements out of service. Such testing is also likely to introduce human error that will cause outages such as items outlined in the NERC lessons learned" and therefore such testing will result in more outages than actual failures. An equivalent non-destructive test needs to be identified to allow entities to sufficiently trace and test trip paths without taking multiple substation line outages to physically test a lockout or breaker failure scheme.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. **1. The "Purpose" is defined by the SAR.** **2. Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.** **3. The SDT instead elected to remove Requirement R2.** **4. The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.** **5. Applicability 4.2.1 has been revised to remove 'applied on". The SDT believes that this addresses your concern. Applicability 4.2.2 and 4.2.3, respectively, address UFLS and UVLS specifically, and are not related to 4.2.1. The Supplementary Reference Document has been revised to clarify. PRC-005-2 would appear to apply to both cited examples.** **6. This is properly a concern to be addressed within the current SDT that is developing a revised definition of Bulk Electric System.** **7. The date in Clause F of the standard related to the Supplementary Reference Document has been revised.** **8. a. The SDT disagrees. Station dc supply for UFLS/UFLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits.** **b. "Tolerances" does not fully describe the parameters for maintenance of station dc supply; "perform as designed" is far more inclusive.** **c. The SDT intends that tripping of the interrupting device for UFLS/UVLS is not required, but that the other portions of the dc control circuitry still shall be maintained. See Section 15.3 of the Supplementary Reference Document.** **d. The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals**		
LCRA Transmission Services Corporation	No	
MidAmerican Energy	Yes	1. MidAmerican remains concerned that including requirements for testing of electromechanical trip or auxiliary devices (Table 1-5 Row 3) will in some cases require entire bus outages that will compromise the BES reliability due to the need for entities across the US to take multiple BES elements out of service during the testing. If this requirement is retained additional time should be included in the implementation plan to allow for system modifications, such as the installation of relay test switches, to potentially allow

Organization	Yes or No	Question 5 Comment
		for this testing while minimizing testing outages. 2. Clarify that in the definition of Component Type that Transmission Owners are allowed the latitude to designate their own definitions for each of the Component Types, not just control circuits. 3. In the implementation schedule time periods are provided within which compliance deadlines and percentages of compliance are given. The following clarifications are recommended: 1. In calculating percentage of compliance for purposes of demonstrating progress on the implementation plan the percentages are calculated based on the total population of the protection system components that an entity has that fit the component category and allowable interval. 2. To obtain compliance with the percentage completion requirements of the implementation schedule an entity needs to have completed at least one prescribed maintenance activity of that component type and interval. 4. In the purpose statement delete “affecting” and replace it with “protecting”. The purpose of the standard deals with systems that protect the BES. 5. In sections R1 and R4.2.1 delete “applied on or” as unneeded and potentially confusing. The goal is to cover protection systems designed to protect. 6. Clarify the meaning of “state of charge” on page 14 in Table 1-4. 7. In Table 1-4 Component Type Station dc Supply, “Any dc supply for a UFLS or UVLS system” should have the same maximum maintenance period as other dc supplies. 8. Table 1-5 Component Type Control Circuitry, the table allows for unmonitored trip coils for UFLS or UVLS breakers to have “no periodic maintenance”. The PRC-005-2 Supplementary Frequently Asked Question #7B and #7C give excellent reasoning for not requiring maintenance on the trip coil component due to the larger number of failures that would be required to have any substantial impact to the BES as well as the statement that distribution breakers are operated often on just fault clearing duty already. We believe that the unmonitored control circuitry has the same level of minimal BES impact and is also being tested each time the distribution breaker undergoes fault clearing duty. With this logic, we do not see why there would be different maintenance requirements for these two components.

Response: Thank you for your comments.

1. **The SDT believes that mechanical solenoid-operated devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.**

Organization	Yes or No	Question 5 Comment
2. For components other than control circuitry, the SDT believes that identification of the components as established within the draft Standard is appropriate. There is no latitude regarding component types. **3. The SDT believes that the Implementation Plan clearly agrees with your interpretation, and no clarification seems necessary.** **4. The "Purpose" is defined by the SAR.** **5. Requirement R1 and Requirement R4, Part 4.2.1 have been modified as you suggested.** **6. Table 1-4 has been revised to remove "state of charge" from the activities.** **7. The SDT disagrees. Station dc supply for UFLS/UVLS only is limited in its impact, and the SDT believes that using the same intervals as for the related control circuits is appropriate.** **8. For the control circuitry of UFLS/UVLS, the relatively frequent breaker operations may not be reflective of proper functioning for UFLS/UVLS function. Therefore, minimal maintenance activities are necessary for these cases.**		
Ameren	Yes	(1) We believe that R1.5 and R4.2 "Calibration tolerances or other equivalent parameters" requirements should be removed. Neither the Supplement nor the FAQ address the expectation for them. While we agree that tolerances are needed and used, they need not be specified as part of this standard. (2) The Data retention is too onerous (a) For those components with numerous cycles between on-site audits, retaining and providing evidence of the two most recent distinct maintenance performances and the date of the others should be sufficient. Additionally, we are subject to self-certification, spot audits and/or inquiries at any time between on-site audits as well. (b) For those components with cycles exceeding on-site audit interval, retaining and providing evidence of the most recent distinct maintenance performance and the date of the preceding one should be sufficient. Auditors will have reviewed the preceding maintenance record. Retaining these additional records consumes resources with no reliability gain. (3) Definition of the BES perimeter should be included in accordance with Project 2009-17 Interpretation. (a)Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. (4)System-connected station service transformers (4.2.5.5) should be omitted, because (a) Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load. Omit 4.2.5.5 from the standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. (b) system-connected station service transformers in the same table as well as from table-to-table can be overwhelming. This would help keep Regional Entities and System Owners from

Organization	Yes or No	Question 5 Comment
		making errors. (5) Retention of maintenance records for replaced equipment should be omitted. FAQ II 2B final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We disagree with this because the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. (6) Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. (7) PSMP Implement Date should commence at the beginning of a Calendar year. This is the most practical way to transition assets from our existing PRC-005-1 plans. (8) Please clarify the meaning of “state of charge” for batteries. Does this mean specific gravity testing or what? (9) Please clarify that instrument transformer itself is excluded. Please clarify that the instrument transformer itself is excluded. The standard indicates that only voltage and current signals need to be verified in Table 1-3, but the recently approved Protection System definition wording can be mis-interpreted to mean they are included. FAQ 11.3.A is helpful.

Response: Thank you for your comments.

1. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**
2. **In order that a Compliance Monitor can be assured of compliance, the SDT believes that the Compliance Monitor will need the data of the most recent performance of the maintenance, as well as the data of the preceding one to validate that entities have been in compliance since the last audit (or currently, since the beginning of mandatory compliance). The SDT has specified the data retention in the posted standard to establish this level of documentation. This seems to be consistent with the current practices of several Regional Entities.**
3. **When the interpretation (Project 2009-17) is approved, the SDT for PRC-005-2 will consider if the interpretation is appropriate for PRC-005-2 and**

Organization	Yes or No	Question 5 Comment
make associated changes. **4. In response to many comments, including yours, the SDT has removed 4.2.5.5 from the Applicability of the standard.** **5. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document. Your comments will be considered within that activity. The SDT believes that entities should retain the evidence necessary to demonstrate compliance for the entire period reflected within Data Retention, and the discussion within the Supplementary Reference Document suggests that this includes records of retired equipment.** **6. The SDT believes that the 3-month interval specified in the Standard is appropriate.** **7. The guidance provided to the SDT provides that the implementation dates should begin on the first day of a calendar quarter.** **8. Table 1-4 has been revised to remove "state of charge" from the activities.** **9. The SDT intends that the instrument transformer and associated circuitry be verified to be functional, but believes that customary apparatus maintenance (dielectric, infrared, etc) are not relevant to PRC-005-2. The SDT has decided to eliminate the FAQ and incorporate topics and discussion from the FAQ within the Supplementary Reference Document.**		
Xcel Energy	Yes	1. Requirement R1.4 in part requires that the entity's PSMP includes all monitoring attributes to include those specified in Tables 1-1 through 1-5. Requirement R2 requires that entities that use maintenance intervals for monitored Protection Systems shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5. The intent and differences between these 2 requirements is unclear. If an entity does not choose to use monitored intervals, it makes no sense to require them to include the monitoring attributes identified in Tables 1-1 through 1-5 within their PSMP. Furthermore if an entity fails to meet requirement R1.4 for including identified monitoring attributes in its program, it will by default also have violated R2. There seems the possibility of double jeopardy between R1.4 and R2. The intent of R2 is fairly obvious but the intent of including monitoring attributes in R1.4 is not evident. Please provide a discussion within the FAQ to better explain the differences between these two requirements as they relate to monitoring attributes. 2. As written, requirement R1.5 and application of R1.5 acceptance criteria via requirement R4.2 would open entities up to vague interpretations by compliance personnel as to what constitutes adequate acceptance criteria – particularly in the area of subjective inspection results – e.g., battery cell visual inspections. We recommend that R1.5 be re-stated to clarify that acceptance criteria need only be provided for numerically measurable parameters. FAQs should be written to better explain the intent of R1.5 and to provide examples of acceptance criteria and to hopefully drive consistency amongst compliance personnel interpretation of acceptance criteria requirements. Consideration should be given to identifying which maintenance requirements in the Tables would generate quantifiable and measurable test results for which acceptance

Organization	Yes or No	Question 5 Comment
		criteria would be expected.

Response: Thank you for your comments.

1. **The SDT had concluded that Requirement R2 is redundant with Requirement R1, Part 1.4, and has deleted R2 (together with the associated Measure and VSL).**
2. **The SDT has determined that the fundamental concerns of Requirement R1, Part 1.5 and the associated changes are addressed within the PSMP definition, and that Requirement R1, Part 1.5 is not necessary; therefore, it has been removed. Requirement R4 has also been re-drafted to address various related concerns noted within comments. The associated VSL has also been revised. Please see Supplementary Reference Document, Section 8 for a discussion of this.**

END OF REPORT

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010
6. Third posting of revised standard on November 17, 2010

Description of Current Draft:
This is the fourth draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and ballot.	April 8-May 7, 2011
2. Conduct successive ballot	April 28-May 7, 2011
3. Drafting Team Responds to Comments	May 11-June 11, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore – Return malfunctioning components to proper operation.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initial on-site activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – A component which has failed and requires repair or replacement, any condition discovered during the verification activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owners

   4.1.2 Generator Owners

   4.1.3 Distribution Providers

   4.2. Facilities:

   4.2.1 Protection Systems designed to provide protection for BES Element(s).

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

   4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

5. **(Proposed) Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

The PSMP shall:

1.1. Address all Protection System **component types.**

1.2. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a

> ***Component Type -*** *Any one of the five specific elements of the Protection System definition.*

combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5 and Table 2.

1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5 and Table 2.

Maintenance Correctable Issue - *Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initial on-site activity. Therefore this issue requires follow-up corrective action.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified **maintenance correctable issues**. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current or updated documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence that its current performance-based maintenance program is in accordance with Requirement R2, which may include but is not limited to equipment lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified Maintenance Correctable Issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For Requirement R2 and Requirement R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System **components**, or all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date, whichever is longer.

Component – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Failed to specify whether one component type is being addressed by time-based or performance-based maintenance. (Part 1.2)	Failed to specify whether two component types are being addressed by time-based or performance-based maintenance. (Part 1.2)	Failed to include station batteries in a time-based program (Part 1.2) OR Failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5. (Part 1.4)	Entity has not established a PSMP. OR The entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1) OR Failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance.
R2	Entity has Protection System elements in a performance-based PSMP but has: 1) Failed to reduce countable events to less than 4% within three years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment OR 3) Maintained a segment with 54-59 components or containing different manufacturers.	NA	Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years.	Entity has Protection System components in a performance-based PSMP but has: 1) Failed to establish the entire technical justification described within R3 for the initial use of the performance-based PSMP OR 2) Failed to reduce countable events to less than 4% within five years OR 3) Failed to annually document program activities, results, maintenance dates, or countable events for over 5% of components in any individual segment OR 4) Maintained a segment with less

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				than 54 components OR 5) Failed to: • Annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, • Annually analyze the program activities and results for each segment.
R3	Entity has failed to complete scheduled program on 5% or less of total Protection System components. OR Entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues.	Entity has failed to complete scheduled program on greater than 5%, but no more than 10% of total Protection System components OR Entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of identified maintenance correctable issues.	Entity has failed to complete scheduled program on greater than 10%, but no more than 15% of total Protection System components OR Entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of identified.	Entity has failed to complete scheduled program on greater than 15% of total Protection System components OR Entity has failed to initiate resolution on greater than 15% of identified maintenance correctable issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — February 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay **Note:** Table requirements apply to all components of Protection Systems except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming. • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics (see Table 2). • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems **Note:** Table requirements apply to all components of Protection Systems, except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	3 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays **Note:** Table requirements apply to all components of Protection Systems except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure.	No periodic maintenance specified	None.

Table 1-4(a) Component Type - Station dc Supply Using Vented Lead-Acid (VLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type - Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) Component Type - Station dc Supply Using Nickel-Cadmium (NiCad) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type - Station dc Supply Using Non Battery Based Energy Storage		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS, UVLS and SPS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type - Station dc Supply for Distribution Breakers		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any dc supply for tripping only distribution breakers as part of a UFLS or UVLS system, or SPS and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify: • Station dc supply voltage

Table 1-4(f) Exclusions for Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2)		No periodic verification of float voltage of battery charger is required
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with monitoring and alarming of internal Ohmic values of every cell (if available for measurement) or each unit and alarming when any cell/unit deviates by an unacceptable value from the baseline internal ohmic value. (See Table 2)		No periodic measurement and comparison to baseline of battery cell/unit internal ohmic values for VRLA batteries and VLA batteries where the cells are not visible are required. .

Table 1-5 **Component Type - Control Circuitry** **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored control circuitry associated with protective functions.	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of DETECTION to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	No periodic maintenance specified.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the verification activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.
5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010
6. Third posting of revised standard on ~~September 24~~November 17, 2010

Description of Current Draft:
This is the ~~third~~ fourth draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and ballot.	~~November 17–December 17, 2010~~1~~5~~- April 12~~5~~, 2011
2. Conduct successive ballot	~~December 7 – December 17, 2010~~May 2 – May 12, 2011
3. Drafting Team Responds to Comments	~~January 5, 2011–January 25~~ May 16 – June 3, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

Protection System (NERC Board of Trustees ~~modification~~Approved Definition)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initial on-site activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of ~~a segment~~a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, ~~such as~~including but not limited to a protective relay or current sensing device. ~~For components such as control circuits, t~~The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a “local zone of protection” basis. Thus, entities are allowed the latitude to designate their own definitions of “control circuit components.” Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – ~~Any failure of a~~A component which has failed ~~requires~~and requires repair or replacement, any condition discovered during the verification activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems ~~applied on, or~~ designed to provide protection for~~, the~~ BES Element(s).

~~4.2.1~~4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

~~4.2.2~~4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

~~4.2.3~~4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

~~4.2.4~~4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

~~4.2.4.1~~4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

~~4.2.4.2~~4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

~~4.2.4.3~~4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

~~4.2.4.4~~4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

~~**4.2.4.5** Protection Systems for system-connected station service transformers for generators that are part of the BES.~~

5. **(Proposed) Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems ~~applied on, or~~ designed to provide protection for~~, the~~ BES Element(s). The PSMP shall: *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

1.1. Address all Protection System component types.

1.2. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type~~s are addressed through time-based, performance-based (per PRC-005 Attachment A), or a combination of these maintenance methods (per PRC-005-Attachment A)~~. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5 and Table 2.

~~**1.4.**~~Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type~~, to include those~~ consistent with the maintenance intervals specified in Tables 1-1 through 1-5 and Table 2.

~~**1.5.** Identify calibration tolerances or other equivalent parameters for each Protection System component type that establish acceptable parameters for the conclusion of maintenance activities.~~

1.4. ~~Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems described in Tables 1-1 through 1-5, shall verify those components possess the monitoring attributes identified in Tables 1-1 through 1-5 in its PSMP. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*~~

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

~~**R3.**~~ Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues~~, including identification of the resolution of all maintenance correctable issues as follows:~~ . *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

~~**R4.** Perform the maintenance activities for all Protection System components according to the PSMP established in accordance with Requirement R1:~~

~~**R5.** For time-based maintenance programs, perform maintenance activities no less frequently than the maximum allowable intervals established in Tables 1-1 through 1-5.~~

~~**R6.** For performance-based maintenance programs, perform the maintenance activities no less frequently than the intervals established in Requirement R3.~~

~~**R7.**~~**R3.** ~~Either verify that the components are within the acceptable parameters established in accordance with Requirement R1, Part 1.5 at the conclusion of the maintenance activities, or initiate resolution of any identified maintenance correctable issues.~~

C. Measures

~~**M1.**~~ Each Transmission Owner, Generator Owner and Distribution Provider shall have a current or updated documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, ~~and~~ maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.~~5~~4.

M1. ~~Each Transmission Owner, Generator Owner, and Distribution Provider that uses maintenance intervals for monitored Protection Systems shall have evidence such as engineering drawings or manufacturer's information showing that the components possess the monitoring attributes identified in Tables 1-1 through 1-5, as required by Requirement R2.~~

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence which may include but not limited to ~~such as~~ equipment lists, dated maintenance records, and dated analysis records and results that its current performance-based maintenance program is in accordance with Requirement ~~R3~~R2.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence ~~such as~~which may include but not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders as evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified maintenance correctable issues in accordance with Requirement ~~R4~~R3.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

~~For R2, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep the evidence that proves the Protection System components possess the identified monitoring attributes as long as they are used to justify the intervals and activities associated with a performance-based maintenance program as identified within Tables 1-1 through 1-5.~~

For Requirement ~~R3~~ R2 and Requirement ~~R4~~R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components,~~-~~ or all performances of each distinct maintenance activity for the Protection System component since ~~or to~~ the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Failed to specify whether one component type is being addressed by time-based or performance-based maintenance. (~~Clause~~Part 1.2)	Failed to specify whether two component types are being addressed by time-based or performance-based maintenance. (~~Clause~~Part 1.2)	Failed to include station batteries in a time-based program (~~Clause~~Part 1.2) OR Failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5. (~~Clause~~Part 1.4) ~~OR~~ ~~Failed to establish calibration tolerance or equivalent parameters to determine if components are within acceptable parameters.~~	Entity has not established a PSMP. OR The entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (~~Clause~~Part 1.1) OR Failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance.
~~R2~~	~~Entity has Protection System components in a condition-based PSMP, but documentation to support the monitoring attributes used to determine relevant intervals is incomplete on no more than 5% of the Protection System components maintained according to Tables 1-1 through 1-5.~~	~~Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 5%, but 10% or less, of the Protection System components maintained according to Tables 1-1 through 1-5.~~	~~Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 10%, but 15% or less, of the Protection System components maintained according to Tables 1-1 through 1-5.~~	~~Entity has Protection System elements in a condition-based PSMP, but documentation to support monitoring attributes used to determine relevant intervals is incomplete on more than 15% of the Protection System components maintained according to Tables 1-1 through 1-5.~~

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following:~~:~~ • Internal self diagnosis and alarming. • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics ~~that are also performing self monitoring and alarming~~ (see Table 2). • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	3 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g ~~such as~~ signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g ~~such as~~ signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (~~e.g~~e.g. ~~such as~~ signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that ~~acceptable measurements of the~~ current and voltage ~~signals~~ signal values are ~~received by~~provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure.	No periodic maintenance specified	None.

~~Table 1-4~~ ~~Component Type - Station dc Supply~~ ~~**Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.~~		
~~**Component Attributes**~~	~~**Maximum Maintenance Interval**~~	~~**Activities**~~
~~Any dc supply for a UFLS or UVLS system.~~	~~When control circuits are verified~~	~~Verify dc supply voltage~~
~~Any unmonitored station dc supply not having the monitoring attributes of a category below. (excluding UFLS and UVLS)~~	~~3 Calendar Months~~	~~Verify:~~ • ~~Station dc supply voltage~~ ~~Inspect:~~ • ~~Electrolyte level (excluding valve-regulated lead acid batteries)~~ • ~~For unintentional grounds~~
	~~18 Calendar Months~~	~~Verify:~~ • ~~State of charge of the individual battery cells/units~~ • ~~Float voltage of battery charger~~ • ~~Battery continuity~~ • ~~Battery terminal connection resistance~~ • ~~Battery internal cell-to-cell or unit-to-unit connection resistance (where available to measure)~~ ~~Inspect:~~ • ~~Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible~~ • ~~Physical condition of battery rack~~ • ~~Condition of non-battery-based dc supply~~
~~Any unmonitored Station dc supply in which a battery is not used and not having the monitoring attributes of a category below. (excluding UFLS and UVLS)~~	~~6 Calendar Years~~	~~Verify that the dc supply can perform as designed when ac power from the grid is not present.~~
~~Unmonitored Station dc supply with Valve Regulated Lead-Acid (VRLA) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)~~	~~3 Calendar Months~~	~~Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.~~

~~Table 1-4~~ ~~Component Type - Station dc Supply~~ ~~Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.~~		
~~Component Attributes~~	~~Maximum Maintenance Interval~~	~~Activities~~
	~~or~~	
	~~3 Calendar Years~~	~~Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank.~~
~~Unmonitored Station dc supply with Vented Lead-Acid Batteries (VLA) that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)~~	~~18 Calendar Months~~	~~Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.~~
	~~or~~	
	~~6 Calendar Years~~	~~Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.~~
~~Unmonitored Station dc supply with Nickel-Cadmium (Ni-Cad) batteries that does not have the monitoring attributes of a category below. (excluding UFLS and UVLS)~~	~~6 Calendar Years~~	~~Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.~~
~~Monitored Station dc supply (excluding UFLS and UVLS) with:~~ ~~Monitor and alarm for variations from defined levels (See Table 2):~~ • ~~Station dc supply voltage (voltage of battery charger)~~ • ~~State of charge of the individual battery cell/units~~ • ~~Battery continuity of station battery~~ • ~~Cell-to-cell (if available) and battery terminal resistance~~	~~18 calendar months~~	~~Inspect:~~ • ~~Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible~~ • ~~Physical condition of battery rack~~ • ~~Condition of non-battery-based dc supply~~

~~Component Attributes~~	~~Maximum Maintenance Interval~~	~~Activities~~
• ~~Electrolyte level of all cells in a station battery~~ • ~~Unintentional dc grounds~~ • ~~Cell/unit internal ohmic values of station battery~~	~~6 calendar years~~	~~Verify that the monitoring devices are calibrated (where necessary)~~
~~Continuously monitored Station dc supply (excludes UFLS and UVLS) with preceding row attributes and the following:~~ • ~~The monitoring devices themselves are monitored.~~	~~18 calendar months~~	~~Inspect:~~ • ~~Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible~~ • ~~Physical condition of battery rack~~ • ~~Condition of non-battery-based dc supply~~

Table 1-4(a) Component Type - Station dc Supply Using Vented Lead-Acid (VLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply with **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type - Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) Component Type - Station dc Supply Using Nickel-Cadmium (NiCad) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d)

Component Type - Station dc Supply Using Non Battery Based Energy Storage

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e)

Component Type - Station dc Supply for Distribution Breakers

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any dc supply for tripping only distribution breakers as part of a UFLS or UVLS system, or SPS and not having monitoring attributes of Table 1-4(f).	When control circuits are verified	Verify: • Station dc supply voltage~~Verify:~~ ~~dc supply voltage~~

Table 1-4(f)

Exclusions for Monitoring Devices and Systems

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)	No periodic maintenance specified ~~6 calendar years~~ ~~6 calendar years~~ ~~6 calendar years~~ ~~6 calendar years~~ ~~6 calendar years~~ ~~6 calendar years~~	No periodic verification of station ~~battery charger~~dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic ~~verification~~ inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic ~~verification~~ inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply.~~Any battery based station dc supply with monitoring and alarming of the state of charge of the battery system (See Table 2)~~		No periodic verification of float voltage of battery charger is required~~No periodic verification of the battery state of charge is required.~~
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)		No periodic verification of the battery ~~string~~ continuity is required.
Any battery based station dc supply with monitoring and alarming of the ~~Cell-to-~~intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the ~~cell-to-~~intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with monitoring and alarming of internal Ohmic values of every cell (if available for measurement) or each unit and alarming when any cell/unit deviates by an unacceptable value from the baseline internal ohmic value. (See Table 2)		No periodic measurement and comparison to baseline of battery cell/unit internal ohmic values for VRLA batteries and VLA batteries where the cells are not visible are required. ~~verification of each cell or unit's Ohmic resistance is required~~.

Table 1-5 Component Type - Control Circuitry **Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical ~~trip or~~ lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored ~~Control~~ control circuitry associated with protective functions.	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location ~~of~~ where corrective action can be initiated, and not having all the attributes of the ~~category~~ "Alarm Path with monitoring" category below. Alarms are ~~automatically~~ reported within 24 hours of DETECTION to a location where corrective action can be ~~taken~~initiated.	~~When alarm producing device or system is verified~~12 Calendar Years	Verify that the alarm path conveys alarm signals ~~are conveyed~~ to a location where corrective action can be ~~taken~~initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be ~~taken~~initiated.	No periodic maintenance specified	No periodic maintenance specified~~None~~.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum segment population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events~~[1]~~ for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.
5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

~~[1] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.~~

Implementation Plan for PRC-005-02

Standards Involved:

- Approval:
  - PRC-005-2 – Protection System Maintenance and Testing

- Retirements:
  - PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing
  - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding
  - Equipment Maintenance Program
  - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
  - PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of “Protection System”

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.
4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within 12 months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.
5. The Implementation Schedule set forth in this document further requires implementation of the revised Protection System Maintenance Program in roughly equally-distributed steps over the maintenance intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the Protection System components identified in PRC-005-2 Tables 1-1 through 1-5) until that Transmission Owner, Generator Owner or Distribution

Provider meets initial compliance for maintenance of the same Protection System component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is still being addressed under PRC-005-1 or is being performed according toPRC-005-2.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:
The existing Standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2.

Implementation Plan for Definition:
Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 and R3 which use this defined term.

Implementation plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.

Implementation plan for Requirements R2 and R3:

1. For Protection System components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 15 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 15 months following Board of Trustees adoption.

2. For Protection System components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 3 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 3 calendar years following Board of Trustees adoption.

3. For Protection System components with maximum allowable intervals of 3 years, as established in Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval (or, for generating plants with

scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 3 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 3 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.

4. For Protection System components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 calendar years following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 3 calendar years following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 5 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 5 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 7 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 7 calendar years following Board of Trustees adoption.

5. For Protection System components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5 and Table 2:
   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 5 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 5 calendar years following Board of Trustees adoption.
   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 9 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 9 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 13 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 13 calendar years following Board of Trustees adoption.

Applicability:

This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

a. The entity shall be at least 30% compliant on the first day of the first calendar quarter ~~2~~ 3 calendar years following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~2~~ 3 calendar years following Board of Trustees adoption.

b. The entity shall be at least 60% compliant on the first day of the first calendar quarter ~~4~~ 5 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~4~~ 5 calendar years following Board of Trustees adoption.

c. The entity shall be 100% compliant on the first day of the first calendar quarter ~~6~~ 7 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~6~~ 7 calendar years following Board of Trustees adoption.

~~4.~~5. For Protection System ~~Components~~ components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5 and Table 2:

a. The entity shall be at least 30% compliant on the first day of the first calendar quarter ~~4~~ 5 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~4~~ 5 calendar years following Board of Trustees adoption.

b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following ~~8~~ 9 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~8~~ 9 calendar years following Board of Trustees adoption.

c. The entity shall be 100% compliant on the first day of the first calendar quarter ~~12~~ 13 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~12~~ 13 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Unofficial Comment Form for 4th Draft of PRC-005-2 – Protection System Maintenance [Project 2007-17]

Please **DO NOT** use this form to submit comments on the 4th draft of the standard for Protection System Maintenance and Testing. Comments must be submitted by **May 12, 2011**. If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:

The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) has made substantial changes to the fourth posting of PRC-005-2 based on comments received from industry. The changes include:

- Removal of the requirements from the previous draft that addressed calibration tolerances (R1 part 1.5, R4 part 4.2, and the related Measures and VSLs)
- Removed Requirement R2 (which was redundant to Requirement R1 Part 4) and the related Measure and VSL.
- Removed system-connected station auxiliary transformers from the Applicability of the Standard (4.2.5.5)
- Restructured and revised Table 1-4 addressing station dc supply, including removal of requirements relating to "state of charge".
- Removed the FAQ and incorporated the topics within the Supplementary Reference Document
- Revised the Implementation Plan

The PSMT SDT would like to receive industry comments on this standard.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. The SDT has restructured the Table for Station DC Supply, separating it into six sub-tables individually addressing the various different technologies. Do you agree that the restructured tables provide more clarity? If not, please provide specific suggestions for improvement.

   ☐ Yes
   ☐ No
   Comments:

2. The SDT has modified the Implementation Periods within the Implementation Plan.. Do you agree with the changes? If not, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

3. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

4. The SDT has incorporated the FAQ document into the "Supplementary Reference" document and has provided the combined document as support for the Requirements within the standard. Do you have any specific suggestions for further improvements?

☐ Yes

☐ No

Comments:

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

PRC-005-2 Protection System Maintenance

Supplementary Reference & FAQ

Draft

to ensure the reliability of the bulk power system

April 12, 2011

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

116-390 Village Blvd., Princeton, NJ 08540

www.nerc.com

Table of Contents

This supplementary reference to PRC-005-2 is not mandatory and enforceable.

1. Introduction and Summary

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*… and that are designed to provide protection for the BES.*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to relays for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution

Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?
BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 16, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse.
This Standard is not applicable to this UVLS.

We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. As stated in Requirement R1, this Standard covers protective relays that use measurements of electrical quantities to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?
This Standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an Auxiliary Tripping Relay?
No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?
You must conduct a test(s) to verify the integrity of the trip circuit. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

The Standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?
An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a Lock-out Relay?
A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?
PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.
The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R3 of the Standard does require that the entity "initiate resolution of any identified maintenance correctable issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electro-mechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be

detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – performance-based maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the “monitored-basis-time-intervals” existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

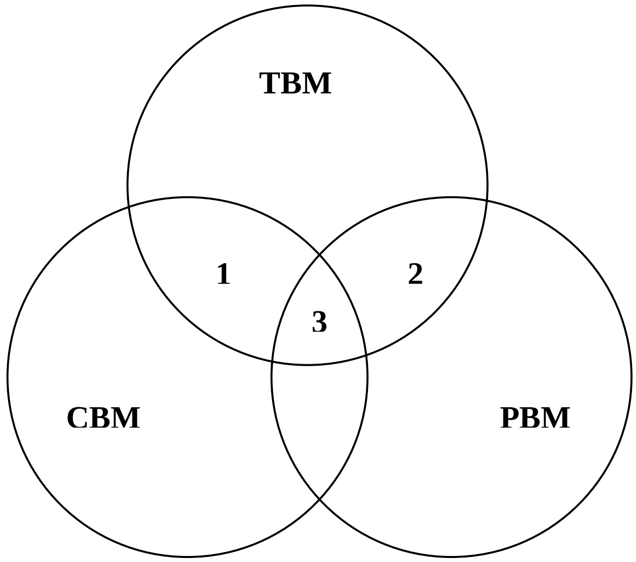
Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



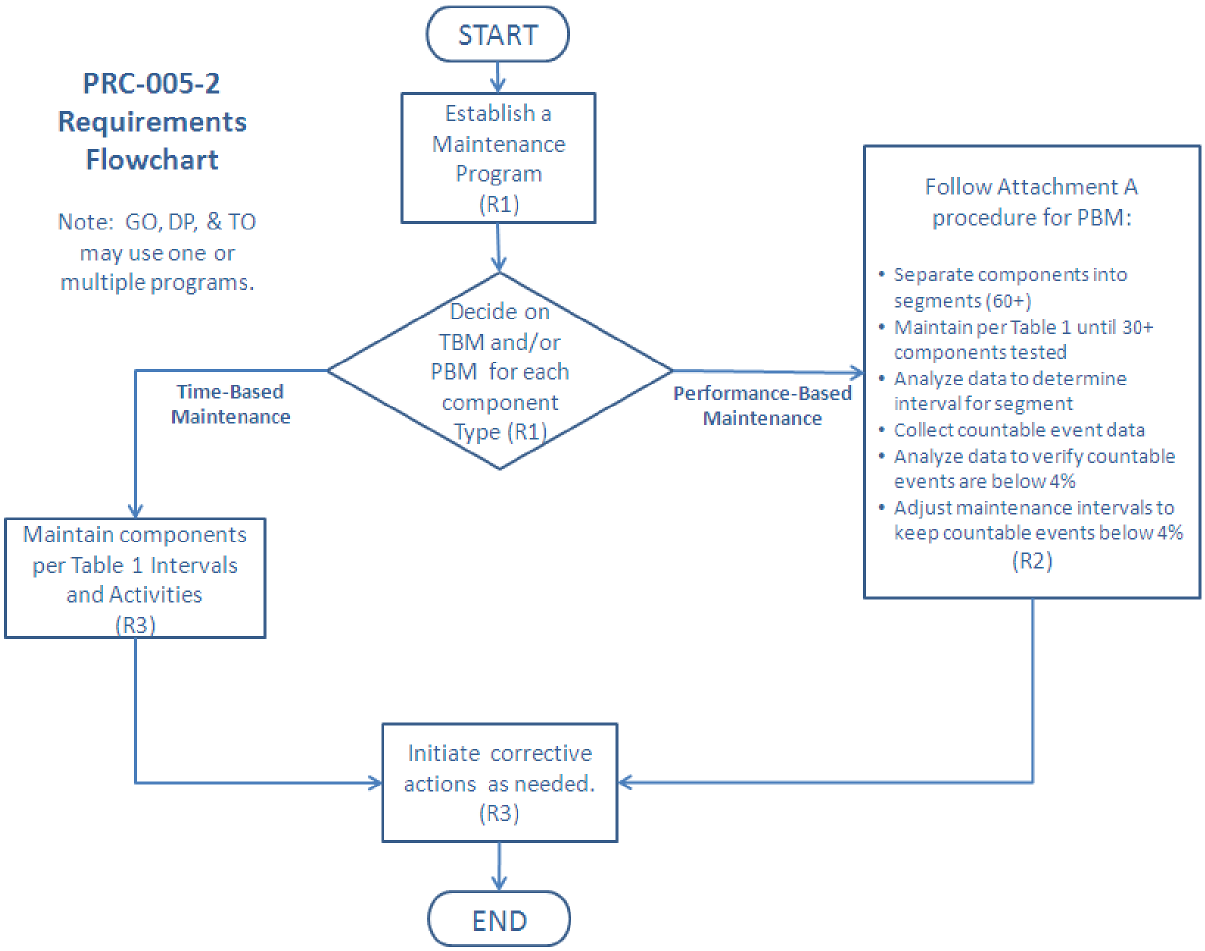
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and performance-based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, then R2 applies.

Please see the following diagram, which provides a "flow chart" of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?
This system is made up of components that are all unmonitored. Assuming a time-based protection system maintenance program schedule (as opposed to a performance-based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP …" if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?
Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1.4 of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?
No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

Please provide an example of the unmonitored versus other levels of monitoring available?
An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be un-monitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electro-mechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified

- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Instrumentation transformers
- Protection system component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all paths of the control and trip circuits

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Instrument transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

<u>Every 3 calendar months</u>, verify:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

<u>Every 18 calendar months</u>, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

<u>Every 6 calendar years</u>, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electro-mechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices
- Battery performance test (if ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Instrumentation transformers
- Protection system component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- Verify all paths of the control and trip circuits

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
- Instrument transformers, with monitoring, connected as inputs to that relay (monitored)
- Vented lead acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components shall have maximum activity intervals of:

Every 3 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

- Cell condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electro-mechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all paths of the control and trip circuits

Why do components have different maintenance activities and intervals if they are monitored?
The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?
No. For some components in a protection system, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?
The protective relay is monitored and can be maintained every 12 years or when a maintenance correctable issue arises. The control circuitry can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the Standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures. UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,

  - Table 1-2 is for the associated communications systems,
  - Table 1-3 is for current and voltage sensing devices,
  - Table 1-4 is for station dc supply and
  - Table 1-5 is for control circuits. There is an additional table,
  - Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.

- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance Activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires <u>more activities</u> then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities <u>more often</u> than the Tables maximum then you must perform and document those activities to your more stringent standard.
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity’s more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

8.1.2 Additional Notes for Tables 1-1 through 1-5

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.

4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can

be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed mostly towards microprocessor based relays.
For relay maintenance departments that choose to test microprocessor based relays in the same manner as electro-mechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration

verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?
Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0. These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?
Table 1 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?
No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?
As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?
Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?
Since components of the SPS, UFLS, or UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the

exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.

The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like Breaker Fail Initiation, Zone Timer Initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dcv to the input and verify that the relay registered the change of state.

Electro-mechanical Lock-out relays (86) and Auxiliary tripping relays (94) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or 94 that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

Other devices in the control circuitry that are used for other protective functions besides tripping (including, but not limited to, electro-mechanical Breaker Fail Initiation relays) need only be verified with the control circuitry every twelve years.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.
The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electro-mechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?
This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the “Calendar Year” language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 protection system components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred protection system components which would equate to two percent for application to the VSL Table for Requirement R3.

How do I achieve a "grace period" without being out of compliance?
For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007. the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years –

the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for “time-interval extensions” or “grace periods” to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. “Maximum time intervals” by their very term negates any “time-interval extension” or “grace periods”. To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electro-mechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was “…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…” The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity’s use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size
An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula
Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:
B = bound on the error of distribution (allowable error)

z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1 - \pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-based Program
One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-based Program
The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation
Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

When establishing a performance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing “86” Lock-Out Relays (LOR). “Entity A” has two types of LOR’s type “X” and type “Y”; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type “X” failures, but human error led to tripping a BES element 100 times; they find 100 type “Y” failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead “Entity A” to change time intervals. Type “X” LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type “Y” would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.

- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and, if you desire, "reset the clock" on everything you've done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring; resulting in the least amount of hands-on maintenance activity, of the battery used in a station dc supply cannot completely eliminate some periodic maintenance. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every protection system component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A performance-based maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?
The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following

a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection system component performs a Protection system function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R3 states (the entity must):

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues.

Also, when a failure occurs in a protection system, power system security maybe comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues..." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.
Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are maybe coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?
Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's protection system maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.

- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds

- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.

- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.

- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?
No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?
Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

Circuit breakers that participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements; however the circuitry must be tested at least once every 12 years. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a bus differential lock-out Relay. While many failures of these distributed system circuit breakers could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are electro-mechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?
Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?
Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?
Table 1-5 specifies that each breaker trip coil, auxiliary relay that carries trip current to a trip coil, and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?
Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,

- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?
The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

<u>Battery Charger</u> - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

<u>Station Battery</u> - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?
The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium), and the maintenance activity chosen.
For example, if you have a Valve Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?
Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment.

For all new installations of Valve Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VLRA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, all manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements.

Although the manufactures provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?
Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), valve-regulated lead-acid (VRLA), and nickel-cadmium (NiCd) batteries respectively discuss state of charge in great detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?
The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulphuric acid, is consumed and the concentration of the sulphuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?
High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum maintenance interval of table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for vented lead-acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for valve-regulated lead-acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to nickel-cadmium batteries also.

What conditions should be inspected for visible battery cells?
The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electro-chemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of table 1-4 by a Performance-based Maintenance Program (PBM) because of the electro-chemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of table 1-4.

Why consider the ability of the station battery to perform as designed?
Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were

designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries.
The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), valve-regulated lead-acid (VRLA), and nickel-cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?
The three IEEE standards (1188, 450, and 1106) for VRLA, vented lead-acid, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.
Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?
In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because to the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example to I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?
A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?
This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at

a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve Regulated Lead Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacture of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manufacture's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery the same ohmic measurement device must be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (maintenance, testing and replacement of VRLA batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, "depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guide lines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity" they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?
There are two required maintenance activities associated with verification of dc voltages in table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.

Why check for the electrolyte level?
In Vented Lead Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of table 1-4. Because the electrolyte level in Valve Regulated Lead Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in table 1-4 of the Standard for checking the electrolyte level.
Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?
There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve Regulated Lead-Acid (VRLA) batteries. The first similar activity for

VRLA batteries (table 1-4(b)) that has the same maximum maintenance interval is to “measure battery cell/unit internal ohmic values.” Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in table 1-4(b) is “verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.” This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to “Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.”

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the “capacity 6 month test” at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the “thermal runaway test” at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.
Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?
For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a

loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.

- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 3-month inspection of communications-assisted trip scheme equipment?

The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the

protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?
An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?
There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Question:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?
There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for

when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

15.7 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.7.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a

Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communicatio ns systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

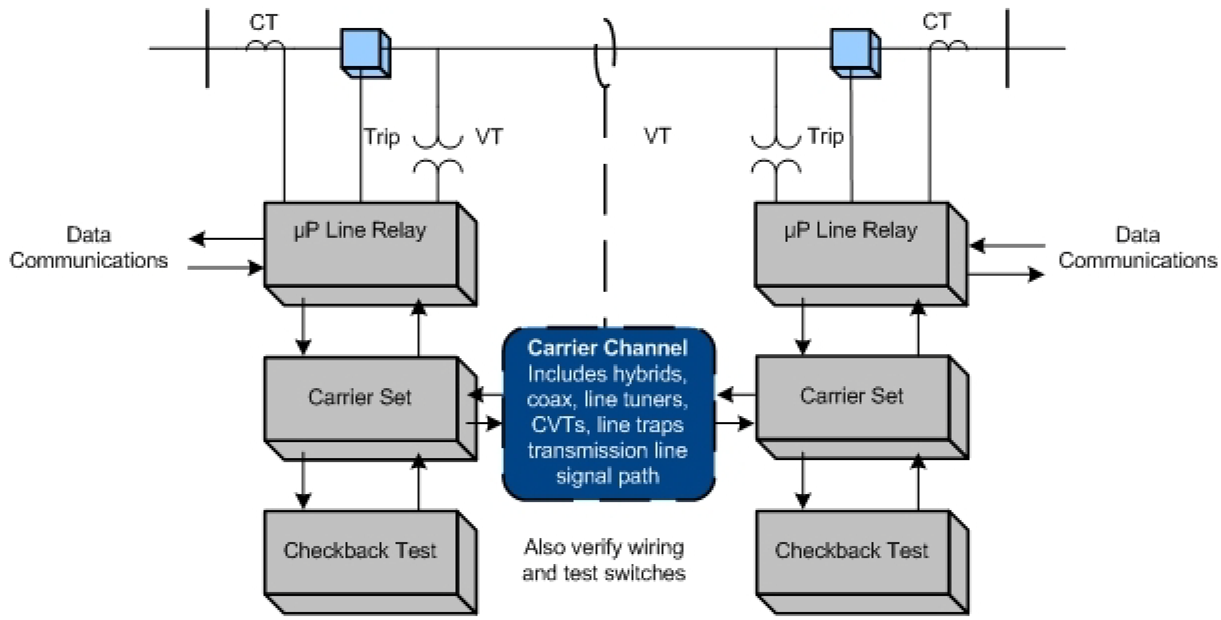
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

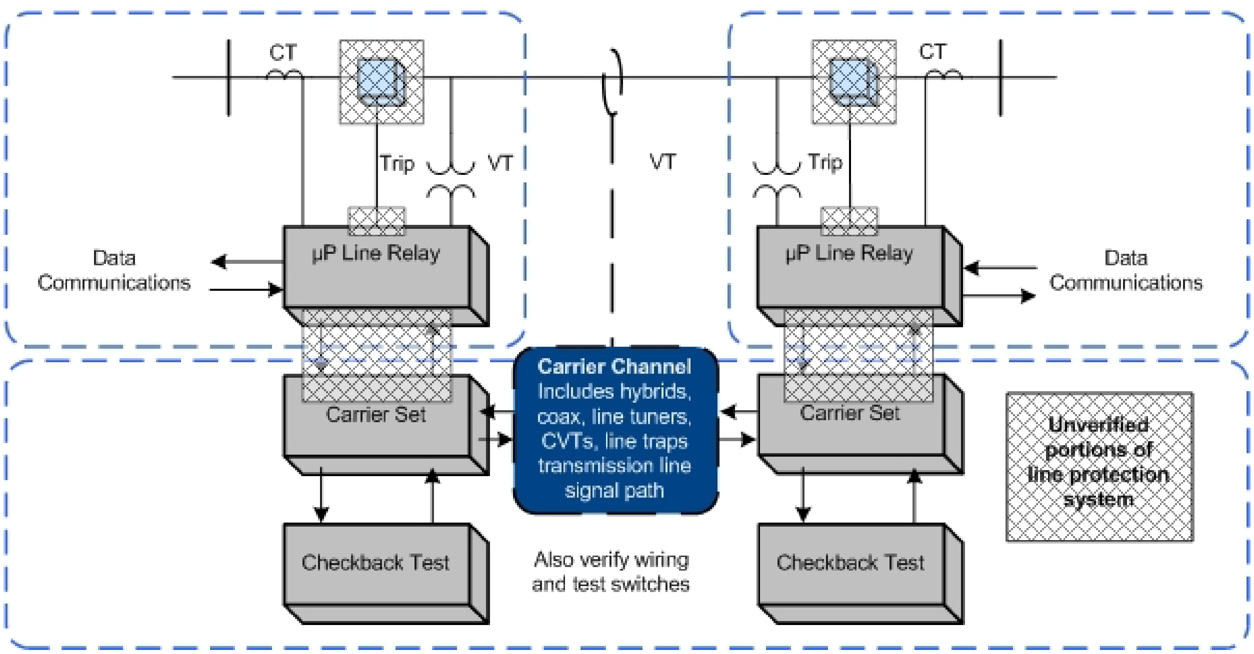
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the

relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Standards Announcement

Successive Ballot and Non-Binding Poll Now Open

May 3 – 12, 2011

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17: Protection System Maintenance and Testing

A successive ballot for the proposed standard, PRC-005-2 — Protection System Maintenance, and a concurrent, non-binding poll of the revised VRFs and VSLs are being conducted through **8:00 pm Eastern on Thursday, May 12, 2011**.

Instructions

All members of the ballot pool must cast a new ballot since the votes and comments from the last ballot will not be carried over. In addition, members of the ballot pool will need to cast a new opinion on the revised VRFs and VSLs. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Special Instructions for Submitting Comments With a Ballot

Comments submitted with ballots are extremely valuable to help the drafting team revise its work. In an effort to reduce the burden on stakeholders providing comments, the drafting team requests that all comments (both those submitted with a ballot and those submitted by stakeholders not balloting) be submitted through the electronic comment form posted at:
https://www.nerc.net/nercsurvey/Survey.asp?s=88fc1b48299643f2b8acd43c76dcc30f.

This will ensure that stakeholders only provide a single set of comments, but have an opportunity to notify the drafting team if they have provided comments.

During the successive ballot window, members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx . **When submitting a ballot with comments, simply record a "Comments submitted" in the comments field of the ballot to indicate that comments were submitted.**

Documents for this project, including an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a "redline" of proposed PRC-005-2 that shows the changes to the last balloted version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference at:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps

The drafting team will consider all comments and will determine whether to make additional changes to the standard and its implementation plan.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing
Successive Formal Comment Period Open
April 13 – May 12, 2011
Successive Ballot: May 3 – May 12, 2011

Now available at: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

The Protection System Maintenance and Testing drafting team has posted its consideration of comments (those submitted with a ballot, those submitted with a non-binding poll, and those submitted with a comment form), and revised PRC-005-2 and its associated implementation plan and VRFs and VSLs in response to feedback received in comments as well as a quality review. Clean and redline versions of PRC-005-2 — Protection System Maintenance, clean and redline versions of the associated implementation plan and VRFs and VSLs, and a revised technical reference document that combines the former supplemental reference and FAQ documents are posted for a 30-day formal comment period through **8:00 pm Eastern on Thursday, May 12th**.

Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net.

Documents for this project, including an off-line unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Note that PRC-005-2 reflects the merging of the following standards into a single standard, making it impractical to post a "redline" of proposed PRC-005-2 that shows the changes to the last balloted version of the standard.

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The last approved versions of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 have been posted on the project's web page for easy reference at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Next Steps – Successive Ballot and New, Non-binding Poll of VRFs and VSLs

A successive ballot of the revised standard and its associated implementation plan, and a new non-binding poll of the revised VRFs and VSLs will be conducted during the last 10 days of the comment period, beginning on Tuesday, May 3, 2011 through Friday, May 13, 2011.

Project Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing
Successive Ballot and Non-binding Poll Results

Now available at: https://standards.nerc.net/Ballots.aspx

A successive ballot on revisions to PRC-005-2 Protection System Maintenance concluded on May 13, 2011, and a concurrent non-binding poll of associated VRF and VSLs concluded on May 16, 2011. The non-binding poll was held open past the closing of the ballot to allow a quorum to be achieved.

Ballot Results for Revisions to PRC-005-2

Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 78.33 %
Approval: 67.00 %

Non-binding Poll Results for Associated VRF and VSLs

Of those who registered to participate, 75% provided an opinion or an abstention; 66% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Next Steps

The drafting team will consider all comments received during the formal comment period, ballot, and non-binding poll, and will determine whether to make additional changes to the standard and its implementation plan and associated VRFs and VSLs. If the team makes substantive changes to address issues raised in comments, an additional 30-day formal comment period will be conducted with a successive ballot during the last 10 days of the comment period. If the team makes only minor clarifying changes to address issues identified in comments, a recirculation ballot may be conducted.

