The SPCTF sees the parallel intent for each of the PRC-005, PRC-008, PRC-011, and PRC-017 as being maintenance and testing standards for different protective systems. In fact, PRC-005 & PRC-008, and PRC-011 & PRC-017 have very similar format respectively. Since all protective relay systems require some means of maintenance and testing, it would seem that all protective system maintenance and testing could be included in one standard regardless of scheme type. The SPCTF recommends that these four standards be reduced to one standard covering the issues detailed for PRC-005 on maintenance and testing.

These four standards were developed primarily by translating the requirements of an earlier Phase I Planning Standard; thus they have not been previously subjected to a critical review of the Requirements.

Executive Summary

Reliability standards PRC-005, 008, 011, and 017 are intended to assure that Transmission & Generation Protection Systems are maintained and tested so as to provide reliable performance when responding to abnormal system conditions. It is the responsibility of the Transmission Owner, Generation Owner, and Distribution Provider to ensure the Transmission & Generation Protection Systems are maintained and tested in such a manner that the protective systems operate to fulfill their function.

Only PRC-005 will be commented on in detail although the other three standards have the same concerns.

SPCTF concluded that:

- Applicable to all four standards — The listed requirements do not provide clear and sufficient guidance concerning the maintenance and testing of the Protection Systems to achieve the commonly stated purpose which is "To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested."
- Applicable to PRC-017 — Part of the stated purpose in PRC-017 states: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is, the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard.
- Applicable to all four standards — The standards should clearly state which power system elements are being addressed.
- Applicable to all four standards — The requirements should reflect the inherent differences between different technologies of protection systems.

- Applicable to all four standards — The terms maintenance programs and testing programs should be clearly defined in the glossary. The terms "maintenance" and "testing" are not interchangeable, and the requirements must be clear in their application. Additional terms may also have to be added to the glossary for clarity.
- Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The R1.2 summary of maintenance and testing procedures needs to have some minimum defined sub-requirements to insure that the stated intent of the standards is met to support review by the compliance monitor.

Assessment of PRC-005-1

Purpose

To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

A review of PRC-005 indicates that this standard is intended to assure that all affected entities have adequate maintenance and testing programs for their Protection Systems to ensure reliability. SPCTF agrees with the Purpose statement of PRC-005-1.

General Comments

The SPCTF offers the following general comments:

- None of the requirements within PRC-005-1 specifically indicate what minimum attributes should be included in protective system maintenance and testing procedures.
- For interval-based procedures, no allowable maximum interval is prescribed.
- None of the requirements in the existing PRC-005-1 reflect condition-based or performance-based maintenance and testing criteria.

Standard PRC-005 should clarify that two goals are being covered:

- The maintenance portion should have requirements that keep the protection system equipment operating within manufacturers' design specification throughout the service life.
- The testing portion should have requirements that verify that the functional performance of the protection systems is consistent with the design intent throughout the service life.

Applicability

4.1. Transmission Owners

4.2. Generation Owners

4.3. Distribution Providers that owns a transmission Protection System

Applicability 4.3 suggests that the definition of a Protection System in the Glossary of Terms should clarify how a Distribution Provider may be the owner of a transmission Protection System.

Requirements

R1

R1. Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall have a Protection System maintenance and testing program for Protection Systems that affect the reliability of the BES. The program shall include:

R1.1. Maintenance and testing intervals and their basis.

R1.2. Summary of maintenance and testing procedures.

The following clarifications should be made to Requirement R1:

1. How is the phrase "that affect the reliability of the BES" to be interpreted? The standard should clearly specify which Protection Systems are subject to the requirements.
2. The standard should clearly specify which components of the Generation Protection System are subject to the requirements.

The following clarifications should be made to Subparts R1.1 & R1.2:

1. Interval-based, condition-based, or performance-based maintenance and testing minimum criteria should be established within R1.1, including, but not limited to the following:
   a. For time-based maintenance and testing programs, maximum maintenance intervals should be specified.
   b. For condition-based or performance-based maintenance and testing programs, the program should have sufficient justification and documentation.
2. Definitions should be established for the terms "maintenance programs" and "testing programs."
3. A minimum set of attributes to be included in maintenance and testing programs should be established within R1.2.