Background:

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

NERC - EA & I
Recommend entities be explictly required to document the Relay Maintenance Program in one document. Many entities presently maintain their Protection Maintenace Program in several documents, such as one for relays, one for batteries, etc. This complicates compliance review and contributes to non-compliance since personnel in diffeernt departments writing these have different levels of understanding of NERC standards. Separate documents also allow inconsistencies to slip in. Recommend Requirement 1 to changed to the following to address this problem. "Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP), RECORDED AND UPDATED AS A SINGLE DOCUMNET for its Protection Systems designed to provide protection for BES Element(s). "

Apologies to the drafting team for submitting this with the ballot, repeated here to insure the comments are captured and addressed. While the SDT has done a very good job at responding to the most objectionable parts of the previous version, there are still a number of issues which makes the standard problematic. 1. The standard introduces the term "initiate resolution". This is an interpretable term, and has the potential for an auditor and an entity to disagree on an action. Would issuing a work order be considered "initiating resolution"? What if the WO had a completion date many years into the future? I would suggest adding the term to the list of definitions which will remain with the standard, and defining it as "preforming any task associated with conducting maintenance activities, including but not limited to issuing purchase orders, soliciting bids, scheduling tasks, issuing work requests, and performing studies". 2. Some clarity is needed to differentiate system connected and generator connected station service transformers. A statement that a station

service transformer connected radially to the generator bus is considered a system connected transformer if the transformer cannot be used for service unless connected to the BES. 3. The "bookends" issue, brought up in the prior round of comments, still exists. Although the SDT rightly notes a CAN has been issued regarding bookends, the CAN covers the documentation for system components that entities were required to self-certify to on June 18, 2007. PRC-005-2 adds additional components to the protection system scheme which were not part of that certification, and has the potential to put entities into violation space due to a lack of records for those components. The SDT should add to M3 a statement that entities may demonstrate compliance with the standard by demonstrating that required activities took place twice within the maximum maintenance interval - starting from the effective date of the standard - for all components not listed in PRC-005-1.

Suggest that to FAQ be added: 1. Regarding Table 2 in the standard, does a fail-safe “form b” contact that is alarmed to a 24/7 operation center qualify as an alarm path with monitoring? 2. Add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested as per Table 1.5.

Marie Knox
Yes
Yes, however, in the “Supplemental reference and FAQ” document on page 65 there are two areas of concern. Page 65, paragraph 4: “... the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.” While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of equipment will not change during this period. On Page 65, paragraph 6, it states: “... all manufacturers of internal ohmic measurement devices have established libraries of baseline values ...” We question the availability of baseline libraries for all manufacturers considering the variety and longevity of installations.
Yes
Yes
Yes
The additional documentation seems to be quite large, and the additional content seems to go far beyond what is necessary for the PRC-005-2 standard. We recommend the SDT lessen the amount of content provided in the “Supplementary Reference” document.
R3 speaks of a Maintenance Correctable Issue and implementing your Protection System Maintenance Program (PSMP). In the definition of Maintenance Correctable Issue, it states "...of the initial on-site activity". The intent seems to be that during any maintenance activity, and something is found not working properly, you should repair it. Some may look at the word "initial" as during the commissioning of a facility. We recommend the SDT delete the word "initial" to cause less confusion.

We recommend the SDT change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 19, Row 1, Column 3 to “Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years”. Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5, Row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). We recommend the SDT change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 19, Row 3, Column 2 to “12 calendar years”. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We recognize the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. Our remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that the SDT will consider these changes.

Electric Market Policy
Mike Garton
Yes
Yes
No
IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.

The document was valuable in understanding PRC-005-2 by providing clarification using practical protective relay system examples. Below are two comments for further improvement. 1. It would be beneficial if the document could provide additional information for relaying in the high-voltage switchyard (transmission owned) - power plant (generation owned) interface. While Figures 1 and 2 are typical generation and transmission relay diagrams, it would be helpful if protective relays typically used in the interface also be included. For example, a transmission bus differential would remove a generator from service by tripping the generator lockout. 2. Figures 1 and 2 refer to a “Figure 1 and 2 Legend” table which provides additional information on qualifications for relay components. Should a footnote be used to point toward Reference 1 (Protective System Maintenance: A Technical Reference) located in Section 16?
The red-lined version did not appear to agree with the clean copy. In reading the "red lined" document it appears that R3 was intended to be "Each Transmission Owner, Generation Owner, and distribution Provider shall implement and follow its PSPM and initiate resolution of any identified maintenance correctable issues."

Michelle D'Antuono
Ingleside Cogeneration LP
Yes
Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test. However, we have found that the remainder of the items in the Tables are logically organized and correspond effectively with the five components of a Protection System. The maintenance activities and intervals are technically solid and reasonable. In our opinion, the benefits to proceed outweigh our one concern with the validation of communications channel performance.
Yes
Yes
No

The removal of R1.5 and R7 which required Protection System owners to identify and verify calibration tolerances or equivalent parameters upon conclusion of a maintenance activity was fundamental to Ingleside Cogeneration's "yes" vote. The amount of ambiguity introduced by the requirements and associated documentation did not serve to improve BES reliability in our view.

Comments: Santee Cooper does not agree with the expansion of the UFLS and UVLS requirements to include the dc supply. We understand that, in the previous consideration of comments, it is stated that "For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general." In the table, the requirement for dc supply for UFLS is to verify the station dc supply voltage when the control circuits are verified, which could be 6 or 12 years. It seems like the restraint shown in the requirement, if an indication of the level of need for the verification, is of a much longer timeframe than what would actually happen in the typical operation of a distribution system. Therefore, proof of this verification seems to be of minimal value compared to the extra documentation required due to this now being an auditable maintenance activity. We also agree that maintenance activities with fast intervals, especially the 3 month ones, should be adjusted to 4 months to allow for the actual interval the entities use to be 3 months. Having the requirement at 3 months forces the utilities to schedule even faster (such as every month or 2 months) to ensure compliance.
Individual
Beth Young
Tampa Electric Company
No
If during a UF operation there were ever any breakers that did not trip properly, there may be enough that do trip to return things to balance. There is more room for error with UFLS than with BES. The standard does make some allowance for differences between UFLS equipment and BES equipment. For example the DC source testing requirement for UFLS is to just test the battery voltage when the control circuit is tested. It is not necessary that the breaker be tripped for UFLS testing every six years as is the case for BES. However, every 12 years all unmonitored control circuitry must be tested, which may include tripping the breaker.
No
The new maintenance plan has to be completed in 1 year. Would that mean it is required to identify and list every element that requires testing in a database within the first year. This will be a time intensive effort that probably that would be difficult to complete in a year with current personnel. After 1 year, would entities be required to start implementing the plan depending on the maintenance intervals of the equipment. Qualified people would have to be in place to start the work, again this would be difficult to accomplish with current personnel.
No
VSL is severe for more than 4% Countable Events on R2. It does not seem feasible.
No
Tampa Electric requests further differentiation between BES protection elements and UFLS equipment.
As written PRC-005-2 would have a very significant impact on Tampa Electric Company with very little reliability benefit. For the testing of the DC control circuits Tampa Electric would need to remove from

service each BES element (circuit, bus, transformer, breaker) and perform an R&C checkout somewhat equivalent to what Tampa Electric does for new construction. That process would have to be repeated no less often than every six years. The testing of DC control circuits to the level described / required in the proposed standard in an energized station is a very risky proposition. Even though an element can be taken out of service for testing, the DC control circuits are often interconnected for functions such as breaker failure, bus and transformer lockouts etc. It is very easy to accidentally trip other in service equipment while doing this testing. Another concern is getting outages on equipment to perform the proposed testing. Tampa Electric believes that there is an unnecessary expansion of the scope of equipment covered by the proposed PRC-005-2 standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The proposed PRC-005-2 includes the non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, the non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the proposed standard with negligible benefit to BES reliability. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load. Tampa Electric's Energy Supply Department has the following comment / question regarding Data Retention: • For Requirement R3 R2 and Requirement R4R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or all performances of each distinct maintenance activity for the Protection System component since or to the previous scheduled audit date, whichever is longer. If all of the data which the proposed PRC-005-2 standard requires to be collected is not be available or kept for the prescribed period of time, how does a registered entity comply with the required data retention?

Many of the maintenance intervals in the standard are given in the terms calendar years or calendar months. There is no description of these terms in the NERC Glossary. My Webster's dictionary defines calendar year as the period that begins on January 1 and ends on December 31. There is no definition in my dictionary of calendar month. Is the intent of the term calendar year in the standard that maintenance intervals start on January 1 and end on December 31? This would make all maintenance due on December 31, and December would be a very busy time. Does this mean that if I do maintenance on something with a maximum interval of six calendar years in June of 2011 that it will be due again on January 1 of 2017 instead of June 1 of 2017? We believe that the drafting team intends for maintenance to be due after a given number of years that begins to elapse immediately after the previous maintenance is completed so that in the previous example the maintenance would be due on June 1, 2017. Please remove the word calendar from the maximum maintenance intervals to remove this confusion.
In the header of Tables 1-1, 1-2, 1-3, and 1-5 there is a note that says "Table requirements apply to all components of Protection Systems except as noted." Since each table only applies to the specific component type shown in the header, we do not understand what this note means. The definition given for component only makes the note more confusing. Please clarify the note. Additionally, BPA is voting no during this round due to an issue with the Applicability Section and Section 4.2. Once this

issue is clarified, BPA would be in support of a yes vote. Issue: Section 4.2 Facilities lists 5 separate items that the standard is applicable for (4.2.1. – 4.2.5). However Requirement 1 uses language that only addresses one of the items (4.2.1). There is no language contained anywhere within any of the requirements in PRC-005-2 that apply to the types of protection systems described in Applicability Sections 4.2.2 – 4.2.5. Therefore, it could be argued that this leaves it open to interpretation as to whether UFLS/UVLS/SPS are addressed by R1. In the NOPR (¶ 105), FERC states that "the Requirements within a standard define what an entity must do to be compliant". Further, in Order 693 (¶ 253) FERC explicitly states that "compliance will in all cases be measured by determining whether a party met or failed to meet the Requirement". Given this, then from a compliance perspective, the actual applicability of the standard appears to not be as broad as intended. We ask that this issue be resolved by modifying the language in R1 in a manner that explicitly encompasses all types of protection systems to which it is intended to be applied.

Steve Rueckert

No
The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. However, section 4.2 identifies five types of protection systems that the standard is applicable to, but the language of Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). We believe the intent is to have a PSMP for all Protection Systems identified in Section 4.2 and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.

1. Are the bullet items listed for the R2 Severe Violation Severity Level , Item 5 an "and" or an "or"? 5) Failed to: • Annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, • Annually analyze the program activities and results for each segment. 2. The wording of the R3 Lower Violation Severity Level seems to imply that an entity that fails to complete 0% (i.e., completes 100%) of its maintenance correctable issues is non-compliant. Entity has failed to complete scheduled program on 5% or less of total Protection System components. OR Entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues. The following re-phrasing is suggested: Entity has failed to complete scheduled program on greater than 0%, but no more than 5% of total Protection System components. OR Entity has failed to initiate resolution on greater than 0%, but less than or equal to 5% of identified maintenance correctable issues.
Yes
The Supplementary Reference and FAQ should be an attachment to the standard (Appendix A)and not just referenced. If not attached it will not be readily accessible to those that will be using the standard.
There were numerous comments submitted for each of the previous drafts indicating that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." Statistics on the causes of BES protective system misoperations, however, do not support this assertion. The PJM Relay Subcommittee has been tracking 230kV and above protective system misoperations on the PJM system for many years. For the six year period from 2002 to 2007, the number of protective system misoperations due to communication system problems was lower (and in many cases significantly lower) than those caused by defective relays, in every year but one. Similarly, RFC has conducted an analysis of BES protection system misoperations for 2008 and 2009, and found the number of misoperations caused by communication system problems to be in line with the number attributed to relay related problems. If unmonitored protective relays have a 6 year maximum maintenance/inspection interval, it does not seem reasonable to require the associated communication system to be inspected 24 times more frequently, particularly when relay failures are statistically more likely to cause protective system misoperations. As such, a 12 or 18 calendar month

interval for inspection of unmonitored communication systems would seem to be more appropriate. FAQ II 6 B states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks. The SDT responded that they still felt the 3 month interval as stated in the standard was appropriate. PHI respectfully requests that the SDT reconsider this issue and also cite what "specific statistical data" they used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays.

Sub-tables are good. A related question: Some devices such as reclosers and circuit breakers may include batteries within the device itself. Does Table 1-4 apply to such batteries and DC supply? Recloser batteries do not provide access to intercell connections.
No
This new standard's calibration intervals outlined here will require additional staff at our organization. In order to get people hired and trained the implementation plan should allow more time for the phase-in period. From experience, calibration should have been de-emphasized since more concerns are discovered during full tests.
no comments at this time
Yes
We used the FAQ Supplemental Reference while reviewing this draft standard and found it useful.
The present PRC-005 standard is 2 pages while the proposed PRC-005-2 is 22 pages, with an implementation plan of 4 pages and a supplemental document of 87 pages. The review process appears to be somewhat daunting especially considering that NERC is trying to simply things with such concepts as the "traffic ticket" approach. In R3 we're not sure if there is a time requirement regarding the completion of the resolution process. We like the use of "calendar year" in requirements which should provide flexibility in getting the work completed. Another comment for our response concerns Table 1-2, Communications Systems (page 11): The first maintenance interval is 3 calendar months. Does this mean the same as 1 calendar quarter? 1. Example for 3 calendar months:Maintenance performed on 1/4/11. Next maint due by 4/30/11. Maintenance performed on 4/12/11. Next maint due by 7/31/11. Maintenance performed on 7/30/11. Next maint due by 10/31/11. This would yield 3 inspections for 2011. Maintenance performed on 10/12/11. Next maint due by 1/31/12. 2. Example for 1 calendar quarter: Maintenance performed on 1/4/11. Next maint due by 6/30/11. This would yield 4 inspections for 2011 (1 per quarter).

We believe the table could be improved further to aid compliance by adding a footnote to the term “baseline” in the sub-tables 1-4(a), 1-4(b) and 1-4(f). The following proposed footnote text is taken from page 65 of the Supplementary and FAQ Reference Document: “Often for older VLRA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to. To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, all manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to.”
Yes
No
Typographical error - the High VSL for R2 has been incorrectly changed to “within three years” from “within four years”. This is now the same as the Lower VSL.
Yes
Along the lines of what we have suggested in our comment to Question #1 above, we believe it would make compliance more certain if selected language from the Supplementary reference could be incorporated into the standard, either directly in requirements, or in footnotes.
The Standard Drafting Team has done an outstanding job on this standard. We are voting “Affirmative” but note that implementation questions remain, particularly with regards to classifying component attributes as “monitored”, “unmonitored”, “internal self diagnosis”, “alarming”, “alarming for excessive error”, and “alarming for excessive performance degradation”. The sheer size of the population of protective relays, communications systems, voltage and current sensing devices, batteries, and dc supply components means that the size of the effort required to categorize each individual component could drive us to test and maintain on the more frequent unmonitored time intervals, simply because of the difficulty in assembling “monitored” compliance documentation.

The scope of the equipment to which the draft standard applies is still overly broad. Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliabiltiy of the BES. This comment/recommendation is provided to address the resource and customer service interests of a TO and/or DP systems serving distribution load. Illinois Municipal Electric Agency supports comments submitted by the Transmission Access Policy Study Group.

The restructured tables are an improvement, but we suggest that conductance (siemens) should be listed as an acceptable measurement in addition to the resistance measurements already included in the tables.
Yes
No
VSL for Requirement 2: -Needs to use consistent terminology. The standard requirements refer to components and component types, not elements. -The violation “Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years” appears in both the Lower VSL column and the High VSL column. The violation cannot be both Lower and High. VSL for Requirement R3: -Suggested wording “completed its scheduled program”.
A red line was not provided making this document difficult to review. We suggest that a redline of this document be posted.
-Grace periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-compliance (removing an asset in a time of constraint). Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for reliability without risking non-compliance. -Battery Check Interval Manitoba Hydro maintains our position that the 3 month battery check interval should be extended to 6 months. The 3 month interval is too frequent based on our experience and while IEEE std 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. With the 3 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval.

Please provide clarification on "Communications" in regards to the following: If our customers are utilizing Schweitzer SEL311 relays and utilizing the fiber for transfer trip, is this considered a communications circuit? Our experiences in regards to testing these devices that have transfer trips out into a main substation, that could affect a main ring tie or open a major 138kV loop, are that the T&D utilities will not allow us to perform these tests and trip their breakers. Therefore, what is required to satisfy testing? In regards to Function / Trip testing, if we have a sudden pressure device, this is considered an auxiliary relay and the sudden pressure relay itself is not required to be tested. However, the trip path is required to be tested for DC tripping, if it directly trips the breaker feeding the BES, on the DC Control verification testing. Please clarify if this is correct.

Comments: IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.

In Section 4.2, 'Facilities' add the following subsection 4.2.6: Protection Systems for generating units in extended forced outage or in inactive reserve status are excluded from the requirements of this standard. However, the required maintenance and testing of the Protection Systems at these units must be completed prior to connecting the units to the Bulk Electric System (BES). Reason for the above comment: The above units are not connected to the BES and therefore do not affect the reliability of the BES. However, to ensure the reliability of the BES, required maintenance and testing of the Protection Systems at these units must be completed prior to connecting them to the BES.

On page 2 of the implementation plan, it is indicated that PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired and that entities will be required to identify which components will be

addressed under PRC-005-1 or PRC-005-2. There is no wording to cover those components that are still being addressed under PRC-008-0, PRC-011-0 or PRC-017-0 during the implementation period.
No
This standard encompasses a very broad range of component types and functionality. It also encompasses broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application.

Table 1-5 The new standard requires that every 6 years it is verified that “each trip coil is able to operate the breaker,…”. The supplementary reference states that this requirement can be met by tracking real-time fault-clearing operations on the circuit breakers. With transmission breakers typically having dual trip coils, how can tracking real-time operations meet this requirement? Would a breaker operations where relays in both the primary and secondary trip coils indicated operation be sufficient or would some type of trip coil monitoring that showed coil energization be needed? Additionally, regarding the verification of all trip paths of the trip circuit. If a microprocessor relay is used to trip a breaker, and two contacts are paralleled on the relay through a single test switch for breaker tripping, would it be necessary to verify each contact independently or could an assertion of both contacts through the test switch be adequate? In this instance, the functionality of each contact would be fully identical. Table 1-2 A 3-month inspection is required for communications equipment that does not have “continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function” has to be verified that the communication equipment is “functional” with a 3-month site visit. Would a carrier on-off system, that did not perform periodic check back testing, but did have an alarm contact (loss of power, failure, etc.) that was monitored through SCADA would need to have a 3-month inspection? According to the supplemental reference, this inspection should be to verify that the equipment is “operable through a cursory inspection and site visit”. It sounds as if this cursory inspection and site visit would accomplish the same as the alarm contact. It does not appear that end-end functional testing of the blocking signal is required by what is provided in the supplemental reference. Is this correct? Table 1-3 The maintenance activity for the 12 calendar year testing should include a little more specificity. It should have something stating the values provided to the relay are accurate. I know that this discussed in the supplemental reference, but requirement in Table1-3 sounds as if any relay that measured for loss of signal, such as a loss-of-potential function, would be sufficient when the purpose to verify that the signal not only gets to the relay but also has some accuracy as needed by the application of the relay.

Yes
However, The requirement to perform battery cell internal ohmic measurements every 18 months for vented lead-acid batteries is excessive, and no technical justification is provided for an 18-month

interval. A 3-year internal ohmic test frequency is adequate to prove battery integrity. IEEE 450 does not provide a recommended interval for internal ohmic measurements. For standard capacity testing, the recommended interval is no greater than 25% of expected battery life. Our normal battery life is 20+ years, so the recommended capacity test interval would be about 5 years. EPRI also recommends capacity testing at 5 year intervals. There is no justification for performing internal ohmic measurements every 18 months (which equals every 7.5% interval of the expected battery life). Recommendation: Set the interval for battery internal cell ohmic testing at 3 years.
Yes
No
TVA has 590 Pilot Relay (Carrier Blocking) Terminals that are tested twice a year. After an extensive study of carrier failures over a 5-year period, it was determined that we were not having any failures that could have been prevented by a functional test. In January 2008, we reduced our frequency from 4 times per year to 2 times per year. The failure rate has remained about the same since that change. As PRC 005-2 currently states, the PM frequency would be 3 months. Allowing for a one-month grace period would actually require the interval to be set at 2 months. Therefore, the interval we used prior to 2008 (4 times per year) still would not make TVA compliant with the stated 3 month interval. TVA Power Control Systems is in the process of developing extensive PM tests for carrier terminals to complement the existing PM program. This PM would record signal levels, reflected power, line losses, and other pertinent data. It is my position that this PM will improve reliability more than increasing the frequency of the functional test.

The reference material provides a significant insight into the intent of the proposed changes to the standard. In some cases an interpretation is provided which is not supported by the explicit interpretation of the standard text. The SDT is encouraged to either attach the reference material to the standard or add relevant sections to standard as Background. The Background section could reference the Supplemental Reference & FAQ. The reference material provides more detail indicating that “Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. . . . . . The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).” This interpretation is not consistent with the text of the standard and would suggest that it be incorporated into Table 1-3.
Section 4.2.5.4 - please clarify generator connected station service transformer. We believe this to mean a station service transformer with no breaker between the transformer and teh generator bus. R3 - the term 'initiate resolution' is vague and needs to be further defined. Does this mean putting in a work order or is further action required. Data Retention: The proposed standard clarifies that two of the most recent records of maintenance are to be retained to demonstrate compliance with the prescribed maintenance intervals. When equipment is replaced, the reference information indicates that the information associated with the original equipment must be retained to show compliance with the standard until the performance with the new equipment can be established. This is not explicitly stated in the requirements and warrants a comment.

We agree the changes to the tables have added clarity, but disagree with the maintenance intervals for DC supply. Comments: “PNGC’s comment group views the Maximum Maintenance Interval for station DC Power Supply (Table -14a/b/c/d) to be unnecessarily onerous and restrictive to many smaller-rural entities, in the west and probably throughout the US, and this prevents us from being able to support PRC-005-2 as written. We make these comments with the understanding that others have made similar comments in the past but we feel strongly that this is an important issue worthy of further review by the SDT. We believe a quarterly inspection schedule can be met while at the same time allowing entities the flexibility they need. IEEE 1188-2005 suggests a quarterly inspection schedule for lead acid batteries and we believe the standard interval for verifying and inspecting dc supply should be 3 months with a maximum interval of 6 months. This meets the quarterly threshold and gives some flexibility to account for unusual conditions. There are substations in Pacific Northwest rural areas that can be inaccessible during long periods of time during the winter, potentially exposing an entity to sanction if weather conditions prevent access to equipment for an extended period of time. Additionally, due to a smaller workforces and greater distances between equipment subject to PRC-005, small-rural entities face obstacles that large entities may not have. The three month maximum interval assumes ideal conditions and resource access and is not realistic. We thank the SDT for considering our comments.”

Section 9.2 (copied below)indicates that small entities can utilize Performance-Based PSMP if they aggregate with other entities. Does this section indicate that only a parent entity with individually owned components can aggregate, or can independent entities under a G&T aggregate? In other words, individual DP/LSE/TOs with different audits. Can they aggregate under a common PSMP for performance based maintenance? 9.2 Frequently Asked Questions: I’m a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity? Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis. The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Although considerable clarity was achieved in the structuring of the table for the different types of technologies associated with the DC supply, there is issue on the maximum allowable intervals. The standard remains too prescriptive in the intervals and maintenance activities. As an example it is believed the intent of the interval for verifying voltages and inspecting electrolyte levels and unintentional grounds level would be every 3 months. However, for the entity to ensure compliance and not incur a violation it would have to have a shorter interval, probably every 2 months just to ensure compliance and not incur a violation. The 3 month interval is in question based on programs that have been in service for many years where four months have been proven as reliable for operation, an even shorter period than 3 or 4 months is not only a burden but an unnecessary expense without a benefit of increase reliability of the Bulk Electric System.
Yes
NERC continues to be too prescriptive in the standard. For example, Table 1-4(a) requires battery verifications and inspection every three months. We have been performing similar tests every four months for over a decade, with no adverse consequences. Although FERC Order 693 directs NERC to establish maximum allowable intervals, the maximum interval must be “appropriate to the type of protection system and its impact on the reliability of the Bulk-Power System.” (Order 693 at 1475) The Standard Drafting Team (SDT) has not demonstrated a mechanism that connects the maximum maintenance interval with its impact on the reliability of the Bulk-Power System. An example can be found on the bottom of page 18 and the top of page 19 of the Consideration of Comments on Protection System Maintenance [Project 2007-17] for draft 3. Although the commenting organization provided a concrete example of successful maintenance under a longer interval, the Standards Drafting Team commented that it “… believes that 18-months is the proper interval for this activity.” (Emphasis added) An organization cannot challenge the SDT’s beliefs, only facts. The basis for each maximum maintenance interval, with appropriate linkage to its impact on the reliability of the Bulk-Power System, needs to be published and voted upon so that factual based proposals to modify the maximum interval can be rationally challenged.

The LOW and HIGH VSL for R2 are the same. There are additional possibilities for the LOW, but it is possible to be in both the LOW and HIGH VSL at the same time. We recommend removing #1 in the LOW VSL category to resolve the issue.
Yes
Comment 1 If PRC-005-2 is going to incorporate PRC-008 (UFLS) and PRC-011 (UVLS) the Purpose needs to be revised to include Distribution Protection Systems designed to protect the BES. Comment 2 We do not believe a distribution relaying system, designed to protect the distribution assets, that may open a transmission element (ie; breaker failure) should be considered part of the BES Protection System. R1 should add the following sentence “Distribution Protection Systems intended solely for the protection of distribution assets are not included as a BES Protection System, even if they may open a BES Element.” Comment 3 Table 1-5 (Component Type – Control Circuitry) Item 4 –

“Unmonitored control circuitry associated with protective functions” require a 12 calendar year maximum maintenance interval. We believe UFLS and UVLS control circuitry should be exempted from this requirement. It would take multiple failures to have any impact, and the impact on the BES would be minimal.

Yes, however, in the “Supplemental reference and FAQ” document on page 65 this is one area of concern. Page 65, paragraph 4 “… the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.” While we understand the importance of creating a baseline, it’s not feasible to expect the test equipment to be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 15 years and it is not feasible to expect that the type of test equipment will not change during this period. We suggest changing the wording to read that consistent test equipment should be used to provide consistent/comparable results.
Yes
Yes
No
In the checkbox for Requirement R3 please change the wording to read, “Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initiating on-site activity. Therefore this issue requires follow-up corrective action.”

Yes
Please carry the grid across in Table 1-4(f) to show the Maintenance Activities that go with the Component Attribute.
Yes
While we agree with the Implementation Periods, it would be best to alter R2 and R3 implementation such that components with maximum allowable intervals of 1 year or longer align with a true calendar year (i.e. begin with January 1).
Yes
Yes
1. Comments: Supplement FAQ 12.1 on page 51 final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. Since BES Element protection is the objective, we suggest a compromise of keeping the evidences of last test for the removed equipment and using that with the equivalent function replacement equipment commissioning or in-service date to prove interval. 2. Clarify p17 Table 1-4(e) interval meaning. We think this means we need to verify the Station dc supply voltage on 12 calendar year interval if unmonitored, or no periodic maintenance if monitored as stated. 3. In Supplement examples on pp 22-23, replace “Instrumentation transformers” with “Verify that current and voltage signal values are provided to the protective relays” to be consistent with Table 1-3. 4. Remove “Reverse power relays” from the sample list of

generator devices in Supplement p31 because reverse power relays are applied for mechanical protection of the prime mover, not electrical protection of the generator. 5. Revise Supplement Figure 1 & 2 Legend p83 to align with Draft 4 (a) state "Protective relays designed to provide protection for BES Element(s)". (b) state "Current and voltage signals provided to the protective relays" 6. Please add a Performance-Based maintenance example for control circuitry, and /or voltage and current sensing.
Measure M3 on page 5 should apply to 99% of the components. "Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99% of its components and initiated…." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. 2. Define BES perimeter in accordance with Project 2009-17 Interpretation. Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. The BOT adopted this 2/17/2011. 3. Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months.

The tables are limited to a few battery technologies and will be out of date in short order with the many types of advanced batteries already on the market. The testing requirements should be performance based as opposed to prescriptive.
No
The last part of the implementation plan is vague, if not undefined. The implementation should "follow the previous maintenance intervals until all maintenance is transitioned to the new intervals."
No
The VSL's for R1 should combine the ones for Lower, Moderate and High VSL into Lower VSL. The Severe VSL should be moved to the Moderate VSL. Because R1 is administrative, it shouldn't have High or Severe VSL's. The R2 High VSL (3 yrs) is more stringent than the Severe VSL (5 yrs). The R3 VSL's need to have combined numbers of components or percentages because small generators may only have 25 relays or 1 battery and would be categorized as High or Severe VSL with a few components affected. The percentage could apply to RE's with more than 250 components included in the PSMP. The Medium VRF for R1 should be Low VRF because R1 is administrative. Only the performance of the maintenance has anything more than Low VRF. The Medium VRF for R2 is OK. Having a High VRF for R3 is without basis. R3 should have Medium VRF.

We need clarification on the UFLS or UVLS system Station DC Supply test. We trip the high side device (non-BES asset) for each of our distribution stations UFLS or UVLS schemes, not the individual distribution breakers. It is hard to distinguish what maintenance interval and maintenance activities we should engage for Station DC Supply test. Since the device is not a distribution breaker as

mentioned in the Table 1-4 (a-f) we would be conservative and choose to perform maintenance at all our distribution stations with UFLS or UVLS schemes as per Table 1-4(a). Reading the statements in the Supplementary Reference and FAQ, we notice our devices perform similar functions as the distribution breakers. Reference pg 60 of Supp. Ref. and FAQ paragraph 4. Since tripping the high side device of a distribution transformer still constitutes a distributed system would our system meat the exclusion criteria although it is not a distribution breaker, would this meet the same requirements and exempt the station from Table 1-4(a) and require only maintenance for DC systems as per Table 1-4(e)? Please clarify. We recommend changing the term distribution breaker to distribution asset interruption device or non-BES equipment interruption device.
Yes
Yes
Yes
See comments for item 1 and continue clarification where we could include high side or distributed interrupting devices, exchange nomenclature removing distribution breaker and adding distributed interrupting device or non-BES equipment.

Yes
Yes, however, in the “Supplemental reference and FAQ” document on page 65 there are two areas of concern. - Page 65, paragraph 4 “… the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measured used by different manufacturer’s equipment.” While ATC understands the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of equipment will not change during this period. - Page 65, paragraph 6 “… all manufacturers of internal ohmic measurement devices have established libraries of baseline values …” ATC question’s the availability of baseline libraries for all manufacturers considering the variety and longevity of installations.
Yes
Change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 19, Row 1, Column 3 to: “Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years” Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in table1-5 row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). Change the text of “Standard PRC-005-2 – Protection System Maintenance” Table 1-5 on page 19, Row 3, Column 2 to: “12 calendar years” The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it

may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. ATC recognizes the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC believes that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.

Daniel Herring
Yes
Yes, the tables do provide more clarity. It is much easier to understand the requirements now that they are broken down by technology, and the exclusion of intervals on certain activities based on the individual monitoring attributes is helpful. I appreciate the thought that went into revising this.
Yes
No
R2 - It appears that the Lower VSL point 1) and High VSL are identical.
No
Countable Event - This definition should be clarified. As it stands, it appears that if a technician were to adjust the settings on an electromechanical relay - even if it were not outside of the entity's acceptable tolerance - it would need to be classified as a countable event. I would recommend that the definition be limited to repairing or replacing a failed component during the maintenance activity. These activities would address conditions that would potentially cause a Protection System misoperation (either a failure to trip or an unintentional trip). Routine maintenance activities to bring component test values back within tolerance should be excluded from the definition of a Countable Event. These activities are performed to keep the protection systems performance at its most ideal state. In addition, the definition as stated appears to classify battery maintenance activities such as cleaning corrosion, adding water, or applying an equalize charge, as countable events. If this is the intent, I disagree. These are activities that are expected to occur on a regular, routine basis due to the chemical properties of the battery (as described at length in the Supplementary Reference). As such, they should also not be classified as countable events. Table 1-1 and Table 1-5 Based on experience with DECo equipment, a 6 year interval for testing monitored relays and performing tests on the breaker trip coil is substantially shorter than required. Currently, the interval for both is 10 years. This interval lines up both with the Transmission Owner's interval for relay maintenance as well as the maintenance interval for the associated current interrupting devices. I would recommend that these intervals be extended, at minimum, back to the 7 year interval proposed in Draft 2 - if not longer. Table 1-4 (a, b, c, e) - Station dc supply using any type of battery I recommend that the maintenance activity to "Verify: Station dc supply voltage" be clarified to state that the voltage should be measured at the positive and negative battery terminals. Until you get to page 72 of the Supplementary Reference, you do not know if this means to check the battery voltage or the bus voltage. The "Station dc supply" could refer to the entire dc system. It needs to be made clear in the table that you are referring to the battery. Also, I noticed that there is no longer a requirement to measure individual cell voltages. I was wondering if you could explain the rationale behind that. Checking for voltages that are out of specification in individual cells helps to identify weak cells that may need to be replaced, if corrective action taken on them does not improve their condition. Individual cell voltage readings, along with ohmic readings, have been an industry standard that I believe many, if not most, companies adhere to. Table 1-4 (a, b, c, d) I recommend eliminating the 3 month requirement. We have found annual inspections to be sufficient in catching problems early enough to take corrective action. Page 30 of the Supplementary Reference states that the SDT

believes that routine monthly inspections are the norm. While this may be the case at manned stations, it is not at unmanned stations. The amount of paperwork that would be required to demonstrate compliance is overwhelming and would be an immense burden. I have seen your suggestion in past draft comments of the same nature that if we don't want to do the 3 month inspections, then we should utilize more advanced monitoring. This is not something that can be implemented in a short time frame. It would take years to put all of that technology in place, and is rather cost prohibitive. Furthermore, some of the monitoring technologies that would enable you to forgo the 3 month requirement do not exist yet (to my knowledge). I recommend keeping with the 18 month requirement. If that seems too long, based on past experience I think a 12 month requirement would suffice. Table 1-4 (c) I propose keeping the option to evaluate ohmic values to baseline. Table 1-4 (a, b) For the requirement to evaluate the ohmic values to baseline, is a checkbox stating that you did this sufficient, or would a report/graph/etc listing the actual baseline and current value be required? Table 1-4 (f) The first attribute is regarding high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. Would a low voltage alarm combined with high voltage shutdown (but not a high voltage alarm) meet this requirement? The high voltage shutdown will shut the charger down in a high voltage condition, and therefore result in a low voltage alarm, so the outcome is the same.
Individual
John Bee
Exelon
Yes
What kind of component we are talking about in table 1.4(d) “Station DC Supply using Non Battery Based Energy Storage” for switchyard in nuclear plants?
In response to Exelon’s comments provided to drafts 1, 2, and 3 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT previously responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. In response to draft 3 of PRC-005, the SDT stated that "If several different regulatory agencies have differing requirements for similar equipment, it seems that the entity must be compliant with the most stringent of the varying requirements. In the cited case, an entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Again this does not explain why a conflict with an existing regulatory requirement is acceptable. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon again requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. In addition, the SDT still did not fully evaluate or address the concern related to the uniqueness of nuclear generating unit refueling outage schedules. Although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant’s routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity or a self report of non-compliance. To

ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. The SDT response to this question in draft 3 is that "(t)he 18-month (and shorter) interval activities are activities that can be completed without outages – primarily inspection-related activities. An entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Respectfully Exelon requests that the SDT review and evaluate the concern.

Glen Sutton
AtCO Electric ltd
Table 1-4: ATCO Electric has a number of remote substations that are difficult to access. The requirement for a 3 calendar month inspection for electrolyte level is too frequent. The requirement would become achievable if electrolyte level inspections were moved to the 18 calendar months category, or if the 3 calendar months frequency were increased to 8 calendar months. Table 1-4(b): for the same reasons, the requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category, or if the 6 calendar months frequency were increased to 14 calendar months. Table 1-4(c): the requirement of a 6 calendar year performance service or modified performance capacity test should be removed. From our experience, there is no benefit in doing battery load tests. Instead, we apply verification of battery intercell resistance as a more efficient method of monitoring battery condition, which provides an 8 to 14 month lead time to replace a battery unit/cell before it goes dead.
Table 1-2: the requirement for a 12 calendar year verification for the channel and essential signals' performance should be removed. We do not see benefit in the maintenance activities under level 2 (the 12 calendar year requirement) and suggest merging it with level 3 (the "no periodic maintenance specified" requirement). The 'loss of function' alarm, will be considered as a countable event to fall under requirement R3 and dealt as maintenance correctable issue. Table 1-5: the requirement of 6 calendar year verification for electrical operation of electromechanical lockout and/or tripping auxiliary devices should be revisited, considering that: • It is not feasible to exercise a lockout relay during maintenance due to high risk to the in-service facility, as well as the complexity of lockout relay connections and protection schemes. Instead, we propose a DC ring test, which verifies the continuity of control circuitry and eliminates the risk impact of lockout or auxiliary tripping device operations. • The interval is too frequent. The requirement would become achievable if the 6 calendar year frequency were increased to 12 calendar years, to be in line with microprocessor relay maintenance frequency

Yes
No
• Suggest clarification of the VSL for R2. It appears that R2 Lower VSL is also contained in the R2 High VSL. • If the maintenance is completed prior to the maximum interval, would it then reset the clock? Or should it read that maintenance should be done at least once per quarter, etc. • The plan should split into generation time horizons and transmission time horizons since these can be significantly different
Yes
The standard should include a footnote indicating this document as reference
A. Requirement R1 • Suggest changing the language in R1.2 to read "Identify which maintenance

method such as the time-based, performance-based (detailed in PRC-005 Attachment A), or a combination of the two would be appropriate to be used for each type of Protection System component. Based upon their own constructive type, all batteries associated with the station DC supply shall be included in a time-based maintenance program consistent with Table 1-4(a) through Table 1-4(f)" • Suggest changing the language for the first paragraph in R1.3 to read "Establish the occurrences associated with the time-based maintenance programs up to but no less than the time intervals specified in Table 1-1 through Table 1-5, and Table 2. Consequently, include all applicable monitoring attributes and related maintenance activities characteristic to each type of Protection System component specified in Table 1-1 through Table 1-5, and Table 2" • Suggest adding a sub-requirement such as R1.5 to read "Include documentation of maintenance, testing interval and their basis and a summary of testing procedures" B. Requirement R3 • The redline version of the standard is misleading. Requirement R3 is crossed out and then replacing requirement R7 which is also crossed out. • The wording "[…] initiates resolution of any identified maintenance correctable issues" it is vague. What a responsible entity should do to become compliant with this requirement? We also believe that is not sufficient to just "initiate resolution"; the standard should call for corrective actions to be performed within the maintenance time interval. • The "identified maintenance correctable issues" may not be a proper choice. The name of the new term suggests that is about issues that can be corrected during maintenance, while the definition from the clean version explains otherwise?! C. Additional requirement • Suggest adding a requirement to read "The Transmission Owner, Generator Owner, and Distribution Provider shall provide documentation of its PSMP and implementation to the appropriate Regional Reliability Organizations on request (within 45 calendar days)." • Add measure for the evidence on documenting the PSMP from the additional requirement D. General comments and notes • If you own electro-mechanical relays and microprocessor based relays is there a need to keep two different logs for these? • On table 1-4 the generator CTs should be tested earlier than the suggested 12 years due to exposure of continuous mechanical stress • Clarify table 1-5 to address verification tests on different circuits. Suggest that the Table 1-5 to read "Complete a terminal test of unmonitored circuitry" instead of the "Unmonitored control circuitry associated with protective functions" • In what instances (what extent) would the standard allow using the real time breaker operation to be considered maintenance as applicable to different types of relays involved in the real time event? This is briefly emphasized under TBM at paragraph 5.1 from the supplementary reference document?

ISO/RTO Standards Review Committee
Albert DiCaprio
The SRC disagrees with the change to the term under 4.2.1. "Protection Systems designed to provide protection for BES elements." We support keeping the previous version's wording of 4.2.1. "Protection Systems applied on, or designed to provide protection for the BES." The revised wording expands the fundamental purpose of the NERC PRC-005 standard from being focused on ensuring relays intended to protect the reliability of the BES are maintained to a standard whose intent is to ensure all BES facilities have relay maintenance programs. Although we do not disagree with maintaining all relays, regardless of what their intended purposes are, it should not be the purpose of a NERC standard to police all protection schemes beyond those needed for interconnected reliability. There are numerous protective relays employed on facilities interconnected to the BES but their purpose may be for operating preference or service/equipment quality purposes such as reclosing schemes and transformer sudden pressure relays. We believe the NERC PRC-005 standard should be focused on maintenance of those protective relays which are needed to ensure that the loss of a single element does not cause cascading effects on the bulk power system.

Transmission Access Policy Study Group
Cynthia S. Bogorad

The scope of the equipment to which the draft standard applies is over-broad. Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliability, for the following reasons. In contrast to transmission and generation protection systems and SPSs, for which there are typically two protection systems per facility and therefore per fault, UFLS and UVLS deal with widespread events. For any under-voltage or under-frequency event, there are literally hundreds of UFLS/UVLS relays to respond. It is therefore far less critical if one UFLS or UVLS relay fails to operate properly. Furthermore, transmission is typically not radial (in fact, radials to load are excluded from the BES). But distribution circuits, where UFLS and UVLS systems are located, are usually radial. Testing some of the non-relay equipment to which the draft standard applies would require blacking out the customers served by that radial. In other words, the draft standard would require entities to definitely cause blackouts in an attempt to prevent very unlikely potential blackouts. This is plainly not justified from a harm/benefit perspective. Finally, many of the types of non-relay equipment to which the standard would apply are in effect tested by faults. Specifically, faults happen on distribution circuits (where UFLS and UVLS systems are located) more frequently than on transmission circuits, due to such things as animal contacts and car accidents. Any such fault is in fact a test of the all the equipment that is involved in clearing the fault. There is no need to require separate tests of that equipment, any more than we would require tests of a phone line that is used on an everyday basis; you already know that the phone works.

The supplementary reference on page 30, under the question beginning “Our maintenance plan requires…” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35, under the question, “How do I achieve a grace period without being out of compliance” provides an example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less in less than the maximum time of six calendar years. This is conflicting advice. The FAQ /supplementary reference should be revised so that it does imply that an entity is out-of-compliance by performing maintenance more frequently than required. Avoiding compliance risk is one reason to do this, but there are other valid motives not directly related to reliable protection system performance. Testing of PT’s and CT’s (12 year max) is non invasive and convenient to schedule at the same time as relays (6 year max) just to keep procedures consistent and reduce program administration. Testing of ties to other TOs or GOs may have to be scheduled more frequently than preferred in order to synchronize schedules.

Although we agree with the timeframes being afforded to achieve compliance, we suggest the

following changes: 1. During the last comment period, we suggested changes to the wording regarding retirement of existing standards on page 2. We do no see a response to these comments. Therefore, we would like to reiterate that the four existing standards are to be retired upon the effective date of the new standard and not upon regulatory approval. 2. In 4a of the plan, since the timeframe for 30% completion is 3 calendar years, we suggest a change to three calendar years for the parenthetical phrase "(or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage)". Change "two" to "three". 3. We suggest the implementation plan be included within the body of the standard. It is very burdensome for entities to have to look for the implementation plan and we believe that a "one-stop shopping" approach would alleviate this burden.
Yes
Yes
We do not agree with the following wording on page 37 of the reference document: (1) "If your PSMP (plan) requires more activities then you must perform and document to this higher standard." and (2) "If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard." We continue to believe that the auditor is required to audit to the standard. If the standard requires maintenance intervals every 6 years, this is what the auditor should verify. This was also verified in the recent NERC Workshop at which it was confirmed that "auditors must audit to the standard". To this end, we also suggest changes to Requirement R3 as explained in our comments in Question 5.
FE offers the following additional comments and suggestions: We do not agree with the wording of requirement R3. The entity is only required to meet the minimum maintenance intervals of the standard as outlined in Tables 1 and 2. We offer a scenario where an entity states that they will go above the standard and maintain relays on a 4 year cycle. The standard, in meeting an adequate level of reliability, sates that this activity must be performed every 6 years. If the entity happened to miss the 4 year timeframe, deciding from a business standpoint to delay the maintenance to the 5th year, an auditor can find the entity non-compliant per the guidance and wording of the requirements in this standard. However, the entity still exceeded an adequate level of reliability by performing the maintenance within 5 years. This scenario would be very unfortunate to the entity that has essentially done their part in providing reliability to the bulk power system, yet they would be punished for not meeting their more stringent timeframes. This standard's guidance and requirements sends an adverse message to industry. It essentially punishes an entity for going above and beyond the standard except on a few rare occasions. If this were to happen, that entity, and possibly others, would not see the value in going above a standard. It would make entities meet the bare minimum requirements, essentially reducing overall system reliability. Therefore, we suggest the following wording for requirement R3: "R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP to ensure adherence to the minimum requirements as outlined in Tables 1 and 2, and initiate resolution of any identified maintenance correctable issues."

The re-structured tables are easier to use.
Yes
Yes
No
We agree with the combination of the two. One document with the FAQ's grouped with the supplemental topics makes it easier to review the whole topic.
For Battery System: - Table 1-4(a) o The maximum maintenance interval for the majority of the battery maintenance is listed at "18 calendar months". The current ITC Standard is "once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st ". ITC would like the maximum maintenance interval at "once per calendar year" -

Table 1-4(b) o VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the “18 calendar months” inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. For Battery System: - Table 1-4(a) o The maximum maintenance interval for the majority of the battery maintenance is listed at “18 calendar months”. The current ITC Standard is “once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st “. ITC would like the maximum maintenance interval at “once per calendar year” - Table 1-4(b) o VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the “18 calendar months” inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. Auxiliary Relays: • ITC does not agree with the 6 year interval for Aux relays in the trip circuit. Although they are EM relays they are simple and have very few moving parts. We believe the maintenance period for auxiliary relays should be 12 years and they should be in conjunction with the control circuit. We recognize that Draft 4 only includes auxiliary relays that are directly in the trip path. That is an improvement in Draft 4. In general, auxiliary relays are very reliable; only certain relay types have been proven to be problematic. A known relay type (HEA) has been proven to be problematic if not exercised frequently. The standard should not require a 6 year interval period for all other auxiliary relays. We believe problematic relays should be addressed through use of a NERC Alert process. Don’t cut down the tree for a bad apple.

Tri-State G&T
On Table 1-2, page 11: The standard describes the following component attributes, “Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.” How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Please clarify the term correct operation and how it applies to redundant communication systems.
The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions?
On Page 19, Table 1-5, the standard requires that monitored electromechanical lockouts be maintained every 6 years. Why is there inconsistency in the interval between the monitored lockouts and monitored relays?
M1 - Why is the document necessary to be “current or updated?” Eliminate “or updated.” R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate? R2 VSL – Keep the comment about the redundancy in Lower VSL and High VSL for clarifying the difference between the two.

Comments: The restructured tables are indeed an improvement; however the tables still need some work for clarity: Table 1-5: Unmonitored control circuitry has a maintenance activity of “Verify all paths of the control and trip circuits.” The wording of “control and trip circuits” leads to circuit verification of more than just trip circuits. In fact multiple circuits would have to verified, such as station house load transfer schemes. Providing documentation to an auditor to prove all paths have been tested will be difficult and is considered excessive. The paperwork required to prove compliance

is extremely excessive for this requirement and doesn’t provide a benefit to reliability. Table 1-5: Table 1-5 requires trip checking every six calendar years for trip coils and electromechanical lockout and/or tripping auxiliary devices. Every six years is excessive, when sutiable monitoring is used. We recommend verification of these components be completed at the same frequency as the associated relay testing when monitoring is used. For electromechanical, no more than every 6 calendar years, for microprocessor, no more than 12 calendar years. Table 2: The interrelationship between Tables 1-1 through 1-5 and Table 2 is ambiguous. Tables 1-1 through 1-5 “component attributes” columns references Table 2 in many cases as the criteria for maximum interval. However, each table entry has a maximum maintenance interval listed as well. There are a few instances where the “trump” interval is not clear. Table 1-5 is a good example. Table 2 states that monitored devices (1-1 through 1-5) not having monitored alarm paths shall be tested every 12 years. However, Table 1-5 states that DC circuits with monitored continuity shall have no periodic maintenance. We suspect that Table 2 attributes needs further clarification to eliminate the confusion, both Table 2 attributes at first glance appear to say the same thing. However, after study it appears to address “detection” monitoring versus continuous (control center type) monitoring. We believe further distinguishing clarifications are needed to make it evident and clear.

Can the SDT add a better definition or clarification of “Calendar Year” as it pertains to PRC-005-2 and provide examples or parameters of Compliance with the Standard requirements and tables? Calendar Year is explained in various details within Pages 35-Pages 37 of the Supplementary Reference and FAQ. This important attribute of a TBM or TBM/CBM combination program is not easily found in the Table of Contents or section sub-headings.
Please explain or clarify the term “mitigating devices” used in Table 1-5 Control Circuitry, Page 19. This term is not well defined in the industry and not easily understood as “interrupting device” or “circuit breaker.”