R2

> **R2.** Each Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generator Owner that owns a generation Protection System shall provide documentation of its Protection System maintenance and testing program and the implementation of that program to its Regional Reliability Organization on request (within 30 calendar days). The documentation of the program implementation shall include:
>
> **R2.1.** Evidence Protection System devices were maintained and tested within the defined intervals.
>
> **R2.2.** Date each Protection System device was last tested/maintained

The following clarification should be made to requirement R2:

- The appropriate entity should have their Protection System maintenance program and testing program and associated documentation, including maintenance records and testing records, available to its Regional Reliability Organization and NERC during audits or upon request within 30 days.

FERC Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

In the October 20, 2006 Notice of Proposed Rulemaking for adoption of NERC Standards (Docket Number RM06-16-000), the Federal Energy Regulatory Commission commented on these four standards and proposed changes. The observations and proposals are excerpted from the NOPR and included below.

PRC-005-1

> The Commission proposes to approve PRC-005-1 as mandatory and enforceable. In addition, we propose to direct that NERC develop modifications to the Reliability Standard as discussed below.
>
> Proposed Reliability Standard PRC-005-1 does not specify the criteria to determine the appropriate maintenance intervals, nor do it specify maximum allowable maintenance intervals for the protections systems. The Commission therefore proposes that NERC include a requirement that maintenance and testing of these protection systems must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-005-1 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System.

PRC-008-0

The Commission notes that the commenters generally share staff's concern that the proposed Reliability Standard does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protection systems. The Commission agrees and proposes to require NERC to modify the proposed Reliability Standard to include a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of relay used and the impact on the reliability of the Bulk-Power System.

Accordingly, the Commission proposes to approve Reliability Standard PRC-008-0 as mandatory and enforceable. In addition, the Commission proposes to direct that NERC submit a modification to PRC-008-0 that includes a requirement that maintenance and testing of UFLS programs must be carried out within a maximum allowable interval appropriate to the relay type and the potential impact on the Bulk-Power System.

PRC-011-0

PRC-011-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes that NERC include a Requirement that maintenance and testing of these UFLS programs must be carried out within a maximum allowable interval that is appropriate to the type of the relay used and the impact of these UFLS on the reliability of the Bulk-Power System.

The Commission believes that Reliability Standard PRC-011-0 serves an important purpose in requiring transmission owners and distribution providers to implement their UVLS equipment maintenance and testing programs. Further, the proposed Requirements are sufficiently clear and objective to provide guidance for compliance.

Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-011-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-011-0 that includes a requirement that maintenance and testing of UVLS programs must be carried out within a maximum allowable interval appropriate to the applicable relay and the impact on the reliability of the Bulk-Power System.

PRC-017-0

> PRC-017-0 does not specify the criteria to determine the appropriate maintenance intervals, nor does it specify maximum allowable maintenance intervals for the protections systems. The Commission proposes to require NERC to include a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used and the impact of these special protection system programs on the reliability of the Bulk-Power System.
>
> Accordingly, giving due weight to the technical expertise of the ERO and with the expectation that the Reliability Standard will accomplish the purpose represented to the Commission by the ERO and that it will improve the reliability of the nation's Bulk-Power System, the Commission proposes to approve Reliability Standard PRC-017-0 as mandatory and enforceable. In addition, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission proposes to direct that NERC submit a modification to PRC-017-0 that: (1) includes a requirement that maintenance and testing of these special protection system programs must be carried out within a maximum allowable interval that is appropriate to the type of relaying used; and (2) identifies the impact of these special protection system programs on the reliability of the Bulk-Power System.

Other Activities Related to PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0

These four Standards are contained in several projects and draft SARs as part of the "Draft Reliability Standards Development Plan: 2007–2009", which was approved by the NERC Board of Trustees.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the Standards Development Plan, and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

Conclusions and Recommendations

PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 require additions, clarifications, and definitions to insure that the Protection Systems are properly maintained and tested.

The SPCTF recommends that standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 be removed from the separate SARS in the "Draft Reliability Standards Development Plan: 2007–2009," and that they be included in a new Standard Authorization Request for a single Protection System maintenance and testing standard.

SPCTF submits the attached SAR for that purpose of consolidating PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 into a single standard to the Planning Committee for endorsement.

June 11, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Comment Periods Open

The Standards Committee (SC) announces the following standards actions:

SAR for System Protection Coordination (Project 2007-06) Posted for 30-day Comment Period June 11–July 10, 2007

The SAR for Project 2007-06 — System Protection Coordination proposes to address the FERC directives in Order 693 and to address a number of technical shortcomings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines."

The purpose of the proposed standard is to assure that protection system application and performance issues are coordinated among all related entities. Please use this comment form to submit comments on this SAR.

SAR for Protection System Maintenance & Testing (Project 2007-17) Posted for 30-day Comment Period June 11–July 10, 2007

This SAR for Project 2007-17 — Protection System Maintenance and Testing proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical shortcomings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines."

The purpose of the proposed standard is to ensure all transmission and generation protection systems affecting the reliability of the bulk power system are maintained and tested to support reliable operation performance when responding to abnormal system conditions. Please use this comment form to submit comments on this SAR.

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☐ Yes

   ☒ No

   Comments: AEP has not had an event, due to deficiencies in protection maintenance, in it's long existence that jeopardized the reliability or availability of Bulk Power transfers. Simply combining multiple standards into one, does nothing for improving reliability.

2. Do you agree with the proposed scope of this SAR?

   ☐ Yes

   ☒ No

   Comments: On the surface, the premise of reducing costs and improving efficiencies by combining multiple standards sounds excellent. Having to only keep up with one standard instead of four will not generate significant savings due to the fact that the maintenance will still have to be performed. But what lies hidden, is the fact that prescribed maximum allowable maintenance intervals will result from the revisions. They may require more frequent testing to be performed. Is there evidence that increasing the interval frequency results in a measurable increase in reliability and availability? Development of prescribed maximum intervals that are vastly different than the utility's existing practices may actual increase their O&M costs and reduce efficiencies.

   The function of the protective system needs to be taken into account. The purpose of the line protection is very different than the purpose of UFLS/UVLS and SPS's. The UFLS program is there as the last line of defense against a decaying system after all other measures have failed. The combination of all the different relaying systems places them on equal ground. Shouldn't the reliability and dependablilty for one be more important than the others?

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☐ No

   Comments:

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

Regional Variance: None
Comments: None

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice: Possibly
   Comments: AEP and other utilities, with many years of experience serving customers and supporting the electric grid, have voluntarily integrated maintenance and testing programs into the core of their work practices and processes. AEP fully supports improvements if they truly foster reliability and availability benefits to bulk power transfers. More Standards, Requirements and Business Practices are not always better. If Standards create burdens on a utility's physical resources and budgets, then some mechanism must be available to allow for the needed changes.

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: The standard should not use the term Bulk Electric System, but should instead specify a voltage threshold for impacts to bulk system transfers - specifically; 'Facilites operated 200 kV and above and Regionally-defined, Operationally Significant facilities operated greater than 100 kv, but less than 199 kV'. The term 'affects' also needs to be clarified. Inclusion of all facilities greater than 100 kV does not benefit the reliability of national bulk power transfers. For example, the loss or misoperation of a 138 kV line serving a localized load center would not be detremental to bulk power transfers multiple busses away.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**.    Business Practice:
   Comments:

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: In the "Detailed Description" section of the SAR, it states:
   "Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003

and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard."

The analysis of SPS misoperations is handled in PRC-016 (SPS Misoperations) and PRC 012 (SPS review Procedure) not in PRC-003 or PRC-004. Therefore, if the phrase is removed from PRC-017, it does not need to be added to PRC-003 or PRC-004.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. Background Information

This SAR proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical short comings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines." The goal is to provide a set of requirements that will support reliable performance when responding to abnormal system conditions.