The document was valuable in understanding PRC-005-2 by providing clarification using practical protective relay system examples. Below are two comments for further improvement. 1. It would be beneficial if the document could provide additional information for relaying in the high-voltage switchyard (transmission owned) - power plant (generation owned) interface. While Figures 1 and 2 are typical generation and transmission relay diagrams, it would be helpful if protective relays

typically used in the interface also be included. For example, a transmission bus differential would remove a generator from service by tripping the generator lockout. 2. Figures 1 and 2 refer to a “Figure 1 and 2 Legend” table which provides additional information on qualifications for relay components. Should a footnote be used to point toward Reference 1 (Protective System Maintenance: A Technical Reference) located in Section 16?
The red-lined version did not agree with the clean copy. In reading the "red lined" document it appears that R3 was intended to be "Each Transmission Owner, Generation Owner, and distribution Provider shall implement and follow its PSPM and initiate resolution of any identified maintenance correctable issues."

Thank you for your diligent efforts in writing the draft standard. The draft standard and associated documents are well written and we believe, after approval, will be instrumental to improving the reliability of the BES. We have the following specific comments: a. The maximum maintenance interval of unmonitored Vented Lead-Acid (VLA) batteries should be changed from 3 calendar months to 12 calendar months. Today’s lead-calcium and lead-selenium-low antimony batteries do not have rapid water loss as compared to the legacy lead-antimony batteries. FPL’s operating experience has shown that electrolyte in today’s VLA cells do not require watering within a 12-month interval. In fact, battery manufacturers now recommend watering intervals of 2 to 3 years for some new batteries. b. The maximum maintenance interval to verify that unmonitored communications systems are functional should be changed from 3 calendar months to 12 calendar months. FPL’s operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). Automated testing such as PLC check-back schemes cannot test for failed PLC protective devices. We believe a 12 calendar month functional test is sufficient because of FPL’s operating experience. FPL’s operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). c. We believe the data retention requirements for R2 and R3 should be documentation for the two most recent maintenance activities. d. Regarding Maintenance Correctable Issue (page2) where it states: “..such that it cannot be restored to functional order during performance of the initial on-site activity”. This terminology is vague: Particularly” initial on-site activity”. Not sure what “functional order” means? The suggestion is to change to “..such that the deficiency cannot be restored to meet applicable acceptance criteria during the performance of the scheduled maintenance activity”. e. Regarding Maintenance Correctable Issue (page 2) and “R4” on Page 5, the suggestion is an entirely new “Maintenance Correctable” definition especially: “Therefore this issue requires followup corrective action”. Regarding this new definition: Why is it here? Is its purpose to ask us to do something with these issues if we discover them? Do issues identified as “Maint. Correctable” need to be tracked and reported in some manner? The referenced term “Maint. Correctable” is only used in PRC-005-2 in “R4” (page 5). The suggestion is to provide clarification. Is this “maintenance cotrrectable terminology implying that NERC PRC005-2 is opening up a new requirement for tracking and reporting resolution of “Maint Correctable” issues? The suggestion is to change to: “This issue includes any activity requiring further follow-up corrective action to restore operability outside of the applicable maint activity”. f. Regarding Countable Event (Page 3), the suggestion is an entirely new “Countable Event” definition. Why is this new term and definition “countable event” included in PRC-005-2 ? Note: In the PRC005-2 text ”countable event” is actually only referred to in PRC-005-2 in Attachment A under “Performance Based Programs” (not referred to in time based programs section). The recommendation is that the PRC-005-2 version explicitly clarify the definition of “countable event” to

clearly indicate that this term is applicable ONLY to “Performance Based Programs”. g. Regarding Countable Event (page 3), where the text says “Any failure of a component which requires repair or replacement, any condition discovered during the verification activities in Tables 1-1/1-5 which requires corrective action…..”, in the definition for “countable event” what does “corrective action” mean? PRC005-2 is unclear. Does the term “countable event” have any ties to “Maint Correctable” issues. The suggestion is to Consider changing wording from “corrective action” to “which requires > 7 days to correct” and clarify whether or not ”countable event” has any correlation to “Maint Correctable”events as discussed on page 2 and in R4? If so please provide language clarifying this correlation.

We commented on this before and we will comment again. The time periods for FERC-jurisdictional entities and non-jurisdictional entities should have at least a 3-month difference to allow some time for FERC approval after BoT adoption in an attempt to more or less put the effective dates of the two groups of entities in the same general time frame. The implementation plan as presented will always result in an effective date for the non-jurisdictional entities to be at least some months (the time between BoT adoption and FERC approval) earlier than their jurisdictional counterparts.
No
(1) We do not agree with the High VRF for R3 which asks for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3 not executable. Hence, we suggest that the VRF for R3 be changed to Medium. (2) The Severe VSL for R2 is improper. First, the reference to R3 is incorrect. Second, the first condition that says: “Failed to establish the entire technical justification described within R3 for the initial use of the performance-based PSMP” introduces a requirement not stipulated in R2 itself. We suggest to remove this condition. If the SDT feels strongly that the technical justification (we’re not sure what exactly it is) needs to be established for the initial use of the performance-based PSMP, then R2 should be revised to capture this requirement.

The SDT should provide notes that reference the sources used for developing the maximum maintenance intervals utilized in the time-based program, and provide a technical explanation as to why they have not provided a tolerance band for use with the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?
PRC-005-2 is a highly prescriptive standard that prevents small entities from establishing a risk-based approach to protective system maintenance that is commonly used in other industry sectors and forces the small entity to utilize the time-based program. Many registered entities do not have a

population size of 60 for each type of protective device. However, they do possess historical records that can be used to calculate the mean time between failures for each equipment type that adequately reflects the service conditions in which the equipment is installed. The SDT should consider allowing registered entities to utilize historical records in their supporting documentation for defining a performance based program. Additionally, by restricting populations by manufacturer model, as referenced in PRC-005-2 Attachment A, the Standard Drafting Team is bordering on anti-competitive behavior as those entities that utilize performance-based programs may be discouraged to utilize alternative suppliers because utilization of a time-based maintenance program on the alternative supplier's equipment may present a cost-benefit analysis hurdle that the supplier of the equipment is not able to overcome. Lastly, the SDT has chosen not to provide a tolerance band for the maximum maintenance intervals it defines in its time-base program. Given that the SDT has not provided sound technical justification (i.e. a study, industry recommended practice, etc.), the SDT should reconsider its stance on providing a tolerance band on the time intervals specified in the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?

Yes
In the background section of the implementation plan in item two it states "...it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: " The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. In addition, it would seem appropriate to allow entities that decide to implement PRC-005-2 requirements before the standard becomes effective to count the maintenance they do before the effective date in the implementation plan schedule and in the testing interval compliance.
Yes
No
Requirement R3 of the standard discusses resolution of "identified maintenance correctable issues". M3 requires evidence of "resolution of Maintenance Correctable Issues". The definition of Maintenance Correctable Issue in the standard includes "during performance of the initial on-site activity". The "initial on-site activity" seems to imply that the corrective steps that need to be tracked are those resulting from the periodic testing that is done for compliance with the standard. It is not clear if the SDT meant to require that records be kept of any required maintenance that is done as a result of a discovered problem or failure that is not identified during the periodic testing.

Regarding the last row of Table 1-4(f): it seems very inconsistent to require a formal trending program for a manual 6 month(VRLA)/18 month (VLA) internal ohmic reading but to require no gathering and analysis of data as an alarm for a ohmic value for each cell/unit is available. If just a raw ohmic value is an adequate predictor of cell life, than why require a trending program for the

manual reading if all that is needed to determine adequacy of remaining cell life is just a simple acceptance criteria (i.e. - alarm setpoint) against which you need to compare your measured data? In theory these are very gradual and predictable changes in ohmic readings over the entire life of the battery, such that the benefit of real time knowledge of exactly when a threshold is reached via alarm is minimal rather than having to wait until the next manual reading to ascertain that the threshold limit has been reached.
Yes
Yes
Yes
1) On page 65, paragraph 4, of the “Supplemental reference and FAQ” document, it states: “… the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.” While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of test equipment will not change during this period. 2) A FAQ to clarify in scope protection systems for variable energy resource facilities (wind, solar, etc) would be very helpful. Does paragraph 4.2.5.3 “Facilities” imply that the only protection system associated with a wind farm that is considered in scope for PRC-005-2 is that for the aggregating transformer? If other protection systems associated with a wind farm are in scope, please clarify which systems would be in scope for PRC-005-2. For example, a typical wind farm in our system might have 30-33, 1.5MVA windmills connected to one 34.5 KV collecting feeder circuit for a total of roughly 50 MVA per collecting feeder. 4 of these 50 MVA collecting feeders are tied via circuit breakers to a low side 34.5 KV bus which in turn is connected via a low side breaker to aggregating step up transformer which then connects to the BES transmission system. Obviously per paragraph 4.2.5.3, the protection system for the aggregating step up transformer is in scope. What about the protection system for the transformer low side 34.5 KV breaker – serving 200 MVA of aggregate generation? What about the protection system of each individual 34.5 KV aggregating feeder – 50 MVA of aggregate generation? What about the “protection system” for each individual 1.5 MVA windmill? An FAQ on this topic would be very helpful.
1) Regarding “Facilities” paragraph 4.2.5, we are in agreement with the elimination from scope of system connected station service transformers for those plants that are normally fed from a generator connected station service transformers. However, in the cases where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team’s intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility? If the end result of the trip of the primary station service transformer is a trip of a BES generating facility, it would be more consistent to include the protection system for that transformer as in scope – whether it be connected to the system or to the generator. 2) We recommend the SDT consider an interval of 12 calendar years for the component in row 3, of Table 1-5 on page 19 of the standard. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that the SDT will consider these changes.

Consideration of Comments on the 4th Draft of Protection System Maintenance and Testing — Project 2007-17

The Protection System Maintenance and Testing Drafting Team thanks all commenters who submitted comments on the 4th draft of the Protection System Maintenance standard, its implementation plan, and the associated reference document. The standard and associated documents were posted for a 30-day public comment period from April 13, 2011 through May 13, 2011. Stakeholders were asked to provide feedback on the standard and associated documents through a special electronic comment form. There were 55 sets of comments, including comments from more than 176 people from approximately 103 companies representing 10 of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted may be reviewed in their original format on the standard's project page:

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

In addition, a successive ballot of the standard was conducted from May 3-13, 2011, and a non-binding poll of the Violation Risk Factors and Violation Severity Levels was conducted from May 3-16, 2011 and comments from the ballot and poll have been included in this report.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Summary Consideration of all Comments Received:

Purpose:

The SDT modified the Purpose to state, "To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order" in response to previous Quality Review comments.

Applicability:

Several comments were offered, suggesting that PRC-005-2 needs to be consistent with the interpretation in Project 2009-17, now implemented as PRC-005-1a, and the SDT modified Applicability 4.2.1 for better consistency with the interpretation 4.2.1 as shown below:

> 4.2.1. Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).

Requirement R1:

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Requirement R1 was modified as shown below for improved specificity, based on stakeholder comments:

> R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.

Tables

Most commenters seemed to agree in general that the restructured tables added clarity, and some commenters offered assorted suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" to address various comments.

Implementation Plan

Some commenters noted that for entities not subject to regulatory approvals, the implementation plan should be longer so that all entities have sufficient time for implementation. The team did modify the Implementation Plan to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines. Additionally, all "calendar year" implementation periods were revised to "months" for additional clarity.

VLSs:

VSLs for Requirement R1

- Phased VSLs were added to address R1 Part 1.1, which was previously addressed only as a "Severe" VSL.
- A reference was added within the R1 VSL to Part 1.3.
- R1 High VSL was revised to add a reference to Table 2.

VSLs for Requirement R2

- One element of the R2 VSL was made binary (Severe), rather than "phased" (in two steps), in response to several comments.
- Many commenters pointed out an error (which was corrected by the SDT) within the VSL for R2, where the Lower and High VSLs contained identical text.

VSLs for Requirement R3

- The R3 VSLs were revised to replace "complete" with "implement and follow" for consistency with the Requirement.
- Other minor editorial changes were made throughout the VSLs in response to comments.

Supplementary Reference and FAQ

- The commenters were generally supportive of the reference document.

- Several questions regarding the enforceability of this document were posed, and the SDT explained that the document is a supporting reference and not enforceable – only standard requirements are enforceable.
- A variety of suggestions were offered regarding additional information for the document, which largely resulted in modifications to the Supplementary Reference document. One specific suggestion of note (resulting in additional discussion within the document) requested a FAQ regarding "Calendar Year".
- Several commenters posed questions regarding "grace periods" and "PSMPs established by entities that are more stringent than the requirements within the standard". No additional changes were made due to these questions. If an entity develops a PSMP that includes time intervals that are more stringent than those in the standard, the entity will be audited against the intervals in its PSMP.

Definitions:

- Several comments were offered regarding Maintenance Correctable Issues, and resulted in modifying this definition to be "…such that the deficiency cannot be corrected during the performance of the maintenance activity …"

Unresolved Minority Views:

- Many comments were offered objecting to the 3-calendar-month intervals for station dc supply and communications systems, and suggesting that a 3-calendar-month interval requires entities to schedule these activities for 2-calendar-months in order to assure compliance. The SDT did not modify the standard in response to these comments, and responded that the intervals were appropriate, and that entities should be able to assure compliance on a 3-calendar-month schedule by using program oversight. The "Supplementary Reference and FAQ" document was augmented with additional explanatory text.

- Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.

- Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.

- Several comments were offered questioning various aspects of Applicability 4.2.5.4 (generation auxiliary transformers). No changes were made in response to these comments, and responses were offered illustrating why these transformers are included.

- Many comments were offered, questioning the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT explained that these Protection Systems are appropriate to be included for consistency with legacy standards PRC-008, PRC-011, and PRC-017, and noted that their inclusion is consistent with Section 202 of the NERC Rules of Procedure.

- Several comments were offered, objecting to the 6-calendar-year interval for lockout and auxiliary relays. The SDT declined to adopt the requested changes, and noted that these "electromechanical" devices with "moving parts" share failure mechanisms with electromechanical protective relays and that the intervals should be identical.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. **The SDT has restructured the Table for Station DC Supply, separating it into six sub-tables individually addressing the various different technologies. Do you agree that the restructured tables provide more clarity? If not, please provide specific suggestions for improvement.**

Summary Consideration: Most commenters seemed to agree in general that the restructured tables added clarity, and some commenters offered assorted suggestions for further improvement. Minor clarifying changes were made to the Tables themselves, and additional discussion was added to the "Supplementary Reference and FAQ" to address various comments.

A number of commenters continued to object to the "3 Calendar Month" maintenance intervals, and the SDT chose not to modify the standard. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems and suggestions to extend the maintenance intervals to 6 or 18 months were not adopted.

Some comments suggested extending the interval to 4 months. Additional discussion (including an example) regarding this item was added to Section 7.1 of the "Supplementary Reference and FAQ". As explained in the reference, a calendar month begins on the first day of a new month following the month in which the activity was performed. Thus every "3 Calendar Months" means to add 3 months from the last time the activity was performed.

Specific changes made to the tables in response to comments:

Tables 1-1 and 1-3 – References to Table 2 were corrected.

Table 1-4(a) and Table 1-4(d) – Modified header to clarify, "Protection System Station dc supply"

Table 1-4(b) and Table 1-4(c) - Modified header and component attributes to clarify, "Protection System Station dc supply"

Table 1-4(e) - Modified header and component attributes to clarify, "Protection System Station dc supply" and replaced, "distribution breakers" with "non-BES interrupting devices".

Table 1-4(f) - Modified header to clarify, "Protection System Station dc supply", modified the seventh table entry for clarity, and added eighth table entry.

Table 1-5 – Added "Associated with Protective Functions" to header

Organization	Yes or No	Question 1 Comment
Tri-State G & T Association, Inc.	Ballot	On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored

Organization	Yes or No	Question 1 Comment
(3) (5)	Comment – Affirmative	communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Also, if a relay is set to operate in a manner typical when communication is not used for protection (i.e. defaulting to step-distance functions with a loss of communication), is the defaulted operation of the relay considered "correct operation" thereby excluding the communication as necessary for its correct operation? Please clarify the term correct operation and how it applies to redundant communication systems and/or the performance of the relay in the absence of communication.
Response: Thank you for your comments. If communication-assisted protection is provided as described in the Applicability of PRC-005-2, it must be tested in accordance with the intervals and activities described in the standard. Redundant equipment and/or channels do not relieve the entity of the responsibility to maintain all equipment as required. An entity is entitled to use any monitoring present on the communications system to adjust its maintenance as established within Table 1-2, and, if sufficient component populations are present and the entity wishes to address the additional included requirements, performance-based maintenance is also available. Correct operation of the protective function means that if the communications system is part of the protection system and loss of it causes the system to fail to meet the schemes protection requirements it has failed. In the example you provide, loss of communications would result in time delay clearing depending on location of the fault. If time delay clearing will be sufficient for your system clearing time requirements, then high speed clearing is not required and the Comm. System would not need to be installed. If it is installed, you must meet the PRC-005 requirements. Redundant communications schemes are installed where high speed clearing is required to meet planning criteria. The second scheme is in place to prevent the line from being removed from service if the primary scheme must be maintained or fails. If redundant schemes are in place, both must meet the PRC-005 standard.		
Tri-State G&T		On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Please clarify the term correct operation and how it applies to redundant communication systems.
Response: Thank you for your comments. If communication-assisted protection is provided as described in the Applicability of PRC-005-2, it must be tested in accordance with the intervals and activities described in the standard. Redundant equipment and/or channels do not relieve the entity of the responsibility to maintain all equipment as required. An entity is entitled to use any monitoring present on the communications system to adjust its maintenance as established		

Organization	Yes or No	Question 1 Comment
within Table 1-2, and, if sufficient component populations are present and the entity wishes to address the additional included requirements, performance-based maintenance is also available. Correct operation of the protective function means that if the communications system is part of the protection system and loss of it causes the system to fail to meet the schemes protection requirements it has failed. In the example you provide, loss of communications would result in time delay clearing depending on location of the fault. If time delay clearing will be sufficient for your system clearing time requirements, then high speed clearing is not required and the Comm. System would not need to be installed. If it is installed, you must meet the PRC-005 requirements. Redundant communications schemes are installed where high speed clearing is required to meet planning criteria. The second scheme is in place to prevent the line from being removed from service if the primary scheme must be maintained or fails. If redundant schemes are in place, both must meet the PRC-005 standard.		
Consumers Energy (4)	Ballot Comment - Negative	Relating to Table 1-3, The SDT has advised that the voltage and current inputs must be checked at each individual relay. This may not be difficult if the relays are microprocessor relays (where internal metering may be used), but for the predominant population of electromechanical relays (particularly for current signals), this requirement will necessitate repeated operation of test switches and associated insertion of meters. Such activities will not only be very difficult and time consuming, but will actually be dangerous because of the dangers of accidentally opening current circuits during testing. It should be sufficient to verify the integrity of the series string of protective relays, etc during maintenance activities, as all devices within the series string will be receiving the same values.
Response: Thank you for your comments. Entities can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, secondary injection, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately “verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays”.		
Tri-State G & T Association, Inc. (3) (5)	Ballot Comment - Affirmative	The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions?
Response: Thank you for your comments. No, an independent DC Supply related only to communication equipment is not considered to be “station dc supply”. The periodic functional observation and testing of the communications equipment is included, but there are no requirements for the independent dc supply.		
Wisconsin Electric Power Co. (5) Wisconsin Electric Power	Ballot Comment - Negative	(1) The maximum maintenance intervals listed in various PRC-005-2 tables are described as “calendar years” which is an undefined term. Since maintenance intervals are critical to this standard, this term should be either clearly defined or explained in the standard. For example, if a component was last tested on 6/1/2005; does that component need to be tested by 6/1/2011 or 12/31/2011 to satisfy its 6 calendar year

Organization	Yes or No	Question 1 Comment
Marketing (3) Wisconsin Energy Corp. (4)		maximum maintenance interval? 2) Clarification and/or direction is desired on the testing of protection systems that contain components owned by various entities. For example, in the instance of non-vertical integrated utilities where a distribution provider has a Protection System that directly trips a transmission owner's circuit breaker(s), how would the distribution provider verify that the trip coil is able to operate the circuit breaker? (3) Maximum testing intervals are defined. Does this imply that there are no minimum testing intervals? In other words, is the maintenance cycle reset anytime maintenance is performed? (4) Requirement R1.1.2 states that" "All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4." Yet, in Table 1-4 under Component Attributes it refers to "…not having monitoring attributes of Table 1-4(f)." Suggest this statement be made more clear by adding "All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4., unless the dc supply has the monitoring attributes listed in Table 1-4(f)." (5) Suggest the inspection Maximum Maintenance Interval for inspection of batteries be 4 months instead of 3 months to allow for workforce constraints that may preclude an inspection being performed within a 3 month window. Every 3 months has been found to be more than adequate to observe changing conditions that affect batteries, therefore we feel 4 months would still be sufficient. (6) In Tables 1-4 (a), (b), (c) – What is your interpretation of battery continuity? In other words, what measurements or indications would be acceptable to affirm an acceptable condition? Table 1-4(b) VRLA batteries, Maximum Maintenance Interval 18 Calendar Months, Maintenance Activities, Verify: Battery terminal connection resistance, Verify: Battery intercell or unit-to-unit connection resistance - comment: Add the following qualifier to these resistance checks: "If battery posts are not readily accessible or too small to allow a good connection, follow the manufacturer's recommendation(s)."

Response: Thank you for your comments.

1. A "calendar year" refers to the years on the Julian calendar commonly used, and should be regarded as referring to a numbered year, comprising the months of January through December. For example, 2010 is one calendar year; 2011 is another. A component, with a 6-year interval, which was last tested in 2005, would next have to be tested by the end of 2011.

2. The standard does not prescribe "how" an entity must meet the requirements, only that the requirements must be met. However, all entities listed in the Applicability are "owner entities", and the SDT believes that the owner of the component should be responsible for its maintenance. However, it may be necessary to have records relating to specific activities from the associated entity in order to demonstrate compliance to an auditor.

3. No minimum intervals are provided. To the degree that any maintenance includes all required activities, that maintenance can be recorded as addressing the

Organization	Yes or No	Question 1 Comment
standard and re-setting the interval. 4. A "time-based" program includes extended intervals for those activities that can be effectively performed by condition monitoring. However, this requirement excludes an entity from utilizing performance-based maintenance per R3 and Attachment A. 5. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month" 6. In Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT gives its interpretation of battery continuity and lists several examples of measurements or indications that would be acceptable to affirm an acceptable condition and contains a discussion of connection resistance. Your comment concerning the inaccessibility of posts or being too small would fit more appropriately as a qualifier there than in the in the standard itself.		
Tennessee Valley Authority (1) (5) (6)	Ballot Comment - Negative	In Table 1-4(a), the requirement to perform battery cell internal ohmic measurements every 18 months for vented lead-acid batteries is excessive, and no technical justification is provided for an 18-month interval. A 3-year internal ohmic test frequency is adequate to prove battery integrity. IEEE 450 does not provide a recommended interval for internal ohmic measurements. For standard capacity testing, the recommended interval is no greater than 25% of expected battery life. Our normal battery life is 20+ years, so the recommended capacity test interval would be about 5 years. EPRI also recommends capacity testing at 5 year intervals. There is no justification for performing internal ohmic measurements every 18 months (which equals every 7.5% interval of the expected battery life). We feel the standard should set the interval for battery internal cell ohmic testing at 3 years.
Response: Thank you for your comments. The Maintenance Activity of evaluating the measured cell/unit internal ohmic values to station battery baseline is an optional activity to verify that the station battery can perform as designed. An owner who desires not to take internal ohmic measurements on a Vented Lead-Acid (VLA) battery can elect to verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank without ever having to perform any internal ohmic measurement on the battery. The maximum maintenance interval for performing this capacity test on a VLA battery bank is 6 Calendar Years. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" - that was posted for review with PRC-005-2 - the SDT answered several Frequently Asked Questions which explain why the 18 month Maximum Maintenance Interval is justified rather than the 3 year frequency that is assumed by some to be adequate.		
Great River Energy (1)	Ballot Comment - Affirmative	1. Table 1-4(b) VRLA Batteries---both" 6 Calendar Months" in the table should be changed to 12 months. This would avoid being in violation if we miss a bank during a "6 month maintenance cycle" 2. Table 1-4(c) Nickel-Cadmium Batteries under the Maintenance Activities column for the 6 Calendar Years---This maintenance activity should be optional if 18 Calendar Month Activities are completed. Or increase load test to 10 years.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. 1. In the IEEE recommended Practice for Maintenance, Testing and Replacement of VRLA batteries (IEEE SDT 1188) a quarterly inspection should include "Cell/unit internal ohmic values." Based on this recommendation the SDT believes that extending the Maximum Maintenance Interval of 6 Calendar Months in Table 1-4(b) to 12 months as suggested would be too excessive. The 6 Calendar Months for this maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few days during the quarterly maintenance cycle. 2. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT answered a Frequently Asked Question explaining why the 6 Calendar Year maintenance activity cannot be optional if the 18 Calendar Month Activity of Table 1-4(c) is performed. The SDT also in the Supplemental Reference & FAQ document justifies why the 6 Calendar Year Maximum Maintenance interval for performing the Maintenance Activity in Table 1-4(c) can not be extended to 10 years as suggested.		
AtCO Electric ltd		Table 1-4: ATCO Electric has a number of remote substations that are difficult to access. 1. The requirement for a 3 calendar month inspection for electrolyte level is too frequent. The requirement would become achievable if electrolyte level inspections were moved to the 18 calendar months category, or if the 3 calendar months frequency were increased to 8 calendar months. 2. Table 1-4(b): for the same reasons, the requirement of a 6 calendar month inspection of individual battery cell/unit internal ohmic values is too frequent. The requirement would become achievable if battery cell/unit internal ohmic value inspections were moved to the 18 calendar months category, or if the 6 calendar months frequency were increased to 14 calendar months. 3. Table 1-4(c): the requirement of a 6 calendar year performance service or modified performance capacity test should be removed. From our experience, there is no benefit in doing battery load tests. Instead, we apply verification of battery intercell resistance as a more efficient method of monitoring battery condition, which provides an 8 to 14 month lead time to replace a battery unit/cell before it goes dead.
Response: Thank you for your comments. 1. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval. If adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". 2. In the IEEE recommended Practice for Maintenance, Testing and Replacement of VRLA batteries (IEEE SDT 1188) a quarterly inspection should include "Cell/unit internal ohmic values." Based on this recommendation the SDT believes that extending the Maximum Maintenance Interval of 6 Calendar Months in Table 1-4(b) to the 18 calendar months category as suggested would be excessive and the SDT notes that this verification may be possible via monitoring methods."(See Table 1-4(f), component attribute row "Any lead acid battery based …"). The 6 Calendar Months for this maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few days during the quarterly maintenance cycle.		

Organization	Yes or No	Question 1 Comment
3. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT answered a Frequently Asked Question explaining why the 6 Calendar Year maintenance activity cannot be optional if the 18 Calendar Month Activity of Table 1-4(c) is performed. The SDT also in the Supplemental Reference & FAQ document justifies why the 6 Calendar Year Maximum Maintenance interval for performing the Maintenance Activity in Table 1-4(c) can not be removed as suggested.		
Kristina M. Loudermilk (8)	Ballot Comment - Affirmative	1) In Table 1-4(b) under the Component Attributes, the sentence begins with Station dc supply; while the other 1-4 tables begin with Protection System Station dc. I propose to make it consistent with the other tables. 2) Table 1-4(e) mentions Maximum intervals and references another table. Is there an easier way in the Standard to send the same information without having them flip pages? As another example in every Component Attribute in Table 1-4(f) we mention (See Table 2). Could it be possible to make that a note, instead of placing it under each attribute? It seems overwhelming when looking at these and for each one that is read, flip over to Table 2. I feel like some of these references give the feel of a scavenger hunt. I am not sure if anything can be done, but thought I would mention it.
Response: Thank you for your comments. 1.The Tables have been modified to use "Protection System Station dc supply" 2. In this regard, the SDT has tried several methods of presentation for this information. Of all methods reviewed, including the one you suggest, the SDT has determined that the method currently represented in the Tables represents the best compromise.		
Consumers Energy (4)	Ballot Comment - Negative	Relative to the 18-month activity to measure battery terminal connection resistance in Table 1-4, measuring the battery terminal connection resistance for all terminals of the battery is an involved process that may force the battery (and thus the system) out-of-service, or alternatively the use of a temporary battery, for the duration of the activity. We suggest that a 6-year interval for this involved and invasive activity is appropriate and adequate. We also suggest that it should alternatively be sufficient to instead re-torque all battery terminal connections at the same interval.
Response: Thank you for your comments. In IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), valve-regulated lead-acid (VRLA) and nickel-cadmium (NiCd) batteries respectively state that a "yearly inspection" should include "Cell-to-cell and terminal connection resistance", "Cell-to-cell and detail resistance of entire battery", and "Condition and resistance of cable connections." Based on these IEEE recommendations the SDT believes that the Maximum Maintenance Interval of 18 Calendar Months for this Maintenance activity will allow an entity to avoid being in violation if they miss a bank by a few weeks during the yearly maintenance cycle. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" - that was posted for review with PRC-005-2 - the SDT explains what hazards can result from high connection resistance. Also in the Supplementary Reference the SDT references where in the IEEE Standards entities can find excellent information and examples of performing this non-intrusive Maintenance Activity. The SDT respectively disagrees with the premise that the activity to		

Organization	Yes or No	Question 1 Comment
measure battery terminal connection resistance in Table 1-4 is “an involved process that may force the battery (and thus the system) out-of-service, or alternatively the use of a temporary battery, for the duration of the activity.” Members of the SDT are familiar with numerous Transmission Owners, Generator Owners and Distribution Providers in NERC who yearly perform this benign maintenance activity on their battery systems while the Protection Systems that the station batteries support are in service.		
Ameren Services (1)	Ballot Comment - Affirmative	Clarify p17 Table 1-4(e) interval meaning. We think this means we need to verify the Station dc supply voltage on 12 calendar year interval if unmonitored, or no periodic maintenance if monitored as stated.
Response: Thank you for your comments. You are correct in your interpretation for Protection System dc supply used only for distribution breakers that are associated with UFLS, UVLS, or SPS, as stated in Table 1-4(e).		
Old Dominion Electric Coop. (4)	Ballot Comment - Affirmative	ODEC believes the standard is very close to being ready for approval. 1. In the Attachment A for the battery testing, you exempt the UFLS and UVLS equipment in tables and then include SPS batteries in the table with UFLS and UVLS. Either SPS should be associated with UFLS and UVLS and you need to add it to the previous tables or fix table 1(f). 2. Also, consider going to 4 calendar months instead of 3 calendar months for the battery maintenance requirements.
Response: Thank you for your comments. 1. Special Protection Systems are often a far more complex system which may comprise a combination of “transmission”, distribution, and generation components, and are often installed to prevent serious system problems. Therefore, the requirements for SPS equipment maintenance align with that for other generic Protection Systems. It is also notable that the legacy PRC-017-1 includes batteries within the list of components to be addressed. However, if the breaker is a distribution breaker that is associated with SPS but is not otherwise associated with generic Protection Systems, the extended interval in Table 1.4(e) applies. 2. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month.”		
Associated Electric Cooperative, Inc. (1)	Ballot Comment - Negative	AECI appreciates the effort by the drafting team. However, the 90 day inspections for batteries and communications circuits should be extended to 120 days to allow for a 30 grace period. Schedules would be set for every 90 days as what is required in this revision.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of		

Organization	Yes or No	Question 1 Comment
unmonitored components. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”		
Manitoba Hydro (1) (3) (5) (6)	Ballot Comment - Negative	1. Battery Check Interval Manitoba Hydro maintains our position that the 3 month battery check interval should be extended to 6 months. The 3 month interval is too frequent based on our experience and while IEEE SDT 450 (which seems to be the basis for table 1-4) does recommend intervals, it also states that users should evaluate these recommendations against their own operating experience. With the 3 month battery check frequency and no allowance for a grace period, there may be a negative impact on reliability caused by diverting resources away from projects that are critical to reliability to meet this maintenance interval. 2. Conductance Measurements Conductance measurement should be listed in Table 1-4 as an acceptable measurement method.
Response: Thank you for your comments. 1. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. 2. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT answered a Frequently Asked Question explaining what cell/unit internal ohmic measurements are. Conductance by definition is an ohmic measurement and although not spelled out in the standard is listed in Table 1-4 because it is an ohmic measurement.		
Georgia Transmission Corporation	No	We need clarification on the UFLS or UVLS system Station DC Supply test. We trip the high side device (non-BES asset) for each of our distribution stations UFLS or UVLS schemes, not the individual distribution breakers. It is hard to distinguish what maintenance interval and maintenance activities we should engage for Station DC Supply test. Since the device is not a distribution breaker as mentioned in the Table 1-4 (a-f) we would be conservative and choose to perform maintenance at all our distribution stations with UFLS or UVLS schemes as per Table 1-4(a). Reading the statements in the Supplementary Reference and FAQ, we notice our devices perform similar functions as the distribution breakers. Reference pg 60 of Supp. Ref. and FAQ paragraph 4. Since tripping the high side device of a distribution transformer still constitutes a distributed system would our system meat the exclusion criteria although it is not a distribution breaker, would this meet the same requirements and exempt the station from Table 1-4(a) and require only maintenance for DC systems as per Table 1-4(e)? Please clarify. We recommend changing the term distribution breaker to distribution asset interruption device or non-BES equipment interruption device.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. Table 1-4 (e) has been modified in consideration of your comment to improve clarity (“non-BES interrupting devices “). If the cited distribution transformer is not a BES element, the Protection Systems for that distribution transformer are not included per the Applicability (4.2.1) as modified.		
PNGC Comment Group	No	We agree the changes to the tables have added clarity, but disagree with the maintenance intervals for DC supply. Comments: PNGC’s comment group views the Maximum Maintenance Interval for station DC Power Supply (Table -14a/b/c/d) to be unnecessarily onerous and restrictive to many smaller-rural entities, in the west and probably throughout the US, and this prevents us from being able to support PRC-005-2 as written. We make these comments with the understanding that others have made similar comments in the past but we feel strongly that this is an important issue worthy of further review by the SDT. We believe a quarterly inspection schedule can be met while at the same time allowing entities the flexibility they need. IEEE 1188-2005 suggests a quarterly inspection schedule for lead acid batteries and we believe the standard interval for verifying and inspecting dc supply should be 3 months with a maximum interval of 6 months. This meets the quarterly threshold and gives some flexibility to account for unusual conditions. There are substations in Pacific Northwest rural areas that can be inaccessible during long periods of time during the winter, potentially exposing an entity to sanction if weather conditions prevent access to equipment for an extended period of time. Additionally, due to a smaller workforces and greater distances between equipment subject to PRC-005, small-rural entities face obstacles that large entities may not have. The three month maximum interval assumes ideal conditions and resource access and is not realistic. We thank the SDT for considering our comments.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended.		
Arizona Public Service Company	No	Although considerable clarity was achieved in the structuring of the table for the different types of technologies associated with the DC supply, there is issue on the maximum allowable intervals. The standard remains too prescriptive in the intervals and maintenance activities. As an example it is believed the intent of the interval for verifying voltages and inspecting electrolyte levels and unintentional grounds level would be every 3 months. However, for the entity to ensure compliance and not incur a violation it would have to have a shorter interval, probably every 2 months just to ensure compliance and not incur a violation. The 3 month interval is in question based on programs that have been in service for many years where four months have been proven as reliable for operation, an even shorter period than 3 or 4 months is not only a burden but an unnecessary expense without a benefit of increase reliability of the Bulk Electric System.

Organization	Yes or No	Question 1 Comment
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month".		
Southern Company Generation (5)	Ballot Comment - Affirmative	The restructured Table for Station DC supply does clarify what is being required for each type of dc system, yet the Station DC Supply requirements, however, are excessively prescriptive in comparison to the other Protection System component types.
Response: Thank you for your comments. The SDT recognizes that Table 1-4 with its tables a through f is considerably larger than any of the tables for the other four Protection System components. However the SDT does not agree that the maintenance activities of Tables 1-4 (a –f) for the station dc supply are "excessively prescriptive." As pointed out in Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the station battery which is part of the station dc supply is unique from any other Protection System component in that it is a perishable product which requires several prescribed maintenance activities to monitor and maintain its ability to perform as designed for its life cycle.		
Indeck Energy Services	No	The tables are limited to a few battery technologies and will be out of date in short order with the many types of advanced batteries already on the market. The testing requirements should be performance based as opposed to prescriptive.
Response: Thank you for your comments. While the SDT agrees that there are a few advanced batteries and new station dc supplies which have non battery based energy storage devices in them on the market, the SDT disagrees that the testing requirements for batteries used in station dc supplies should be performance based as opposed to prescriptive. FERC Order 693 and the approved SAR assign the SDT to develop a standard with maximum allowable intervals and minimum maintenance activities. Please note that the Standard specifically addresses requirements for non-battery based energy storage devices within Table 1-4(d). According to the NERC Reliability Standard Development Process, NERC Reliability Standards must be reviewed at least once every five years, and any changes related to new technologies can be addressed within that process.		
Tampa Electric Company	No	If during a UF operation there were ever any breakers that did not trip properly, there may be enough that do trip to return things to balance. There is more room for error with UFLS than with BES. The standard does make some allowance for differences between UFLS equipment and BES equipment. For example the DC source testing requirement for UFLS is to just test the battery voltage when the control circuit is tested. It is not necessary that the breaker be tripped for UFLS testing every six years as is the case for BES. However, every 12 years all unmonitored control circuitry must be tested, which may include tripping the breaker.
Response: Thank you for your comments. Table 1-5 does not require tripping of the breaker for UFLS/UVLS.		
Tri-State G & T Association, Inc.	Ballot	On Page 19, Table 1-5, the standard requires that electromechanical lockout control circuits be maintained

Organization	Yes or No	Question 1 Comment
(3) (5)	Comment - Affirmative	every 6 years and protective function unmonitored control circuits be maintained every 12 years. Why is there inconsistency in the interval between the electromechanical lockout and protective function control circuits?
Response: Thank you for your comments. The circuit itself is 12-years, but the interval for electromechanical devices such as auxiliary or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.		
Constellation Energy Commodities Group (6)	Ballot Comment - Negative	As with previous revisions of this standard, the maintenance intervals and activities described in Table 1-1 through Table 1-5 are too prescriptive.
Constellation Power Source Generation, Inc. (5)	Ballot Comment - Negative	CPG believes, as with previous revisions of this standard, that the maintenance intervals and activities described in Table 1-1 through Table 1-5 are too prescriptive.
Response: Thank you for your comments. The SDT is not prescribing or suggesting what methods an entity employs within their program. The intervals remain as prescribed within the standard and are designed to be clear and effective to support reliability of the BES.		
Alliant Energy Corp. Services, Inc. (4)	Ballot Comment - Negative	Table 1-5 (Component Type – Control Circuitry) Item 4 – "Unmonitored control circuitry associated with protective functions" require a 12 calendar year maximum maintenance interval. We believe UFLS and UVLS control circuitry should be exempted from this requirement. It would take multiple failures to have any impact, and the impact on the BES would be minimal.
Response: Thank you for your comments. The SDT disagrees; however, the requirements related to interrupting devices used only for UFLS/UVLS are less detailed than those for other Protection Systems because of the reason cited in your comment.		
Consumers Energy (4)	Ballot Comment - Negative	Relative to Table 1-5, the activities will likely require that system components be removed from service to complete those activities. In the case of system elements that do not have redundant protection systems (such as those related to lower-voltage systems within the BES), it may not be possible to do so with outaging customers for the duration of the maintenance activity. The standard must exempt these components from the activities of Table 1-5 if the activity would result in deenergizing customers.
Response: Thank you for your comments. The intervals and activities specified are believed by the SDT to be technically effective. It is left to the entity to determine how to align these requirements with requirements of other regulations and with operational concerns. Entities should be able to complete the activities within the shorter intervals without outages.		
American Transmission	Ballot	1. ATC recognizes the substantial efforts and improvements to PRC-005-2 that have been made and

Organization	Yes or No	Question 1 Comment
Company, LLC (1)	Comment - Negative	appreciate the dedicated work of the SDT. ATC appreciates the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 2. ATC's remaining concerns to PRC-005-2 are with the definition and timelines established in Table 1-5. ATC is recommending a negative ballot since, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. Note: Additional Comments to overall Standard also submitted.
Response: Thank you for your comments. 1. Thank you for your support. 2. The lockout relays and trip coils contain "moving parts" which must be periodically exercised to remain reliable. Operational results, if desired by an entity, MAY be used to meet maintenance requirements to the degree that they verify, etc, the relevant performance. Whether their use is effective for a specific entity is left to the entity to determine.		
Wisconsin Electric Power Co. (5) Wisconsin Electric Power Marketing (3) Wisconsin Energy Corp. (4)	Ballot Comment - Negative	Clarification is required in Table 1-5 as to what trip and control paths should be tested. Specifically, should non-protection paths, such as local control switches, that are not part of the Protection System, but operate Protection System Component, be tested? In Table 1-5, the maintenance activity for unmonitored control circuitry associated with protective functions is to "verify all paths of the control and trip circuits". We recommend that only the protection system paths of the control and trip circuits require verification by PRC-005-2.
Response: Thank you for your comments. The SDT believes that Protection Systems that protect BES elements should be included. This position is consistent with the currently-approved PRC-005-1 and consistent with the SAR for Project 2007-17. The header section of Table 1-5 has been modified to clarify that only the control circuitry associated with protective functions is being addressed.		
Kristina M. Loudermilk (8)	Ballot Comment - Affirmative	In table 1-5 is it necessary to mention the second and last item in the table. If there is nothing to do, then why have it as an attribute making it mandatory to keep track of, well, nothing. If those items do need to stay, then could we reorganize the table so where it is in ascending order from Maximum maintenance intervals, like the other tables?
Response: Thank you for your comments. The SDT believes that inclusion of these two items add clarity. The Table entry for trip coils associated only with UVLS/UVLS has been left in the original position to relate it directly to the companion activities for other applications.		

Organization	Yes or No	Question 1 Comment
Nebraska Public Power District	No	The restructured tables are indeed an improvement; however the tables still need some work for clarity: 1. Table 1-5: Unmonitored control circuitry has a maintenance activity of "Verify all paths of the control and trip circuits." The wording of "control and trip circuits" leads to circuit verification of more than just trip circuits. In fact multiple circuits would have to verified, such as station house load transfer schemes. Providing documentation to an auditor to prove all paths have been tested will be difficult and is considered excessive. The paperwork required to prove compliance is extremely excessive for this requirement and doesn't provide a benefit to reliability. 2. Table 1-5: Table 1-5 requires trip checking every six calendar years for trip coils and electromechanical lockout and/or tripping auxiliary devices. Every six years is excessive, when suitable monitoring is used. We recommend verification of these components be completed at the same frequency as the associated relay testing when monitoring is used. For electromechanical, no more than every 6 calendar years, for microprocessor, no more than 12 calendar years.
Response: Thank you for your comments. 1. The header section of Table 1-5 has been revised to clarify that it applies to "Control Circuitry Associated with Protective Functions", and the SDT believes that this revision addresses your concerns. 2. The electromechanical devices such as auxiliary or lockout relays remains at 6 years, as these devices contain "moving parts" which must be periodically exercised to remain reliable.		
Consolidated Edison Co. of New York (1) (3) (5)	Ballot Comment - Affirmative	1. We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend.
Consolidated Edison Co. of New York (6)	Ballot Comment - Affirmative	1. We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend. 2. We recommend that the drafting team recognize that a "fail safe" or "self-reporting" alarm design serves as an acceptable alternative to periodic testing. This "fail safe" or "self-reporting" alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to "alarm on" and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments.		

Organization	Yes or No	Question 1 Comment
1. The SDT believes that the monitoring and reporting will be generally done by automatic reporting methods such as SCADA and previously removed a reference to "automatic reporting" specifically to address those cases where the facility is manned. 2. The application discussed seems to the SDT to be an effective method of "monitoring the monitoring circuit". (See Table 2, last row with heading "Alarm Path with monitoring.")		
Nebraska Public Power District	No	1. Table 2: The interrelationship between Tables 1-1 through 1-5 and Table 2 is ambiguous. Tables 1-1 through 1-5 "component attributes" columns references Table 2 in many cases as the criteria for maximum interval. However, each table entry has a maximum maintenance interval listed as well. There are a few instances where the "trump" interval is not clear. Table 1-5 is a good example. 2. Table 2 states that monitored devices (1-1 through 1-5) not having monitored alarm paths shall be tested every 12 years. However, Table 1-5 states that DC circuits with monitored continuity shall have no periodic maintenance. We suspect that Table 2 attributes needs further clarification to eliminate the confusion, both Table 2 attributes at first glance appear to say the same thing. However, after study it appears to address "detection" monitoring versus continuous (control center type) monitoring. We believe further distinguishing clarifications are needed to make it evident and clear.
Response: Thank you for your comments. 1. The SDT believes that the activities and intervals, as they relate to whatever monitoring attributes are present, are clear. Table 2 is specifically labeled to address whatever maintenance is necessary to the monitoring and alarming equipment itself. The references to Table 2 have been corrected where necessary. 2. Table 1 is related to the component itself, and Table 2 relates to maintenance of the monitoring and alarming if relevant. If the monitoring specified is present, no periodic maintenance of the control circuitry itself is needed. However, as indicated in Table 2, maintenance (or monitoring) is required to assure that the monitoring on the control circuitry is operational.		
ExxonMobil Research and Engineering	No	
Ameren	Yes	Please carry the grid across in Table 1-4(f) to show the Maintenance Activities that go with the Component Attribute.
Response: Thank you for your comments. The grid in Table 1-4(f) is drawn as the SDT intended, to show "No periodic maintenance specified" for all table entries. The activity listed is the activity that is being accomplished by the monitoring mechanism.		
Tennessee Valley Authority	Yes	However, The requirement to perform battery cell internal ohmic measurements every 18 months for vented lead-acid batteries is excessive, and no technical justification is provided for an 18-month interval. A 3-year

Organization	Yes or No	Question 1 Comment
		internal ohmic test frequency is adequate to prove battery integrity. EEE 450 does not provide a recommended interval for internal ohmic measurements. For standard capacity testing, the recommended interval is no greater than 25% of expected battery life. Our normal battery life is 20+ years, so the recommended capacity test interval would be about 5 years. EPRI also recommends capacity testing at 5 year intervals. There is no justification for performing internal ohmic measurements every 18 months (which equals every 7.5% interval of the expected battery life). Recommendation: Set the interval for battery internal cell ohmic testing at 3 years.
Response: Thank you for your comments. The Maintenance Activity of evaluating the measured cell/unit internal ohmic values to station battery baseline is an optional activity to verify that the station battery can perform as designed. An owner who desires not to take internal ohmic measurements on a Vented Lead-Acid (VLA) battery can elect to verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank without ever having to perform any internal ohmic measurement on the battery. The maximum maintenance interval for performing this capacity test on a VLA battery bank is 6 Calendar Years. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” - that was posted for review with PRC-005-2 - the SDT answered several Frequently Asked Questions which explain why the 18 month Maximum Maintenance Interval is justified rather than the 3 year frequency that is assumed by some to be adequate.		
Exelon	Yes	What kind of component we are talking about in table 1.4(d) “Station DC Supply using Non Battery Based Energy Storage” for switchyard in nuclear plants?
Response: Thank you for your comments. An example of a “station dc supply” component of this nature would be fuel cells. The SDT is aware that some entities are beginning to apply non-battery-based dc supplies, but we are unaware whether anyone is using these in switchyards for nuclear plants.		
Xcel Energy	Yes	Regarding the last row of Table 1-4(f): it seems very inconsistent to require a formal trending program for a manual 6 month (VRLA)/18 month (VLA) internal ohmic reading but to require no gathering and analysis of data as an alarm for a ohmic value for each cell/unit is available. If just a raw ohmic value is an adequate predictor of cell life, than why require a trending program for the manual reading if all that is needed to determine adequacy of remaining cell life is just a simple acceptance criteria (i.e. - alarm set point) against which you need to compare your measured data? In theory these are very gradual and predictable changes in ohmic readings over the entire life of the battery, such that the benefit of real time knowledge of exactly when a threshold is reached via alarm is minimal rather than having to wait until the next manual reading to ascertain that the threshold limit has been reached.
Response: Thank you for your comments. Your comment concerning the last row of Table 1-4(f) being inconsistent with the two distinct maintenance activities for internal ohmic value measurement found in the unmonitored station dc supply tables 1-4(a) and 1-4(b) was very incisive. As pointed out in section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT recognized that there are two maintenance activities in Table 1-4(b) which appear to be the same, but require a different method of interpretation to complete the required maintenance activity. The Drafting Team has considered your comment in light of its own discussion in the Supplementary Reference & FAQ document and has divided the last row of Table 1-4(f) into two rows to reflect the		

Organization	Yes or No	Question 1 Comment
two distinct maintenance activities required in the unmonitored tables (inspection of the condition of individual VRLA cell/units, and evaluating internal ohmic measurements to a baseline to verify the station battery can perform as designed).		
Duke Energy	Yes	We believe the table could be improved further to aid compliance by adding a footnote to the term “baseline” in the sub-tables 1-4(a), 1-4(b) and 1-4(f). The following proposed footnote text is taken from page 65 of the Supplementary and FAQ Reference Document: “Often for older VLRA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to. To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, all manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to.”
Response: Thank you for your comments. The addition that you suggest is properly considered application guidance; the SDT has been advised that such information is not to be included within the standard, and that it is appropriately included in separate reference materials.		
Ingleside Cogeneration LP	Yes	1. Ingleside Cogeneration, LP, continues to believe that the six year requirement to verify channel performance on associated communications equipment will prove to be more detrimental than beneficial on older relays. Clearly newer technology relays which provide read-outs of signal level or data-error rates will easily verified, but the tools which measure power levels and error rates on non-monitored communication links are far more intrusive. After the technician uncouples and re-attaches a fiber optic connection, the communications channel may be left in worse shape after verification than it was prior to the start of the test. 2. However, we have found that the remainder of the items in the Tables are logically organized and correspond effectively with the five components of a Protection System. The maintenance activities and intervals are technically solid and reasonable. In our opinion, the benefits to proceed outweigh our one concern with the validation of communications channel performance.
Response: Thank you for your comments. 1. We agree that it is not good practice to disturb fiber connections as you indicate. Draft 4 does not require that. The Entity must perform the activities in the “Maintenance Activities” column. The SDT does not interpret this as taking anything apart. 2. Thank you.		
Manitoba Hydro	Yes	The restructured tables are an improvement, but we suggest that conductance (siemens) should be listed as

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 1 Comment</th></tr>
<tr><td></td><td></td><td>an acceptable measurement in addition to the resistance measurements already included in the tables.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT answered a Frequently Asked Question explaining what cell/unit internal ohmic measurements are. Conductance is an ohmic measurement and although not spelled out in the standard is listed in Table 1-4 because it is an ohmic measurement.</td></tr>
<tr><td>NIPSCO</td><td>Yes</td><td>Sub-tables are good. A related question: Some devices such as reclosers and circuit breakers may include batteries within the device itself. Does Table 1-4 apply to such batteries and DC supply? Recloser batteries do not provide access to intercell connections.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. In most instances Table 1-4 does not apply to recloser batteries or batteries within the device because they are not generally used to provide dc power to Protection Systems designed to provide protection for BES elements. However, these types of devices with self contained batteries may be used at the distribution level to provide Protection Systems used for underfrequency and undervoltage load-shedding. Maintenance activities and maximum maintenance intervals for such batteries are found in Table 1-4(e) of the Standard.</td></tr>
<tr><td>MISO Standards Collaborators

American Transmission Company, LLC</td><td>Yes</td><td>1. Yes, however, in the “Supplemental reference and FAQ” document on page 65 there are two areas of concern. Page 65, paragraph 4:” the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.”