Please review the SAR and then answer the questions on the following page. Please e-mail your comments on this form to sarcomm@nerc.net with the subject "Protection Maintenance SAR" by **July 10, 2007**.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☐ No

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☐ Yes

   ☒ No

   Comments: Combining PRC-005, 008, 011 and 017 into one new standard does not seem to be the best approach. Duke Energy does not have UVLS systems or Special Protection Systems. Furthermore, Duke Energy's Underfrequency Load Shedding system is on the transmission system in the Carolinas, but on the distribution system in the Midwest. Combining these standards would likely create confusion and compliance issues for us and others as well. Also, combining the standards is unlikely to result in simplification, as different requirements associated with the different protection systems could have different Violation Risk Factors and levels of non-compliance, which would necessitate keeping them separate in the combined standard, which would defeat the purpose of combining them in the first place.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

Background Information

This SAR proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical short comings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines." The goal is to provide a set of requirements that will support reliable performance when responding to abnormal system conditions.

Please review the SAR and then answer the questions on the following page. Please e-mail your comments on this form to sarcomm@nerc.net with the subject "Protection Maintenance SAR" by **July 10, 2007**.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments: Bullet #5 of the "Detailed Description" on page SAR-2 indicates the following:

   "Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor."

   FE supports the scope of the SAR to consider adding the ability for condition-based and performanced based testing, as suggested by the System Protection and Control Task Force. Additionally, the SDT should consider the need to perform some level of preventative maintenance on a periodic basis at an established maximum interval length, that would vary per the equipment being maintained. The interval established would be based on established guidelines from vendors, EPRI, industry experts, etc.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☐ No

   Comments: The inclusion of the Distribution Provider is generally needed for UFLS and UVLS relays. The confusion that previously existed in PRC-005 by including the DP entity should be mitigated by the proposed consolidation of the four maintenance standards.

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

☒ Yes

☐ No

Comments: Centralizing System Protection equipment maintenance and testing requirements in a single standard will add clarity, minimize synchronization issues across standards, help provide consistent terminology and improve understanding of system protection standards.

2. Do you agree with the proposed scope of this SAR?

☒ Yes

☒ No

Comments: Use of subject matter experts (NERC SPCTF) along with the NERC Planning Committee review of the assessment is an effective and efficient way to supplement project SARs and provides critical input at the front-end of the standards process.

Attachment A is described as the SPCTF assessment, but attachment A to the SAR is the SPCTF roster. The assessment referenced in the scope of the SAR should include "Draft 1.0" if the full assessment is not included as part of the SAR.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

☐ Yes

☐ No

Comments: This question may be better addressed as the standards are integrated.

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

Regional Variance:
Comments:

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

Business Practice:

Comments:

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: There are many standards being addressed (Disturbance Monitoring, System Protection Coordination, Reliability Coordination, along with Regional standard developments). As these standards are integrated into PRC-005, the existing and new terminology should be consistently applied in all system protection standards (with respect to defined terms). Where terms are undefined or being revised, the drafting team should carefully consider the terms used to ensure coordination of revised or new definitions with other Reliability standards or flag conflicts within the implementation plan.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☒ No

   Comments: Each requirement needs to specifically address what protection systems need to comply with the standard - i.e. a generator not connected to the BPS with under frequency trip relay should only be subject to under frequency relay maintenance requirements

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

   Regional Variance: None
   Comments:

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice:
   Comments: none that we know of

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: Due consideration should be given to potential difficulties in obtaining required outages. System reliability concerns may preclude performing maintenance at the intervals required. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided, with "appropriate" approvals, for delays in the testing process.

There is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes (“GPS”) that would be subject to this Standard – i.e., what subset of GPS are critical to bulk power system operation, as distinct from generator operation. For example, typically there is no single generating unit that would, if a contingency event occurs on that generating unit, result in significant adverse impacts outside of the local area in which the single generating unit is located. As a result, if these NERC Standards are to apply to all NERC-registered Generators, only a subset of the GPS need to be subjected to the maintenance testing intervals.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "Protection Maintenance" in the subject line.    Regional Variance:
   Comments:

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice:
   Comments:

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments:

   1. The IESO commends NERC, the SDT and the SPCTF for providing clarity and for efforts to reduce the costs of compliance.

2 In the Standard PRC-008-0, Generation Owners were not included in the applicable entities. Generation Owners may have underfrequency tripping devices for protection of their units. Hence, it would be appropriate to include these devices for maintenance and testing requirements also.

3. There is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes ("GPS") that are critical to bulk power system operation, as distinct from generator operation. For example, a single generating unit may experience contingency events that would not result in any significant adverse impacts outside the local area in which the single generating unit is located. As a result, there remains a need to subject those GPSs that are important to the Bulk Power System, such as generator underfrequency trip settings, to the maintenance testing intervals to be derived in these standards.

4. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided for delays in the testing process.

5. However, the SAR team needs to also consider, as part of its scope, assurance that the asset owner has taken all appropriate steps to ensure that required outages are appropriately planned, can be reasonably accommodated, and approved by the TOP or RC.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☐ Yes

   ☒ No

   Comments: There is a need to better define and explain the terms "maintenance" and "testing" as they relate to this standard. Also a tighter definition as to which systems are considered to affect the BES is required. The need to improve the standard is driven by the administration of the standard rather than reliability.

2. Do you agree with the proposed scope of this SAR?

   ☐ Yes

   ☒ No

   Comments: We disagree that there is a need to change the standard to include more specificity for maintenance and test procedures. We also disagree with mandating minimum maintenance intervals for protection system equipment.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☐ Yes

   ☐ No

   Comments:

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

   Regional Variance:
   Comments:

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice:
   Comments:

6. If you have any other comments on this SAR that you haven’t provided above, please provide them here.

Comments: Manitoba Hydro takes exception to the prescriptive nature of the proposed changes to the maintenace procedures and maintenance intervals. The type of maintenance performed and the minimum maintenance intervals should be determined by the utility within the operating context of the protection system. There is no need for the standard to reflect the inherent difference between various protection system technologies as the utility would account for differences within their stated maintenance practices.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "Protection Maintenance" in the subject line. If you have questions please contact Al Calafiore at al.calafiore@nerc.net or by telephone at 609-452-8060.

Background Information

This SAR proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical short comings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines." The goal is to provide a set of requirements that will support reliable performance when responding to abnormal system conditions.

Please review the SAR and then answer the questions on the following page. Please e-mail your comments on this form to sarcomm@nerc.net with the subject "Protection Maintenance SAR" by **July 10, 2007**.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☐ Yes

   ☒ No

   Comments: FERC Order 693 in both paragraph 1466 and in footnote 384, indicates that in some areas of the country, Load Serving Entities (LSE) and Transmission Operators (TOP) may individually or jointly own and operate a protection system. Thus, these additional entities should be subject to the resulting consolidated standard. The MRO believes that the following caveat should be added to the LSE where it is listed as an Applicable Entity, (where operation of the protection system can affect the Bulk Electric System).
   2. The MRO requests that the SDT review whether or not the Reliability Coordinator (RC) should be added to the list of Applicable Entities given their wide area view-for example, the RC may need to be involved in determining which protection systems below 100kV will affect the BES.

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

   Regional Variance: None
   Comments:

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice: None

Comments:

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

Comments:
1. The MRO commends NERC and the SDT for taking steps to remove some of the redundancy that currently exists among many of the standards today. The consolidation of the protection system maintenance and testing standards is a good first step.
2. The MRO requests that the following be considered during the initial drafting of the Requirements for this new protection and maintenance standard. A minimum set of evidence to be included in a maintenance and testing program should be established in the measures for R1.2.
3. In the SPCTF Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0, the clarification for R2 states that documentation is available to its Regional Reliability Organization and NERC during audits or upon request within 30 days but paragraph 1545 of FERC Order 693 states "be routinely provided to the ERO or Regional Entity and not only when it is requested." The MRO believes that the FERC request would be satisfied if the standard were to state: "the applicable entities shall provide testing records to the Regional Entity on a periodic basis e.g. (annually).
4. In the event that the SAR DT does not become the SDT, the MRO requests that these comments be forwarded on to the group that will do tha actual drafting of the Standard.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "Protection Maintenance" in the subject line. If you have questions please contact Al Calafiore at al.calafiore@nerc.net or by telephone at 609-452-8060.