While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of equipment will not change during this period.

2. On Page 65, paragraph 6, it states:”all manufacturers of internal ohmic measurement devices have established libraries of baseline values.” We question the availability of baseline libraries for all manufacturers considering the variety and longevity of installations.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.

1. The “Supplementary Reference and FAQ” concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment.

2. Many manufacturers of “Ohmic” test equipment have established libraries of baseline data. You are correct that test equipment manufacturers may not have data on every battery in service today. Several manufacturers of batteries (not all) have libraries for some (but perhaps not all) of their products. To achieve significant results from a trending program one needs to have good baseline data. The “Supplementary Reference and FAQ” document has been revised to reflect your concern – the word, “all” was changed to “many”.</td></tr>
</table>

Organization	Yes or No	Question 1 Comment
MRO's NERC Standards Review Subcommittee	Yes	Yes, however, in the “Supplemental reference and FAQ” document on page 65 this is one area of concern. Page 65, paragraph 4 ”the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment” While we understand the importance of creating a baseline, it’s not feasible to expect the test equipment to be the same as the manufacturer’s test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 15 years and it is not feasible to expect that the type of test equipment will not change during this period. We suggest changing the wording to read that consistent test equipment should be used to provide consistent/comparable results.
Response: Thank you for your comments. The statements concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment.		
The Detroit Edison Company	Yes	Yes, the tables do provide more clarity. It is much easier to understand the requirements now that they are broken down by technology, and the exclusion of intervals on certain activities based on the individual monitoring attributes is helpful. I appreciate the thought that went into revising this.
Response: Thank you for your comments.

2. The SDT has modified the Implementation Periods within the Implementation Plan. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Most commenters who responded to this question agreed with the proposed Implementation Plan. There was no predominant theme in the comments. A few commenters focused on the perceived short time period allowed for the initial conversion and development of their maintenance program while and other commenters suggested specifying Jan. 1 as an interval marker to ease in calendar year interval determination.

The SDT believes that the time frames in the proposed Implementation Plan are adequate for conversion when considering the complete time frame that is likely to occur between industry approval vote and regulatory approvals.

The Implementation Plan was modified to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines. Additionally, all "calendar year" implementation periods were revised to "months" for additional clarity.

The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2, or according to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.

Under Item 4a, the team corrected the reference to generating plant outages to change "two years" to "three years" to align with the time allocated for becoming 30% compliant (3 years) with maintenance of components subject to a 6 year interval.

Organization	Yes or No	Question 2 Comment
Tri-State G&T		The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions?
Response: Thank you for your comments. This comment does not apply to the Implementation Plan.		
Consumers Energy (4)	Ballot Comment - Negative	The implementation period for R1 and R3 for the component types addressed in Tables 1-3 and 1-5 is not adequate. The requirements may cause entities to identify components very differently than they are currently doing, and doing so may take several years to complete. The Implementation Plan for R1 and R3 is too aggressive in that it may not permit entities to complete the identification of discrete components and the associated maintenance and implement their program as currently proposed. We propose that the Implementation Plan specifically address the components in Table 1-3 and 1-5 with a minimum of 3 calendar

Organization	Yes or No	Question 2 Comment
		years for R1 and 12 calendar years after that for R4.
Response: Thank you for your comments. The SDT believes that the degree of flexibility written in the standard for categorizing (and subcategorizing) is sufficient for accomplishing the requirements within the time frames given in the Implementation Plan. For example, the voltage and current sensing devices may be individually identified or identified by group (associated with a relay). Examples of different ways to group the dc control circuitry discrete components include individual circuits, individual lockout devices, component protected, by control panel, or by station. The method chosen for the representation will impact the amount of time required to transform a maintenance program.		
Ameren Services (1)	Ballot Comment - Affirmative	PSMP Implement Date should commence at the beginning of a Calendar year (i.e., January 1st). This is the most practical way to transition assets from our existing PRC-005-1 plans
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program. The guidance provided to drafting teams by NERC suggests that standards should be effective at the beginning of a calendar quarter, rather than a calendar year.		
Independent Electricity System Operator	No	We commented on this before and we will comment again. The time periods for FERC-jurisdictional entities and non-jurisdictional entities should have at least a 3-month difference to allow some time for FERC approval after BoT adoption in an attempt to more or less put the effective dates of the two groups of entities in the same general time frame. The implementation plan as presented will always result in an effective date for the non-jurisdictional entities to be at least some months (the time between BoT adoption and FERC approval) earlier than their jurisdictional counterparts.
Response: Thank you for your comments. The Implementation Plan was modified to provide for a lengthened implementation period for R1 and the less-than-1-calendar-year activities in R2 and R3 to allow entities not subject to regulatory approvals of 9 additional months following BOT approvals, and, for the remaining activities, of 12 additional months following BOT approvals, to be more consistent with the expected Regulatory Approval timelines.		
NIPSCO	No	This new standard's calibration intervals outlined here will require additional staff at our organization. In order to get people hired and trained the implementation plan should allow more time for the phase-in period. From experience, calibration should have been de-emphasized since more concerns are discovered during full tests.
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program.		

Organization	Yes or No	Question 2 Comment
Tampa Electric Company	No	The new maintenance plan has to be completed in 1 year. 1. Would that mean it is required to identify and list every element that requires testing in a database within the first year? This will be a time intensive effort that probably that would be difficult to complete in a year with current personnel. 2. After 1 year, would entities be required to start implementing the plan depending on the maintenance intervals of the equipment? Qualified people would have to be in place to start the work, again this would be difficult to accomplish with current personnel.
Response: Thank you for your comments. 1. No. Please read R1 carefully to determine what's necessary to be implemented. There is no requirement to have a database – just to have a PSMP that identifies the component "types" and for each component type, the associated type of maintenance program, associated maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes. There is no requirement to identify and list every element. 2. Yes. The implementation of the plan must proceed as indicated.		
Indeck Energy Services	No	The last part of the implementation plan is vague, if not undefined. The implementation should "follow the previous maintenance intervals until all maintenance is transitioned to the new intervals."
Response: Thank you for your comments. The SDT presumes that your comment is related to the last paragraph of the General Consideration section of the proposed Implementation Plan. The entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the transition is occurring, the entity should adjust its maintenance and testing schedule so that it is able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in this Implementation Plan.		
American Electric Power	No	On page 2 of the implementation plan, it is indicated that PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 shall be retired and that entities will be required to identify which components will be addressed under PRC-005-1 or PRC-005-2. There is no wording to cover those components that are still being addressed under PRC-008-0, PRC-011-0 or PRC-017-0 during the implementation period.
Response: Thank you for your comments. As noted in the "General Considerations", the entity should follow the previous maintenance intervals for any specific components until that component is addressed by PRC-005-2. As the transition is occurring, the entity should adjust its maintenance and testing schedule so that they are able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in this Implementation Plan. The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2 or according to PRC-005-1, PRC-008-0, PRC-011-0, or PRC-017-0.		

Organization	Yes or No	Question 2 Comment
Bonneville Power Administration	No	Many of the maintenance intervals in the standard are given in the terms calendar years or calendar months. There is no description of these terms in the NERC Glossary. My Webster's dictionary defines calendar year as the period that begins on January 1 and ends on December 31. There is no definition in my dictionary of calendar month. Is the intent of the term calendar year in the standard that maintenance intervals start on January 1 and end on December 31? This would make all maintenance due on December 31, and December would be a very busy time. Does this mean that if I do maintenance on something with a maximum interval of six calendar years in June of 2011 that it will be due again on January 1 of 2017 instead of June 1 of 2017? We believe that the drafting team intends for maintenance to be due after a given number of years that begins to elapse immediately after the previous maintenance is completed so that in the previous example the maintenance would be due on June 1, 2017. Please remove the word calendar from the maximum maintenance intervals to remove this confusion.
Response: Thank you for your comments. The intent of the term calendar year is to indicate that the maintenance is due sometime during a particular calendar year (Jan-Dec). If you perform maintenance in June 2011 and have a 6 calendar year interval, then the same maintenance is again due sometime in 2017 (2011 + 6). The NERC Compliance Application Notice CAN-0010, posted 19 Apr 2011, supports this compliance guideline. An interval of one calendar year means that the activity or event must be conducted at least once within each calendar year.		
FHEC	No	Can't locate the implementation plan in the posted materials.
Response: Thank you for your comments. The implementation plan was provided as a separate document within the posting and is available in the Standards Under Development section of the NERC website under Project 2007-17: http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html		
FirstEnergy	No	Although we agree with the timeframes being afforded to achieve compliance, we suggest the following changes: 1. During the last comment period, we suggested changes to the wording regarding retirement of existing standards on page 2. We do no see a response to these comments. Therefore, we would like to reiterate that the four existing standards are to be retired upon the effective date of the new standard and not upon regulatory approval. 2. In 4a of the plan, since the timeframe for 30% completion is 3 calendar years, we suggest a change to three calendar years for the parenthetical phrase “(or, for generating plants with scheduled outage intervals exceeding two calendar years, at the conclusion of the first succeeding maintenance outage)”. Change ”two” to “three” 3. We suggest the implementation plan be included within the body of the standard. It is very burdensome for

Organization	Yes or No	Question 2 Comment
		entities to have to look for the implementation plan and we believe that a "one-stop shopping" approach would alleviate this burden.
Response: Thank you for your comments. 1. The Effective Date within the Standard was stated as it is based on verbal advice of NERC Compliance – several drafts ago. 2. The Implementation Plan has been modified as you suggested. 3. The Implementation Plan is provided separately in accordance with instructions from the NERC Standards Department and Standards Committee. Further, at the end of all transition periods, it is not needed in the standard.		
ExxonMobil Research and Engineering	No	
Ameren	Yes	While we agree with the Implementation Periods, it would be best to alter R2 and R3 implementation such that components with maximum allowable intervals of 1 year or longer align with a true calendar year (i.e. begin with January 1).
Response: Thank you for your comments. The SDT believes that the proposed Implementation Plan intervals are long enough to provide an entity the amount of time it will take to transition to the new intervals. Considering the additional time between an approved ballot by the industry through the NERC BOT approval and regulatory agency approval, it is very likely that an entity may have an additional 6-9 months to transition to the new program. The guidance provided to drafting teams by NERC suggests that standards should be effective at the beginning of a calendar quarter, rather than a calendar year.		
MidAmerican Energy Company	Yes	1. In the background section of the implementation plan in item two it states "...it is unrealistic for those entities to be immediately in compliance with the new intervals." Recent compliance application notices indicate that auditors are requiring entities to include proof of compliance to maintenance intervals by providing the most recent and prior maintenance dates. The implementation document could be improved by providing clarity to what is expected with regard to when an entity is expected to provide evidence of maintenance interval compliance given the quoted item above. As an example in the section the implementation plan for a 6 year interval item it states: "The entity shall be at least 30% compliant on the first day of the first calendar quarter 3 years following applicable regulatory approval.." In keeping with the previously quoted "reasonableness" criteria it would seem that 30% compliant would mean only one test action would be needed to be completed by the indicated deadline and the next one would be required no later than 6 years from that first test. It is recommended that the implementation plan document be improved to clarify this issue. 2. In addition, it would seem appropriate to allow entities that decide to implement PRC-005-2 requirements

Organization	Yes or No	Question 2 Comment
		before the standard becomes effective to count the maintenance they do before the effective date in the implementation plan schedule and in the testing interval compliance.

Response: Thank you for your comments.

1. The Implementation Plan establishes that an entity must follow its current plan until the new standard is implemented for any specific component. Therefore, an entity should have documentation that it has maintained any given component according to its current program until it is addressed in the revised program (including all relevant activities addressed in PRC-005-2). An entity should adjust it's maintenance and testing schedule so that it is able to demonstrate that the required % of components meet the maintenance intervals given in the PRC-005-2 tables at each of the % compliant milestones given in the Implementation Plan. The team also clarified that during the phase-in of the requirements in PRC-005-2, entities must be prepared to identify whether each component is being maintained according to PRC-005-2 or according to PRC-005-1, PRC-008-0, PRC-011-0, or PRC-017-0.

2. If entities begin to implement the PRC-005-2 activities before the effective date, it seems to the SDT that this entity will find that they it has fully implemented PRC-005-2 sooner, and will thus have attained a stable sustainable program that much sooner.

3. The SDT has modified the VSLs, VRFs and Time Horizons with this posting. Do you agree with the changes? If not, please provide specific suggestions for improvement.

Summary Consideration: Many commenters pointed out an error (which was corrected by the SDT) within the VSL for R2, where the Lower and High VSLs contained identical text.

Many comments were offered on the VRFs that demonstrated unfamiliarity with the relationship between VSLs and VRFs. Violation Risk Factors identify the reliability-related risk associated with non-compliance; VSLs are applied after a finding of non-compliance to identify the degree of non-compliance.

Many duplicate comments were offered on the content of the standard which were not relevant to the VRFs, VSLs, or Time Horizons and these were answered elsewhere in this document

VSLs for R1:

- Phased VSLs were added to address R1 Part 1.1, which was previously addressed only as a “Severe” VSL.
- A reference was added within the R1 VSL to Part 1.3.
- R1 High VSL was revised to add a reference to Table 2.

VSLs for R2:

- One element of the R2 VSL was made binary (Severe), rather than “phased” (in two steps), in response to several comments.

VSLs for R3:

- The R3 VSLs were revised to replace “complete” with “implement and follow” for consistency with the Requirement.

Other minor editorial changes were made throughout the VSLs in response to comments.

Organization	Yes or No	Question 3 Comment
Tri-State G&T		On Page 19, Table 1-5, the standard requires that monitored electromechanical lockouts be maintained every 6 years. Why is there inconsistency in the interval between the monitored lockouts and monitored relays?
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		

Organization	Yes or No	Question 3 Comment
SPP reliability standard development Team	No	1. If the maintenance is done prior to the maximum interval would it then reset the clock. Or should it read that maintenance and testing should be done at least once per quarter etc. 2. We would like to see the plan split up into generation time horizons and transmission time horizons, these can be significantly different.
Response: Thank you for your comments. 1. Provided that all required maintenance activities are done, the activity for that interval is taken care of, and the clock is reset. 2. The options for the Time Horizons are “Long-term Planning” (a planning horizon of one year or longer), “Operations Planning” (operating and resource plans from day-ahead up to and including seasonal), “Same Day Operations” (actions required within the timeframe of a day, but not real-time), “Real-time Operations” (actions required within one hour or less to preserve the reliability of the bulk electric system), and “Operations Assessment” (follow-up evaluations and reporting of real time operations). All of the requirements are properly assigned a Time Horizon of “Long Term Planning”. There is no provision for different Time Horizon between entity types.		
Indeck Energy Services	No	1. The VSL’s for R1 should combine the ones for Lower, Moderate and High VSL into Lower VSL. The Severe VSL should be moved to the Moderate VSL. Because R1 is administrative, it shouldn’t have High or Severe VSL’s. 2. The R2 High VSL (3 yrs) is more stringent than the Severe VSL (5 yrs). 3. The R3 VSL’s need to have combined numbers of components or percentages because small generators may only have 25 relays or 1 battery and would be categorized as High or Severe VSL with a few components affected. The percentage could apply to RE’s with more than 250 components included in the PSMP. 4. The Medium VRF for R1 should be Low VRF because R1 is administrative. Only the performance of the maintenance has anything more than Low VRF. 5. The Medium VRF for R2 is OK. 6. Having a High VRF for R3 is without basis. R3 should have Medium VRF.
Response: Thank you for your comments. 1. R1 is not administrative – it is foundational to developing the program. The VSLs as established conform to the NERC Violation Severity Level Guidelines. 2. The SDT disagrees. R2 “High” reflects a failure to return the “Countable Events” to an acceptable level in three years. R2 “Severe” reflects even worse performance, in that the entity has failed to return the “Countable Events” to an acceptable level in an even longer period – five years.		

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 3 Comment</th></tr>
<tr><td colspan="3">3. The SDT disagrees. A smaller entity will have less to maintain in accordance with the standard, and thus the percentages are still appropriate.

4. R1 is not administrative – it is foundational to developing the program, and not having a program could “directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system” as established in the criteria for a Medium VRF, even if the devices are being maintained to some degree. Without having an established program, the remaining requirements are far less meaningful.

5. Thank you.

6. The SDT believes that failure to maintain Protection Systems could “place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures” as established in the criteria for a High VRF. This concern is borne out by observations relating to several disturbances over the last several years. Also, a High VRF for R3 is consistent with the PRC-005-1 VRF for the corresponding requirement (R2).</td></tr>
<tr><td>FRCC (10)</td><td>Non-binding Poll Comment</td><td>The VSL's need additional work. Here are some of the issues I see:

1. For R1, the High VSL has a condition that states "Failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5. (Part 1.4)" This condition is really a combination of what is required in Part 1.3 AND Part 1.4. How would the compliance enforcement determine an appropriate VSL if the registered entity only did not do Part 1.3 (maintenance activities)? These should be separated.

2. Also the Severe VSL is also identified for failure to specify three or more component types. I believe it is more appropriate to have three in High VSL and leave the Severe VSL for 4 or more.

3. For R2, the Lower VSL lists item 1) as "Failed to reduce countable events to less than 4% within three years." This is also the same condition that is identified for the High VSL. It is also the same condition that is listed as item 2) for the Severe VSL. In Lower and Severe, the items are separated by OR so they are each distinct. So, which VSL should the compliance enforcement authority use?

4. Also for R2, Lower VSL is indicated for failure to document for countable events for 5% or less of components. Then you jump to Severe VSL for over 5%. That seems like a very huge jump. The Moderate and High VSLs should be used to make a more gradual difference.

5. Finally, for R2, the Lower VSL is indicated if a segment has 54-59 components and a Severe is more than 54 components. In reading Attachment A, it states that a segment MUST contain at least sixty (60) individual components. This would appear to me to be all or nothing. I would suggest that the only VSL for this would be a Severe if it did not have 60 or more.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.</td></tr>
</table>

Organization	Yes or No	Question 3 Comment
1. The SDT disagrees. For the assessment of compliance to R1, Part 1.3 and Part 1.4 work together in the fashion identified in the VSL. 2. The SDT disagrees, and believes that failure to address three or more component types (out of a total of five) indeed reflects a Severe violation of the requirement. 3. Thank you for catching this. The High VSL has been modified from three years to four years. Where elements of the VSL are separated by "or", the compliance enforcement authority should use each of them as appropriate. 4. The SDT disagrees. The documentation of countable events is so fundamental to a performance-based maintenance program that the SDT has assigned a Lower VSL to minor transgressions, with all other transgressions being regarded as a Severe VSL. 5. The SDT has modified the R2 VSL for the segment population to be binary as you suggested.		
Tri-State G & T Association, Inc. (3) (5)	Ballot Comment	1. On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs? 2. R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate?
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. VSLs have been added to Moderate and High to address lesser violations.		
Tri-State G & T Association Inc. (3)	Non-binding Poll Comment	1. Comment 1: On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs? 2. Comment 2: R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate?
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. VSLs have been added to Moderate and High to address lesser violations.		
Tri-State G & T Association Inc. (5)	Non-binding Poll	1: On Table 1-2, page 11: The standard describes the following component attributes, "Any unmonitored communications system necessary for correct operation of protective functions, and

Organization	Yes or No	Question 3 Comment
	Comment	not having all the monitoring attributes of a category below." How does this apply to redundant communication systems? If the primary communications channel fails the protective relay automatically fails over to the back-up channel and continues to function properly. Are redundant communication channels excluded from this component attribute and associated interval? Also, if a relay is set to operate in a manner typical when communication is not used for protection (i.e. defaulting to step-distance functions with a loss of communication), is the defaulted operation of the relay considered "correct operation" thereby excluding the communication as necessary for its correct operation? Please clarify the term correct operation and how it applies to redundant communication systems and/or the performance of the relay in the absence of communication. 2: The draft standard requires the PSMP to include maintenance and testing intervals for Station DC supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply). Does this requirement include DC systems (batteries not included in station batteries) used by communication systems necessary for the correct operation of protective functions? 3: On Page 19, Table 1-5, the standard requires that electromechanical lockout control circuits be maintained every 6 years and protective function unmonitored control circuits be maintained every 12 years. Why is there inconsistency in the interval between the electromechanical lockout and protective function control circuits? 4: On Page 7, R2 Violation Severity Levels, "Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years" is shown as both a Lower VSL and a High VSL. What differentiates the two VSLs?
Response: Thank you for your comments. 1. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 2. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 3. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 4. Thank you for catching this. The High VSL has been modified from three years to four years.		
Farmington Electric Utility System	No	VSL on R2: Lower criteria item 1; the wording is identical High VSL. FEUS recommends keeping the criteria in the Lower VSL.

Organization	Yes or No	Question 3 Comment
City of Farmington (3)		
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Alliant Energy Corp. Services, Inc. (4)	Non-binding Poll Comment	The Lower and High VSL for Requirement 2 have the same description. The Lower VSL has other possible items, but there is a conflict where an entity could argue for both a Lower and High VSL. That needs to be clarified.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
GDS Associates	No	1. Suggest clarification of the VSL for R2. It appears that R2 Lower VSL is also contained in the R2 High VSL. 2. If the maintenance is completed prior to the maximum interval, would it then reset the clock? Or should it read that maintenance should be done at least once per quarter? 3. The plan should split into generation time horizons and transmission time horizons since these can be significantly different
Response: Thank you for your comments. 1. Thank you for catching this. The High VSL has been modified from three years to four years. 2. Yes – it would reset the clock, provided that all required activities are completed during the performance of the maintenance. 3. The SDT disagrees. The options for the Time Horizons are “Long-term Planning” (a planning horizon of one year or longer), “Operations Planning” (operating and resource plans from day-ahead up to and including seasonal), “Same Day Operations” (actions required within the timeframe of a day, but not real-time), “Real-time Operations” (actions required within one hour or less to preserve the reliability of the bulk electric system), and “Operations Assessment” (follow-up evaluations and reporting of real time operations). All of the requirements are properly assigned a Time Horizon of “Long Term Planning”. There is no provision for different Time Horizon between entity types.		
Alabama Power Company (3) Georgia Power Company (3) Gulf Power (3) Mississippi Power (3)	Non-binding Poll Comment	But only if the clean version on Page 7 under Violation Severity Levels R2/High VSL match the redline dated 4/12/2011. Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within four years.
Response: Thank you for your comments. The clean version represents the content desired for the Standard. The red-line is affected by peculiarities of		

Organization	Yes or No	Question 3 Comment
the red-lining tool within Microsoft Word.		
Tampa Electric Company	No	VSL is severe for more than 4% Countable Events on R2. It does not seem feasible.
Response: Thank you for your comments. R2, by reference to Attachment A, requires that entities using performance-based maintenance reduce Countable Events to less than 4% within three years. The R2 Severe VSL reflects failure to do so within five years.		
Manitoba Hydro	No	1. VSL for Requirement 2:-Needs to use consistent terminology. The standard requirements refer to components and component types, not elements. 2. The violation “Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years” appears in both the Lower VSL column and the High VSL column. The violation cannot be both Lower and High. VSL for Requirement R3: -Suggested wording “completed its scheduled program”.
Manitoba Hydro (1) (3) (5) (6)	Non-binding Poll Comment	Manitoba Hydro is voting negative for the following reasons: 1. VSL for Requirement 2: -Needs to use consistent terminology. The standard requirements refer to components and component types, not elements. 2. The violation “Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within three years” appears in both the Lower VSL column and the High VSL column. The violation cannot be both Lower and High. 3. VSL for Requirement R3: -Suggested wording “completed its scheduled program”.
Response: Thank you for your comments. The term, “element” is not used in any of the VSLs. 2. Thank you for catching this. The High VSL has been modified from three years to four years. 3. The SDT disagrees; the VSL address failure to complete the scheduled program. The suggested change does not reflect this.		
Duke Energy	No	Typographical error - the High VSL for R2 has been incorrectly changed to “within three years” from “within four years”. This is now the same as the Lower VSL.
Duke Energy	Non-binding Poll	There is a typographical error on the High VSL for R2. It has been incorrectly changed to “within three years” from “within four years”. This is now the same as the Lower VSL.

Organization	Yes or No	Question 3 Comment
	Comment	
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Kristina M. Loudermilk	Non-binding Poll Comment	1. In VSL R2 I find it confusing for the Lower VSL and High VSL. In the Lower VSL for R2 #1 is mentioned, but again mentioned in High VSL. IS there an easier way to make that flow? 2. Also I found that I have forgotten a comment for the Standard itself.... In Attachment A, #5 is mentioned twice. I understand as to why, so I think, but in the "To Maintain" #5 says that one has to use the prior year's data. It matches the exact form of "how to establish the performance based PSMP". I find this confusing. So does this mean that testing will be once a year for parts of the segment. I did not get that same understanding from the support documents. Is there way to reword one of the #5's to show case a difference. Or is this on purpose? I just found it confusing.
Response: Thank you for your comments. 1. The High VSL has been modified from three years to four years. 2. The “first” #5 applies to establishing the performance-based program; the “second” one – now modified to be #4 in the second section, applies to maintaining the performance-based program on a continuing basis.		
Alliant Energy	No	The LOW and HIGH VSL for R2 are the same. There are additional possibilities for the LOW, but it is possible to be in both the LOW and HIGH VSL at the same time. We recommend removing #1 in the LOW VSL category to resolve the issue.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
The Detroit Edison Company	No	R2 - It appears that the Lower VSL point 1) and High VSL are identical.
Response: Thank you for your comments. Thank you for catching this. The High VSL has been modified from three years to four years.		
Consolidated Edison Co. of New York (1) (3) (5) (6)	Ballot Comment - Affirmative	Clarification is needed to assure that the industry more fully understands how the percentage of “maintenance correctable issues” will be computed in the R3 VSL.
Consolidated Edison Co. of New York (1) (5) (6)	Non-binding Poll	1: Clarification is needed to assure that the industry more fully understands how the percentage of “maintenance correctable issues” will be computed in the R3 VSL.

Organization	Yes or No	Question 3 Comment
	Comment	2: We recommend increasing the Table 2 reporting window from 24-hours to 72-hours for facilities not continuously manned in order to accommodate discovery and reporting of failed alarms at these facilities which may occur over a long (3-day) holiday weekend. 3: We recommend that the drafting team recognize that a “fail safe” or “self-reporting” alarm design serves as an acceptable alternative to periodic testing. This “fail safe” or “self-reporting” alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to “alarm on” and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments. 1. The SDT believes that this is clear; if an entity has 20 maintenance-correctable issues and has failed to initiate resolution of one, it has failed to initiate resolution of 5% of the maintenance-correctable issues. 2. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report. 3. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		
Independent Electricity System Operator Independent Electricity System Operator (2)	No Non-binding Poll Comment	(1) We do not agree with the High VRF for R3 which asks for implementing the maintenance plan (and initiate corrective measures) whose development and content requirements (R1 and R2) themselves have a Medium VRF. Failure to develop a maintenance program with the attributes specified in R1, and stipulation of the maintenance intervals or performance criteria as required in R2, will render R3 not executable. Hence, we suggest that the VRF for R3 be changed to Medium. (2) The Severe VSL for R2 is improper. First, the reference to R3 is incorrect. Second, the first condition that says: “Failed to establish the entire technical justification described within R3 for the initial use of the performance-based PSMP” introduces a requirement not stipulated in R2 itself. We suggest to remove this condition. If the SDT feels strongly that the technical justification (we’re not sure what exactly it is) needs to be established for the initial use of the performance-based PSMP, then R2 should be revised to capture this requirement.
Response: Thank you for your comments. 1. The SDT believes that failure to maintain Protection Systems could “place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures” as established in the criteria for a High VRF. This concern is borne out by observations relating to several disturbances over the last several years. However, even if the program is not fully documented per R1 and R2, devices may still be maintained; thus the reduced VRF for these requirements. Also, the R3 “High” VRF is consistent with the VRF assigned to the similar PRC-005-1 requirement (R2).		

Organization	Yes or No	Question 3 Comment
2. The Severe VSL for R2 has been corrected to refer to R2. The remainder of the Severe VSL for R2 is correct, in that R2 itself specifies that the procedure in Attachment A must be used, both to establish and maintain a performance-based maintenance program. The definition of maintenance correctable issue has been revised to be clearer.		
Tennessee Valley Authority	No	TVA has 590 Pilot Relay (Carrier Blocking) Terminals that are tested twice a year. After an extensive study of carrier failures over a 5-year period, it was determined that we were not having any failures that could have been prevented by a functional test. In January 2008, we reduced our frequency from 4 times per year to 2 times per year. The failure rate has remained about the same since that change. As PRC 005-2 currently states, the PM frequency would be 3 months. Allowing for a one-month grace period would actually require the interval to be set at 2 months. Therefore, the interval we used prior to 2008 (4 times per year) still would not make TVA compliant with the stated 3 month interval.TVA Power Control Systems is in the process of developing extensive PM tests for carrier terminals to complement the existing PM program. This PM would record signal levels, reflected power, line losses, and other pertinent data. It is my position that this PM will improve reliability more than increasing the frequency of the functional test.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to your comments on the standard provided elsewhere in this report.		
American Electric Power	No	This standard encompasses a very broad range of component types and functionality. It also encompasses broad segments of the BES. The proposed VSLs and VRFs place the same level of severity or priority on facilities that serve local load with that of an EHV facility. The percentages indicated in the VSLs seem to be too strict based upon the vast quantity of elements in scope and broad range of application.
Response: Thank you for your comments. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. The NERC VRF Guidelines establish the criteria for assigning VRFs and do not provide for multiple VRFs for a single requirement, and the percentages (where used) assigned within the VSLs conform to the criteria established within the NERC VSL guidelines.		
FHEC	No	For Distribution Provider level equipment there should be no High or Severe VSLs
Response: Thank you for your comments. The SDT disagrees; the VSLs are intended to address the degree to which an entity fails to comply with each requirement, and the nature of the entity has no bearing on this determination.		

Organization	Yes or No	Question 3 Comment
Pepco Holdings Inc	No	1. Are the bullet items listed for the R2 Severe Violation Severity Level , Item 5 an "and" or an "or"? 5) Failed to: • Annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, • Annually analyze the program activities and results for each segment. 2. The wording of the R3 Lower Violation Severity Level seems to imply that an entity that fails to complete 0% (i.e., completes 100%) of its maintenance correctable issues is non-compliant. Entity has failed to complete scheduled program on 5% or less of total Protection System components. OR Entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues. The following re-phrasing is suggested: Entity has failed to complete scheduled program on greater than 0%, but no more than 5% of total Protection System components. OR Entity has failed to initiate resolution on greater than 0%, but less than or equal to 5% of identified maintenance correctable issues.
Response: Thank you for your comments. 1. The VSL has been modified to separate these items with "or". 2. The SDT disagrees; this description conforms to the guidance in the NERC VSL Guidelines, and VSLs only apply if there is a failure to comply with the relevant requirement.		
Liberty Electric Power LLC (5)	Non-binding Poll Comment	The use of percentages, without accounting for the size of the entity, unfairly burdens small IPPs.
Response: Thank you for your comments. The SDT disagrees. A smaller entity will have less to maintain in accordance with the standard, and thus the percentages are still appropriate.		
Liberty Electric Power LLC	No	See comments at end.

response to NIPSC's comments on the standard provided elsewhere in this report.		
Public Utility District No. 2 of Grant County	Non-binding Poll Comment	GCPD has made it a practical practice of not voting affirmative for VRF and VSL until the standard is edited to our satisfaction and can vote affirmative on the standard.
Response: Thank you for your comments. Please see the revisions made to the standard and the drafting team's responses to the comments.		
Florida Municipal Power Agency (4) (5) FMPP (6)	Non-binding Poll Comment	· Section 4.2.1 states that the Standard is applicable to "Protections Systems designed to provide protection BES Elements." Section 15.1 of the Supplementary Reference Document defines the scope as those "devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES." These two statements are not exactly equivalent, and in fact, are in conflict with the Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State, Approved by the Board of Trustees on February 17, 2011. Section 4.2.1 should be changed to "Any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES." · Examples #1, #2 and #3 in Section 7.1 of the Supplementary Reference all indicate that it is a requirement to "verify all paths of control and trip circuits" every 12 years. As stated, there would be circuits included in the testing requirement that the SDT did not mean to include in the scope of the Standard (e.g., SCADA closing circuit.) The statements in the illustrative examples should be changed to "verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices" to be in line with the definition of a Protection System. · Section 15.5 of the Supplementary Reference Document states: "It was the intent of this Standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted". The SDT should reword this statement recognizing that tests performed on communication systems may not be performed at the same time an entity chooses to perform trip tests on the associated breaker(s). The notion of "overlapping" can be applied, for instance, by taking an outage on one relay set in a fully redundant system, initiating a trip signal from the remote end and observing

Organization	Yes or No	Question 3 Comment
		the trip signal locally. All remaining portions in the local communication-assisted trip paths can then be tested when the local line panel is taken out of service for maintenance.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
Seattle City Light (5)	Non-binding Poll Comment	Pursuant to the negative ballot relating to the Standard. Both votes will be affirmed if the comments are addressed.
Response: Thank you for your comments. Please see the drafting team's responses to the comments offered by Seattle on the proposed standard.		
Seattle City Light (6)	Non-binding Poll Comment	Seattle City Light (SCL) commends the Standard Drafting Team (SDT) for the many improvements in the latest draft of proposed standard PRC-005-2. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. Each draft has been better than that preceding, and the supporting material is very helpful in understanding the impact and implementation of the proposed Standard. However, SCL votes NO for this draft because of 1) the inclusion and treatment of electromechanical lockout relays within the scope of draft Standard and 2) confusion about language between section 4.2 and Requirement 1. Regarding electromechanical lockout relays, SCL is highly concerned about the reliability risks and logistical difficulties associated with meeting the requirements proposed for these relays. Lockout relays operate rarely and are known for reliable service. For many such relays, the proposed maintenance would require clearance of entire bus sections or even multiple bus sections (such as for a bus differential lockout relay). In SCL's opinion, the reliability risks posed by such switching and outages to the Bulk Electric System outweigh the reliability benefits of including lockout relays in the scope of PRC-005-2. If the SDT deems it necessary to include electromechnical lockout relays within PRC-005-2, SCL recommends that a difference be made between the maintenance activities specified for monitored and unmonitored types. The draft Standard describes the requirements for "electromechanical lockout and/or tripping auxiliary devices" in Table 1-5 (p.19) and assigns a 6-year maximum maintenance interval, the same as for other unmonitored relays. Modern electromechanical lockout relays may be specified with a built-in self-monitoring trip-coil alarm. SCL believes the maintenance requirements for electromechanical lockout relays with such an alarm should be similar to those for other alarmed or monitored relays. As such we recommend that a new entry be added to Table 1-5 for monitored electromechanical

Organization	Yes or No	Question 3 Comment
		lockout relays, as follows: • Component Attributes: Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil AND include built-in self-monitoring trip-coil alarm • Maximum Maintenance Interval: 12 calendar years • Maintenance Activities: Verify electrical operation of electromechanical trip and auxiliary devices. Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated. Regarding confusion over language, section 4.2 section identifies five types of Facilities that the standard is applicable to, whereas Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). As such, it is not clear if PRC-005-2 applies to five Facilities or to certain Protection Systems. SCL believes the intent is to have a PSMP for all Protection Systems identified in "Part A, Section 4.2 - Facilities" and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Facilities identified in Part A, Section 4.2.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
Beaches Energy Services (1)	Non-binding Poll Comment	We believe that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. We agree wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical

Organization	Yes or No	Question 3 Comment
		that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of distribution breakers will likely result in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on Transmission Facilities due to more frequent failures due to trees, animals
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
City of Green Cove Springs (3)	Non-binding Poll Comment	GCS believes that there is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. GCS agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-

Organization	Yes or No	Question 3 Comment
		before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load.
Response: Thank you for your comments. These comments are not relative to the non-binding poll of the VRFs and VSLs for PRC-005. Please see our response to the same comments on the proposed standard provided elsewhere in this report.		
ReliabilityFirst	Non-binding Poll Comment	ReliabilityFirst agrees with the VRFs but votes negative on the VSLs for the following reasons: 1. VSL for R1 a. Part 1.3 is not mentioned in the VSLs b. The VSLs should start off with the phrase “The responsible entities PSMP…” c. For the VSLs dealing with Part 1.2, the term “or a combination” should be added as one of the methods for maintenance. d. The last VSL under the Severe category should reference Part 1.2 e. The VSLs for Part 1.1 should be gradated similar to Part 1.2 (e.g. what VSL does an entity fall under if they failed to address two component types included in the definition of ‘Protection System’?) 2. VSL for R2 a. To be consistent with Requirement 2, the VSLs should start off with the phrase “The responsible entity uses performance-based maintenance intervals in its PSMP, but…” b. The first VSL under the “Lower” category is a duplicate of the VSL under the “High” category c. The third VSL under the “Lower” category has language stating “or containing different manufacturers.” Neither R2 nor Attachment A mentions this language. This is a violation of the FERC Guideline 3: “Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement” d. Recommend that the VSL regarding entities that “maintained a segment with less than X amount of components” should be a binary “Severe” VSL 3. VSL for R3 a. The VSLs should start off with the phrase “The responsible entity…”

Organization	Yes or No	Question 3 Comment
		b. R3 does not require an entity to "…complete scheduled program…" This is a violation of the FERC Guideline 3: "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement" c. The "implement and follow its PSMP" language in R3 is not mentioned in the VSLs for R3. Recommend including this language in the VSLs for R3

Response: Thank you for your comments.

1.

a. Part 1.3 has been added to the R1 High VSL.

b. The R1 Lower, Medium, and Higher VSLs have been modified as you suggest.

c. The R1 Lower, Medium, and Severe VSLs have been modified as you suggest.

d. The R1 Severe VSL has been modified as you suggest

e. The R1 Moderate and High VSLs have been modified to add graduated VSLs for part 1.1.

2.

a. The R2 VSLs have been modified as you suggest.

b. Thank you for catching this. The High VSL has been modified from three years to four years.

c. This portion of the R2 Lower VSL has been removed, making the VSL for this portion of R2 binary (with only a Severe VSL).

d. The VSL for R2 has been modified as you suggest.

3.

a. The R3 VSLs have been modified as you suggest.

b. The R3 VSLs have been modified by replacing "complete" with "implement and follow" in consideration of your comment.

c. The R3 VSLs have been modified by replacing "complete" with "implement and follow" in consideration of your comment.

4. The SDT has incorporated the FAQ document into the "Supplementary Reference" document and has provided the combined document as support for the Requirements within the standard. Do you have any specific suggestions for further improvements?

Summary Consideration: The commenters were generally supportive of the combination of documents.

Several comments were offered, repeating previous questions regarding the enforceability of this document, and the SDT repeated previous responses explaining the status of this document as a supporting reference – reference documents have no enforceability.

A variety of suggestions were offered regarding additional information for the document, which largely resulted in modifications to the Supplementary Reference document. One specific suggestion of note (resulting in additional discussion within the document) requested a FAQ regarding "Calendar Year".

Several commenters posed questions regarding "grace periods" and "PSMPs established by entities that are more stringent than the requirements within the standard". No additional changes were made due to these questions, but the SDT further explained previous guidance on these issues within the responses. Entities are always allowed to implement practices that are more stringent than those identified in a standard.

Organization	Yes or No	Question 4 Comment
Manitoba Hydro		A red line was not provided making this document difficult to review. We suggest that a redline of this document be posted.
Response: Thank you for your comments. A red-line was not provided because of overall extensive changes, resulting from merging of the previous Supplementary Reference Document and FAQ; the entire document would have been red-line. The next posting will include a red-lined document, as well as the "clean" document.		
U.S. Bureau of Reclamation (5)	Ballot Comment - Affirmative	1. The reference material provides a significant insight into the intent of the proposed changes to the standard. In some cases an interpretation is provided which is not supported by the explicit interpretation of the standard text. The SDT is encouraged to either attach the reference material to the standard or add relevant sections to standard as Background. The Background section could reference the Supplemental Reference & FAQ. 2. The reference material provides more detail indicating that "Voltage & Current Sensing Device circuit input

Organization	Yes or No	Question 4 Comment
		connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. . . . . . The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).” This interpretation is not consistent with the text of the standard and would suggest that it be incorporated into Table 1-3. 3. When protective equipment is replaced, the reference information indicates that the information associated with the original equipment must be retained to show compliance with the standard until the performance with the new equipment can be established. This is not stated in the Measurements and should be added if the expectation exists.
Response: Thank you for your comments. 1. This standard is not being developed in a “results-based” format. Attaching the extra document as you suggest would make the supporting information within the FAQ and Supplementary Reference part of the standard, and this would add extensive and unnecessary prescription to the standard. As you suggest the reference material is listed within the Standard (Section F – Supplemental Reference Document). The next revision will likely resemble your suggestion. 2. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks. 3. M1 states “Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and…” Documenting the implementation of the PSMP certainly requires evidence that maintenance was performed at the prescribed intervals and the data retention requirements state that evidence of the two most recent performances of each distinct maintenance activity be retained. Also, please see the NERC Compliance Process Bulletin #2011-001 (“Data Retention Requirements”) for similar guidance.		
Ameren Services (1)	Ballot Comment – Affirmative	1. Omit retention of maintenance records for replaced equipment. Supplement FAQ 12.1 on page 51 final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. Since BES Element protection is the objective, we suggest a compromise of keeping the evidences of last test for the removed equipment and using that with the equivalent function replacement equipment commissioning or in-service date to prove interval. 2. In Supplement examples on pp 22-23, replace “Instrumentation transformers” with “Verify that current and voltage signal values are provided to the protective relays” to be consistent with Table 1-3. 3. Remove “Reverse power relays” from the sample list of generator devices in Supplement p31 because reverse power relays are applied for mechanical protection of the prime mover, not electrical protection of the

Organization	Yes or No	Question 4 Comment
		generator. 4. Revise Supplement Figure 1 & 2 Legend p83 to align with Draft 4 (a) state “Protective relays designed to provide protection for BES Element(s)” (b) state “Current and voltage signals provided to the protective relays”. 5. Please add a Performance-Based maintenance example for control circuitry, and /or voltage and current sensing.
Response: Thank you for your comments. 1. This cited reference in the Supplementary Reference Document is present to maintain consistent evidence that maintenance was performed within prescribed intervals. Please see the NERC Compliance Process Bulletin #2011-001 (“Data Retention Requirements”) for similar guidance. 2. Thank you, the change has been made. 3. The commenter is correct that it is the prime mover that is protected by the Reverse Power relay; however the Standard considers relays (such as Reverse Power relays) that sense voltage and current are within the scope. Furthermore, Part 4.2.5.1 (Applicability) of the Standard includes Protection Systems for generator Facilities that are part of the BES including Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays. 4. The column marked Component of Protection System closely aligns with the definition of Protection System as approved by the NERC Board of Trustees and is included within the Standard itself. The next column (“Includes”) is more explanatory in nature and is intended to give insight on the SDT’s intent. 5. Thank you, the requested changes have been made. Additional Q&A (including one for control circuitry and one for voltage and current sensing devices) have been added to Section 9.2.		
National Grid (1)	Ballot Comment - Affirmative	National Grid suggests that FAQ be added: 1. Regarding Table 2 in the standard, Does a fail-safe “form b” contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring? 2. Please add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		

Organization	Yes or No	Question 4 Comment
New York Power Authority (1)	Ballot Comment - Affirmative	Comments: We suggest that FAQ be added: 1. Regarding Table 2 in the standard, Does a fail-safe “form b” contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring? 2. Please add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		
Muscatine Power & Water (3)	Ballot Comment - Affirmative	In the “Supplemental Reference and FAQ” document on page 65 there is one area of concern. In paragraph 4 “…the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer’s equipment.” While MP&W understands the importance of creating a valid baseline, it is disingenuous to expect the test equipment to be the same as the manufacturer’s test equipment. For that matter, it would be highly unlikely the same test equipment would be used over the life of the battery. The expected life of a battery may be in excess of 15 years in most cases and it would not be probable to expect that the type of test equipment is not going to change during this period. MP&W suggests changing the wording to read that CONSISTENT test equipment should be used to provide consistent/comparable results.
Response: Thank you for your comments, the change has been made. The statements concerning types of equipment have been changed per your suggestion to reflect consistent test data as opposed to exactly the same piece of test equipment.		
Florida Municipal Power Agency (4) (5) (6) Florida Municipal Power Pool (6)	Ballot Comment - Negative	1. Examples #1, #2 and #3 in Section 7.1 of the Supplementary Reference all indicate that it is a requirement to “verify all paths of control and trip circuits” every 12 years. As stated, there would be circuits included in the testing requirement that the SDT did not mean to include in the scope of the Standard (e.g., SCADA closing circuit.) The statements in the illustrative examples should be changed to “verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices” to be in line with the definition of a Protection System. 2. Section 15.5 of the Supplementary Reference Document states: “It was the intent of this Standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping (or blocking) occurs locally when the remote action

Organization	Yes or No	Question 4 Comment
		has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted". The SDT should reword this statement recognizing that tests performed on communication systems may not be performed at the same time an entity chooses to perform trip tests on the associated breaker(s). The notion of "overlapping" can be applied, for instance, by taking an outage on one relay set in a fully redundant system, initiating a trip signal from the remote end and observing the trip signal locally. All remaining portions in the local communication-assisted trip paths can then be tested when the local line panel is taken out of service for maintenance.
Response: Thank you for your comments. 1. Thank you, the change has been made. 2. Thank you, the change has been made.		
ITC	No	We agree with the combination of the two. One document with the FAQ's grouped with the supplemental topics makes it easier to review the whole topic.
Response: Thank you for your comments.		
Central Lincoln	No	The first FAQ under 2.3.1 is incorrect, referencing a FERC informational filing. Included in the filing was a WECC test that was never approved by the WECC board and is not being used. Using this document as suggested will get WECC entities into trouble.
Response: Thank you for your comments. There are presently regional differences allowed that may cease to exist once the BES is redefined. The SDT for the BES Definition (Project 2010-17) is charged with developing a continent-wide BES definition; however, this FERC informational filing is on the public record, and was part of the basis for FERC Order 743.		
Tampa Electric Company	No	Tampa Electric requests further differentiation between BES protection elements and UFLS equipment.
Response: Thank you for your comments. UFLS equipment is presently covered under PRC-008. PRC-005-2 will cover all Protection Systems components including components used for UFLS. The Standard addresses UFLS and UVLS to the degree that they are installed per NERC Standards, even though entities may choose to install them on distribution systems. This is an intentional difference between UFLS/UVLS and the remainder of the Protection Systems addressed within the Standard, because of the distributed nature of UFLS/UVLS and because these devices are usually tripping non-BES system elements.

Organization	Yes or No	Question 4 Comment
NIPSCO	Yes	We used the FAQ Supplemental Reference while reviewing this draft standard and found it useful.
Response: Thank you for your comments.		
FirstEnergy	Yes	1. We do not agree with the following wording on page 37 of the reference document: (1) “If your PSMP (plan) requires more activities then you must perform and document to this higher standard.” and (2) “If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.” 2. We continue to believe that the auditor is required to audit to the standard. If the standard requires maintenance intervals every 6 years, this is what the auditor should verify. This was also verified in the recent NERC Workshop at which it was confirmed that “auditors must audit to the standard”. To this end, we also suggest changes to Requirement R3 as explained in our comments in Question 5.
Response: Thank you for your comments. 1. The SDT respectfully disagrees with the commenter. R1 of the Standard states that “… shall establish a Protection System Maintenance Program (PSMP)…, and R3 states that “… shall implement and follow its (PSMP)…” Therefore, if an entity has a more stringent PSMP then they must follow their own PSMP. An example of this might be a case that has an entity with Performance Based Maintenance; this entity could find time intervals between maintenance activities that are more frequent than are laid out in the Tables. This entity must follow their PSMP. Another example might be an entity that requires CT Saturation tests every 10 years; this is a more stringent requirement than is contained within the minimum maintenance activities of the Standard. Neither the SDT nor any auditor has any idea why an entity may require more stringent requirements of themselves than the Standard requirements. Even under the present PRC-005-1 an auditor audits to the entity’s PSMP; a case in point is if an entity PSMP requires relay testing with simulated fault values of voltage and current every year then they are audited to that requirement (even though PRC-005-1 specifically does not require any particular relay testing and certainly has no time intervals stated). Please note that FERC Order 693 directs NERC to establish maximum allowable intervals not minimum intervals, and the entity’s program must, at a minimum, conform to those intervals. 2. The SDT has set no requirements that an entity have a more stringent PSMP than the minimum requirements set out in the Standard, only that any PSMP meet the minimums laid out within the Standard. But, should an entity have a PSMP that is more stringent then, according to R3, they must maintain to their own more stringent PSMP.		
BGE	Yes	1. The supplementary reference on page 30, under the question beginning “Our maintenance plan requires” states that an entity is “out of compliance” if maintenance occurs at a time longer than that specified in the entity’s plan, even if that maintenance occurred at less than the maximum interval in PRC-005-2. But then on page 35, under the question, “How do I achieve a grace period without being out of compliance” provides an example of scheduling maintenance at four year intervals in order to manage scheduling complexities and assure completion in less in less than the maximum time of six calendar years. This is

Organization	Yes or No	Question 4 Comment
		conflicting advice. The FAQ /supplementary reference should be revised so that it does imply that an entity is out-of-compliance by performing maintenance more frequently than required. Avoiding compliance risk is one reason to do this, but there are other valid motives not directly related to reliable protection system performance. 2. Testing of PT's and CT's (12 year max) is non invasive and convenient to schedule at the same time as relays (6 year max) just to keep procedures consistent and reduce program administration. Testing of ties to other TOs or GOs may have to be scheduled more frequently than preferred in order to synchronize schedules.
Response: Thank you for your comments. 1. There is no conflict, the first commenter-cited PSMP example has language that has no grace-period built in, and the second commenter-cited PSMP example has language with a built-in grace period. Both cited examples are measurable to a time limit between testing activities. 2. Your observations are correct; an entity may choose to perform activities more often than is specified in the Standard. For that matter, an entity may choose to perform activities more often than their own PSMP; the entity simply cannot exceed their own PSMP intervals which in turn cannot exceed the intervals in the Standard.		
Pepco Holdings Inc	Yes	The Supplementary Reference and FAQ should be an attachment to the standard (Appendix A) and not just referenced. If not attached it will not be readily accessible to those that will be using the standard.
Response: Thank you for your comments. The Supplementary Reference and FAQ is referenced in Section F of the standard (which was on Page 9 of the clean version of the recent posting), in accordance with the Standards Development Process, and will be posted with the standard as "Reference Materials".		
GDS Associates	Yes	The standard should include a footnote indicating this document as reference
Response: Thank you for your comments. This document is addressed within the Standard as a reference document by listing it in Section F (which was on Page 9 of the clean version of the recent posting), in accordance with the Standards Development Process.		
ExxonMobil Research and Engineering	Yes	The SDT should provide notes that reference the sources used for developing the maximum maintenance intervals utilized in the time-based program, and provide a technical explanation as to why they have not provided a tolerance band for use with the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?
Response: Thank you for your comments. The SDT was tasked to create a standard with maximum time intervals between maintenance activities. Thus the task, in and of itself, sets the limit as absolute. Where the intervals were set at six years (or any interval for that matter), there was no assessment of risk beyond the time interval chosen as the absolute. The question always would arise as "Why not an additional thirty days after that?" The reference material cites methodology		

Organization	Yes or No	Question 4 Comment
to determine initial time intervals. The SDT took further care to try to align the initial maintenance intervals with common maintenance schedules like plant outages and other published guidelines. Please note that the Tables refer to "Calendar Year" for the intervals referenced in the comment; the noted concern would only be relevant if the entity actually completes the activity at the very end of the calendar year.		
US Army Corps of Engineers	Yes	1. The reference material provides a significant insight into the intent of the proposed changes to the standard. In some cases an interpretation is provided which is not supported by the explicit interpretation of the standard text. The SDT is encouraged to either attach the reference material to the standard or add relevant sections to standard as Background. The Background section could reference the Supplemental Reference & FAQ. 2. The reference material provides more detail indicating that "Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. . . . . . The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify)." This interpretation is not consistent with the text of the standard and would suggest that it be incorporated into Table 1-3.
Response: Thank you for your comments. 1. This standard is not being developed in a "results-based" format. As you suggest the reference material is listed within the Standard (Section F – Supplemental Reference Document). The next revision will likely resemble your suggestion. 2. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks.		
Luminant	Yes	The document was valuable in understanding PRC-005-2 by providing clarification using practical protective relay system examples. Below are two comments for further improvement. 1. It would be beneficial if the document could provide additional information for relaying in the high-voltage switchyard (transmission owned) - power plant (generation owned) interface. While Figures 1 and 2 are typical generation and transmission relay diagrams, it would be helpful if protective relays typically used in the interface also be included. For example, a transmission bus differential would remove a generator from service by tripping the generator lockout. 2. Figures 1 and 2 refer to a "Figure 1 and 2 Legend" table which provides additional information on qualifications for relay components. Should a footnote be used to point toward Reference 1 (Protective

Organization	Yes or No	Question 4 Comment
		System Maintenance: A Technical Reference) located in Section 16?
Response: Thank you for your comments. 1. There are so many variations possible that it is impractical to try to capture all configurations on a single picture or in a single document. However, for the cited example - a transmission bus Protection System would be included. All five of the Protection System component types would fall within the Standard including the trip paths and the electrical test requirements of the generator lockout device. 2. Thank you, a link has been provided to the references.		
MISO Standards Collaborators	Yes	The additional documentation seems to be quite large, and the additional content seems to go far beyond what is necessary for the PRC-005-2 standard. We recommend the SDT lessen the amount of content provided in the "Supplementary Reference" document.
Response: Thank you for your comments. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The intent of the supplementary information is to spur insight into possible means of satisfying requirements and is not intended to promote a single technical method of accomplishing tasks.		
Northeast Power Coordinating Council	Yes	Suggest that to FAQ be added: 1. Regarding Table 2 in the standard, does a fail-safe "form" contact that is alarmed to a 24/7 operation center qualify as an alarm path with monitoring? 2. Add a clarification as part of the FAQ document that defines whether the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, must be tested as per Table 1.5.
Response: Thank you for your comments. 1. Thank you, the change has been made. An additional Q&A has been added to Section 15.6.1. 2. Thank you, the change has been made. An additional Q&A has been added to Section 15.3.1.		
Georgia Transmission Corporation	Yes	See comments for item 1 and continue clarification where we could include high side or distributed interrupting devices, exchange nomenclature removing distribution breaker and adding distributed interrupting device or non-BES equipment.
Response: Thank you for your comments. Circuit interrupting devices that only participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements. The "non-BES equipment interruption device" phrase has been inserted as suggested.		

Organization	Yes or No	Question 4 Comment
PNGC Comment Group	Yes	Section 9.2 (copied below) indicates that small entities can utilize Performance-Based PSMP if they aggregate with other entities. Does this section indicate that only a parent entity with individually owned components can aggregate, or can independent entities under a G&T aggregate? In other words, individual DP/LSE/TOs with different audits. Can they aggregate under a common PSMP for performance based maintenance? 9.2 Frequently Asked Questions: I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity? Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis. The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.
Response: Thank you for your comments. Two entities in such a shared program must have populations of components that can be aggregated and the PSMP for those components are the same between the two entities. Thus the combined entities can show total populations, total numbers of components tested and total failures found. The combined entities would thus be forced to follow the same intervals, test procedures and statistical analysis. There would have to be cooperation between entities but in the end the outcome would be the same as if the PBM process were applied to a single entity. There is no inherent advantage or disadvantage to multiple entities cooperating in such a manner. The SDT intends that small entities with small populations of equipment have the same access to PBM as the larger entities.		
FHEC	Yes	It is unclear what compliance obligations may be created or clarified with the FAQ. It is a good explanatory document and a helpful reference, but the Standard should speak for itself as it relates to what it takes to achieve compliance.
Response: Thank you for your comments. The Standard is the only "mandatory and enforceable" document. Details within the Supplemental Reference Document are provided as examples and should not be construed as limitations or additional requirements. The SDT intends that it be posted as a Reference Document, accompanying the standard. As established in SDT Guidelines, the Standard is to be a terse statement of requirements, etc, and is not to include explanatory information like that included in the Supplementary Reference Document. The Supplementary Reference FAQ will be revised in the course of the revision process of the standard.		
Western Area Power	Yes	Can the SDT add a better definition or clarification of "Calendar Year" as it pertains to PRC-005-2 and provide

Organization	Yes or No	Question 4 Comment
Administration		examples or parameters of Compliance with the Standard requirements and tables? Calendar Year is explained in various details within Pages 35-Pages 37 of the Supplementary Reference and FAQ. This important attribute of a TBM or TBM/CBM combination program is not easily found in the Table of Contents or section sub-headings.
Response: Thank you for your comments. Per your suggestion, a “What is a Calendar Year?” Q&A has been added to the front end of Section 7.1.		
Duke Energy	Yes	Along the lines of what we have suggested in our comment to Question #1 above, we believe it would make compliance more certain if selected language from the Supplementary reference could be incorporated into the standard, either directly in requirements, or in footnotes.
Response: Thank you for your comments. The addition that you suggest is properly considered application guidance; the SDT has been advised that this information is not to be included within the standard, and that it is appropriately included in separate reference materials.		
Ameren	Yes	1. Comments: Supplement FAQ 12.1 on page 51 final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement. Since BES Element protection is the objective, we suggest a compromise of keeping the evidences of last test for the removed equipment and using that with the equivalent function replacement equipment commissioning or in-service date to prove interval. 2. Clarify p17 Table 1-4(e) interval meaning. We think this means we need to verify the Station dc supply voltage on 12 calendar year interval if unmonitored, or no periodic maintenance if monitored as stated. 3. In Supplement examples on pp 22-23, replace “Instrumentation transformers” with “Verify that current and voltage signal values are provided to the protective relays” to be consistent with Table 1-3. 4. Remove “Reverse power relays” from the sample list of generator devices in Supplement p31 because reverse power relays are applied for mechanical protection of the prime mover, not electrical protection of the generator. 5. Revise Supplement Figure 1 & 2 Legend p83 to align with Draft 4 (a) state “Protective relays designed to provide protection for BES Element(s)”. (b) state “Current and voltage signals provided to the protective relays” 6. Please add a Performance-Based maintenance example for control circuitry, and /or voltage and current sensing.

Organization	Yes or No	Question 4 Comment
Response: Thank you for your comments. 1. This cited reference in the proposed Standard is present to maintain consistent evidence that maintenance was performed within prescribed intervals. 2. The SDT agrees. 3. Thank you, the change has been made 4. The commenter is correct that it is the prime mover that is protected by the Reverse Power relay, however the Standard considers relays (such as Reverse Power relays) that sense voltage and current as within the scope. Furthermore, Part 4.2.5.1 of the Standard states that Protection Systems for generator Facilities that are part of the BES including Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays 5. The column marked Component of Protection System closely aligns with the definition of Protection System as approved by the NERC Board of Trustees and is included within the Standard itself. The next column ("Includes") is more explanatory in nature and is intended to give insight on the SDT intent 6. Thank you, the changes have been made. Additional Q&A have been added to Section 9.2.		
Xcel Energy	Yes	1) On page 65, paragraph 4, of the "Supplemental reference and FAQ" document, it states:"the type of test equipment used to establish the baseline must be used for any future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment." While we understand the importance of creating a baseline, it is not feasible to expect the test equipment be the same as the manufacturer's test equipment or even the same test equipment over the life of the battery. The expected life of a battery may be in excess of 20 years and it is not feasible to expect that the type of test equipment will not change during this period.2) A FAQ to clarify in scope protection systems for variable energy resource facilities (wind, solar, etc) would be very helpful. 2) Does paragraph 4.2.5.3 "Facilities" imply that the only protection system associated with a wind farm that is considered in scope for PRC-005-2 is that for the aggregating transformer? If other protection systems associated with a wind farm are in scope, please clarify which systems would be in scope for PRC-005-2. For example, a typical wind farm in our system might have 30-33, 1.5MVA windmills connected to one 34.5 KV collecting feeder circuit for a total of roughly 50 MVA per collecting feeder. 4 of these 50 MVA collecting feeders are tied via circuit breakers to a low side 34.5 KV bus which in turn is connected via a low side breaker to aggregating step up transformer which then connects to the BES transmission system. Obviously per paragraph 4.2.5.3, the protection system for the aggregating step up transformer is in scope. What about the protection system for the transformer low side 34.5 KV breaker - serving 200 MVA of aggregate generation? What about the protection system of each individual 34.5 KV aggregating

Organization	Yes or No	Question 4 Comment
		feeder - 50 MVA of aggregate generation? What about the"protection system" for each individual 1.5 MVA windmill? An FAQ on this topic would be very helpful.
Response: Thank you for your comments. 1. Thank you for your suggestion; the paragraph cited has been changed. 2. Clause 4.2.5.3 states specifically that the Protection Systems on the aggregating transformer are included. The SDT has not specifically included other equipment, but, depending on what, specifically, is defined to be BES for these facilities, either within current Regional definitions or within the emerging NERC definition, other equipment may be drawn in.		
Alliant Energy	Yes	

5. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: Several commenters were concerned that an entity has to be "perfect" in order to be compliant; the SDT responded that NERC Standards currently allow no provision for any degree of non-performance relative to the requirements.

Several commenters continued to insist that "grace periods" should be allowed. The SDT continued to respond that grace periods would not be measurable.

Several comments were offered, suggesting that PRC-005-2 needs to be consistent with the interpretation in Project 2009-17, now implemented as PRC-005-1a, and the SDT modified Applicability 4.2.1 for better consistency with the interpretation 4.2.1 (Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc).

Many comments were offered objecting to the 3-calendar-month intervals for station dc supply and communications systems, and suggesting that a 3-calendar-month interval requires entities to schedule these activities for 2-calendar-months in order to assure compliance. The SDT did not modify the standard in response to these comments, and responded that the intervals were appropriate, and that entities should be able to assure compliance on a 3-calendar-month schedule by using program oversight. The "Supplementary Reference and FAQ" document was augmented with additional explanatory text.

Several comments were offered questioning various aspects of Applicability 4.2.5.4 (generation auxiliary transformers). No changes were made in response to these comments, and responses were offered illustrating why these transformers are included.

Many (essentially identical) comments were offered, questioning the propriety of including distribution system Protection Systems, almost all related to UFLS/UVLS. The SDT explained that these Protection Systems are appropriate to be included for consistency with legacy standards PRC-008, PRC-011, and PRC-017, and noted that their inclusion is consistent with Section 202 of the NERC Rules of Procedure.

Several comments were offered, objecting to the 6-calendar-year interval for lockout and auxiliary relays. The SDT declined to adopt the requested changes, and noted that these "electromechanical" devices with "moving parts" share failure mechanisms with electromechanical protective relays and that the intervals should be identical.

Several comments were offered regarding Maintenance Correctable Issues, and resulted in modifying this definition to be "…such that the deficiency cannot be corrected during the performance of the maintenance activity …"

Assorted additional comments were offered by individual commenters (most of them similar to comments on previous postings), which resulted in responses similar to those offered during previous posting periods.

Organization	Yes or No	Question 5 Comment
Consolidated Edison Co. of New York (1) (3) (5)	Ballot Comment - Affirmative	We recommend that the drafting team recognize that a “fail safe” or “self-reporting” alarm design serves as an acceptable alternative to periodic testing. This “fail safe” or “self-reporting” alarm design is equivalent to continuous testing the alarm. When the alarm circuit fails the alarm is set to “alarm on” and automatically notifies the control center, initiating a corrective action.
Response: Thank you for your comments. The application discussed seems to the SDT to be an effective method of “monitoring the monitoring circuit”. (See Table 2, last row with heading “Alarm Path with monitoring.”)		
Ameren Services (1)	Ballot Comment - Affirmative	(1) Need some tolerance – require 99% of components to meet R3. Measure M3 on page 5 should apply to 99% of the components. “Each … shall have evidence that it has implemented the Protection System Maintenance Program for 99% of its components and initiated….” PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. (2) Define BES perimeter in accordance with Project 2009-17 Interpretation. Facilities Section 4.2.1 “or designed to provide protection for the BES” needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. The BOT adopted this 2/17/2011. (3) Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. 1. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 2. The referenced interpretation relates to a quasi-definition of “transmission Protection System”, and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introducing any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004-1 is not affected by PRC-005-2. 3. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes		

Organization	Yes or No	Question 5 Comment
that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Xcel Energy		1) Regarding "Facilities" paragraph 4.2.5, we are in agreement with the elimination from scope of system connected station service transformers for those plants that are normally fed from a generator connected station service transformers. However, in the cases where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility? If the end result of the trip of the primary station service transformer is a trip of a BES generating facility, it would be more consistent to include the protection system for that transformer as in scope - whether it be connected to the system or to the generator. 2) We recommend the SDT consider an interval of 12 calendar years for the component in row 3, of Table 1-5 on page 19 of the standard. The maximum maintenance interval for "Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil" should be consistent with the "Unmonitored control circuit" interval which is 12 calendar years. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. We believe that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that the SDT will consider these changes.
Response: Thank you for your comments. 1. The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. 2. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
Northeast Power Coordinating Council, Inc. (10)	Ballot Comment -	A concern exists that an entity with a very strict PSMP with intervals that are much shorter than neighboring entities or the standard will rewrite their PSMP and loosen their requirements to allow postponed maintenance

Organization	Yes or No	Question 5 Comment
	Affirmative	up the maximum specified in the standard. This standard, as written penalizes non-adherence to more stringent and better PSMPs and may inadvertently driving entities to the least common denominator. I am hopeful that Phase 2 will address this issue.
Response: Thank you for your comments. The Standard is defining maximum allowable intervals and minimum acceptable activities for a PSMP. Entities are empowered to develop PSMPs that exceed these requirements if they determine such a PSMP to be necessary.		
GDS Associates		Requirement R1 1. Suggest changing the language in R1.2 to read "Identify which maintenance method such as the time-based, performance-based (detailed in PRC-005 Attachment A), or a combination of the two would be appropriate to be used for each type of Protection System component. Based upon their own constructive type, all batteries associated with the station DC supply shall be included in a time-based maintenance program consistent with Table 1-4(a) through Table 1-4(f)" 2. Suggest changing the language for the first paragraph in R1.3 to read "Establish the occurrences associated with the time-based maintenance programs up to but no less than the time intervals specified in Table 1-1 through Table 1-5, and Table 2. Consequently, include all applicable monitoring attributes and related maintenance activities characteristic to each type of Protection System component specified in Table 1-1 through Table 1-5, and Table 2" 3. Suggest adding a sub-requirement such as R1.5 to read "Include documentation of maintenance, testing interval and their basis and a summary of testing procedures" Requirement R3 4. The redline version of the standard is misleading. Requirement R3 is crossed out and then replacing requirement R7 which is also crossed out. 5. The wording "initiates resolution of any identified maintenance correctable issues" it is vague. What a responsible entity should do to become compliant with this requirement? We also believe that is not sufficient to just "initiate resolution"; the standard should call for corrective actions to be performed within the maintenance time interval. 6. The "identified maintenance correctable issues" may not be a proper choice. The name of the new term suggests that is about issues that can be corrected during maintenance, while the definition from the clean version explains otherwise?

Organization	Yes or No	Question 5 Comment
		Additional requirement 7. Suggest adding a requirement to read "The Transmission Owner, Generator Owner, and Distribution Provider shall provide documentation of its PSMP and implementation to the appropriate Regional Reliability Organizations on request (within 45 calendar days)." 8. Add measure for the evidence on documenting the PSMP from the additional requirement General comments and notes 9. If you own electro-mechanical relays and microprocessor based relays is there a need to keep two different logs for these? 10. On table 1-4 the generator CTs should be tested earlier than the suggested 12 years due to exposure of continuous mechanical stress 11. Clarify table 1-5 to address verification tests on different circuits. Suggest that the Table 1-5 to read "Complete a terminal test of unmonitored circuitry" instead of the "Unmonitored control circuitry associated with protective functions" 12. In what instances (what extent) would the standard allow using the real time breaker operation to be considered maintenance as applicable to different types of relays involved in the real time event? This is briefly emphasized under TBM at paragraph 5.1 from the supplementary reference document?

Response: Thank you for your comments.

1. It is not enough for an entity to determine if time-based, performance-based, or a combination of the two would be "appropriate"; the entity must specify which method is being used, so that it is clear to both the entity and an auditor if R2 and Attachment A apply.

2. The SDT has considered your comment and has determined that the text currently within the requirement is appropriate.

3. The requirement that you suggest is identical to one of the most troublesome requirements from the approved PRC-005-1. By providing Tables 1-1 through 1-5, as well as Table 2, the SDT is establishing maximum allowable intervals as well as minimum required activities, and thus replacing this PRC-005-1 requirement with a more prescriptive one. If an entity chooses to extend the intervals and alter the activities by using monitoring, or to apply performance-based maintenance per R2 and Attachment A, the additional requirements related to those choices effectively establish a requirement such as you suggest.

4. The red-lining tools in Microsoft Word can sometimes be misleading, but the red-line is provided in an effort to illustrate the changes made to the document. We recommend that the entity use the "clean" version in order to see the final resulting text.

5. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with

Organization	Yes or No	Question 5 Comment
other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct the maintenance correctable issue"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues within PRC-005-2 and rely on the operating focus on the degraded system to ensure that they are completed. The associated measure provides examples of relevant documentation. The definition of maintenance correctable issue has been revised to be clearer. 6. The phrase from the entire sentence states "initiate resolution of any identified maintenance correctable issues". This is to ensure follow-up for items which cannot be corrected during maintenance. The definition of maintenance correctable issue has been revised to be clearer. 7. No direct BES reliability purpose is supported by "on request documentation of a program"; this has value only for monitoring compliance. Additionally, Compliance Enforcement Authorities are empowered by the NERC Rules of Procedure to request information demonstrating compliance at any time. 8. No additional measure is necessary, as the suggested requirement is unnecessary. 9. The SDT is not specifying how the maintenance records are maintained relative to the Standard. It is up to the entity to determine how to best document the detailed implementation of their program. 10. Instrument transformers are addressed in Table 1-3, not Table 1-4. Entities are allowed to maintain components more frequently than required within the Standard if they feel it necessary. 11. The SDT does not believe that the suggested text adds clarity to the standard. Please see Section 15.3 of the Supplementary Reference Document for additional discussion. 12. The SDT suggests that observed in-service performance may be usable for any activities that are clearly verified by the in-service performance.		
Liberty Electric Power LLC		Apologies to the drafting team for submitting this with the ballot, repeated here to insure the comments are captured and addressed. While the SDT has done a very good job at responding to the most objectionable parts of the previous version, there are still a number of issues which makes the standard problematic. 1. The standard introduces the term "initiate resolution". This is an interpretable term, and has the potential for an auditor and an entity to disagree on an action. Would issuing a work order be considered "initiating resolution"? What if the WO had a completion date many years into the future? I would suggest adding the term to the list of definitions which will remain with the standard, and defining it as "performing any task associated with conducting maintenance activities, including but not limited to issuing purchase orders, soliciting bids, scheduling tasks, issuing work requests, and performing studies". 2. Some clarity is needed to differentiate system connected and generator connected station service transformers. A statement that a station service transformer connected radially to the generator bus is considered a system connected transformer if the transformer cannot be used for service unless connected to the BES. 3. The "bookends" issue, brought up in the prior round of comments, still exists. Although the SDT rightly notes a CAN has been issued regarding bookends, the CAN covers the documentation for system

Organization	Yes or No	Question 5 Comment
		components that entities were required to self-certify to on June 18, 2007. PRC-005-2 adds additional components to the protection system scheme which were not part of that certification, and has the potential to put entities into violation space due to a lack of records for those components. The SDT should add to M3 a statement that entities may demonstrate compliance with the standard by demonstrating that required activities took place twice within the maximum maintenance interval -starting from the effective date of the standard - for all components not listed in PRC-005-1.
Response: Thank you for your comments. 1. The SDT believes that issuing a work order would satisfy this requirement. M3 presents several examples of relevant evidence. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct the maintenance correctable issue"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 3. The Implementation Plan specifies that entities may implement PRC-005-2 incrementally throughout the intervals specified, and that they shall follow their existing program for components not yet implemented. The SDT believes that the "bookends" issue to which you refer is therefore addressed. Also, please see Compliance Process Bulletin 2011-001 for a discussion about data retention.		
Central Lincoln		As we stated two ballots ago, we continue to believe that IEEE battery standard quarterly maintenance was never intended to be performed at a maximum interval of three months. Instead, three months is a target value that might be extended due to emergency. We continue to support a maximum interval of four months for these activities.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Tampa Electric Company		1. As written PRC-005-2 would have a very significant impact on Tampa Electric Company with very little reliability benefit. For the testing of the DC control circuits Tampa Electric would need to remove from

Organization	Yes or No	Question 5 Comment
		service each BES element (circuit, bus, transformer, breaker) and perform an R&C checkout somewhat equivalent to what Tampa Electric does for new construction. That process would have to be repeated no less often than every six years. The testing of DC control circuits to the level described / required in the proposed standard in an energized station is a very risky proposition. Even though an element can be taken out of service for testing, the DC control circuits are often interconnected for functions such as breaker failure, bus and transformer lockouts etc. It is very easy to accidentally trip other in service equipment while doing this testing. Another concern is getting outages on equipment to perform the proposed testing. 2. Tampa Electric believes that there is an unnecessary expansion of the scope of equipment covered by the proposed PRC-005-2 standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The proposed PRC-005-2 includes the non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, the non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the proposed standard with negligible benefit to BES reliability. 3. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. 4. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load. 5. Tampa Electric's Energy Supply Department has the following comment / question regarding Data Retention: For Requirement R3 R2 and Requirement R4R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or all performances of each distinct maintenance activity for the Protection System component since or to the previous scheduled audit date, whichever is longer. If all of the data which the proposed PRC-005-2 standard requires to be collected is not be available or kept for the prescribed period of time, how does a registered entity comply with the required data retention?

Response: Thank you for your comments.

1. Entities must employ processes and training on how to best manage risk . Not performing DC control circuit verification of protection functions is a risk to the

Organization	Yes or No	Question 5 Comment
reliability of the BES. 2. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. The SDT notes that several Table entries for components that are used only for UFLS or UVLS involve fewer activities and/or longer intervals than for other similar components for generic Protection Systems. 3. The requirements related to UFLS and UVLS, which are commonly applied on non-BES equipment, are less involved than those for other Protection System equipment in recognition of the observations by the commenter. 4. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 5. The stated data retention period is consistent with what auditors are expecting (per the SDT’s experience), and is also consistent with Compliance Process Bulletins 2011-001 and 2009-05. The entity is urged to assure that data is retained as specified within the Standard.		
American Transmission Company, LLC		1. Change the text of Standard PRC-005-2 - Protection System Maintenance Table 1-5 on page 19, Row 1, Column 3 to: ”Verify that a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, ”Electrically operate each interrupting device every 6 years” Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in table 1-5 row 1 will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). 2. Change the text of Standard PRC-005-2 -Protection System Maintenance Table 1-5 on page 19, Row 3, Column 2 to: “12 calendar years” The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. In order to test the lockout relays, it

Organization	Yes or No	Question 5 Comment
		may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays.ATC recognizes the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 3. ATC's remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. ATC believes that, as written, the testing of "each" trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. ATC hopes that the SDT will consider these changes.
Response: Thank you for your comments. 1. The SDT considers it important to verify that each breaker trip coil has indeed operated within the established intervals. While breakers may be operated much more frequently at times (and allow the entity to document these operations to address this activity), other breakers may not be called on to operate for many years. 2. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 3. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
Tri-State G & T Association, Inc. (3)	Ballot Comment - Affirmative	1: Section A.4.2. They are referencing Protection Systems as if they are Facilities in the Applicability section. Facilities are BES Elements, but Protection Systems are not. That needs to be modified somehow. Perhaps the drafting team needs to add another category under Applicability entitled "Protection Systems" and then list which types are included. 2: Maintenance Correctable Issue - This definition seems to be more of a Maintenance Non-Correctable Issue since it can only be resolved by follow-up corrective action. Suggest changing the term. 3: Change Definitions as indicated below: Segment - Protection System components that are identical or share common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual components in order to be considered for inclusion in a performance-based PSMP Component -An individual piece of equipment included in the definition of a Protection System., Entities are allowed some latitude to designate their own definitions of a Component. An example of where the entity

Organization	Yes or No	Question 5 Comment
		has some discretion on determining what constitutes a single Component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single Component. 4: M1 - Why is the document necessary to be "current or updated?" Eliminate "or updated." 5: The Applicability section needs to be changed, regardless of whether it has been discussed before. Protection Systems are not Facilities.
Response: Thank you for your comments. 1. The standard template allows for two separate sections within Applicability, "Entities" and "Facilities". The listing under Facilities is describing the applicable facilities to which the Protection Systems are applied, clarified further to indicate that only the Protection Systems on those Facilities are relevant. 2. The definition of maintenance correctable issue has been revised to be clearer. Please see Section 4.1 of the Supplementary Reference Document for additional discussion. The revised definition is: **Maintenance Correctable Issue** – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 3. The SDT does not believe that your suggested changes add clarity. 4. M1 has been modified as you suggest. 5. The standard template allows for two separate sections within Applicability, "Entities" and "Facilities". The listing under Facilities is describing the applicable Facilities to which the Protection Systems are applied, clarified further to indicate that only the Protection Systems on those Facilities are relevant.		
Progress Energy		Comments on Draft Standard 1. Table 1-1, 2nd row, 2nd bullet: The comment "(see Table 2)" does not apply to this bullet, but applies to the first bullet. 2. Table 1-3, 2nd row: Need to add "(See Table 2)." Comments on Implementation Plan 1. Section 3a states that "The entity shall be at least 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval" If regulatory approval occurs on January 31, 2012, does this mean that the entity has until December 31, 2014 to be 30% compliant? It might be beneficial to provide an example explaining "calendar year." Comments on Supplementary Reference

Dominion Virginia Power		Comments: IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Santee Cooper		Comments: 1. Santee Cooper does not agree with the expansion of the UFLS and UVLS requirements to include the dc supply. We understand that, in the previous consideration of comments, it is stated that "For UFLS and UVLS, the maintenance activities related to station dc supply and control circuitry are somewhat constrained relative to similar activities for Protection Systems in general." In the table, the requirement for dc supply for UFLS is to verify the station dc supply voltage when the control circuits are verified, which could be 6 or 12 years. It seems like the restraint shown in the requirement, if an indication of the level of need for the verification, is of a much longer timeframe than what would actually happen in the typical operation of a distribution system. Therefore, proof of this verification seems to be of minimal value compared to the extra documentation required due to this now being an auditable maintenance activity. 2. We also agree that maintenance activities with fast intervals, especially the 3 month ones, should be adjusted to 4 months to allow for the actual interval the entities use to be 3 months. Having the requirement at 3 months forces the utilities to schedule even faster (such as every month or 2 months) to ensure compliance.
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure define "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		

Organization	Yes or No	Question 5 Comment
2. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
The Detroit Edison Company		1. Countable Event - This definition should be clarified. As it stands, it appears that if a technician were to adjust the settings on an electromechanical relay - even if it were not outside of the entity's acceptable tolerance - it would need to be classified as a countable event. I would recommend that the definition be limited to repairing or replacing a failed component during the maintenance activity. These activities would address conditions that would potentially cause a Protection System misoperation (either a failure to trip or an unintentional trip). Routine maintenance activities to bring component test values back within tolerance should be excluded from the definition of a Countable Event. These activities are performed to keep the protection systems performance at its most ideal state. In addition, the definition as stated appears to classify battery maintenance activities such as cleaning corrosion, adding water, or applying an equalize charge, as countable events. If this is the intent, I disagree. These are activities that are expected to occur on a regular, routine basis due to the chemical properties of the battery (as described at length in the Supplementary Reference). As such, they should also not be classified as countable events. 2. Table 1-1 and Table 1-5 Based on experience with DECo equipment, a 6 year interval for testing monitored relays and performing tests on the breaker trip coil is substantially shorter than required. Currently, the interval for both is 10 years. This interval lines up both with the Transmission Owner's interval for relay maintenance as well as the maintenance interval for the associated current interrupting devices. I would recommend that these intervals be extended, at minimum, back to the 7 year interval proposed in Draft 2 - if not longer. 3. Table 1-4 (a, b, c, e) - Station dc supply using any type of battery recommend that the maintenance activity to "Verify: Station dc supply voltage" be clarified to state that the voltage should be measured at the positive and negative battery terminals. Until you get to page 72 of the Supplementary Reference, you do not know if this means to check the battery voltage or the bus voltage. The "Station dc supply" could refer to the entire dc system. It needs to be made clear in the table that you are referring to the battery. 4. Also, I noticed that there is no longer a requirement to measure individual cell voltages. I was wondering if you could explain the rationale behind that. Checking for voltages that are out of specification in individual cells helps to identify weak cells that may need to be replaced, if corrective action taken on them does not improve their condition. Individual cell voltage readings, along with ohmic readings, have been an industry standard that I believe many, if not most, companies adhere to. 5. Table 1-4 (a, b, c, d)I recommend eliminating the 3 month requirement. We have found annual inspections to be sufficient in catching problems early enough to take corrective action. Page 30 of the Supplementary

Organization	Yes or No	Question 5 Comment
		Reference states that the SDT believes that routine monthly inspections are the norm. While this may be the case at manned stations, it is not at unmanned stations. The amount of paperwork that would be required to demonstrate compliance is overwhelming and would be an immense burden. I have seen your suggestion in past draft comments of the same nature that if we don't want to do the 3 month inspections, then we should utilize more advanced monitoring. This is not something that can be implemented in a short time frame. It would take years to put all of that technology in place, and is rather cost prohibitive. Furthermore, some of the monitoring technologies that would enable you to forgo the 3 month requirement do not exist yet (to my knowledge). I recommend keeping with the 18 month requirement. If that seems too long, based on past experience I think a 12 month requirement would suffice. 6. Table 1-4 (c) I propose keeping the option to evaluate ohmic values to baseline. 7. Table 1-4 (a, b) For the requirement to evaluate the ohmic values to baseline, is a checkbox stating that you did this sufficient, or would a report/graph/etc listing the actual baseline and current value be required? 8. Table 1-4 (f) The first attribute is regarding high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. Would a low voltage alarm combined with high voltage shutdown (but not a high voltage alarm) meet this requirement? The high voltage shutdown will shut the charger down in a high voltage condition, and therefore result in a low voltage alarm, so the outcome is the same.

Response: Thank you for your comments.

1.”Tweaking the settings” on a component that is not outside tolerances is not a Countable Event, which is partially defined as “A component which has failed and requires repair or replacement, any condition discovered during the verification maintenance activities in Tables 1-1 through 1-5 which requires corrective action …”. However, as described in Clause 9.2 (Question 4) of the Supplementary Reference Document, a device which is outside tolerances should be considered to have experienced a “calibration failure” and thus has experienced a countable event.

2. If an entity’s experience is that these components require less-frequent maintenance, a performance-based program in accordance with R2 and Attachment A is an option. The intervals were revised after Draft 3 such that the various intervals are multiples of each other, such that entities may establish a systematic PSMP.

3. Your observation that in section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” the SDT stated that “verification of dc supply voltage is simply an observation of battery voltage” is correct, but the SDT does not agree that the location where voltage should be measured (verified) be contained in PRC-005-2 or the Supplementary Reference document. Due to the variances in topography of dc control circuitry for Protection Systems, a single location for verification of dc supply voltage cannot be specified and must be determined by the Protection System owner.

4. As you correctly stated taking Individual cell voltage readings has been a standard that many companies adhere to. However, this maintenance activity was removed from the standard because it was a “how to requirement”.

5. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the

Organization	Yes or No	Question 5 Comment
intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed. 6. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" the SDT explains why in Table 1-4 (c) (Station dc supply using NiCad batteries) the option to evaluate ohmic values to baseline is not available. 7. The SDT believes that just providing "a checkbox stating that you did this" is sufficient proof. Section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" provides additional discussion on this topic. However, the SDT is unable to fully predict what evidence may be required by the Compliance Enforcement Authority to demonstrate compliance. 8. "A low voltage alarm combined with high voltage shutdown (but not a high voltage alarm)" would only partially meet the requirement. To ensure that the automatic shutdown of the battery charger for high voltage conditions is achieved, a high voltage alarm must be a component attribute of the monitoring system in order.		
Florida Keys Electric Cooperative Assoc. (1)	Ballot Comment - Negative	Extreme unreasonableness and undue hardships on entities, specifically smaller entities. Just one example is "battery inspections". What is an inspection - simply visual or cell readings? Some entities may have to assign full time battery maintenance duties. Can SCADA monitor DC voltage trends?
Response: Thank you for your comments. In section 15.4 of "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" – that was provided for review and comment with PRC-005-2 – details what should be inspected for visual battery cells. The SDT disagrees that the PRC-005-2 with its accompanying Table 1 imposes "extreme unreasonableness and undue hardships on entities, specifically smaller entities" to maintain a reliable Protection Systems. Monitoring the dc voltages via SCADA is an option.		
FirstEnergy		FE offers the following additional comments and suggestions: We do not agree with the wording of requirement R3. The entity is only required to meet the minimum maintenance intervals of the standard as outlined in Tables 1 and 2. We offer a scenario where an entity states that they will go above the standard and maintain relays on a 4 year cycle. The standard, in meeting an adequate level of reliability, sates that this activity must be performed every 6 years. If the entity happened to miss the 4 year timeframe, deciding from a business standpoint to delay the maintenance to the 5th year, an auditor can find the entity non-compliant per the guidance and wording of the requirements in this standard. However, the entity still exceeded an adequate level of reliability by performing the maintenance within 5 years. This scenario would be very unfortunate to the entity that has essentially done their part in providing reliability to the bulk power system, yet they would be punished for not meeting their more stringent timeframes. This standard's guidance and requirements sends an adverse message to industry. It essentially punishes an entity for going above and beyond the standard except on a few rare occasions. If this were to happen, that entity, and possibly others, would not see the value in going above a standard. It would make entities meet the bare minimum requirements, essentially reducing overall system reliability. Therefore, we

Organization	Yes or No	Question 5 Comment
		suggest the following wording for requirement R3: "R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP to ensure adherence to the minimum requirements as outlined in Tables 1 and 2, and initiate resolution of any identified maintenance correctable issues."
Response: Thank you for your comments. The Standard requires an entity to implement a PSMP that meets the minimum requirements to the standard. An entity may choose to implement a program that exceeds the requirements.		
City of Farmington (3)	Ballot Comment - Affirmative	FEUS would like to thank the Drafting Team. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. However, section 4.2 identifies five types of protection systems that the standard is applicable to, but the language of Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). We believe the intent is to have a PSMP for all Protection Systems identified in Section 4.2 and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.
Response: Thank you for your comments. R1 has been modified as you suggest.		
FirstEnergy Energy Delivery FirstEnergy Solutions Ohio Edison Company (1) (3) (4) (5) (6)	Ballot Comment - Affirmative	FirstEnergy appreciates the efforts of the drafting team and supports PRC-005-2. We would also like the team to address our comments and suggestions submitted through the separate comment period.
Response: Thank you for your comments. Please see our responses to your comments submitted with the Formal Comments.		
ITC		1. For Battery System:- Table 1-4(a)o The maximum maintenance interval for the majority of the battery maintenance is listed at "18 calendar months". The current ITC Standard is"once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st ".

Organization	Yes or No	Question 5 Comment
		ITC would like the maximum maintenance interval at "once per calendar year" 2. Table 1-4(b) o VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the "18 calendar months" inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. 3. For Battery System:- Table 1-4(a) o The maximum maintenance interval for the majority of the battery maintenance is listed at "18 calendar months". The current ITC Standard is "once per calendar year and a calendar year is defined as a twelve-month period beginning January 1st and ending December 31st ". ITC would like the maximum maintenance interval at "once per calendar year" 4. Table 1-4(b) VRLA (Valve Regulated Lead Acid) batteries have an additional inspection at 6 calendar months that includes inspecting the condition of all individual units by measuring the battery cell/unit internal ohmic values. This is in addition to the "18 calendar months" inspection. ITC would like to be consistent with the VLA (Vented Lead Acid) batteries and have only one internal ohmic value inspection once per calendar year. 5. Auxiliary Relays: ITC does not agree with the 6 year interval for Aux relays in the trip circuit. Although they are EM relays they are simple and have very few moving parts. We believe the maintenance period for auxiliary relays should be 12 years and they should be in conjunction with the control circuit. We recognize that Draft 4 only includes auxiliary relays that are directly in the trip path. That is an improvement in Draft 4. In general, auxiliary relays are very reliable; only certain relay types have been proven to be problematic. A known relay type (HEA) has been proven to be problematic if not exercised frequently. The standard should not require a 6 year interval period for all other auxiliary relays. We believe problematic relays should be addressed through use of a NERC Alert process. Don't cut down the tree for a bad apple.

Response: Thank you for your comments.

1. In choosing the 18 calendar month interval for the maximum maintenance interval for the maintenance activities of table 1-4(a) the SDT was aware that the majority of these activities are recommended to be performed in IEEE 450 "Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications "at the Yearly inspection. The SDT does not agree that "once per calendar year" would be a more appropriate interval for these activities but notes that entities may choose to perform required activities more frequently than the maximum intervals expressed in the Tables.

Organization	Yes or No	Question 5 Comment
2. In section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” – that was provided for review and comment with PRC-005-2 explaining why the for VRLA battery systems (Table 1-4(b)) the maximum maintenance intervals and maintenance activities cannot be consistent with the intervals and activities of VLA battery systems (Table 1-4(a)). 3. In choosing the 18 calendar month interval for the maximum maintenance interval for the maintenance activities of table 1-4(a) the SDT was aware that the majority of these activities are recommended to be performed in IEEE 450 “Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications “at the Yearly inspection. However, the SDT has considered that IEEE 450 presents these activities as recommended activities in a vacuum, without considering other activities that are being performed at the 3-calendar-month interval and has established the 18-calendar-month interval to comport to the most aggressive intervals being used in common practice. The SDT does not agree that “once per calendar year” would be a more appropriate interval for these activities but notes that entities may choose to perform required activities more frequently than the maximum intervals expressed in the Tables. 4. Section 15.4 of “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” (question – “What are cell/unit internal ohmic measurements “– that was provided for review and comment with PRC-005-2 – explains why the for VRLA battery systems (Table 1-4(b)) the maximum maintenance intervals and maintenance activities cannot be consistent with the intervals and activities of VLA battery systems (Table 1-4(a)). 5. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. If an entities' experience is that these components require less-frequent maintenance, a performance-based program in accordance with R3 and Attachment A is an option.		
Manitoba Hydro		-Grace periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time
Manitoba Hydro (1) (3) (5) (6)	Ballot Comment - Negative	Manitoba Hydro is voting negative for the following reasons: -Grace periods Grace periods should be permitted on the maintenance time intervals. While we understand that grace periods can be built into a PSMP, maintenance decisions that compromise reliability may still have to be made just to meet the specified time intervals and avoid penalty. An example of this would be removing a hydraulic generator from service at a time of low reserve to meet a maintenance interval and avoid non-compliance (removing an asset in a time of constraint). Grace periods are also required in the case of extreme weather conditions. Such conditions may make it unsafe to perform maintenance within the maintenance interval or may create a risk to reliability if the equipment being maintained is removed from service during these conditions. Utilities need to retain a reasonable amount of discretion and flexibility to make maintenance decisions that are best for reliability without risking non-compliance.
Response: Thank you for your comments. “Grace Periods” within the standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the		

Organization	Yes or No	Question 5 Comment
intervals within the standard.		
Georgia System Operations Corporation (3)	Ballot Comment	GSOC supports comments submitted by Georgia Transmission Corporation
Response: Thank you for your comments. Please see the SDT response to the comments submitted by Georgia Transmission Corporation.		
Electric Market Policy		IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months must implement a policy of two months with one month of grace period thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, Dominion suggests that all battery maintenance intervals expressed as 3 calendar months be changed to 4 calendar months.
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Alliant Energy Corp. Services, Inc. (4)	Ballot Comment - Negative	1. If PRC-005-2 is going to incorporate PRC-008 (UFLS) and PRC-011 (UVLS) the Purpose needs to be revised to include Distribution Protection Systems designed to protect the BES. 2. We do not believe a distribution relaying system, designed to protect the distribution assets, that may open a transmission element (ie; breaker failure) should be considered part of the BES Protection System. R1 should add the following sentence “Distribution Protection Systems intended solely for the protection of distribution assets are not included as a BES Protection System, even if they may open a BES Element.”
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. UFLS and UVLS are described in the Applicability as being included within the Protection System addressed within the standard if they are applied per other NERC Standards. 2. Section 202 of the NERC Rules of Procedure define “Reliability standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirement, as written, supports this.		

Organization	Yes or No	Question 5 Comment
Exelon		1. In response to Exelon's comments provided to drafts 1, 2, and 3 of PRC-005, the SDT did not explain why a conflict with an existing regulatory requirement is acceptable. The SDT previously responded that a conflict does not exist and that the removal of grace periods simply is there to comply with FERC Order directive 693. In response to draft 3 of PRC-005, the SDT stated that "If several different regulatory agencies have differing requirements for similar equipment, it seems that the entity must be compliant with the most stringent of the varying requirements. In the cited case, an entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Again this does not explain why a conflict with an existing regulatory requirement is acceptable. This response does not answer or address dual regulation by the NRC and by the FERC. Specifically, the request has not been adequately considered for an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or become non-compliant with PRC-005. Therefore, Exelon again requests that the SDT communicate with the NRC and with the FERC to ensure a conflict of dual regulation is not imposed on a nuclear generating unit without the necessary evaluation. In addition, the SDT still did not fully evaluate or address the concern related to the uniqueness of nuclear generating unit refueling outage schedules. 2. Although Exelon Nuclear agrees with the SDT that the maximum allowed battery capacity testing intervals of not to exceed 6 calendar years for vented lead acid or NiCad batteries (not to exceed 3 calendar years for VRLA batteries) could be integrated within the plant's routine 18 month to 2 year interval refueling outage schedule, the SDT has not considered that nuclear refueling outages may be extended past the 18 month to 2 year "normal" periodicity. There are some unique factors related to nuclear generating units that the SDT has not taken into consideration in that these units are typically online continuously between refueling outages without shutting down for any other required maintenance. Historically, generating units have at times extended planned refueling outage shutdown dates days and even weeks due to requests from transmission operations, fuel issues and electrical demand. Without the grace period exclusion currently allowed by existing maintenance programs, a nuclear plant will be forced to either extend outage duration to include testing on an every other refueling outage (i.e., every four years to ensure compliance for a typical boiling water reactor) or leave the testing on a six year periodicity with the vulnerability of a forced shut down simply to perform maintenance to meet the six year periodicity or a self report of non-compliance. To ensure compliance, the nuclear industry will be forced to schedule battery testing on a four year periodicity to ensure the six year periodicity is met, thus imposing a requirement on nuclear generating units that would not apply to other types of generating units. The SDT response to this question in draft 3 is that "(t)he 18-month (and shorter) interval activities are activities that can be completed without outages - primarily inspection-related activities. An entity may need to perform maintenance more frequently than specified within the requirements to assure that they are compliant." Respectfully Exelon requests that the SDT review and evaluate the concern.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. 1. It appears that the SDT's response was mis-understood. The SDT intended that the response be understood as" in order to be compliant with all requirements, regardless of the different agencies imposing those requirements, the entity will likely have to be compliant with the most stringent of the requirements". Regarding PRC-005-2, an entity must be compliant with the included requirements, even if they are more stringent than other regulatory requirements. 2. The SDT believes that the activities addressed in the comment can be integrated with the 18-24 month plant refueling outage. This may result in the activities being performed more frequently than specified.		
Entergy (3) Entergy Services, Inc. (6)	Ballot Comment - Negative	In Section 4.2, 'Facilities' add the following subsection 4.2.6: Protection Systems for generating units in extended forced outage or in inactive reserve status are excluded from the requirements of this standard. However, the required maintenance and testing of the Protection Systems at these units must be completed prior to connecting the units to the Bulk Electric System (BES). Reason for the above comment: The above units are not connected to the BES and therefore do not affect the reliability of the BES. However, to ensure the reliability of the BES, required maintenance and testing of the Protection Systems at these units must be completed prior to connecting them to the BES.
Response: Thank you for your comments. Please refer to Compliance Application Notice CAN-0011, footnote 5, which states, "The registered entity's Protection System maintenance and testing program is only applicable for Protection System devices in service …" The SDT believes that this guidance will remain durable for PRC-005-2.		
Entergy Services		In Section 4.2, "Facilities" add the following subsection 4.2.6: Protection Systems for generating units in extended forced outage or in inactive reserve status are excluded from the requirements of this standard. However, the required maintenance and testing of the Protection Systems at these units must be completed prior to connecting the units to the Bulk Electric System (BES). Reason for the above comment: The above units are not connected to the BES and therefore do not affect the reliability of the BES. However, to ensure the reliability of the BES, required maintenance and testing of the Protection Systems at these units must be completed prior to connecting them to the BES.
Response: Thank you for your comments. Please refer to Compliance Application Notice CAN-0011, footnote 5, which states, "The registered entity's Protection System maintenance and testing program is only applicable for Protection System devices in service …" The SDT believes that this guidance will remain durable for PRC-005-2.		
MRO's NERC Standards Review Subcommittee		In the checkbox for Requirement R3 please change the wording to read, "Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the initiating on-site activity. Therefore this issue requires follow-

Organization	Yes or No	Question 5 Comment
		up corrective action.”
Response: Thank you for your comments. The definition of maintenance correctable issue has been revised to be clearer: Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Bonneville Power Administration		1. In the header of Tables 1-1, 1-2, 1-3, and 1-5 there is a note that says "Table requirements apply to all components of Protection Systems except as noted." Since each table only applies to the specific component type shown in the header, we do not understand what this note means. The definition given for component only makes the note more confusing. Please clarify the note. 2. Additionally, BPA is voting no during this round due to an issue with the Applicability Section and Section 4.2. Once this issue is clarified, BPA would be in support of a yes vote. Issue: Section 4.2 Facilities lists 5 separate items that the standard is applicable for (4.2.1. - 4.2.5). However Requirement 1 uses language that only addresses one of the items (4.2.1). There is no language contained anywhere within any of the requirements in PRC-005-2 that apply to the types of protection systems described in Applicability Sections 4.2.2 - 4.2.5. Therefore, it could be argued that this leaves it open to interpretation as to whether UFLS/UVLS/SPS are addressed by R1.In the NOPR (Â¶ 105), FERC states that “the Requirements within a standard define what an entity must do to be compliant” Further, in Order 693 (Â¶ 253) FERC explicitly states that “compliance will in all cases be measured by determining whether a party met or failed to meet the Requirement”. Given this, then from a compliance perspective, the actual applicability of the standard appears to not be as broad as intended. We ask that this issue be resolved by modifying the language in R1 in a manner that explicitly encompasses all types of protection systems to which it is intended to be applied.
Response: Thank you for your comments. 1. In Table 1-1, for example, this note means that all activities apply to all protective relay components unless specifically differentiated within individual table entries. Because Tables 1-1, 1-2, and 1-3 do not include any additional differentiation within the table, the note was removed from these tables in consideration of your comment. 2. The R1 requirement has been revised in consideration of your comments.		
JEA (3)	Ballot Comment - Negative	JEA maintains testing of lockout relays will have major reliability impact to the JEA system.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. The SDT believes that electromechanical devices share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
Tri-State G&T		1. M1 - Why is the document necessary to be "current or updated?" Eliminate "or updated." 2. R1 VSL - Second item in Severe VSL is not addressed in any lower VSL. Should there also be a comparable violation in Lower and Moderate? 3. R2 VSL - Keep the comment about the redundancy in Lower VSL and High VSL for clarifying the difference between the two.
Response: Thank you for your comments. 1. M1 has been revised as suggested and the phrase, "or updated" has been removed 2. The VSL for R1 has been revised to add phased VSLs for Moderate and High related to this item. 3. The High VSL has been modified from three years to four years.		
Ameren		1. Measure M3 on page 5 should apply to 99% of the components. "Each __shall have evidence that it has implemented the Protection System Maintenance Program for 99% of its components and initiate" PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. 2. Define BES perimeter in accordance with Project 2009-17 Interpretation. Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. The BOT adopted this 2/17/2011. 3. Battery inspection every 4 months is sufficient. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months.

Organization	Yes or No	Question 5 Comment
Response: Thank you for your comments. 1. The NERC criteria for VSLs do not currently permit them to allow some level of non-performance without being in violation. 2. The referenced interpretation relates to a quasi-definition of "transmission Protection System", and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introduce any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004 is not affected by PRC-005-2. 3. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a "grace period" if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the "PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ" for a discussion about "calendar month". Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.		
Madison Gas and Electric Co. (4)	Ballot Comment - Affirmative	MGE is voting affirmative with the following recommendation to the definition of Maintenance Correctable Issue. Maintenance Correctable Issue - Failure of a component to operate within design parameters such that it cannot be restored to functional order by repair or calibration during performance of the "initiating" on-site activity. Therefore this issue requires follow-up corrective action. The removal of the word "initial" will cause less confusion because the industry does not understand if this is initial (commissioning) or is initial used as when a component requires repair. Recommend "initiating" replace "initial".
Response: Thank you for your comments. The definition of maintenance correctable issue has been revised to be clearer: Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Arizona Public Service Company		NERC continues to be too prescriptive in the standard. For example, Table 1-4(a) requires battery verifications and inspection every three months. We have been performing similar tests every four months for over a decade, with no adverse consequences. Although FERC Order 693 directs NERC to establish maximum allowable intervals, the maximum interval must be "appropriate to the type of protection system and its impact on the reliability of the Bulk-Power System." (Order 693 at 1475)The Standard Drafting Team (SDT) has not demonstrated a mechanism that connects the maximum maintenance interval with its impact on the reliability of the Bulk-Power System. An example can be found on the bottom of page 18 and the top of page 19 of the Consideration of Comments on Protection System Maintenance [Project 2007-17] for draft 3. Although the commenting organization provided a concrete example of successful maintenance under a longer interval, the Standards Drafting Team commented that it "believes that 18-months is the proper interval for this activity." (Emphasis added) An organization cannot challenge the SDT's beliefs, only facts. The basis for each maximum maintenance interval, with appropriate linkage to its impact on the reliability of the Bulk-

Organization	Yes or No	Question 5 Comment
		Power System, needs to be published and voted upon so that factual based proposals to modify the maximum interval can be rationally challenged.
Response: Thank you for your comments. The basis for the intervals established within the standard is described throughout the Supplementary Reference document.		
Northern Indiana Public Service Co. (3)	Ballot Comment - Negative	One of our concerns is that, while the present standard is 2 pages and is the most highly violated and fined standard, the new proposed standard is 22 pages, the implementation plan is 4 pages and the Supplemental FAQ document is 87 pages.
Response: Thank you for your comments. The SDT has established maximum allowable intervals in accordance with FERC Order 693. Additionally, the SDT has addressed many of the common program-related causes of observed violations, and has provided the Supplementary Reference and FAQ to assist entities in implementing their program.		
PJM Interconnection, L.L.C. (2)	Ballot Comment - Negative	PJM has a general problem with how this current draft defines "protection system". The issue is that PJM believes the standard should only apply to Protection relays that are designed to protect the BES. It should not apply to relays that protect the asset itself.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements as written directly support this definition.		
Western Area Power Administration		Please explain or clarify the term “mitigating devices” used in Table 1-5 Control Circuitry, Page 19. This term is not well defined in the industry and not easily understood as “interrupting device” or “circuit breaker.”
Response: Thank you for your comments. This term is primarily focused on Special Protection Systems, where they may perform some activity other than “interrupt” to address their design objectives.		
Shermco Industries		1. Please provide clarification on "Communications" in regards to the following: If our customers are utilizing Schweitzer SEL311 relays and utilizing the fiber for transfer trip, is this considered a communications circuit? Our experiences in regards to testing these devices that have transfer trips out into a main substation that could affect a main ring tie or open a major 138kV loop, are that the T&D utilities will not allow us to perform these tests and trip their breakers. Therefore, what is required to satisfy testing? 2. In regards to Function / Trip testing, if we have a sudden pressure device, this is considered an auxiliary relay and the sudden pressure relay itself is not required to be tested. However, the trip path is required to be tested for DC tripping, if it directly trips the breaker feeding the BES, on the DC Control verification

Organization	Yes or No	Question 5 Comment
		testing. Please clarify if this is correct.
Response: Thank you for your comments. 1. The fiber you indicate is a relay communications circuit. The SEL311 monitors the condition of the fiber. It will provide an alarm on loss of communications. If this alarm is not monitored then the entity will be required to check it every 3 months and verify it is still operational. If the communications alarm is brought back to the control center, and the error rate or pilot signal is verified continuously, the interval will be 12 years. 2. Yes, this is correct.		
ExxonMobil Research and Engineering		1. PRC-005-2 is a highly prescriptive standard that prevents small entities from establishing a risk-based approach to protective system maintenance that is commonly used in other industry sectors and forces the small entity to utilize the time-based program. Many registered entities do not have a population size of 60 for each type of protective device. However, they do possess historical records that can be used to calculate the mean time between failures for each equipment type that adequately reflects the service conditions in which the equipment is installed. The SDT should consider allowing registered entities to utilize historical records in their supporting documentation for defining a performance based program. 2. Additionally, by restricting populations by manufacturer model, as referenced in PRC-005-2 Attachment A, the Standard Drafting Team is bordering on anti-competitive behavior as those entities that utilize performance-based programs may be discouraged to utilize alternative suppliers because utilization of a time-based maintenance program on the alternative supplier's equipment may present a cost-benefit analysis hurdle that the supplier of the equipment is not able to overcome. 3. Lastly, the SDT has chosen not to provide a tolerance band for the maximum maintenance intervals it defines in its time-base program. Given that the SDT has not provided sound technical justification (i.e. a study, industry recommended practice, etc.), the SDT should reconsider its stance on providing a tolerance band on the time intervals specified in the time-based program. What is the increase in risk owned by an entity when a protective device is tested at the 6 year and 30 day mark instead of the 6 year mark?
Response: Thank you for your comments. 1. If the historical records fully address the criteria in Attachment A, they would be useful in establishing the basis for a performance-based maintenance program. If the population is not in accordance with the definition of segment in Attachment A, the SDT does not believe that the entity has a statistically-significant sample on which to base a PBM. 2. In order to properly apply a performance-based maintenance program, the components within a segment must be such that they will exhibit similar behavior. Similarly-functioning components from different manufacturers will likely not satisfy this criterion. If an entity does not have sufficient component populations to apply performance-based maintenance, they must revert to time-based maintenance per the Tables or find another entity with whom they can aggregate		

Organization	Yes or No	Question 5 Comment
components within a performance-based maintenance program. Please see Section 9 of the Supplementary Reference Document for a discussion regarding aggregating components between entities within a performance-based maintenance program. 3. There may be minimal additional risk for missing the required interval by only a small amount. However, "grace periods" within the standard are not measurable, and would probably lead to persistently increasing intervals. However, an entity may establish an internal program with grace-period allowance, as long as the entire program (including grace periods) does not exceed the intervals within the standard. Also, this concern is only a practical one if an entity is persistently maintaining its Protection System components at the very end of each maximum allowable interval.		
Luminant		The red-lined version did not appear to agree with the clean copy. In reading the "red lined" document it appears that R3 was intended to be "Each Transmission Owner, Generation Owner, and distribution Provider shall implement and follow its PSPM and initiate resolution of any identified maintenance correctable issues."
Response: Thank you for your comments. The red-lining tools in Microsoft Word can sometimes be misleading, but the red-line is provided in an effort to illustrate the changes made to the document. We recommend that the entity use the "clean" version in order to see the final resulting text.		
MidAmerican Energy Company		Requirement R3 of the standard discusses resolution of "identified maintenance correctable issues". M3 requires evidence of "resolution of Maintenance Correctable Issues". The definition of Maintenance Correctable Issue in the standard includes "during performance of the initial on-site activity". The "initial on-site activity" seems to imply that the corrective steps that need to be tracked are those resulting from the periodic testing that is done for compliance with the standard. It is not clear if the SDT meant to require that records be kept of any required maintenance that is done as a result of a discovered problem or failure that is not identified during the periodic testing.
Response: Thank you for your comments. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised, though, to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.		
Consumers Energy (5)	Ballot Comment - Negative	While most of the changes are quite good, I believe R3 may not be what was intended. R3 concludes with "initiate resolution of any identified maintenance correctable issues." My copy of Webster's Dictonary defines initiate as "to set going : start". Thus to meet R3, I need never order a replacement component I just need to write a purchase order (it's the start of the process). If rewiring is needed, I only need to write a maintenance order, rather than sending out an electrician with tools and wire. I believe reliability would be better served to

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 5 Comment</th></tr>
<tr><td></td><td></td><td>require resolution of the problem rather than just starting a process to begin work.</td></tr>
<tr><td colspan="3">Response: Thank you for your comments. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed.</td></tr>
<tr><td>Constellation Energy Commodities Group (6)

Constellation Power Source Generation, Inc. (5)</td><td>Ballot Comment - Negative</td><td>1. R3 is vague and can be easily interpreted in a variety of ways. For example, “initiate resolution” may mean closing a work order on a correctable issue or it may mean simply to create a work order with the intent of closing it out. The difference is not just in compliance evidence but it potentially allows an auditor to interpret the requirement to state that closed work orders should be completed in a timely manner.
2. Lastly, the technical man power and compliance documentation needed to implement a performance based protection system maintenance program are so onerous that it is highly unlikely that any entity would use it.”</td></tr>
<tr><td colspan="3">Response: Thank you for your comments.
1. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer.
Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.
2. The SDT understands that the requirements to establish and operate a performance-based PSMP may be beyond what many entities will wish to pursue. However, these are provided for the use of those entities who wish to make use of the analytical resources to optimize their field maintenance.</td></tr>
<tr><td>MISO Standards Collaborators</td><td></td><td>1. R3 speaks of a Maintenance Correctable Issue and implementing your Protection System Maintenance Program (PSMP). In the definition of Maintenance Correctable Issue, it states "...of the initial on-site activity". The intent seems to be that during any maintenance activity, and something is found not working properly, you should repair it. Some may look at the word "initial" as during the commissioning of a facility.
We recommend the SDT delete the word "initial" to cause less confusion.
2. We recommend the SDT change the text of Standard PRC-005-2 - Protection System Maintenance Table</td></tr>
</table>

Organization	Yes or No	Question 5 Comment
		1-5 on page 19, Row 1, Column 3 to “Verify that each a trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.” Or alternately, “Electrically operate each interrupting device every 6 years.” Trip coils are designed to be energized no longer than the breaker opening time (3-5 cycles). They are robust devices that will successfully operate the breaker for 5,000-10,000 electrical operations. The most likely source of trip coil failure is the breaker operating mechanism binding, thereby preventing the breaker auxiliary stack from opening and keeping the trip coil energized for too long of a time period. Therefore, trip coil failure is a function of the breaker mechanism failure. Exercising the breakers and circuit switchers is an excellent practice. We would encourage language that would suggest this task be done every 2 years, not to exceed 3 years. Exercising the interrupting devices would help eliminate mechanism binding, reducing the chance that the trip coils are energized too long. The language as currently written in Table 1-5, Row 1, will also have the unintentional effect of changing an entities existing interrupting device maintenance interval (essentially driving interrupting device testing to a less than 6 year cycle). 3. We recommend the SDT change the text of Standard PRC-005-2 - Protection System Maintenance Table 1-5 on page 19, Row 3, Column 2 to “12 calendar years”. The maximum maintenance interval for “Electromechanical lockout and/or tripping devices which are directly in a trip path from the protective relay to the interrupting device trip coil” should be consistent with the “Unmonitored control circuit” interval which is 12 calendar years. 4. In order to test the lockout relays, it may be necessary to take a bus outage (due to lack of redundancy and associated stability issues with delayed clearing). Increasing the frequency of bus outages (with associated lines or transformers) will also increase the amount of time that the BES is in a less intact system configuration. Increasing the time the BES is in a less intact system configuration also increases the probability of a low frequency, high impact event occurring. Therefore, the Maximum Maintenance Interval should be 12 years for lockout relays. 5. We recognize the substantial efforts and improvements to PRC-005-2 that have been made and appreciate the dedicated work of the SDT. We appreciate the removal of Requirement R1.5 and R4 and other clarifications from draft 3. 6. Our remaining concern for PRC-005-2 is with definition and timelines established in Table 1-5. We believe that, as written, the testing of “each” trip coil and the proposed maintenance interval for lockout testing will result in the increased amount of time that the BES is in a less intact system configuration. We hope that

Organization	Yes or No	Question 5 Comment
		the SDT will consider these changes.
Response: Thank you for your comments. 1. The word, "initial" is intended to emphasize that an identified concern becomes a Maintenance Correctable Issue when the entity is not able to immediately resolve it, and must return to correct the problem. The definition of maintenance correctable issue has been revised to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 2. The SDT considers it important to verify each breaker trip coil will indeed operate within the established intervals. While breakers may be operated much more frequently at times (and allow the entity to document these operation to address this activity), other breakers may not be called on to operate for many years. 3. The SDT believes that electromechanical devices contain moving parts and share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 4. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. 5. Thank you. 6. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.		
NERC - EA & I		Recommend entities be explicitly required to document the Relay Maintenance Program in one document. Many entities presently maintain their Protection Maintenance Program in several documents, such as one for relays, one for batteries, etc. This complicates compliance review and contributes to non-compliance since personnel in different departments writing these have different levels of understanding of NERC standards. Separate documents also allow inconsistencies to slip in. Recommend Requirement 1 to changed to the following to address this problem. "Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP), RECORDED AND UPDATED AS A SINGLE DOCUMNET for its Protection Systems designed to provide protection for BES Element(s). "
Response: Thank you for your comments. The SDT believes that, because of the diversity of different entities and their business arrangements that such a requirement could serve to decrease the quality of an entity's PSMP, particularly for a vertically-integrated entity that includes several of the specified Applicable Entities. For example, the Generator Owner and Transmission Owner are likely to have significant differences for very good reasons.		
Florida Municipal Power Agency (4) (5) (6)	Ballot Comment - Negative	1. Section 4.2.1 states that the Standard is applicable to "Protections Systems designed to provide protection BES Elements." Section 15.1 of the Supplementary Reference Document defines the scope as those "devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES." These two statements are not exactly equivalent, and in fact, are in conflict

Organization	Yes or No	Question 5 Comment
Florida Municipal Power Pool (6)		with the Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State, Approved by the Board of Trustees on February 17, 2011. 2. Section 4.2.1 should be changed to "Any Protection System that is installed for the purpose of detecting faults on transmission elements (lines, buses, transformers, etc.) identified as being included in the Bulk Electric System (BES) and trips an interrupting device that interrupts current supplied directly from the BES."
Response: Thank you for your comments. 1. The referenced interpretation relates to a quasi-definition of "transmission Protection System", and in the context of the approved PRC-004-1 and PRC-005-1, presents a consistent context for this term. However, the interpretation was constrained to not introduce any requirements or applicability not already included within the approved standards. PRC-005-2 does not use this term, and expands upon the applicability in the interpretation to address what seems to the SDT to be an appropriate applicability for PRC-005-2. The applicability of the interpretation to PRC-004 is not affected by PRC-005-2. 2. Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements as written directly support this definition.		
US Army Corps of Engineers		1. Section 4.2.5.4 - please clarify generator connected station service transformer. We believe this to mean a station service transformer with no breaker between the transformer and the generator bus. 2. R3 - the term 'initiate resolution' is vague and needs to be further defined. Does this mean putting in a work order or is further action required. 3. Data Retention: The proposed standard clarifies that two of the most recent records of maintenance are to be retained to demonstrate compliance with the prescribed maintenance intervals. When equipment is replaced, the reference information indicates that the information associated with the original equipment must be retained to show compliance with the standard until the performance with the new equipment can be established. This is not explicitly stated in the requirements and warrants a comment.
Response: Thank you for your comments. 1. The commenter is correct. 2. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. The definition of maintenance correctable issue has been revised to be clearer. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the		

Organization	Yes or No	Question 5 Comment
performance of the maintenance activity. Therefore this issue requires follow-up corrective action. 3. The data retention section is stated to describe what an entity must do to demonstrate compliance to an auditor on a persistent basis. The additional clarification in the Supplemental Reference Document is provided to share the experiences of SDT members with other entities, and to suggest a possible effective practice.		
Public Utility District No. 1 of Lewis County (5)	Ballot Comment - Negative	Standard does not recognize the affects and great burdens to smaller utilities that have limited staff and great distance to travel out west. Generally, our facilities to not affect the BES. We believe that the battery testing requirements are overkill. The intervals for testing should be placed at minimum of 2 or 3 years
Response: Thank you for your comments. The activities involved in the 3-calendar-month maintenance intervals all relate to inspection-type activities of unmonitored battery systems. The SDT believes that an entity may schedule activities for a 3-calendar-month interval without a “grace period” if adequate program oversight is exercised, and disagrees that the intervals should be extended. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month”. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed. As for the other shorter-duration activities, the SDT believes that all of these activities, at the specified intervals, are necessary to assure reliability. From the experience of the SDT members, and as supported by various IEEE Standards, it seems clear that delaying the battery maintenance activities to 2-3 years would be detrimental to the reliability of the BES.		
AtCO Electric ltd		1. Table 1-2: the requirement for 12 calendar year verification for the channel and essential signals’ performance should be removed. We do not see benefit in the maintenance activities under level 2 (the 12 calendar year requirement) and suggest merging it with level 3 (the “no periodic maintenance specified” requirement). The “loss of function” alarm, will be considered as a countable event to fall under requirement R3 and dealt as maintenance correctable issue. 2. Table 1-5: the requirement of 6 calendar year verification for electrical operation of electromechanical lockout and/or tripping auxiliary devices should be revisited, considering that: ” It is not feasible to exercise a lockout relay during maintenance due to high risk to the in-service facility, as well as the complexity of lockout relay connections and protection schemes. Instead, we propose a DC ring test, which verifies the continuity of control circuitry and eliminates the risk impact of lockout or auxiliary tripping device operations.” The interval is too frequent. The requirement would become achievable if the 6 calendar year frequency were increased to 12 calendar years, to be in line with microprocessor relay maintenance frequency
Response: Thank you for your comments. 1. Though a channel with continuous alarming may not be in an alarm state during a quiescent state, the alarm function alone does not identify if the channel will fail during fault conditions. Fault noise level and, fault location impact a channels’ noise immunity margin. The activities are specified are to ensure reliable		

Organization	Yes or No	Question 5 Comment
performance of the communication channel. 2. The SDT believes that performing these maintenance activities will benefit the reliability of the BES.The SDT believes that electromechanical devices with moving parts share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals.		
CPS Energy		1. Table 1-5 The new standard requires that every 6 years it is verified that “each trip coil is able to operate the breaker,”. The supplementary reference states that this requirement can be met by tracking real-time fault-clearing operations on the circuit breakers. With transmission breakers typically having dual trip coils, how can tracking real-time operations meet this requirement? Would a breaker operations where relays in both the primary and secondary trip coils indicated operation be sufficient or would some type of trip coil monitoring that showed coil energization be needed? 2. Additionally, regarding the verification of all trip paths of the trip circuit. If a microprocessor relay is used to trip a breaker, and two contacts are paralleled on the relay through a single test switch for breaker tripping, would it be necessary to verify each contact independently or could an assertion of both contacts through the test switch be adequate? In this instance, the functionality of each contact would be fully identical. 3. Table 1-2A 3-month inspection is required for communications equipment that does not have “continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function” has to be verified that the communication equipment is “functional” with a 3-month site visit. Would a carrier on-off system, that did not perform periodic check back testing, but did have an alarm contact (loss of power, failure, etc.) that was monitored through SCADA would need to have a 3-month inspection? According to the supplemental reference, this inspection should be to verify that the equipment is “operable through a cursory inspection and site visit”. It sounds as if this cursory inspection and site visit would accomplish the same as the alarm contact. It does not appear that end-end functional testing of the blocking signal is required by what is provided in the supplemental reference. Is this correct? 4. Table 1-3 - The maintenance activity for the 12 calendar year testing should include a little more specificity. It should have something stating the values provided to the relay are accurate. I know that this discussed in the supplemental reference, but requirement in Table1-3 sounds as if any relay that measured for loss of signal, such as a loss-of-potential function, would be sufficient when the purpose to verify that the signal not only gets to the relay but also has some accuracy as needed by the application of the relay.
Response: Thank you for your comments. 1. If you are able to independently track both trip coils via real-time operations tracking, you could use this tracking to address this activity. If not, you will likely need to perform focused maintenance activities.		

Organization	Yes or No	Question 5 Comment
2. This would be adequate. 3. This is not correct. As you indicate, the 3 month check for unmonitored relay channels is to verify that the channel is functional. For a guard signal, a visual inspection will indicate if a guard or pilot signal is being received. A blocking channel can only be verified by either a checkback test or an end to end signal check. A visual check that the equipment is not failed does not indicate that the channel medium or auxiliary devices are still intact. We will revise the supplementary reference to clear this up (See Section 15.5.1, question "What is needed for the 3-month inspection of communications-assisted trip scheme equipment?"). 4. If the voltage and current signals are measured by the relay and verified to be correct, this would satisfy the required activity in the Table. Please note that, in the definition of Protection System Maintenance Program, "verify" means, "determine that the component is functioning correctly".		
NextEra Energy		Thank you for your diligent efforts in writing the draft standard. The draft standard and associated documents are well written and we believe, after approval, will be instrumental to improving the reliability of the BES. We have the following specific comments: a. The maximum maintenance interval of unmonitored Vented Lead-Acid (VLA) batteries should be changed from 3 calendar months to 12 calendar months. Today's lead-calcium and lead-selenium-low antimony batteries do not have rapid water loss as compared to the legacy lead-antimony batteries. FPL's operating experience has shown that electrolyte in today's VLA cells do not require watering within a 12-month interval. In fact, battery manufacturers now recommend watering intervals of 2 to 3 years for some new batteries. b. The maximum maintenance interval to verify that unmonitored communications systems are functional should be changed from 3 calendar months to 12 calendar months. FPL's operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). Automated testing such as PLC check-back schemes cannot test for failed PLC protective devices. We believe a 12 calendar month functional test is sufficient because of FPL's operating experience. FPL's operating experience has shown that power line carrier (PLC) failures are primarily due to PLC protective devices (MOVs, gas tubes & spark gaps). c. We believe the data retention requirements for R2 and R3 should be documentation for the two most recent maintenance activities. d. Regarding Maintenance Correctable Issue (page2) where it states: ".such that it cannot be restored to functional order during performance of the initial on-site activity". This terminology is vague: Particularly "initial on-site activity". Not sure what "functional order" means? The suggestion is to change to "..such that the deficiency cannot be restored to meet applicable acceptance criteria during the performance of the scheduled maintenance activity". e. Regarding Maintenance Correctable Issue (page 2) and R4 on Page 5, the suggestion is an entirely new "Maintenance Correctable" definition especially: "Therefore this issue requires followup corrective action".

Organization	Yes or No	Question 5 Comment
		Regarding this new definition: Why is it here? Is its purpose to ask us to do something with these issues if we discover them? Do issues identified as “Maint. Correctable” need to be tracked and reported in some manner? The referenced term “Maint. Correctable” is only used in PRC-005-2 in R4 (page 5). The suggestion is to provide clarification. Is this maintenance correctable terminology implying that NERC PRC005-2 is opening up a new requirement for tracking and reporting resolution of “Maint Correctable” issues? The suggestion is to change to: This issue includes any activity requiring further follow-up corrective action to restore operability outside of the applicable maint activity f. Regarding Countable Event (Page 3), the suggestion is an entirely new “Countable Event” definition. Why is this new term and definition “countable event” included in PRC-005-2 ? Note: In the PRC005-2 text “countable event” is actually only referred to in PRC-005-2 in Attachment A under “Performance Based Programs” (not referred to in time based programs section). The recommendation is that the PRC-005-2 version explicitly clarify the definition of â ”countable event” to clearly indicate that this term is applicable ONLY to “Performance Based Programs”. g. Regarding Countable Event (page 3), where the text says “Any failure of a component which requires repair or replacement, any condition discovered during the verification activities in Tables 1-1/1-5 which requires corrective action..”, in the definition for “countable event” what does “corrective action” mean? PRC005-2 is unclear. Does the term “countable event” have any ties to”Maint Correctable” issues. The suggestion is to Consider changing wording from “corrective action” to “which requires > 7 days to correct” and clarify whether or not “countable event” has any correlation to “Maint Correctable” events as discussed on page 2 and in R4? If so please provide language clarifying this correlation.

Response: Thank you for your comments.

a. This activity is primarily inspection-related, and addresses an inspection of electrolyte levels, dc grounds, and station dc supply voltages. Good practice is that entities will conduct a visual inspection of the overall battery condition during these activities, although the Standard does not require it. Also, please note that, while some batteries may reliably go longer between “watering”, this activity is to detect gross failures, rather than specifically to address “watering”. Please see Section 15.4 of the Supplementary Reference Document for further discussion.

b. A relay communications channel and equipment provide logic for a pilot protective relay system to operate correctly to clear faults instantaneously. Channel failure would cause the protective system to not operate or to operate incorrectly. An unmonitored channel failure will decrease reliability of that protective system until its failure is discovered. One year is too long to risk BES protective systems out of service. The three month interval is devised to maintain BES system reliability. If an entity’s experience suggests that longer intervals are appropriate, they may employ performance-based maintenance per R2 and Attachment A. The definition of maintenance correctable issue has been revised to be clearer.

c. From SDT members’ experiences, it is clear that auditors will generally wish to monitor compliance all the way back to the previous audit. Please see

Organization	Yes or No	Question 5 Comment
Compliance Application Notice CAN-008 for a discussion about pre-2007 data. d. The definition has been modified in consideration of your comment. Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action. e. Yes – the entity is expected to do something in response to an identified Maintenance Correctable Issue, but it is left to the entity to determine the best method for them to track the initiation of resolution of Maintenance Correctable issues. The definition of maintenance correctable issue has been revised to be clearer.. Please refer to M3 for some sample types of evidence. f. Countable events are used only within Attachment A. g. "Countable Event" applies only to performance-based maintenance, and is used solely to determine and evaluate the PBM maintenance intervals. A countable event may (or may not) be a maintenance correctable issue, depending on whether the deficiency is corrected while performing the maintenance activity or requires additional follow-up.		
U.S. Bureau of Reclamation (5)	Ballot Comment - Affirmative	The application of the PSMP should be explicitly defined in the standard. Currently the PSMP is required to protect rather than a PSMP to identify the components defined by the standard. The language should be altered to ensure the PSMP is developed for the component types specified in the standard. The following language should be considered: "Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2".
Response: Thank you for your comments. R1 has been modified as you suggest.		
NIPSCO		1. The present PRC-005 standard is 2 pages while the proposed PRC-005-2 is 22 pages, with an implementation plan of 4 pages and a supplemental document of 87 pages. The review process appears to be somewhat daunting especially considering that NERC is trying to simply things with such concepts as the "traffic ticket" approach. 2. In R3 we're not sure if there is a time requirement regarding the completion of the resolution process. We like the use of "calendar year" in requirements which should provide flexibility in getting the work completed. 3. Another comment for our response concerns Table 1-2, Communications Systems (page 11):The first maintenance interval is 3 calendar months. Does this mean the same as 1 calendar quarter?1. Example for 3 calendar months: Maintenance performed on 1/4/11. Next maint due by 4/30/11. Maintenance performed on 4/12/11. Next maint due by 7/31/11. Maintenance performed on 7/30/11. Next maint due by

Organization	Yes or No	Question 5 Comment
		10/31/11. This would yield 3 inspections for 2011. Maintenance performed on 10/12/11. Next maint due by 1/31/12.2. Example for 1 calendar quarter: Maintenance performed on 1/4/11. Next maint due by 6/30/11. This would yield 4 inspections for 2011 (1 per quarter).
Response: Thank you for your comments. 1. The SDT has established maximum allowable intervals in accordance with FERC Order 693. Additionally, the SDT has addressed many of the common program-related causes of observed violations, and has provided the Supplementary Reference and FAQ to assist entities in implementing their program. The “traffic ticket” approach is focused on how the compliance monitor will assess violations, and has no bearing on the Standard itself. 2. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as “complete” during the scheduled interval for these more extended activities to “correct”; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. 3. The intervals, “3 calendar months” and “once per calendar quarter” are not synonymous. “Once per calendar quarter” would effectively permit entities to have six months (less two days) between successive activities, while a “3 calendar month” interval limits an entity to four months (less two days) between activities. See Section 7.1 of the “PRC-005-2 Protection System Maintenance Supplementary Reference & FAQ” for a discussion about “calendar month” Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.		
Tenaska, Inc. (5)	Ballot Comment - Negative	1. The biggest concern we have with the proposed standard is the inclusion of 4.2.5.4. As written it is not clear, but more importantly it is overly broad and provides little, if any, increase to reliability. It needs to be deleted. 2. In Section 4.2, five types of protection systems are identified as being applicable, but the language of Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). We believe the intent is to have a PSMP for all Protection Systems identified in Section 4.2 and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection

Organization	Yes or No	Question 5 Comment
		System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2.
Response: Thank you for your comments. 1. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. 2. R1 of the standard has been modified as you suggest.		
Seattle City Light (1) (3) (4)	Ballot Comment - Negative	Seattle City Light (SCL) commends the Standard Drafting Team (SDT) for the many improvements in the latest draft of proposed standard PRC-005-2. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. Each draft has been better than that preceding, and the supporting material is very helpful in understanding the impact and implementation of the proposed Standard. However, SCL votes NO for this draft because of 1) the inclusion and treatment of electromechanical lockout relays within the scope of draft Standard and 2) 2) confusion about language between section 4.2 and Requirement 1. 1. Regarding electromechanical lockout relays, SCL is highly concerned about the reliability risks and logistical difficulties associated with meeting the requirements proposed for these relays. Lockout relays operate rarely and are known for reliable service. For many such relays, the proposed maintenance would require clearance of entire bus sections or even multiple bus sections (such as for a bus differential lockout relay). In SCL's opinion, the reliability risks posed by such switching and outages to the Bulk Electric System outweigh the reliability benefits of including lockout relays in the scope of PRC-005-2. If the SDT deems it necessary to include electromechanical lockout relays within PRC-005-2, SCL recommends that a difference be made between the maintenance activities specified for monitored and unmonitored types. The draft Standard describes the requirements for "electromechanical lockout and/or tripping auxiliary devices" in Table 1-5 (p.19) and assigns a 6-year maximum maintenance interval, the same as for other unmonitored relays. Modern electromechanical lockout relays may be specified with a built-in self-monitoring trip-coil alarm. SCL believes the maintenance requirements for electromechanical lockout relays with such an alarm should be similar to those for other alarmed or monitored relays. As such we recommend that a new entry be added to Table 1-5 for monitored electromechanical lockout relays, as follows:

Organization	Yes or No	Question 5 Comment
		• Component Attributes: Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil AND include built-in self-monitoring trip-coil alarm • Maximum Maintenance Interval: 12 calendar years • Maintenance Activities: Verify electrical operation of electromechanical trip and auxiliary devices. Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated. 2. We also would like to comment regarding confusion over language in section 4.2.This section identifies five types of Facilities that the standard is applicable to, whereas Requirement 1 indicates that applicable entities need to establish a Protection System Maintenance Program (PSMP) for the Protection Systems designed to provide protection for BES Element(s) (Part 4.2.1 of Section 4.2). As such, it is not clear if PRC-005-2 applies to five Facilities or to certain Protection Systems. SCL believes the intent is to have a PSMP for all Protection Systems identified in "Part A, Section 4.2 - Facilities" and that the language of Requirement 1 may cause confusion or be misleading. We suggest changing the language of Requirement 1 from: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems designed to provide protection for BES Element(s). to: • Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Facilities identified in Part A, Section 4.2.
Response: Thank you for your comments. 1. The SDT believes that performing these maintenance activities will benefit the reliability of the BES. The SDT believes that electromechanical devices having moving parts share performance attributes (and failure modes) with electromechanical relays and need to be tested at similar intervals. Performance-Based maintenance is an option to increase the intervals if the performance of these devices supports those intervals. 2. R1 has been modified as you suggest.		
Seattle City Light (5) (6)	Ballot Comment - Negative	Seattle City Light (SCL) commends the Standard Drafting Team (SDT) for the many improvements in the latest draft of proposed standard PRC-005-2. The proposed PRC-005-2 standard is an improvement over the four standards that it will replace. Response: Thank you for your comments. The Standard has been modified as you suggest.		
Ingleside Cogeneration LP		The removal of R1.5 and R7 which required Protection System owners to identify and verify calibration tolerances or equivalent parameters upon conclusion of a maintenance activity was fundamental to Ingleside Cogeneration's yes vote. The amount of ambiguity introduced by the requirements and associated documentation did not serve to improve BES reliability in our view.
Response: Thank you for your comments.		
Transmission Access Policy		The scope of the equipment to which the draft standard applies is over-broad.

Organization	Yes or No	Question 5 Comment
Study Group		Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliability, for the following reasons. In contrast to transmission and generation protection systems and SPSs, for which there are typically two protection systems per facility and therefore per fault, UFLS and UVLS deal with widespread events. For any under-voltage or under-frequency event, there are literally hundreds of UFLS/UVLS relays to respond. It is therefore far less critical if one UFLS or UVLS relay fails to operate properly. Furthermore, transmission is typically not radial (in fact, radials to load are excluded from the BES). But distribution circuits, where UFLS and UVLS systems are located, are usually radial. Testing some of the non-relay equipment to which the draft standard applies would require blacking out the customers served by that radial. In other words, the draft standard would require entities to definitely cause blackouts in an attempt to prevent very unlikely potential blackouts. This is plainly not justified from a harm/benefit perspective. Finally, many of the types of non-relay equipment to which the standard would apply are in effect tested by faults. Specifically, faults happen on distribution circuits (where UFLS and UVLS systems are located) more frequently than on transmission circuits, due to such things as animal contacts and car accidents. Any such fault is in fact a test of the all the equipment that is involved in clearing the fault. There is no need to require separate tests of that equipment, any more than we would require tests of a phone line that is used on an everyday basis; you already know that the phone works.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Illinois Municipal Electric Agency		The scope of the equipment to which the draft standard applies is still overly broad. Specifically, PRC-005-2 should not apply to non-relay equipment for UFLS and UVLS systems. Subjecting UFLS and UVLS batteries, instrument transformers, DC control circuitry, and communications to the requirements of PRC-005-2 would drastically increase the scope of equipment covered by the standard, with no corresponding benefit to reliability of the BES. This comment/recommendation is provided to address the resource and customer service interests of a TO and/or DP systems serving distribution load. Illinois Municipal Electric Agency supports comments submitted by the Transmission Access Policy Study Group.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure define "Reliability standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
ISO/RTO Standards Review		The SRC disagrees with the change to the term under 4.2.1. "Protection Systems designed to provide protection for BES elements." We support keeping the previous version's wording of 4.2.1. "Protection

Organization	Yes or No	Question 5 Comment
Committee		Systems applied on, or designed to provide protection for the BES." The revised wording expands the fundamental purpose of the NERC PRC-005 standard from being focused on ensuring relays intended to protect the reliability of the BES are maintained to a standard whose intent is to ensure all BES facilities have relay maintenance programs. Although we do not disagree with maintaining all relays, regardless of what their intended purposes are, it should not be the purpose of a NERC standard to police all protection schemes beyond those needed for interconnected reliability. There are numerous protective relays employed on facilities interconnected to the BES but their purpose may be for operating preference or service/equipment quality purposes such as reclosing schemes and transformer sudden pressure relays. We believe the NERC PRC-005 standard should be focused on maintenance of those protective relays which are needed to ensure that the loss of a single element does not cause cascading effects on the bulk power system.
Response: Thank you for your comments. Clause 4.2.1 has been modified to improve consistency with the Interpretation that has become part of PRC-005-1a.		
Duke Energy		The Standard Drafting Team has done an outstanding job on this standard. We are voting "Affirmative" but note that implementation questions remain, particularly with regards to classifying component attributes as "monitored," "unmonitored," "internal self diagnosis," "alarming," "alarming for excessive error" and "alarming for excessive performance degradation". The sheer size of the population of protective relays, communications systems, voltage and current sensing devices, batteries, and dc supply components means that the size of the effort required to categorize each individual component could drive us to test and maintain on the more frequent unmonitored time intervals, simply because of the difficulty in assembling "monitored" compliance documentation.
Response: Thank you for your comments. The opportunity to use "monitoring" to extend the intervals and reduce the activities, as well as the opportunity to use performance-based maintenance, is provided for those entities who wish to apply the administrative resources in order to minimize the field maintenance. If entities choose not to use those opportunities, the SDT believes that the un-monitored intervals and activities will establish an effective PSMP.		
Pepco Holdings Inc		There were numerous comments submitted for each of the previous drafts indicating that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: "The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays." Statistics on the causes of BES protective system misoperations, however, do not support this assertion. The PJM Relay Subcommittee has been tracking 230kV and above protective system misoperations on the PJM system for many years. For the six year period from 2002 to 2007, the number of protective system misoperations due to communication system problems was lower (and in many cases significantly lower) than those caused by defective relays, in every year but one. Similarly, RFC has conducted an analysis of BES protection system misoperations for 2008

Organization	Yes or No	Question 5 Comment
		and 2009, and found the number of misoperations caused by communication system problems to be in line with the number attributed to relay related problems. If unmonitored protective relays have a 6 year maximum maintenance/inspection interval, it does not seem reasonable to require the associated communication system to be inspected 24 times more frequently, particularly when relay failures are statistically more likely to cause protective system misoperations. As such, a 12 or 18 calendar month interval for inspection of unmonitored communication systems would seem to be more appropriate. FAQ II 6 B states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks. The SDT responded that they still felt the 3 month interval as stated in the standard was appropriate. PHI respectfully requests that the SDT reconsider this issue and also cite what "specific statistical data" they used to validate that unmonitored communication systems are 24 times more prone to failure than unmonitored protective relays.
Response: Thank you for your comments. The SDT believes that relay communications channels are more susceptible to failure from an outside influence than a protective relay. Leased circuits from communications providers and carrier channels are highly exposed to lightning, automobiles, backhoes, etc. We believe the existing statistics from PJM and RFC on relay communications system based misoperation causes is due to the present practice of periodic channel verifications being performed. Many utilities presently use channel monitoring and carrier checkbacks to ensure reliable operation.		
Liberty Electric Power LLC (5)	Ballot Comment - Negative	While the SDT has done a very good job at responding to the most objectionable parts of the previous version, there are still a number of issues which makes the standard problematic. 1. The standard introduces the term "initiate resolution". This is an interpretable term, and has the potential for an auditor and an entity to disagree on an action. Would issuing a work order be considered "initiating resolution"? What if the WO had a completion date many years into the future? I would suggest adding the term to the list of definitions which will remain with the standard, and defining it as "performing any task associated with conducting maintenance activities, including but not limited to issuing purchase orders, soliciting bids, scheduling tasks, issuing work requests, and performing studies". 2. Some clarity is needed to differentiate system connected and generator connected station service transformers. A statement that a station service transformer connected radially to the generator bus is considered a system connected transformer if the transformer cannot be used for service unless connected to the BES. 3. The "bookends" issue, brought up in the prior round of comments, still exists. Although the SDT rightly notes a CAN has been issued regarding bookends, the CAN covers the documentation for system

Organization	Yes or No	Question 5 Comment
		components that entities were required to self-certify to on June 18, 2007. PRC-005-2 adds additional components to the protection system scheme which were not part of that certification, and has the potential to put entities into violation space due to a lack of records for those components. 4. The SDT should add to M3 a statement that entities may demonstrate compliance with the standard by demonstrating that required activities took place twice within the maximum maintenance interval -starting from the effective date of the standard - for all components not listed in PRC-005-1.
Response: Thank you for your comments. 1. The SDT believes that issuing a work order would satisfy this requirement. M3 presents several examples of relevant evidence. The SDT has considered that, while some maintenance correctable issues may be completed very quickly, others may take an extended period (perhaps even several years) to complete effectively, during which time the degraded system must be reported and reflected within the operation of the BES in accordance with other standards. The SDT is concerned that the entity will not be able to record the maintenance activity as "complete" during the scheduled interval for these more extended activities to "correct the maintenance correctable issue"; therefore, the SDT has opted to require only that the entity initiate correction of maintenance correctable issues and rely on the operating focus on the degraded system to ensure that they are completed. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft. 3. The Implementation Plan specifies that entities may implement PRC-005-2 incrementally throughout the intervals specified, and that they shall follow their existing program for components not yet implemented. The SDT believes that the "bookends" issue to which you refer is therefore addressed. 4. The Standard requires that activities only take place once within the established interval.		
SPP reliability standard development Team		Would like more clarification in table 1-5 to address verification tests on different circuits. Is this an end to end test or partial test can you test one part of the circuit one way and another a different way? Should table 1-5 read Complete a terminal test of unmonitored circuitry?
Response: Thank you for your comments. The SDT does not believe that the suggested text adds clarity to the standard. Please see Section 15.3 of the Supplementary Reference Document for additional discussion.		
Lakeland Electric (1)	Ballot Comment - Negative	The new PRC-005-2 includes non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. While Lakeland Electric agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities).

Organization	Yes or No	Question 5 Comment
		However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
City of Bartow, Florida (3)	Ballot Comment - Negative	There is an unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. Currently, PRC-005-1 includes batteries, instrument transformers, DC control circuitry and communications in addition to the relays for BES protection systems. PRC-008 (UFLS) and PRC-011 (UVLS) are ambiguous as to whether non-relay components are included in those standards. The new PRC-005-2 includes these non-relay components into UFLS and UVLS. The problem is, for UFLS and UVLS, these non-relay components are mostly distribution class equipment; hence, the result of this version 2 standard will be inclusion of most distribution class protection system components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. We agree wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested.
Response: Thank you for your comments. Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
Lakeland Electric (6)	Ballot Comment -	Unnecessary expansion of the scope of equipment covered by this standard into the distribution system related to UVLS and UFLS. 		components into PRC-005-2. This is a huge expansion of the scope of equipment covered by the standard with negligible benefit to BES reliability. FMPA agrees wholeheartedly with the inclusion of non-relay components for BES Protection Systems. It is critical that BES Protection Systems work and clear the fault (e.g., on > 100 kV Facilities). However, UFLS and UVLS are quite different. For an event requiring UFLS and UVLS operation, there are many, e.g., hundreds and possibly thousands of relays, that operate to shed load automatically and if a small percentage of those do not operate as expected, the impact is minimal. So, it is not important for BES reliability to include non-relay components of UFLS and UVLS in the PRC-005-2 standard. In addition, testing of protection systems on distribution circuits is difficult for distribution circuits that are radial in nature. For instance, testing trip coils of a distribution breakers will likely results in service interruption to customers on that distribution circuit in order to test the breaker or to perform break-before-make switching on the distribution system often required to manage maximum available fault current on the distribution system for worker safety, etc.. Hence, the standard would be sacrificing customer service quality for an infinitesimal increase in BES reliability. In addition, non-relay protection components operate much more frequently on distribution circuits than on transmission Facilities due to more frequent failures due to trees, animals, lightning, traffic accidents, etc., and have much less of a need for testing since they are operationally tested. 2. As another comment, station service transformers are not BES Elements and should not be part of the Applicability - they are radial serving only load.
Response: Thank you for your comments. 1. Section 202 of the NERC Rules of Procedure defines “Reliability Standard” as “a requirement to provide for reliable operation of the bulk power system …” The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition. 2. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1. System connected station service transformers were removed from the Applicability in a previous draft.		
Alliant Energy		1. If PRC-005-2 is going to incorporate PRC-008 (UFLS) and PRC-011 (UVLS) the Purpose needs to be revised to include Distribution Protection Systems designed to protect the BES. 2. We do not believe a distribution relaying system, designed to protect the distribution assets, that may open a transmission element (ie; breaker failure) should be considered part of the BES Protection System. R1 should add the following sentence “Distribution Protection Systems intended solely for the protection of distribution assets are not included as a BES Protection System, even if they may open a BES Element.” 3. Table 1-5 (Component Type - Control Circuitry) Item 4 “Unmonitored control circuitry associated with protective functions” require a 12 calendar year maximum maintenance interval. We believe UFLS and

Organization	Yes or No	Question 5 Comment
		UVLS control circuitry should be exempted from this requirement. It would take multiple failures to have any impact, and the impact on the BES would be minimal.
Response: Thank you for your comments. 1. There is no distinction in the purpose between “Distribution Protection Systems” and “Transmission Protection Systems”. The SDT believes that the Applicability appropriately describes both the entities and the facilities. 2. The SDT modified Applicability 4.2.1 for better consistency with the interpretation that is reflected in PRC-005-1a, and believes that this change may address your concern. 3. The Table 1-5 activities for UFLS/UVLS are constrained to those activities that the SDT considers to be appropriate relative to the reliability impact of these applications. Please see Section 15.3 of the Supplemental Reference Document for additional discussion on this topic.		
Y-W Electric Association, Inc. (4)	Ballot Comment - Affirmative	Y-WEA thanks the SDT for its long, hard work on this standard and for its consideration of previous comments.
Response: Thank you for your comments.		
BGE		No comments.
PNGC Power		Thank you for the opportunity to comment on the draft Standard PRC-005-2 – Protection System Maintenance. We appreciate the work that NERC has put into a new standard to encapsulate and replace the current PRC-005, PRC-008, PRC-011 and PRC-017. But, we believe that the draft Standard needs one important revision before the NERC Board of Trustees should approve it. Specifically, NERC should revise the draft version of PRC-005-2 so that the beginning of Section 4.2 reads as follows: *“4.2. Facilities:* *Protection Systems that (1) are not facilities used in the local distribution of electricity, (2) are facilities and control systems necessary for operating an interconnected electric energy transmission network, and (3) are any of the following:”* This revision is necessary to capture the limits that Congress placed on FERC, NERC, and the Regional Entities in developing and enforcing mandatory reliability standards. Specifically, Section 215(i) of the Federal Power Act provides that the Electric Reliability Organization (ERO) “shall have authority to develop and enforce compliance

Organization	Yes or No	Question 5 Comment
		with reliability standards *for only* the Bulk-Power System." And, Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems *necessary* for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. *The term does not include facilities used in the local distribution of electric energy*." With this language, Congress expressly limited FERC, NERC, and the Regional Entities' jurisdiction with regard to local distribution facilities as well as those facilities not necessary for operating a transmission network. Given that these facilities are statutorily excluded from the definition of the BPS, reliability standards may not be developed or enforced for facilities used in local distribution. In Order No. 672, FERC adopted the statutory definition of the BPS. In Order No. 743-A, issued earlier this year, the Commission acknowledged that "Congress has specifically exempted 'facilities used in the local distribution of electric energy'" from the BPS definition. FERC also held that to the extent *any* facility is a facility used in the local distribution of electric energy, it is exempted from the requirements of Section 215. In Order No. 743-A, FERC delegated to NERC the task of proposing for FERC approval criteria and a process to identify the facilities used in local distribution that will be excluded from NERC and FERC regulation. The critical first step in this process is for NERC to propose criteria for approval by FERC to determine which facilities are used in local distribution, and are therefore <u>not</u> BPS facilities. The criteria to be developed by NERC must exclude any facilities that are used in the local distribution of electric energy, because all such facilities are beyond the scope of the statutory definition of the BPS, which establishes the limit of FERC and NERC jurisdiction. Accordingly, it is critical that NERC draft the new PRC-005-2 standard to expressly exclude facilities used in local distribution. NERC must also expressly exclude from PRC-005-2 those facilities "not necessary for operating an interconnected electric energy transmission network (or any portion thereof)". Similar to the local distribution exclusion, the facilities not necessary for operating a transmission network are not part of the BPS and therefore must be expressly excluded from the standard. We understand, but disagree with, the argument that, because the FPA clearly excludes local distribution facilities and facilities necessary for operating an interconnected electric transmission network from FERC, NERC, and Regional Entity jurisdiction, it is not necessary to expressly exclude these facilities again in reliability standards. This approach might be legally accurate, but could lead to significant confusion for entities attempting to implement the new PRC-005-2 standard. There are numerous examples of Regional Entities, particularly WECC, attempting to assert jurisdiction over such facilities, and regulated entities face significant uncertainty as to which facilities they should consider as within jurisdiction. Clarifying FERC, NERC, and Regional Entity

Organization	Yes or No	Question 5 Comment
		jurisdiction in the BES definition, even if such clarification is already provided in the FPA, would avoid such problems under the new PRC-005-2 standard. Again, we appreciate the work NERC has put in so far on a new Standard. We look forward to working within the drafting process to help implement our recommended revision.
Response: Thank you for your comments. The SDT has revised R1 to refer to Applicability 4.2. The SDT believes that your comments are otherwise already reflected in the Standard, and that no further changes are necessary. The Standard currently addresses maintenance of all Protection Systems that are applied on or to protect BES elements, as well as maintenance of UFLS installed for the BES per PRC-007, UVLS installed on or for the BES per PRC-010, and Special Protection Systems installed on or for the BES per PRC-012, PRC-013, PRC-014, and PRC-015. Therefore, the Standard is already constrained as you suggest. Additionally, Section 202 of the NERC Rules of Procedure defines "Reliability Standard" as "a requirement to provide for reliable operation of the bulk power system …" The requirements regarding maintenance of Protection Systems for UFLS and UVLS directly support this definition.		
ReliabilityFirst	Ballot Comment - Affirmative	ReliabilityFirst votes affirmative but offers the following suggestions/comments: 1. R3 should be split into two separate requirements since there are two distinct actions being requested (e.g. "…shall implement and follow its PSMP" is one requirement and "… shall initiate resolution of any identified maintenance correctable issues" is the second requirement. 2. There are a number of terms which are defined only for the use of the PRC-005-2 standard which will not be moved to the Glossary of Terms., and even though I completely agree with this concept, I believe this concept is not mentioned nor is it allowed per the NERC Standard Processes Manual.
Response: Thank you for your comments. 1. The SDT believes that the two activities are intertwined and should remain within a single requirement. 2. The SDT has been advised by NERC Standards staff that this is acceptable, and has adopted the methodology for doing so as suggested by staff.		

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010
6. Third posting of revised standard on November 17, 2010
7. Fourth posting of revised standard on April 13, 2011

Description of Current Draft:
This is the fifth draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and ballot.	July 5 – August 4, 2011
2. Conduct successive ballot	July 26 – August 4, 2011
3. Drafting Team Responds to Comments	August 4 – September 6, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owners

   4.1.2 Generator Owners

   4.1.3 Distribution Providers

   4.2. Facilities:

   4.2.1 Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

   4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

5. **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

The PSMP shall:

1.1. Address all Protection System **component types.**

1.2. Identify which maintenance method (time-based,

> ***Component Type -*** *Any one of the five specific elements of the Protection System definition.*

performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5 and Table 2.

1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5 and Table 2.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Maintenance Correctable Issue - *Failure of a component to operate within design parameters* such that the deficiency cannot be corrected during the performance of the maintenance activity. *Therefore this issue requires follow-up corrective action.*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified **maintenance correctable issues**. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence that its current performance-based maintenance program is in accordance with Requirement R2, which may include but is not limited to equipment lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified Maintenance Correctable Issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For Requirement R2 and Requirement R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System **components**, or all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date, whichever is longer.

Component – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one component type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address one component type included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to specify whether two component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address two component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to include station batteries in a time-based program (Part 1.2) OR The responsible entity failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5 and Table 2. (Part 1.3 and 1.4)	The responsible entity has not established a PSMP. OR The responsible entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to reduce countable events to less than 4% within three years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but has failed to reduce countable events to less than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to establish the entire technical justification described within R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce countable events to less than 4% within five years OR 3) Failed to annually document program activities, results, maintenance dates, or countable

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				events for over 5% of components in any individual segment OR 4) Maintained a segment with less than 60 components OR 5) Failed to: • Annually update the list of components, OR • Perform maintenance on the greater of 5% of the segment population or 3 components, OR • Annually analyze the program activities and results for each segment.
R3	The responsible entity has failed to implement and follow scheduled program on 5% or less of total Protection System components. OR The responsible entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues.	The responsible entity has failed to implement and follow scheduled program on greater than 5%, but no more than 10% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of identified maintenance correctable issues.	The responsible entity has failed to implement and follow scheduled program on greater than 10%, but no more than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of identified.	The responsible entity has failed to implement and follow scheduled program on greater than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 15% of identified maintenance correctable issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — February 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay		
Component Attributes	**Maximum Maintenance Interval**[1]	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed.
For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2
Component Type - Communications Systems

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	3 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.

Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) **Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries**		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS, UVLS and SPS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Device		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply for tripping only non-BES interrupting devices as part of a UFLS, UVLS or SPS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify: • Station dc supply voltage

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2)		No periodic verification of float voltage of battery charger is required
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with internal ohmic value monitoring, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2)		.No periodic measurement and evaluation relative to baseline of battery cell/unit internal ohmic values is required to verify the station battery can perform as designed .
Any Valve Regulated Lead-Acid (VRLA) station battery with monitoring and alarming of each cell/unit internal Ohmic value. (See Table 2)		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions **Note:** Table requirements apply to all Control Circuitry components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored control circuitry associated with protective functions.	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of DETECTION to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	No periodic maintenance specified.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

4. Using the prior year’s data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.
5. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010
6. Third posting of revised standard on November 17, 2010
7. Fourth posting of revised standard on April 13, 2011

Description of Current Draft:
This is the f~~our~~ifth draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 30-day comment and ballot.	~~1 April 12~~July 5 – August 4, 2011
2. Conduct successive ballot	~~May 2 – May 12~~July 26 – August 4, 2011
3. Drafting Team Responds to Comments	~~May 16 – June 3~~August 4 – September 6, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- ~~Restore — Return malfunctioning components to proper operation.~~

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Maintenance Correctable Issue – Failure of a component to operate within design parameters such that ~~it~~the deficiency cannot be ~~restored to functional order by repair or calibration~~corrected during the performance of the ~~initial on-site~~maintenance activity. Therefore this issue requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – A component which has failed and requires repair or replacement, any condition discovered during the ~~verification~~maintenance activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To ~~ensure all transmission~~document and ~~generation~~implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) ~~are maintained~~so that these Protection Systems are kept in working order.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owners

   4.1.2 Generator Owners

   4.1.3 Distribution Providers

   4.2. Facilities:

   4.2.1 Protection Systems ~~designed to provide protection~~that are installed for the purpose of detecting faults on BES ~~Element(s).~~Elements (lines, buses, transformers, etc.)

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

   4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

5. ~~**(Proposed)**~~ **Effective Date:** See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems ~~designed to provide protection for BES Element(s). The PSMP shall: [~~identified in Section 4.2. *Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

The PSMP shall:

1.1. Address all Protection System **component types.**

1.2. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5 and Table 2.

1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5 and Table 2.

Maintenance Correctable Issue - Failure of a component to operate within design parameters such that the deficiency cannot be corrected during the performance of the maintenance activity. *Therefore this issue requires follow-up corrective action.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified **maintenance correctable issues**. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current ~~or updated~~ documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence that its current performance-based maintenance program is in accordance with Requirement R2, which may include but is not limited to equipment lists, dated maintenance records, and dated analysis records and results ~~that its current performance-based maintenance program is in accordance with Requirement R2~~.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have ~~evidence which may include but not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders as~~ evidence that it has implemented the Protection System Maintenance Program and initiated resolution of identified Maintenance Correctable Issues in

Component Type - Any one of the five specific elements of the Protection System definition.

accordance with Requirement R3~~.~~, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

Component – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

For Requirement R2 and Requirement R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System **components**, or all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one component type is being addressed by time-based or performance-based maintenance~~.~~, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address one component type included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to specify whether two component types are being addressed by time-based or performance-based maintenance~~.~~, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address two component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to include station batteries in a time-based program (Part 1.2) OR The responsible entity failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5 and Table 2. (Part 1.3 and 1.4)	The responsible entity has not established a PSMP. OR The responsible entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance~~.~~, or a combination of both. (Part 1.2).
R2	~~Entity has Protection System elements in a~~The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to reduce countable events to less than 4% within three years OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment ~~OR~~ ~~3) Maintained a segment with 54-59~~	NA	~~Entity has Protection System elements in a~~The responsible entity uses performance-based maintenance intervals in its PSMP but has failed to reduce countable events to less than 4% within four years.	~~Entity has Protection System components in a~~The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to establish the entire technical justification described within ~~R3 and Attachment A~~R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce countable events to less than 4% within five years OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
	~~components or containing different manufacturers.~~			3) Failed to annually document program activities, results, maintenance dates, or countable events for over 5% of components in any individual segment OR 4) Maintained a segment with less than ~~54~~60 components OR 5) Failed to: • Annually update the list of components, OR • Perform maintenance on the greater of 5% of the segment population or 3 components, OR • Annually analyze the program activities and results for each segment.
R3	The responsible entity has failed to ~~complete~~implement and follow scheduled program on 5% or less of total Protection System components. OR The responsible entity has failed to initiate resolution on 5% or less of identified maintenance correctable issues.	The responsible entity has failed to ~~complete~~implement and follow scheduled program on greater than 5%, but no more than 10% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of identified maintenance correctable issues.	The responsible entity has failed to ~~complete~~implement and follow scheduled program on greater than 10%, but no more than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of identified.	The responsible entity has failed to ~~complete~~implement and follow scheduled program on greater than 15% of total Protection System components OR The responsible entity has failed to initiate resolution on greater than 15% of identified maintenance correctable issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — February 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay ~~Note: Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.~~		
Component Attributes	**Maximum Maintenance Interval**[1]	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming~~.~~ (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics ~~(see Table 2)~~. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2
Component Type - Communications Systems
~~**Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.~~

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	3 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.

Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3

Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays

~~**Note:** Table requirements apply to all components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.~~

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value as measured by the microprocessor relay to an independent ac measurement source, with alarming for unacceptable error or failure~~.~~ (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type ~~-~~– Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply ~~with~~using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type ~~–~~– Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) Component Type ~~-~~– Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for distribution breakers for UFLS or UVLS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d)		
Component Type ~~-~~– Protection System Station dc Supply Using Non Battery Based Energy Storage		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for distribution breakers for UFLS ~~or~~, UVLS and SPS are excluded (see Table 1-4(e)).	3 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type ~~-~~ – Protection System Station dc Supply for ~~Distribution Breakers~~non-BES Interrupting Device		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply for tripping only ~~distribution breakers~~non-BES interrupting devices as part of a UFLS ~~or~~, UVLS ~~system,~~ or SPS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify: • Station dc supply voltage

Table 1-4(f)

Exclusions for Protection System Station dc Supply Monitoring Devices and Systems

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)		No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply~~.~~ (See Table 2)		No periodic verification of float voltage of battery charger is required
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)	No periodic maintenance specified	No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with internal ohmic value monitoring, and ~~alarming of internal Ohmic~~evaluating present values ~~of every cell (if available for measurement) or each unit and alarming when any cell/unit deviates by an unacceptable value from the~~relative to baseline internal ohmic ~~value.~~ values for every cell/unit (See Table 2)		.No periodic measurement and ~~comparison~~evaluation relative to baseline of battery cell/unit internal ohmic values ~~for VRLA batteries and VLA batteries where the cells are not visible are~~is required~~.~~ to verify the station battery can perform as designed .
Any Valve Regulated Lead-Acid (VRLA) station battery with monitoring and alarming of each cell/unit internal Ohmic value. (See Table 2)		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA battery is required.

Table 1-5 **Component Type - Control Circuitry Associated With Protective Functions** **Note:** Table requirements apply to all Control Circuitry components of Protection Systems, UVLS and UFLS Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (excluding UFLS or UVLS systems).	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Trip coils of circuit breakers and interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.
Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored control circuitry associated with protective functions.	12 calendar years	Verify all paths of the control and trip circuits.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of DETECTION to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	No periodic maintenance specified.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-~~1through~~1 through 1-5 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Countable Event – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

4. ~~If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.~~
5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.
6. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

Implementation Plan for PRC-005-02

Standards Involved:

- Approval:
  - PRC-005-2 – Protection System Maintenance and Testing

- Retirements (phased to coincide with each entity's implementation of PRC-005-2 as specified in the Implementation Plan for Requirements R1 through R3 later in this document):
  - PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing
  - PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
  - PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
  - PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

- Revised definition of "Protection System"

Background:

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

4. The Implementation Schedule set forth in this document requires that entities develop their revised Protection System Maintenance Program within 12 months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twelve months following Board of Trustees adoption.

5. The Implementation Schedule set forth in this document further requires implementation of the revised Protection System Maintenance Program in roughly equally-distributed steps over the maintenance intervals prescribed for each respective maintenance activity in order that entities may implement this standard in a systematic method that facilitates an effective ongoing Protection System Maintenance Program.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the Protection System components identified in PRC-005-2 Tables 1-1 through 1-5) until that Transmission Owner, Generator Owner or Distribution

Provider meets initial compliance for maintenance of the same Protection System component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components.
- For each component, whether maintenance of that component is being addressed according to PRC-005-2 or under PRC-005-1, PRC-008-0, PRC-011-0, or PRC-017-0.
- Evidence that each component has been maintained under the relevant requirements.

Retirement of Existing Standards:

The existing Standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired upon regulatory approval of PRC-005-2.

Implementation Plan for Definition:

Protection System Maintenance Program – Entities shall use this definition when implementing any portions of R1, R2 and R3 which use this defined term.

Implementation Plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-one (21) months following Board of Trustees adoption.

Implementation Plan for Requirements R2 and R3:

1. For Protection System components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 15 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 24 months following Board of Trustees adoption.

2. For Protection System components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.

3. For Protection System components with maximum allowable intervals of 3 years, as established in Tables 1-1 through 1-5:

a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 24 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 36 months following Board of Trustees adoption.
b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
c. The entity shall be 100% compliant on the first day of the first calendar quarter 48 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 60 months following Board of Trustees adoption.

4. For Protection System components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5:
    a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 36 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 48 months following Board of Trustees adoption.
    b. The entity shall be at least 60% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 96 months following Board of Trustees adoption.

5. For Protection System components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5 and Table 2:
    a. The entity shall be at least 30% compliant on the first day of the first calendar quarter 60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 72 months following Board of Trustees adoption.
    b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following 108 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 120 months following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 156 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 168 months following Board of Trustees adoption.

Applicability:

This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Implementation Plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~twelve~~twenty-one (21) months following Board of Trustees adoption.

Implementation Plan for Requirements R2 and R3:

1. For Protection System components with maximum allowable intervals of less than 1 year, as established in Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 15 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~15~~24 months following Board of Trustees adoption.
2. For Protection System components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Tables 1-1 through 1-5:
   a. The entity shall be 100% compliant on the first day of the first calendar quarter ~~3 calendar years~~36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~3 calendar years~~48 months following Board of Trustees adoption.
3. For Protection System components with maximum allowable intervals of 3 years, as established in Tables 1-1 through 1-5:

a. The entity shall be at least 30% compliant on the first day of the first calendar quarter ~~2 calendar years~~24 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding two ~~calendar~~ years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~2 calendar years~~36 months following Board of Trustees adoption.

~~b.~~ The entity shall be at least 60% compliant on the first day of the first calendar quarter ~~3 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 3 calendar years following Board of Trustees adoption.~~

~~c.~~b. ~~The entity shall be 100% compliant on the first day of the first calendar quarter 4 calendar years~~36 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~4 calendar years~~48 months following Board of Trustees adoption.

c. The entity shall be 100% compliant on the first day of the first calendar quarter 48 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 60 months following Board of Trustees adoption.

4. For Protection System components with maximum allowable intervals of 6 years, as established in Tables 1-1 through 1-5:

   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter ~~3 calendar years~~36 months following applicable regulatory approval (or, for generating plants with scheduled outage intervals exceeding ~~two calendar~~three years, at the conclusion of the first succeeding maintenance outage), or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~3 calendar years~~48 months following Board of Trustees adoption.

   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter ~~5 calendar years~~60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~5 calendar years~~72 months following Board of Trustees adoption.

   c. The entity shall be 100% compliant on the first day of the first calendar quarter ~~7 calendar years~~84 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~7 calendar years~~96 months following Board of Trustees adoption.

5. For Protection System components with maximum allowable intervals of 12 years, as established in Tables 1-1 through 1-5 and Table 2:

   a. The entity shall be at least 30% compliant on the first day of the first calendar quarter ~~5 calendar years~~60 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~5 calendar years~~72 months following Board of Trustees adoption.

   b. The entity shall be at least 60% compliant on the first day of the first calendar quarter following ~~9 calendar years~~108 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 120 months following Board of Trustees adoption.

~~b.~~c. The entity shall be 100% compliant on the first day of the first calendar quarter 156 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~9 calendar years~~168 months following Board of Trustees adoption.

~~c.The entity shall be 100% compliant on the first day of the first calendar quarter 13 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 13 calendar years following Board of Trustees adoption.~~

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Project 2007-17 Protection System Maintenance & Testing

New Definition for Approval:

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Upkeep — Perform routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.
- Restore — Return malfunctioning components to proper operation.

PRC-005-2
Protection System Maintenance

Supplementary Reference & FAQ

Draft

to ensure the reliability of the bulk power system

June 2, 2011

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

116-390 Village Blvd., Princeton, NJ 08540
609.452.8060 | 609.452.9550 fax
www.nerc.com

Table of Contents

This supplementary reference to PRC-005-2 is not mandatory and enforceable.

1. Introduction and Summary

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to relays for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse. This Standard is not applicable to this UVLS.

We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. As stated in Requirement R1, this Standard covers protective relays that use measurements of electrical quantities to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This Standard addresses only devices “that are applied on, or are designed to provide protection for the BES.” Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as “A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed.”

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.

- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the “Tables”), and the various components of the definition established for a “Protection System Maintenance Program”, PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R3 of the Standard does require that the entity "initiate resolution of any identified maintenance correctable issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

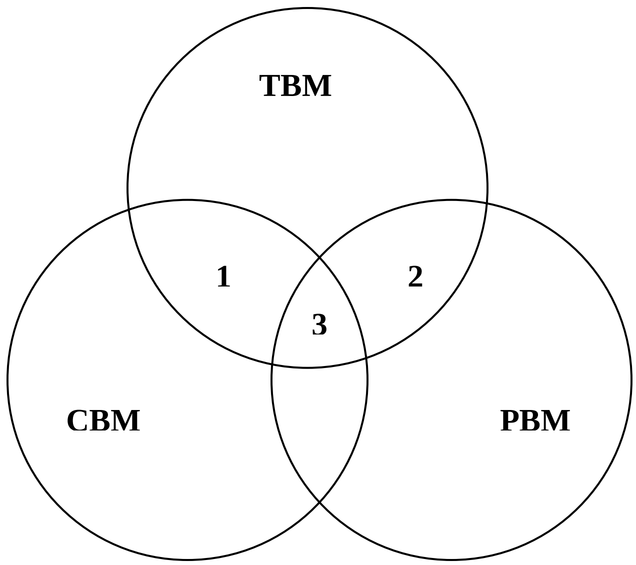
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



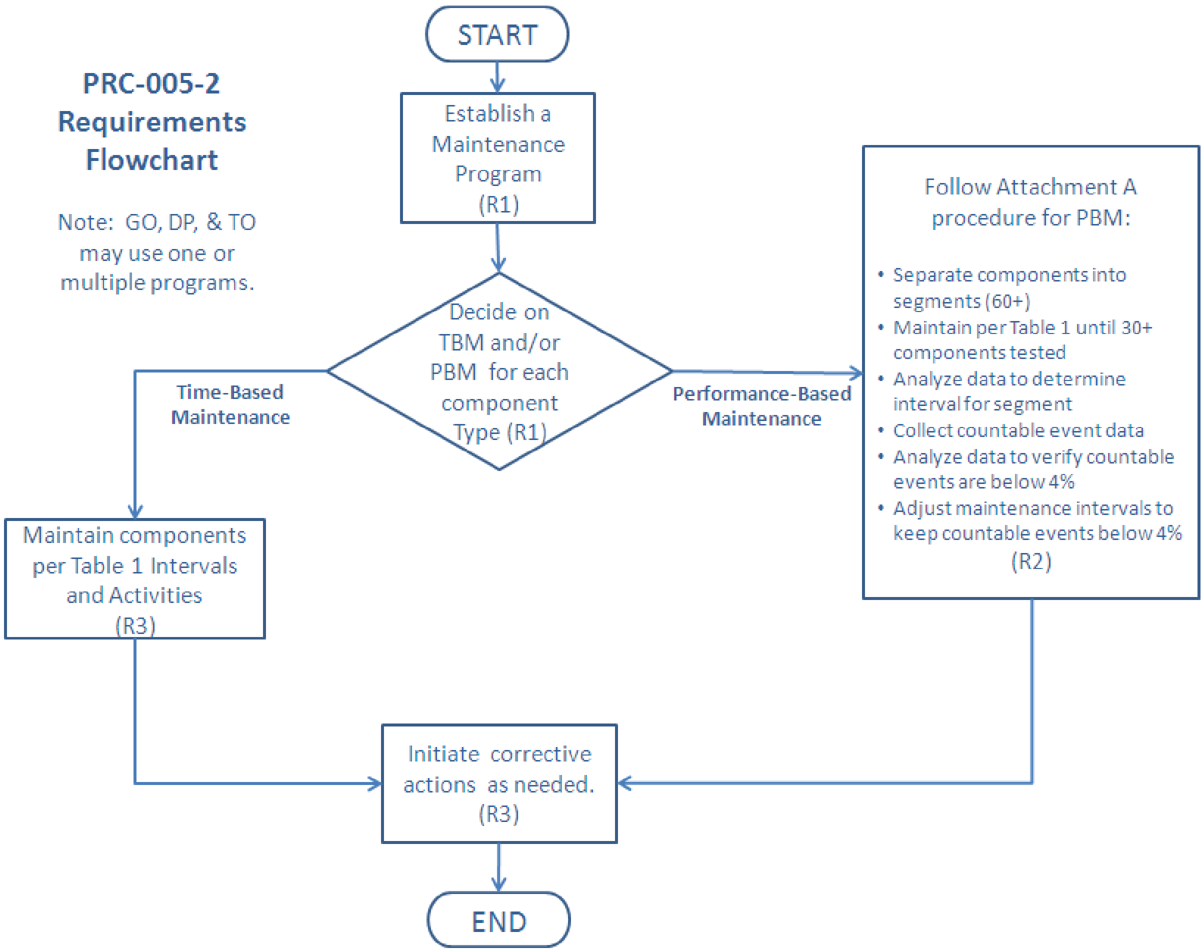
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or

manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP …" if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1.4 of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?
Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval", the next event would have to occur on or before December 31, 2010.

Please provide an example of "3 Calendar Months".
If a maintenance activity is described as being needed every 3 Calendar Months then it is performed in a (given) month and due again 3 months later. For example a battery bank is inspected in month number 1 then it is due again in month number 4. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of April. Another example could be that a 3-month inspection was performed in January is due in April, but if performed in March (instead of April) would still be due three

months later therefore the activity is due again June. Basically every “3 Calendar Months” means to add 3 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?
An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2 , the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance

- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices
- Battery performance test (if ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Verify that current and voltage signal values are provided to the protective relays
- Verify that Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- Verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices **Example #3:** A combination of monitored and unmonitored components within a given Protection System might be:
  - A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
  - Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
  - Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
  - Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”) and Table 2 (“Alarming Paths and Monitoring”), the particular components shall have maximum activity intervals of:

Every 3 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Cell condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?
The protective relay is monitored and can be maintained every 12 years or when a maintenance correctable issue arises. The control circuitry can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the Standard, specifies maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits. There is an additional table,
    - Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.

- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

8.1.2 Additional Notes for Tables 1-1 through 1-5

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc, are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation

battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.
6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).
7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.
8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.
9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed mostly towards microprocessor based relays.
For relay maintenance departments that choose to test microprocessor based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0. These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?
As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?
Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for Centralized UFLS or UVLS Systems?
Since components of the SPS, UFLS, or UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.
For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?
No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.
The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?
The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the

minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays

- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) and auxiliary tripping relays (94) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or 94 that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

Other devices in the control circuitry that are used for other protective functions besides tripping (including, but not limited to, electromechanical breaker fail initiation relays) need only be verified with the control circuitry every twelve years.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.
The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: “Company A” has a maintenance plan that requires its electromechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within “Company A’s” stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3.

How do I achieve a "grace period" without being out of compliance?

For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007. the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the

IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.

- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.
The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods". To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems***

— *Requirements;* or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:
B = bound on the error of distribution (allowable error)
z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation
Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.
Note that the following example captures “Control Circuitry” as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of “Component”:

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:
Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.
For the sake of further example the following facts are given:
Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity’s specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity’s population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant

microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme". Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes", all of which have three current signals supplied from bushing CT's and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT's and voltage signals from PT's built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.
The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).
(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?
Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may

indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?
For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific

requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?
The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?
If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays “out-of-service”. What are our responsibilities when it comes to “out-of-service” devices?
Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would

dictate that an “out-of-service” device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?
Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R3 states (the entity must):

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues.

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.
The maintenance and testing requirements (R3) (in essence) state “…shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues...” The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.
Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?
Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied.

Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.

- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified

by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?
No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?
Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer.

Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

Circuit breakers that participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements; however the circuitry must be tested at least once every 12 years. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single

Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are electromechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?
Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?
Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?
Table 1-5 specifies that each breaker trip coil, auxiliary relay that carries trip current to a trip coil, and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5?

An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.
The relay must be verified.
The voltage signal to the relay must be verified.
All of the relevant dc supply tests still apply.
The unmonitored trip circuit must be verified every 12 years.
The trip coil of the circuit breaker does not have to be individually proven with an electrical trip.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?
The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

<u>Battery Charger</u> - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

<u>Station Battery</u> - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

<u>Emerging Technologies</u> - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?
The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the

various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (Valve-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.

For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon

installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, consistent test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment).

Although many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great

detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?
The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulphuric acid, is consumed and the concentration of the sulphuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?
High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum

maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries “informative” annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries “informative” annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery’s cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?

Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.
The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the

entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third manfacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit

internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, "depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity" they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the

station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.

Why check for the electrolyte level?

In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is “verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline.” This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to “Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.”

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the “capacity 6 month test” at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the “thermal runaway test” at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be performed on any communications-assisted trip scheme regardless of the vintage of technology.The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?
For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 3-month inspection of communications-assisted trip scheme equipment?

The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and

set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?
An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?
There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Question:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?
There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to

revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe “form b” contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?
If the fail-safe “form-b” contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

15.7 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.7.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?
In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?

Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

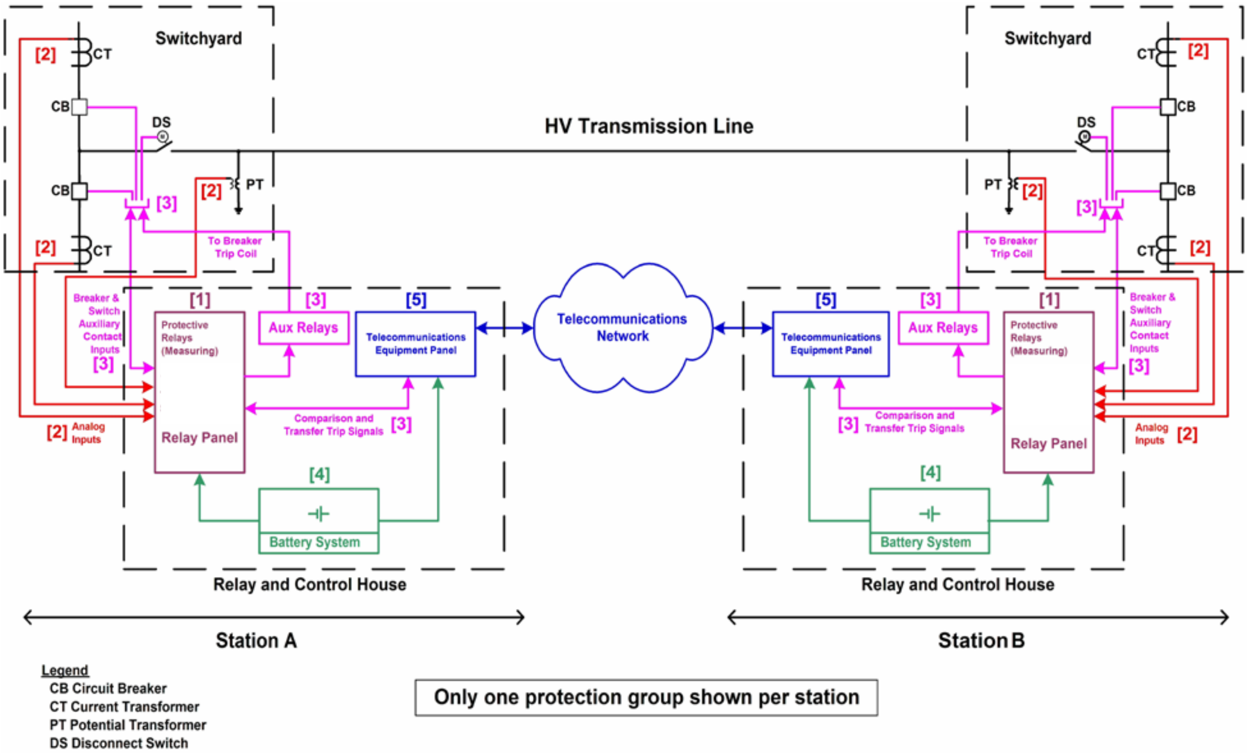
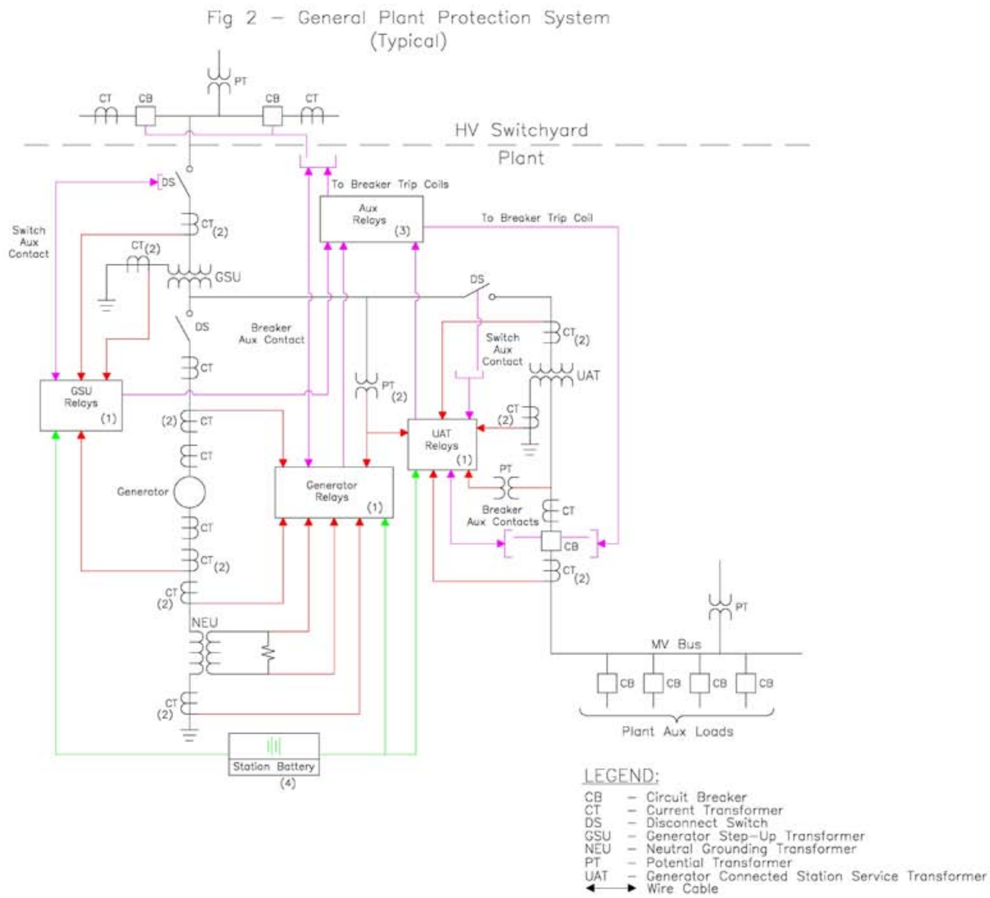
Figure 1: Typical Transmission System



For information on components, see ***[Figure 1 & 2 Legend – Components of Protection Systems]()***

Figure 2: Typical Generation System



For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

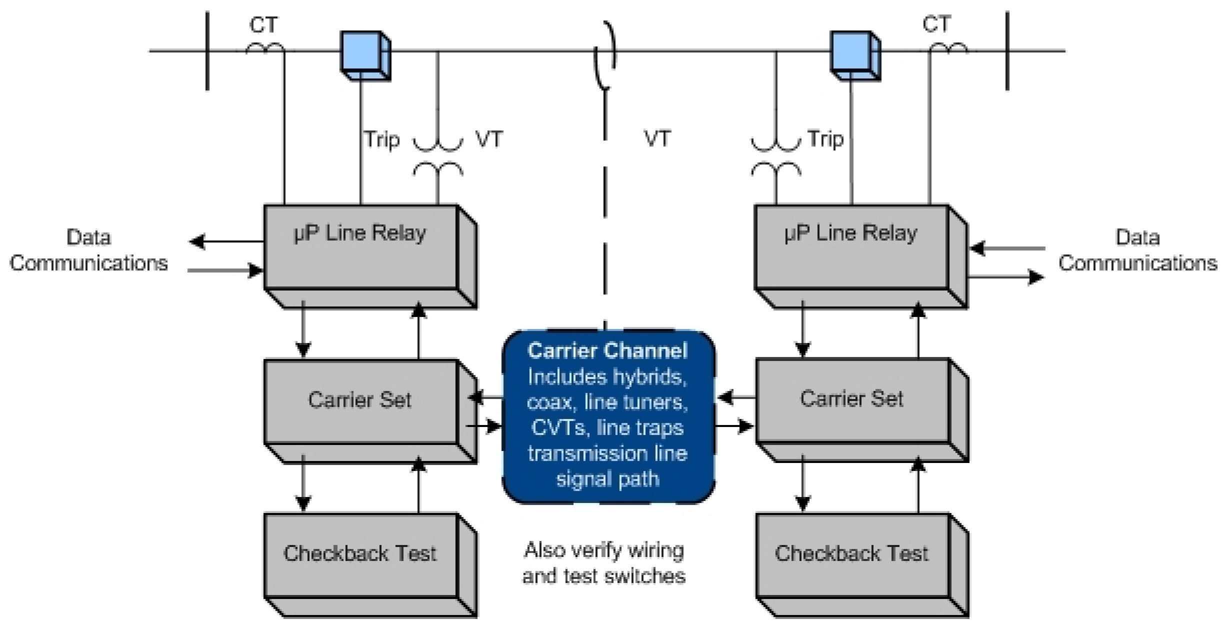
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

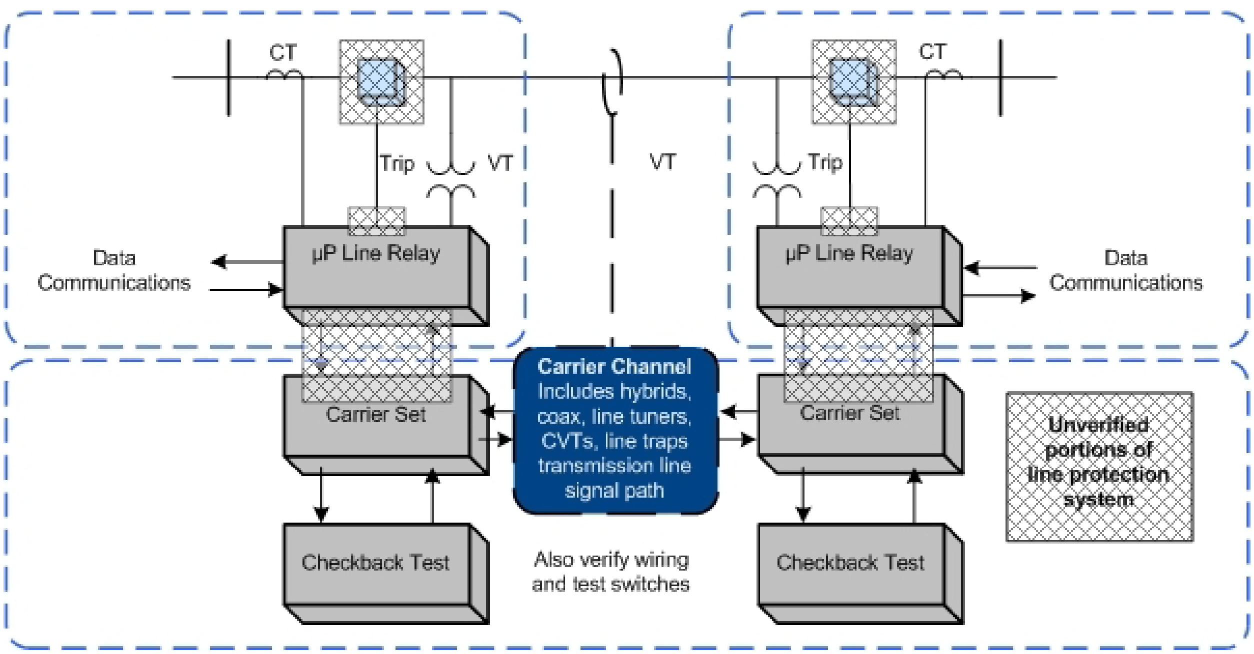
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the

relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Table of Contents

This supplementary reference to PRC-005-2 is not mandatory and enforceable.

1. Introduction and Summary

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-2 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries which are an important part of the station dc supply are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC Standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ~~ensure all transmission~~document and ~~generation~~implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) ~~are maintained and tested~~so that these Protection Systems are kept in working order.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- communications systems necessary for correct operation of protective functions,
- voltage and current sensing devices providing inputs to protective relays,
- station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*… ~~and~~ that are ~~designed to provide protection~~installed for the purpose of detecting faults on BES~~."~~ Elements (lines, buses, transformers, etc.)."*

The drafting team intends that this Standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the element is a BES element then the Protection System protecting that element should then be included within this Standard. If there is regional variation to the definition then there will be a corresponding regional variation to the Protection Systems that fall under this Standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the Standard language should simply be applicable to relays for BES elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC glossary of terms for the present, in-force, definition. See the applicable regional reliability organization for any applicable allowed variations.

While this Standard will undergo revisions in the future, this Standard will not attempt to keep up with revisions to the NERC definition of BES but rather simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GO's and TO's have equipment that is BES equipment. The Standard brings in Distribution Providers (DP) because depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

As this Standard is intended to replace the existing PRC-005, PRC-008, PRC-011 and PRC-017, those Standards are used in the construction of this revision of PRC-005-1. Much of the original intent of those Standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

Additionally, since this Standard will now replace PRC-011 it will be important to make the distinction between under-voltage Protection Systems that protect individual loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 will now be applicable under this revision of PRC-005-1. An example of an Under-Voltage Load Shedding scheme that is not applicable to this Standard is one in which the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing a cascading outage or transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus a Standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems and replace some other Standards at the same time.

2.3.1 Frequently Asked Questions:

What, exactly, is the BES, or Bulk Electric System?
BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft Standard.
NERC's approved definition of Bulk Electric System is:

As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June ~~16~~14, 2007 Informational Filing*.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this Standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage to a specific load from a transmission system that was intact except for the line that was out of service, as opposed to preventing cascading outage or transmission system collapse. This Standard is not applicable to this UVLS.

We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this Standard.

We have a UFLS scheme that, in some locales, sheds the necessary load through non-BES circuit breakers and occasionally even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as (for example) a single failure to trip of a Transmission Protection System Bus Differential lock-out relay.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this Standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

No. As stated in Requirement R1, this Standard covers protective relays that use measurements of electrical quantities to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?
This Standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

Is a Sudden Pressure Relay an auxiliary tripping relay?
No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63. Sudden pressure relays are excluded from the Standard because it does not utilize voltage and/or current measurements to determine anomalies. Devices that use anything other than electrical detection means are excluded.

My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?
You must conduct a test(s) to verify the integrity of the trip circuit. This Standard does not cover circuit breaker maintenance or transformer maintenance. The Standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

The Standard specifically mentions auxiliary and lock-out relays; what is an auxiliary tripping relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection Systems Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture fault records showing how the Protection System responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages or from relay front panel button requests.

- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of Battery Chargers, Associated Communications Equipment, Voltage and Current Measuring Devices and even the control circuitry (in the form of software-latches replacing lock-out relays, etc).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Restore — Return malfunctioning components to proper operation.

4.1 Frequently Asked Questions:

Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous Standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the tables 1-1 through 1-5 and Table 2 (collectively the “Tables”), and the various components of the definition established for a “Protection System Maintenance Program”, PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by restore in the definition of maintenance.

The description of "Restore" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R3 of the Standard does require that the entity "initiate resolution of any identified maintenance correctable issues". Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of ~~electro-mechanical~~electromechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This Standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this Standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection Systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System components can have the ability to remotely conduct tests, either on-command or routinely, the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the Standard itself, it is important to note that the concepts of CBM are a part of the Standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the Standard the explanatory discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

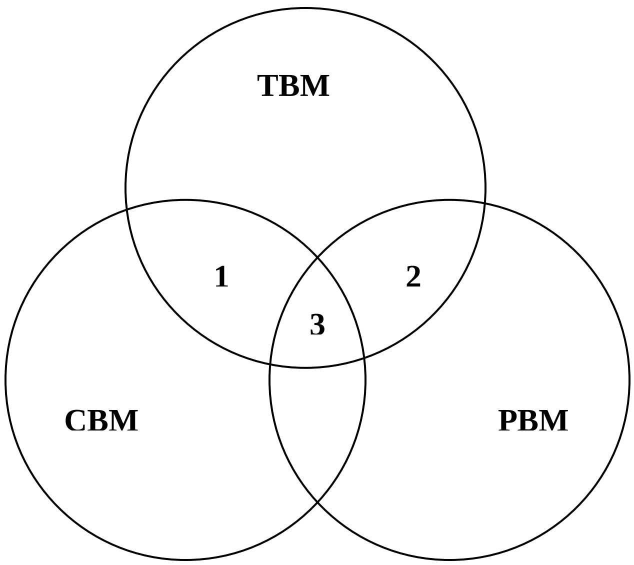
  Microprocessor based Protection System components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



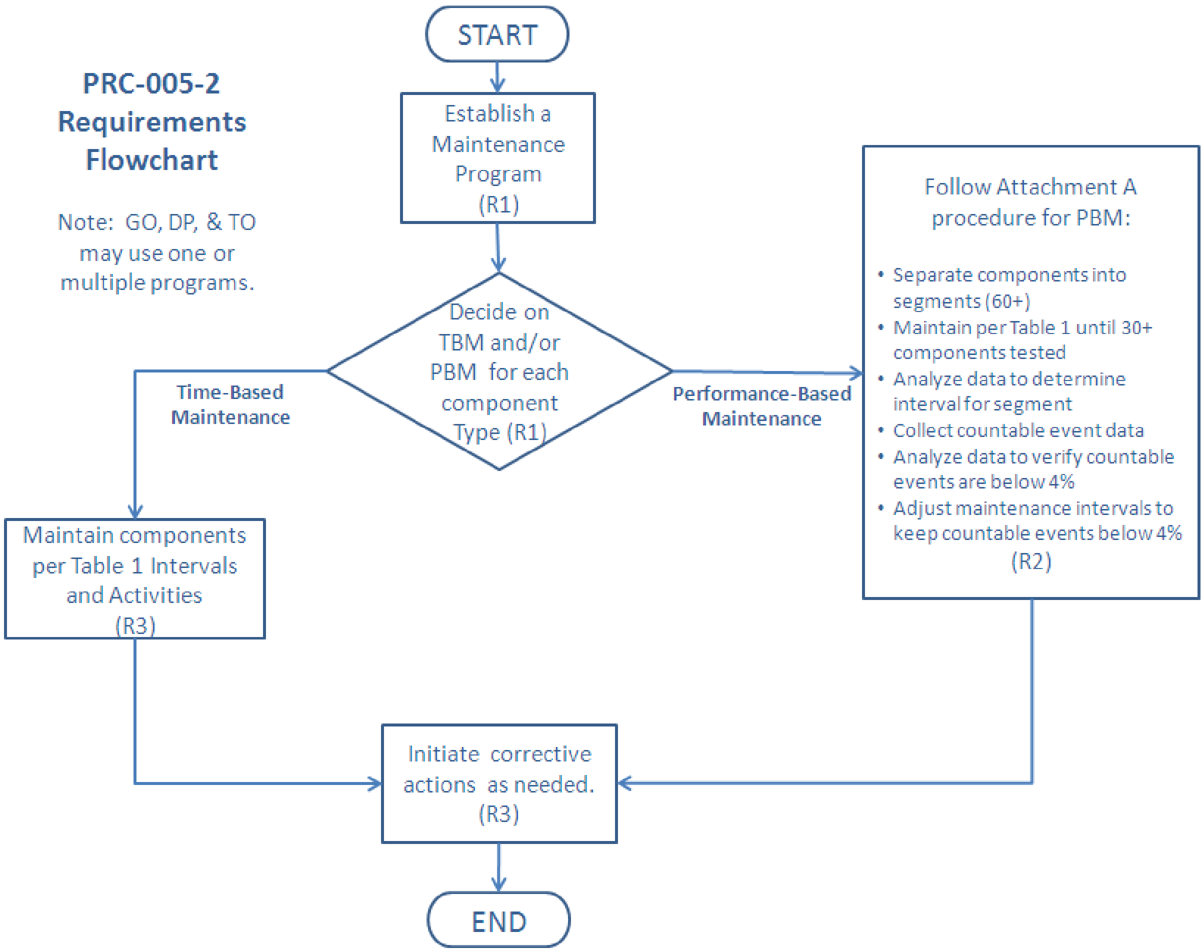
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The Standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the Standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a “flow chart” of the Standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System maintenance program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables 1-1 through 1-5.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self monitoring device), then the intervals may be extended or

manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Question:

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R3) (in essence) state "…shall implement and follow its PSMP …" if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R1.4 of the Standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are Monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered Monitored and subject to the rows for monitored equipment of Table 1-4 requirements as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered Unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The Standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC Standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection Systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in Tables 1-1 through 1-5 and Table 2 of PRC-005-2.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval", the next event would have to occur on or before December 31, 2010.

Please provide an example of "3 Calendar Months".

If a maintenance activity is described as being needed every 3 Calendar Months then it is performed in a (given) month and due again 3 months later. For example a battery bank is inspected in month number 1 then it is due again in month number 4. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of April. Another example could be that a 3-month inspection was performed in January is due in April, but if performed in March (instead of April) would still be due three

months later therefore the activity is due again June. Basically every "3 Calendar Months" means to add 3 months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?
An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be ~~un-monitored~~unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but not limited to an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using ~~the~~ Table 1 ~~("Maximum Allowable Testing Intervals and Maintenance Activities")~~ and Table 2 ~~("Alarming Paths and Monitoring"),~~, the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity

- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For ~~electro-mechanical~~electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- ~~Instrumentation transformers~~Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all paths ~~of~~in the control ~~and~~circuitry associated with protective functions through the trip ~~circuits~~coil(s) of the circuit breakers or other interrupting devices

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- ~~Instrument transformers~~Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A Vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components have maximum activity intervals of:

Every 3 calendar months, verify:

- Electrolyte level (Station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every 6 calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For ~~electro-mechanical~~electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices
- Battery performance test (if ohmic tests are not opted)

Every 12 calendar years, verify the following:

- ~~Instrumentation transformers~~
- Verify that current and voltage signal values are provided to the protective relays
- Verify that Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- Verify all paths ~~of the control and trip circuits~~
- in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices **Example #3:** A combination of monitored and unmonitored components within a given Protection System might be:
  - A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self diagnosis and alarms. (monitored)
  - ~~Instrument transformers~~Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
  - Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
  - Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities") and Table 2 ("Alarming Paths and Monitoring"), the particular components shall have maximum activity intervals of:

Every 3 calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Cell condition of all individual battery cells (where visible)

Every 6 calendar years, perform/verify the following:

- Battery performance test (if ohmic tests are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For ~~electro-mechanical~~electromechanical lock-out relays and auxiliary relays, electrical operation of electromechanical trip and auxiliary devices

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all paths ~~of~~in the control ~~and~~circuitry associated with protective functions through the trip ~~circuits~~coil(s) of the circuit breakers or other interrupting devices

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?
No. For some components in a Protection System, monitoring will not be relevant. For example a battery will always need some kind of inspection.

We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?
The protective relay is monitored and can be maintained every 12 years or when a maintenance correctable issue arises. The control circuitry can be maintained every 12 years. The trip coil(s) has to be electrically operated at least once every 6 years.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), in the Standard, specifies maximum allowable verification intervals for various generations of Protection Systems and categories of equipment that comprise Protection Systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these figures. UFLS, UVLS and SPS all use identical equipment as Protection Systems in the performance of their functions and therefore have the same maintenance needs.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-2:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits. There is an additional table,
    - Table 2, which brings alarms into the maintenance arena; this was broken out to simplify the other tables.
- Next look within that table for your device and its degree of monitoring. The tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more activities then you must perform and document to this higher standard.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must perform and document those activities to your more stringent standard.

- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every 3 months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available on each of the 5 Tables. While the maintenance activities resulting from this choice would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-2. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-2, most notable of which is an entity using performance based maintenance methodology. (Another reason for having a more stringent plan than is required could be a regional entity could have more stringent requirements.) Regardless of the rationale behind an entity's more stringent plan, it is incumbent upon them to perform the activities, and perform them at the stated intervals, of the entity's PSMP. A quality PSMP will help assure system reliability and adhering to any given PSMP should be the goal.

8.1.2 Additional Notes for Tables 1-1 through 1-5

1. For ~~electro-mechanical~~electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor ~~-~~ relays with no remote monitoring of alarm contacts, etc, are ~~un-monitored~~unmonitored relays and need to be verified within the Table interval as other ~~un-monitored~~unmonitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or SPS (as opposed to a monitoring task) must be verified as a component in a Protection System.
4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components physical inspection of station batteries for signs of component failure, reduced performance, and degradation

are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & Current Sensing Device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. "End-to-end test" as used in this Supplementary Reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the Standard is technology and method neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?
Verification of settings is an activity directed mostly towards microprocessor based relays.

For relay maintenance departments that choose to test microprocessor based relays in the same manner as ~~electro-mechanical~~electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states "…settings are as specified."

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0. These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this Standard, to be checked.

Do I have to perform a full end-to-end test of a Special Protection System?
No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about SPS interfaces between different entities or owners?
As in all of the Protection System requirements, SPS segments can be tested individually thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?
Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Special Protection System or relay sensing for Centralized UFLS or UVLS Systems?
Since components of the SPS, UFLS, or UVLS are the same types of components as those in Protection Systems then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for SPS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.
For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example an SPS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the real-time tripping of an SPS scheme should that occur. Forced trip tests of circuit breakers (etc) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?
No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this Standard.
The Sanction Guidelines of the North American Electric Reliability Corporation effective January 15, 2008 provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But, any entity can choose to test some or all of their Protection System components more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest. The BES and an entity's bottom line both suffer.

We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables and yet you must conform to your own maintenance plan. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan. You will end up being compliant with both the Standard and your own plan.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems

- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the protection systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating facility?

The SDT does not intend that the system-connected station auxiliary transformers be included in the Applicability. The generator-connected station service transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping" one needs to realize that sometimes there are more Inputs and Outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed ~~dev~~dc voltage to the input and verify that the relay registered the change of state.

~~Electro-mechanical~~Electromechanical lock-out relays (86) and auxiliary tripping relays (94) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every 6 years, unless PBM methodology is applied.

The contacts on the 86 or 94 that change state to pass on the trip current to a breaker trip coil need only be checked every twelve years with the control circuitry.

Other devices in the control circuitry that are used for other protective functions besides tripping (including, but not limited to, ~~electro-mechanical~~electromechanical breaker fail initiation relays) need only be verified with the control circuitry every twelve years.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous scheduled (on-site) audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

8.2.1 Frequently Asked Questions:

Please use a specific example to demonstrate the data retention requirements.
The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its ~~electro-mechanical~~electromechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to require three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

Realistically, the Standard is providing advanced notice of audit team documentation requests; this type of information has already been requested by auditors.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the Standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This Standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified in the Tables of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the Standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-2 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?
The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.
It is conceivable that there can be a (substantial) difference in time between the date of testing as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized there are cases when degradation can take place even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2 percent or 8 percent when counting Violation Severity Level (VSL) for R3?
The entity failed to complete its scheduled program on two of its one hundred Protection System components which would equate to two percent for application to the VSL Table for Requirement R3.

How do I achieve a "grace period" without being out of compliance?
For the purposes of this example, concentrating on just unmonitored protective relays,– Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of 6 calendar years. Your plan must ensure that your unmonitored relays are tested at least once every 6 calendar years. You could, within your PSMP, require that your unmonitored relays be tested every 4 calendar years with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders but still have the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, a grace period, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of 4 years; it also has a built-in time extension allowed within the PSMP and yet does not exceed the maximum time interval allowed by the Standard. So while there are no time extensions allowed beyond the Standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007. the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for ~~un-monitored~~unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for “time-interval extensions” or “grace periods” to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally it was again noted that FERC Order 693 demanded maximum time intervals. “Maximum time intervals” by their very term negates any “time-interval extension” or “grace periods”. To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension while still following FERC Order 693 the Standard Drafting Team arrived at a 6 year interval for the ~~electro-mechanical~~electromechanical relay instead of the 5 year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10 year interval was chosen even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus the maximum allowed interval for these components has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An ~~electro-mechanical~~electromechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this Standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

~~U~~Enti~~li~~ties with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Protection Systems or components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries but can be applied to all other components of a Protection System including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

"… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

"If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)

"The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

"… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program
The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation
Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the Standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?
Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?
Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?
No. You must use actual in-service test data for the components in the segment.

What types of misoperations or events are not considered countable events in the Performance-Based Protection System Maintenance (PBM) Program?
Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.
For this purpose of tracking hardware issues, human errors resulting in Protection System misoperations during system installation or maintenance activities are not considered countable

events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing “86” lock-out relays (LOR). “Entity A” has two types of LOR’s type “X” and type “Y”; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type “X” failures, but human error led to tripping a BES element 100 times; they find 100 type “Y” failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead “Entity A” to change time intervals. Type “X” LOR can be placed into extended time interval testing because of its low failure rate (zero failures) while Type “Y” would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed can count as a maintenance activity, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of 4 relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of 4 years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the ~~electro-chemical~~electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring~~;~~, resulting in the least amount of hands-on maintenance activity, ~~of the battery used in a station dc supply~~ cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.

After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen

1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:
Entity has 1000 circuit breakers, all of which have two trip coils for a total of 2000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard then this is greater than the minimum sample requirement of 60.
For the sake of further example the following facts are given:
Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their Control Circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population, (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant

microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the Operations Control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored, therefore the trip paths are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification and is taking care of this activity through other documentation of real-time fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12 year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific element. This entity calls this set of protective relays a "Relay Scheme". Thus this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages whereas a transmission maintenance group might create a process that utilizes real-time system values measured at the relays. Under the included definition of "Component":

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes", all of which have three current signals supplied from bushing CT's and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1000) are supplied with current signals from ANSI STD C800 bushing CT's and voltage signals from PT's built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs) as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored, therefore the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.
The entity now has 1000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).
(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PT's). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level thus any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.)

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30.

For the sake of example only the following will show 3 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 3 failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 20 years.

This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year.

After that year of testing these 50 units the entity again finds 3 failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected.

After a year they again find 3 failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected.

After a year they again find 3 failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years and they were under the 4% limit and they tried 14 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12).

After a year they again find 3 failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12 year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the “5% of components” requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the “3 years” requirement; this is there to prevent an entity from “gaming the system”. An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above or Attachment A of the Standard;
- Opportunistic verification using analysis of fault records as described in Section 11

10.1 Frequently Asked Question:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?
Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC Standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain Protection Systems in the vicinity of the fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the Protection System.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may

indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.
PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Question:

I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?
For relays used only as disturbance monitoring equipment, the NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays “that are designed to provide protection for the BES,” this Standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5~~].~~] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific

requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?
The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle. (However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?
If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the Standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?
Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection System component performs a Protection System function then it must be maintained. If the component no longer performs Protection System functions then it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would

dictate that an “out-of-service” device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?
Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2 requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R3 states (the entity must):

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues.

Also, when a failure occurs in a Protection System, power system security ~~maybe~~may be comprised, and notification of the failure must be conducted in accordance with relevant NERC Standards.

If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.
The maintenance and testing requirements (R3) (in essence) state “…shall implement and follow its PSMP and initiate resolution of any identified maintenance correctable issues...” The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.
Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Table 1.

13.1 Frequently Asked Question:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?
Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that ~~are maybe~~may be coming to the industry.

14. Notification of Protection System Failures

When a failure occurs in a Protection System, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC Standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-2 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted element of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Question:

What calibration tolerance should be applied on electromechanical relays?
Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this Standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied.

Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.

- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.2.1 Frequently Asked Questions:

What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified

by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?
No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?
Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the Standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer.

Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be eliminated, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this Standard is to require maintenance intervals and activities on Protection Systems equipment and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years and any electromechanically operated device will have to be tested every 6 years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

Circuit breakers that participate in a UFLS or UVLS scheme are excluded from the tripping requirement, but not from the circuit test requirements; however the circuitry must be tested at least once every 12 years. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single

Transmission Protection System failure such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just fault clearing duty and therefore these circuit breakers are operated at least as frequently as any requirements that appear in this Standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If these devices are ~~electro-mechanical~~electromechanical components then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as ~~electro-mechanical~~electromechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?
Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?
Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?
Table 1-5 specifies that each breaker trip coil, auxiliary relay that carries trip current to a trip coil, and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?
Yes. PRC-005-2 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5?
An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial loads but has a trip that originates from an under-frequency (81) relay.
The relay must be verified.
The voltage signal to the relay must be verified.
All of the relevant dc supply tests still apply.
The unmonitored trip circuit must be verified every 12 years.
The trip coil of the circuit breaker does not have to be individually proven with an electrical trip.

15.4 Batteries and DC Supplies (Table 1-4)

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The currently proposed NERC definition of a Protection System is

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the ~~electro-chemical~~electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply as mentioned in the definition of Protective System?
The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers as well as dc systems that do not utilize batteries. This revision of PRC-005-2 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?
The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the Standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1-4 of the Standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

An open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.

- Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the Standard prescribes what must be accomplished during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the

various dc-supplied equipment in the station should be considered before using this approach.

- Manufacturers of microprocessor controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.

- Internal ohmic measurements of the cells and units of Lead Acid Batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string and when used in conjunction with resistance measurements of the battery's external connections can prove continuity. Also some methods of taking internal ohmic measurements by their very nature can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.

- Specific Gravity tests can infer continuity because without continuity there could be no charging occurring and if there is no charging then Specific Gravity will go down below acceptable levels.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (Valve~~-regulated lead-acid, vented lead-~~-Regulated Lead-Acid, Vented Lead-Acid, or Nickel-Cadmium), and the maintenance activity chosen.

For example, if you have a Valve-Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every six months. While this interval might seem to be quite short, keep in mind that the 6 month interval is consistent with IEEE guidelines for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is no longer capable of its design capacity.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station batteries ability to perform as designed they should be made upon

installation of the station battery and the completion of a performance test of the battery's capacity.

When internal ohmic measurements are taken, ~~the type of~~consistent test equipment should be used to establish the baseline ~~must be~~and used for ~~any~~the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Impedance" test equipment even though both manufacturers have produced "Ohmic" test equipment.

For all new installations of Valve-Regulated Lead-Acid (VRLA) batteries and Vented Lead-Acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as designed, the establishment of the baseline as described above should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older V~~L~~RLA batteries the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, ~~all~~many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However it is important that when using battery manufacturer supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements~~.~~ (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment).

Although ~~the manufactures~~many manufacturers may have provided base line values which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively discuss state of charge in great

detail in their standards or annexes to their standards. The above IEEE standards are excellent sources for describing how to determine state of charge of the battery system.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged the battery is available to deliver its existing capacity. As a battery is discharged its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For Vented Lead-Acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges the active electrolyte, sulphuric acid, is consumed and the concentration of the sulphuric acid in water is reduced. This in turn reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can therefore be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely if taken shortly after adding water to the cell the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-Cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and Valve-Regulated Lead-Acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries and also for VLA batteries, where another method besides taking hydrometer readings is desired, the state of charge may be determined by using the battery charger and taking voltage and current readings during float and equalize (high-rate charge mode). This method is an effective means of determining when the state of charge is low and when it is approaching a fully charged condition which gives the assurance that the available battery capacity will be maximized.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external circuit terminations.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen not to exceed the maximum

maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

IEEE Standard 450 for Vented Lead-Acid (VLA) batteries "informative" annex F, and IEEE Standard 1188 for Valve-Regulated Lead-Acid (VRLA) batteries "informative" annex D provide excellent information and examples on performing connection resistance measurements using a microohmmeter and connection detail resistance measurements. Although this information is contained in standards for lead acid batteries the information contained is applicable to Nickel-Cadmium batteries also.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the ~~electro-chemical~~electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal color (possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections such as the bus bar connection to each plate and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell or cells must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the ~~electro-chemical~~electrochemical aging process of the station battery nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why consider the ability of the station battery to perform as designed?

Determining the ability of a station battery to perform as designed is critical in the process of determining when the station battery must be replaced or when an individual cell or battery unit must be removed or replaced. For lead acid batteries the ability to perform as designed can be determined in more than one manner.

The two acceptable methods for proving that a station lead acid battery can perform as designed are based on two different philosophies. The first maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the station battery to determine that each component can perform as designed and therefore the entire station battery can be verified to perform as designed. The second activity requires a capacity discharge test of the entire station battery to verify that degradation of one or several components (cells) in the station battery has not deteriorated to a point where the total capacity of the station battery system falls below its designed rating.

The first maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement low-capacity cells can be identified and eliminated or the whole station battery replaced to keep the station battery capable of performing as designed. Since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

It should be noted that even if a lead acid battery unit is composed of multiple cells where the ohmic measurement of each cell cannot be taken, the ohmic test can still be accomplished. The data produced becomes trending data on the multi-cell unit instead of trending individual cells. Care must be taken in the evaluation of the ohmic measures of entire units to detect a bad cell that has a poor ohmic value. Good ohmic values of other cells in the same battery unit can make it harder to detect the poor ohmic measurement of a bad cell because the only ohmic measurement available is of all the cells in the battery unit.

This first maintenance activity is applicable only for Vented Lead-Acid (VLA) and Valve-Regulated Lead-Acid (VRLA) batteries; this trending activity has not shown to be effective for NiCd batteries thus the only choices for owners of NiCd batteries are the performance tests of the second activity (see applicable IEEE guideline for specifics on performance tests).

The second maintenance activity listed in Table 1-4 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries.
The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a station battery may degrade to an unacceptable level without causing the total station battery to fall below its designed rating under capacity testing.

IEEE Standards 450, 1188, and 1106 for vented lead-acid (VLA), Valve-Regulated Lead-Acid (VRLA), and Nickel-Cadmium (NiCd) batteries respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the

entire battery set to determine that a battery can perform as designed or needs to be replaced soon.

Why in Table 1-4 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, Vented Lead-Acid, and Nickel-Cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.

Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the "Unintentional dc Grounds" requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional DC grounds. The Standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for Unintentional DC Grounds because ~~to~~of the possible consequences to the Protection System.

Where the Standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example ~~to~~do I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this Standard refer to Station batteries or all batteries, for example Communications Site Batteries?

This Standard refers to Station Batteries. The drafting team does not believe that the scope of this Standard refers to communications sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point the corrective actions can be initiated.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand dc resistance of a cell is measured by a third man~~u~~facturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery ~~the same~~consistent ohmic measurement ~~device must~~devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit

internal ohmic measurements~~"~~ (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a base line and trending it over time says, "depending on the degree of change a performance test, cell replacement or other corrective action may be necessary.

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several ~~guide lines~~guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity" they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as designed. By evaluation of the trending of the ohmic measurements over time the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as designed.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning. Low battery voltage below float voltage indicates that the battery may be on discharge and if not corrected the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the

station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits.

Why check for the electrolyte level?
In Vented Lead-Acid (VLA) and Nickel-Cadmium (NiCd) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in Valve-Regulated Lead-Acid (VRLA) batteries cannot be observed there is no maintenance activity listed in Table 1-4 of the Standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCd station battery is a condition requiring correction. Typically the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCd) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery or other unforeseen events can cause rapid loss of electrolyte the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?
There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for Valve-Regulated Lead-Acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for Vented Lead-Acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. A comparison and trending against the baseline new battery ohmic reading can be used in lieu of capacity tests to determine remaining battery life. Remaining battery life is analogous to stating that the battery is still able to "perform as designed". This is the intent of the "capacity 6 month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not have a formal trending program to track when a cell has reached a 25% increase over baseline. Rather it will stick out like a sore thumb when compared to the other cells in a string at a given point in time regardless of the age of all the cells in a string. In other words, if the battery is 10 years old and all the cells are gradually approaching a 25% increase in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is in thermal runaway and catastrophic failure is imminent.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the 6 month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a 6 month basis.

It is possible to accomplish both tasks listed (trend testing for capacity and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this Standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this Standard to require that a test be ~~made of~~performed on any communications-assisted trip scheme regardless of the vintage of ~~the~~ technology.The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?
For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests, with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the 3-month inspection of communications-assisted trip scheme equipment?

The 3-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e. FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communications equipment.

In Table 1-2, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?
Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For unmonitored systems this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and

set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This Standard does not state what the performance criteria will be~~—~~; it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?
An entity determines the acceptable performance criteria depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?
There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot and thus make it easier to read the Tables 1-1 through 1-5. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a Standard alarming system or an auto-polling system, the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours then it too is considered monitored.

15.6.1 Frequently Asked Question:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?
There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The Standard Drafting Team wants to avoid the need to

revise the Standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?
If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center then this can be classified as an alarm path with monitoring.

15.7 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC Standards that could, at times, fulfill evidence requirements of this Standard.

15.7.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records
- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?
In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-2?
Maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

I maintain disturbance records which show Protection System operations. Can I use these records to show compliance?
These records can be concurrently utilized as dc trip path verifications to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my components of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?
Yes.

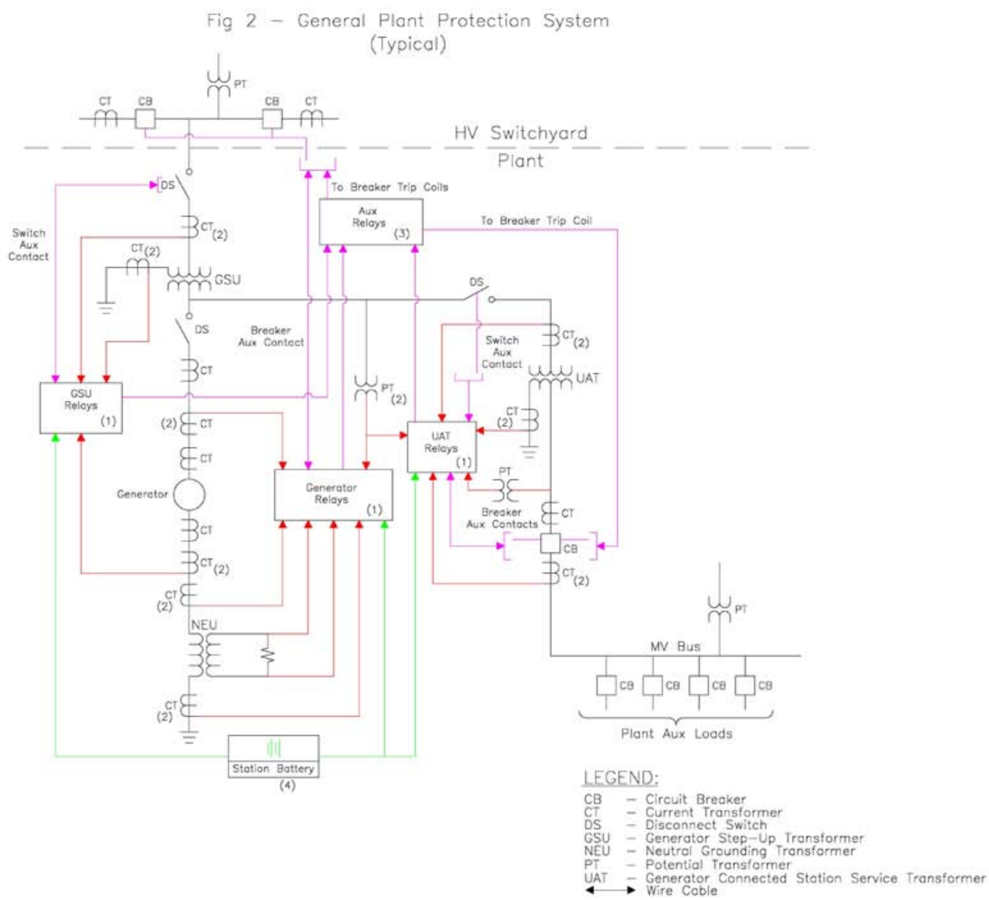
Figure 2: Typical Generation System



For information on components, see ***Figure 1 & 2 Legend – Components of Protection Systems***

~~(Return)~~

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

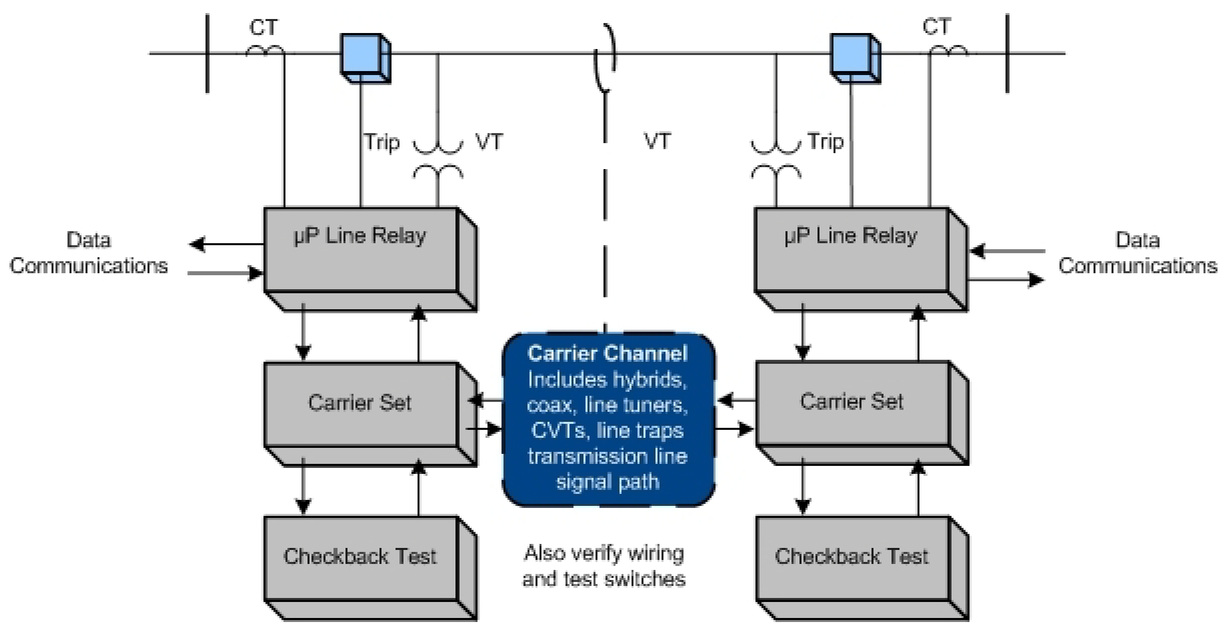
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are

reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

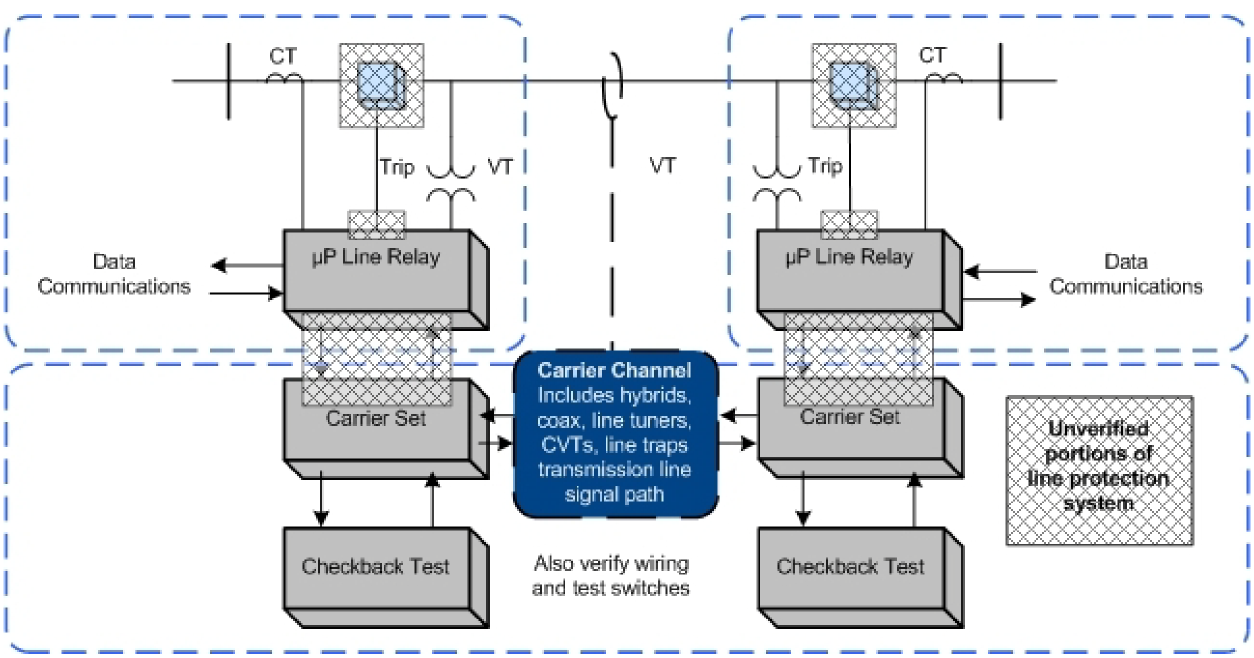
5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.

6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.

7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.
2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

A. Introduction

1. Title: **Transmission and Generation Protection System Maintenance and Testing**

2. Number: PRC-005-1

3. Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

4. Applicability

4.1. Transmission Owner.

4.2. Generator Owner.

4.3. Distribution Provider that owns a transmission Protection System.

5. Effective Date: May 1, 2006

B. Requirements

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

R2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:

R2.1. Evidence Protection System devices were maintained and tested within the defined intervals.

R2.2. Date each Protection System device was last tested/maintained.

C. Measures

M1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have an associated Protection System maintenance and testing program as defined in Requirement 1.

M2. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System that affects the reliability of the BES, shall have evidence it provided documentation of its associated Protection System maintenance and testing program and the implementation of its program as defined in Requirement 2.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Time Frame

One calendar year.

1.3. Data Retention

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for three years.

The Compliance Monitor shall retain any audit data for three years.

1.4. Additional Compliance Information

The Transmission Owner and any Distribution Provider that owns a transmission Protection System and the Generator Owner that owns a generation Protection System, shall each demonstrate compliance through self-certification or audit (periodic, as part of targeted monitoring or initiated by complaint or event), as determined by the Compliance Monitor.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program provided was incomplete as required in R1, but records indicate maintenance and testing did occur within the identified intervals for the portions of the program that were documented.

2.2. Level 2: Documentation of the maintenance and testing program provided was complete as required in R1, but records indicate that maintenance and testing did not occur within the defined intervals.

2.3. Level 3: Documentation of the maintenance and testing program provided was incomplete, and records indicate implementation of the documented portions of the maintenance and testing program did not occur within the identified intervals.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
1	December 1, 2005	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. 3. Changed “Timeframe” to “Time Frame” in item D, 1.2.	01/20/05

A. Introduction

1. **Title:** **Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program**

2. **Number:** PRC-008-0

3. **Purpose:** Provide last resort system preservation measures by implementing an Under Frequency Load Shedding (UFLS) program.

4. **Applicability:**

   4.1. Transmission Owner required by its Regional Reliability Organization to have a UFLS program

   4.2. Distribution Provider required by its Regional Reliability Organization to have a UFLS program

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall have a UFLS equipment maintenance and testing program in place. This UFLS equipment maintenance and testing program shall include UFLS equipment identification, the schedule for UFLS equipment testing, and the schedule for UFLS equipment maintenance.

R2. The Transmission Owner and Distribution Provider with a UFLS program (as required by its Regional Reliability Organization) shall implement its UFLS equipment maintenance and testing program and shall provide UFLS maintenance and testing program results to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner’s and Distribution Provider’s UFLS equipment maintenance and testing program contains the elements specified in Reliability Standard PRC-007-0_R1.

M2. Each Transmission Owner and Distribution Provider shall have evidence that it provided the results of its UFLS equipment maintenance and testing program’s implementation to its Regional Reliability Organization and NERC on request (within 30 calendar days).

D. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Monitoring Responsibility

   Compliance Monitor: Regional Reliability Organization.

   1.2. Compliance Monitoring Period and Reset Timeframe

   On request (within 30 calendar days).

   1.3. Data Retention

   None specified.

   1.4. Additional Compliance Information

   None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation was not provided.

E. Regional Differences

1. None identified.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New

A. Introduction

1. **Title:** **Undervoltage Load Shedding System Maintenance and Testing**

2. **Number:** PRC-011-0

3. **Purpose:** Provide system preservation measures in an attempt to prevent system voltage collapse or voltage instability by implementing an Undervoltage Load Shedding (UVLS) program.

4. **Applicability:**

   4.1. Transmission Owner that owns a UVLS system

   4.2. Distribution Provider that owns a UVLS system

5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner and Distribution Provider that owns a UVLS system shall have a UVLS equipment maintenance and testing program in place. This program shall include:

R1.1. The UVLS system identification which shall include but is not limited to:

R1.1.1. Relays.

R1.1.2. Instrument transformers.

R1.1.3. Communications systems, where appropriate.

R1.1.4. Batteries.

R1.2. Documentation of maintenance and testing intervals and their basis.

R1.3. Summary of testing procedure.

R1.4. Schedule for system testing.

R1.5. Schedule for system maintenance.

R1.6. Date last tested/maintained.

R2. The Transmission Owner and Distribution Provider that owns a UVLS system shall provide documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program to its Regional Reliability Organization and NERC on request (within 30 calendar days).

C. Measures

M1. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have documentation that its UVLS equipment maintenance and testing program conforms with Reliability Standard PRC-011-0_R1.

M2. Each Transmission Owner and Distribution Provider that owns a UVLS system shall have evidence it provided documentation of its UVLS equipment maintenance and testing program and the implementation of that UVLS equipment maintenance and testing program as specified in Reliability Standard PRC-011-0_R2.

D. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization.

1.2. Compliance Monitoring Period and Reset Timeframe

On request (30 calendar days).

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

1. None identified.

A. Introduction

1. **Title:** **Special Protection System Maintenance and Testing**
2. **Number:** PRC-017-0
3. **Purpose:** To ensure that all Special Protection Systems (SPS) are properly designed, meet performance requirements, and are coordinated with other protection systems. To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected.
4. **Applicability:**
   - **4.1.** Transmission Owner that owns an SPS
   - **4.2.** Generator Owner that owns an SPS
   - **4.3.** Distribution Provider that owns an SPS
5. **Effective Date:** April 1, 2005

B. Requirements

R1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place. The program(s) shall include:

- **R1.1.** SPS identification shall include but is not limited to:
  - **R1.1.1.** Relays.
  - **R1.1.2.** Instrument transformers.
  - **R1.1.3.** Communications systems, where appropriate.
  - **R1.1.4.** Batteries.
- **R1.2.** Documentation of maintenance and testing intervals and their basis.
- **R1.3.** Summary of testing procedure.
- **R1.4.** Schedule for system testing.
- **R1.5.** Schedule for system maintenance.
- **R1.6.** Date last tested/maintained.

R2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall provide documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

C. Measures

M1. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have a system maintenance and testing program(s) in place that includes all items in Reliability Standard PRC-017-0_R1.

M2. The Transmission Owner, Generator Owner, and Distribution Provider that owns an SPS shall have evidence it provided documentation of the program and its implementation to the appropriate Regional Reliability Organizations and NERC on request (within 30 calendar days).

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Compliance Monitor: Regional Reliability Organization. Each Region shall report compliance and violations to NERC via the NERC Compliance Reporting process.

Timeframe:
On request (30 calendar days.)

1.2. Compliance Monitoring Period and Reset Timeframe

Compliance Monitor: Regional Reliability Organization.

1.3. Data Retention

None specified.

1.4. Additional Compliance Information

None.

2. Levels of Non-Compliance

2.1. Level 1: Documentation of the maintenance and testing program was incomplete, but records indicate implementation was on schedule.

2.2. Level 2: Complete documentation of the maintenance and testing program was provided, but records indicate that implementation was not on schedule.

2.3. Level 3: Documentation of the maintenance and testing program was incomplete, and records indicate implementation was not on schedule.

2.4. Level 4: Documentation of the maintenance and testing program, or its implementation, was not provided.

E. Regional Differences

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing
Recirculation Ballot and Non-binding Poll Open June 20-30, 2011

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Recirculation Ballot Window Open Until 8 p.m. Eastern on June 30, 2011

A recirculation ballot window for standard PRC-005-2 – Protection System Maintenance is open **until 8 p.m. Eastern on Thursday, June 30, 2011**.

The Protection System Maintenance and Testing Standard Drafting Team has made minor, non-substantive changes to PRC-005-2 Protection System Maintenance after reviewing comments received during a formal comment period and successive ballot that ended on May 13, 2011. In addition, the team made changes to the VSLs associated with PRC-005-2 to address feedback from a quality review. Because the changes made to the standard were not substantive, the Standards Committee has authorized posting the standard and associated implementation plan for a recirculation ballot. To provide an opportunity for stakeholders to cast their opinion on the revised VSLs, a concurrent non-binding poll of the VRFs and VSLs associated with PRC-005-2 will be conducted.

Instructions for Casting a Ballot and Non-binding Opinion

In the recirculation ballot, votes are counted by exception. Only members of the ballot pool may cast a ballot; all ballot pool members may change their prior votes. A ballot pool member who failed to cast a ballot during the last ballot window may cast a ballot in the recirculation ballot window. If a ballot pool member does not participate in the recirculation ballot, that member's last vote cast in the successive ballot that ended on May 13, 2011 will be carried over and used to determine if there are sufficient affirmative votes for this standard to pass.

Because the revisions to the VSLs were substantive, members of the ballot pool are asked to review the revised VSLs and cast a new opinion in the non-binding poll; in the non-binding poll opinions from the non-binding poll that ended on May 13, 2011 were not carried over.

Members of the ballot pool associated with this project may log in and submit their votes for the ballot and opinions for the non-binding poll from the following page: https://standards.nerc.net/CurrentBallots.aspx

Next Steps

Voting results will be posted and announced after the ballot window closes. If the standard is approved by a two-thirds majority, it will be submitted for adoption by the NERC Board of Trustees prior to filing with regulatory authorities for approval.

Background

The proposed PRC-005-2 – Protection System Maintenance standard addresses FERC directives from FERC Order 693, as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices. For a performance-based maintenance program, it ascertains where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Standards Announcement

Project 2007-17 Protection System Maintenance and Testing Recirculation Ballot and Non-binding Poll Results

Now available at: https://standards.nerc.net/Ballots.aspx

A recirculation ballot on PRC-005-2 Protection System Maintenance and a concurrent non-binding poll of associated VRF and VSLs concluded on June 30, 2011.

Ballot Results for Revisions to PRC-005-2

Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 82.97 %
Approval: 64.76 %

Non-binding Poll Results for Associated VRF and VSLs

Of those who registered to participate, 52.63% provided an opinion or an abstention; 60% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Next Steps

The drafting team will review comments submitted with the recirculation ballot as well as comments submitted during the formal comment period and successive ballot that concluded May 13, 2011 to determine whether to revise the standard. If the drafting team makes substantive revisions, the standard will be posted for a 30-day formal comment period with a successive ballot conducted during the final 10 days of the comment period.

Ballot Results	
Non-Binding Poll Name:	Project 2007-17_non-binding recirculation ballot June 20, 2011_in
Poll Period:	6/20/2011 - 6/30/2011
Total # Opinions:	170
Total Ballot Pool:	323
Ballot Summary:	52.63% of those who registered to participate provided an opinion or abstention; 60% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Individual Ballot Pool Results

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves posting SAR and draft standard on August 11, 2011

Description of Current Draft:

This is the first draft of the Standard. This standard merges previous standards PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined 45-day comment and ballot.	September – October, 2011
2. Conduct initial ballot	October, 2011
3. Drafting Team Responds to Comments	November – December, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

Unresolved Maintenance Issue – A deficiency that cannot be corrected during the performance of the maintenance activity and requires follow-up corrective action.

Segment – Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.

Component – A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.

A. Introduction

1. Title: **Protection System Maintenance**

2. Number: PRC-005-2

3. Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

4. Applicability:

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems that are installed for the purpose of detecting faults on BES Elements (lines, buses, transformers, etc.)

4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection Systems installed as a Special Protection System (SPS) for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection Systems that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

5. Effective Date: See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems identified in Section 4.2. *Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

The PSMP shall:

1.1. Address all Protection System **component types.**

Component Type - *Any one of the five specific elements of the Protection System definition.*

1.2. Identify which maintenance method (time-based, performance-based (per PRC-005 Attachment A), or a combination) is used to address each Protection System component type. All batteries associated with the station dc supply component type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

1.3. Identify the associated maintenance intervals for time-based programs, to be no less frequent than the intervals established in Table 1-1 through 1-5, Table 2, and Table 3.

1.4. Include all applicable monitoring attributes and related maintenance activities applied to each Protection System component type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, and Table 3.

Unresolved Maintenance Issue - *A deficiency that cannot be corrected during the performance of the maintenance activity and requires follow-up corrective action.*

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement and follow its PSMP and initiate resolution of any **unresolved maintenance issues**. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a current documented Protection System Maintenance Program that addresses all component types of its Protection Systems, as required by Requirement R1. For each Protection System component type, the documentation shall include the type of maintenance program applied (time-based, performance-based, or a combination of these maintenance methods), maintenance activities, maintenance intervals, and, for component types that use monitoring to extend the intervals, the appropriate monitoring attributes as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses a performance-based maintenance program shall have evidence that its current performance-based maintenance program is in accordance with Requirement R2, which may include but is not limited to equipment lists, dated maintenance records, and dated analysis records and results.

M3. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has implemented the Protection System Maintenance Program and initiated resolution of unresolved maintenance issues in accordance with Requirement R3, which may include but is not limited to dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits
Self-Certifications
Spot Checking
Compliance Violation Investigations
Self-Reporting
Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to demonstrate compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program including the documentation that specifies the type of maintenance program applied for each Protection System component type.

For Requirement R2 and Requirement R3, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the two most recent performances of each distinct maintenance activity for the Protection System **components**, or all performances of each distinct maintenance activity for the Protection System component since the previous scheduled audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

> **Component** – *A component is any individual discrete piece of equipment included in a Protection System, including but not limited to a protective relay or current sensing device. The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.*

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The responsible entity's PSMP failed to specify whether one component type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address one component type included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to specify whether two component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2)	The responsible entity's PSMP failed to address two component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity's PSMP failed to include station batteries in a time-based program (Part 1.2) OR The responsible entity failed to include all maintenance activities or intervals relevant for the identified monitoring attributes specified in Tables 1-1 through 1-5, Table 2, and Table 3. (Part 1.3 and 1.4)	The responsible entity has not established a PSMP. OR The responsible entity's PSMP failed to address three or more component types included in the definition of 'Protection System' (Part 1.1) OR The responsible entity failed to specify whether three or more component types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.2).
R2	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to reduce countable events to less than 4% within three years. OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment.	NA	The responsible entity uses performance-based maintenance intervals in its PSMP but has failed to reduce countable events to less than 4% within four years.	The responsible entity uses performance-based maintenance intervals in its PSMP but has: 1) Failed to establish the entire technical justification described within R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce countable events to less than 4% within five years OR 3) Failed to annually document program activities, results, maintenance dates, or countable

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				events for over 5% of components in any individual segment OR 4) Maintained a segment with less than 60 components OR 5) Failed to: • Annually update the list of components, OR • Perform maintenance on the greater of 5% of the segment population or 3 components, OR • Annually analyze the program activities and results for each segment.
R3	The responsible entity has failed to implement and follow scheduled program on 5% or less of total Protection System components. OR The responsible entity has failed to initiate resolution on 5% or less of unresolved maintenance issues.	The responsible entity has failed to implement and follow scheduled program on greater than 5%, but no more than 10% of total Protection System components. OR The responsible entity has failed to initiate resolution on greater than 5%, but less than or equal to 10% of unresolved maintenance issues.	The responsible entity has failed to implement and follow scheduled program on greater than 10%, but no more than 15% of total Protection System components. OR The responsible entity has failed to initiate resolution on greater than 10%, but less than or equal to 15% of unresolved maintenance issues.	The responsible entity has failed to implement and follow scheduled program on greater than 15% of total Protection System components. OR The responsible entity has failed to initiate resolution on greater than 15% of unresolved maintenance issues.

E. Regional Variances

None

F. Supplemental Reference Document

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program..

1. PRC-005-2 Protection System Maintenance Supplementary Reference and FAQ — July 2011.

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[1]	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[1] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) • Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2
Component Type - Communications Systems
Excluding distributed UFLS and UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 calendar months	Verify that the communications system is functional.
	6 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.

Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function. (See Table 2)	12 calendar years	Verify that the channel meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify essential signals to and from other Protection System components.
Any communications system with continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2)	No periodic maintenance specified	None.

Table 1-3
Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays
Excluding distributed UFLS and UVLS (see Table 3)

Component Attributes	Maximum Maintenance Interval	Maintenance Activities
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 calendar years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent ac measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station dc Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply using **Vented Lead-Acid (VLA) batteries** not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UVLS systems are excluded (see Table 1-4(e)).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station dc Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **with Valve Regulated Lead-Acid (VRLA) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. -or- Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank

Table 1-4(c) Component Type – Protection System Station dc Supply Using Nickel-Cadmium (NiCad) Batteries Excluding UFLS and non-distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station dc supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f). Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack
	6 Calendar Years	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station dc Supply Using Non Battery Based Energy Storage Excluding UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station dc supply not using a battery and not having monitoring attributes of Table 1-4(f). Protection System Station dc supply for non-BES interrupting devices for SPS or non-distributed UFLS and UVLS systems are excluded (see Table 1-4(e)).	4 Calendar Months	Verify: • Station dc supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based dc supply
	6 Calendar Years	Verify that the dc supply can perform as designed when ac power is not present.

Table 1-4(e) Component Type – Protection System Station dc Supply for non-BES Interrupting Device for SPS and non-distributed UVLS and UFLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System dc supply for tripping only non-BES interrupting devices as part of a SPS or non-distributed UVLS and UFLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station dc supply voltage

Table 1-4(f) Exclusions for Protection System Station dc Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station dc supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure. (See Table 2)	No periodic maintenance specified	No periodic verification of station dc supply voltage is required.
Any battery based station dc supply with electrolyte level monitoring and alarming in every cell (See Table 2)		No periodic inspection of the electrolyte level for each cell is required.
Any station dc supply with unintentional dc ground monitoring and alarming (See Table 2)		No periodic inspection of unintentional dc grounds is required.
Any station dc supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station dc supply (See Table 2)		No periodic verification of float voltage of battery charger is required
Any battery based station dc supply with monitoring and alarming of battery string continuity (See Table 2)		No periodic verification of the battery continuity is required.
Any battery based station dc supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2)		No periodic verification of the intercell and terminal connection resistance is required.
Any lead acid battery based station dc supply with internal ohmic value monitoring, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2)		.No periodic measurement and evaluation relative to baseline of battery cell/unit internal ohmic values is required to verify the station battery can perform as designed .
Any Valve Regulated Lead-Acid (VRLA) station battery with monitoring and alarming of each cell/unit internal Ohmic value. (See Table 2)		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and UVLS (see Table 3) **Note:** Table requirements apply to all Control Circuitry components of Protection Systems, and SPSs except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices	6 calendar years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Unmonitored control circuitry associated with SPS	12 calendar years	Verify all paths of the control circuits essential for proper operation of the SPS.
Electromechanical lockout and/or tripping auxiliary devices which are directly in a trip path from the protective relay to the interrupting device trip coil.	6 calendar years	Verify electrical operation of electromechanical trip and auxiliary devices.
Unmonitored control circuitry associated with protective functions.	12 calendar years	Verify all paths of the trip circuits through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry whose continuity and energization or ability to operate are monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of DETECTION to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 calendar years	Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 calendar years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ac measurement source, with alarming for excessive error. (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure. (See Table 2) Alarming for change of settings. (See Table 2)	12 calendar years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 calendar years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System dc supply for tripping only non-BES interrupting devices as part of a UFLS or UVLS system.	12 calendar years	Verify Protection System dc supply voltage
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices.	12 calendar years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems.	12 calendar years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices.	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population, with a minimum **segment** population of 60 components.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5 and Table 3 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences **countable events** on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

> **Segment** – *Protection Systems or components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

> **Countable Event** – *A component which has failed and requires repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5 and Table 3 which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are not included in Countable Events.*

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.

4. Using the prior year’s data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.
5. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves ~~SAR for~~ posting SAR and draft standard on ~~June 5, 2007~~August 11, 2011.
2. ~~The SAR was posted for comment from June 11, 2007 July 10, 2007.~~
3. ~~The SC approves development of the standard on August 13, 2007.~~
4. ~~First posting of revised standard on July 24, 2009.~~
5. ~~Second posting of revised standard on June 11, 2010~~
6. ~~Third posting of revised standard on November 17, 2010~~
7. ~~Fourth posting of revised standard on April 13, 2011~~

Description of Current Draft:
This is the ~~fifth~~ first draft of the Standard. This standard merges previous standards PRC-005-1, PRC-005-1a, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined ~~30~~45-day comment and ballot.	~~July~~ September ~~5~~ – ~~August~~ October4, 2011
2. Conduct ~~successive~~ initial ballot	~~July~~ October26 ~~– August 4~~, 2011
3. Drafting Team Responds to Comments	~~August~~ November4 – Dec~~Sept~~ember ~~6~~, 2011

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verify — Determine that the component is functioning correctly.
- Monitor — Observe the routine in-service operation of the component.
- Test — Apply signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Detect visible signs of component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Protection System (NERC Board of Trustees Approved Definition)

- Protective relays which respond to electrical quantities,
- ~~communications~~ Communications systems necessary for correct operation of protective functions,
- ~~voltage~~ Voltage and current sensing devices providing inputs to protective relays,
- ~~station~~ Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- ~~control~~ Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The following terms are defined for use only within PRC-005-2, and should remain with the standard upon approval rather than being moved to the Glossary of Terms.

~~Maintenance Correctable~~Unresolved Maintenance Issue – ~~Failure of a component to operate within design parameters such that the~~A deficiency that cannot be corrected during the performance of the maintenance activity~~. Therefore this issue~~ and requires follow-up corrective action.

Segment – Protection Systems or components -of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.

Component Type - Any one of the five specific elements of the Protection System definition.