Background Information

This SAR proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical short comings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines." The goal is to provide a set of requirements that will support reliable performance when responding to abnormal system conditions.

Please review the SAR and then answer the questions on the following page. Please e-mail your comments on this form to sarcomm@nerc.net with the subject "Protection Maintenance SAR" by **July 10, 2007**.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☒ No

   Comments: Each requirement needs to specifically address what protection systems need to comply with the standard - i.e. a generator not connected to the BPS with under frequency trip relay should only be subject to under frequency relay maintenance requirements

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

   Regional Variance: None
   Comments: Certain unavoidable delays like the inability to schedule outages for reliability reasons or labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude, with the "appropriate approvals", needs to be provided for delays in the testing process.

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

   Business Practice:
   Comments: none that we know of

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: Due consideration should be given to potential difficulties in obtaining required outages. System reliability concerns may preclude performing maintenance at the intervals required. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided, with "appropriate" approvals, for delays in the testing process.

   There is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes ("GPS") that would be subject to this Standard – i.e., what subset of GPS are critical to bulk power system operation, as distinct from generator operation. For example, typically there is no single generating unit that would, if a contingency event occurs on that generating unit, result in significant adverse impacts outside of the local area in which the single generating unit is located. As a result, if these NERC Standards are to apply to all NERC-registered Generators, only a subset of the GPS need to be subjected to the maintenance testing intervals.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "Protection Maintenance" in the subject line. If you have questions please contact Al Calafiore at al.calafiore@nerc.net or by telephone at 609-452-8060.

Background Information

This SAR proposes to merge the requirements from the following standards into a single standard to reduce the costs of compliance while also improving efficiencies:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The SAR also proposes to address the FERC directives in Order 693 and to address a number of technical short comings identified by stakeholders and the System Protection and Control Task Force and to bring the standard into conformance with the "Standard Review Guidelines." The goal is to provide a set of requirements that will support reliable performance when responding to abnormal system conditions.

Please review the SAR and then answer the questions on the following page. Please e-mail your comments on this form to sarcomm@nerc.net with the subject "Protection Maintenance SAR" by **July 10, 2007**.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the proposed scope of this SAR?

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

   ☒ Yes

   ☐ No

   Comments:

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments: In the SAR you state "The revised PRC-005 standard should address the issues raised in the FERC Order 693". With the exception of mentioning the consolidation of the standards into one standard, the SAR drafting team didn't provide readers with the exact language from FERC that would be useful to know with respect to PRC-005 in the directive below:

The Commission directs the ERO to develop a modification to PRC-005-1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System. We further direct the ERO to consider FirstEnergy's and ISO-NE's suggestion to combine PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0 into a single Reliability Standard through the Reliability Standards development process.

Please use this form to submit comments on the proposed SAR for Project 2007-17 — Protection System Maintenance and Testing. Comments must be submitted by **July 10, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words "Protection Maintenance" in the subject line. If you have questions please contact Al Calafiore at al.calafiore@nerc.net or by telephone at 609-452-8060.

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

   Comments:

   1. The SRC commends NERC, the SDT and the SPCTF for providing clarity and for efforts to reduce the costs of compliance.

2 In the Standard PRC-008-0, Generation Owners were not included in the applicable entities. Generation Owners may have underfrequency tripping devices for protection of their units. It would be appropriate to include these devices for maintenance and testing requirements also.

3. Further, there is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes ("GPS") that are critical to bulk power system operation, as distinct from generator operation. For example, a single generating unit may experience contingency events that would not result in any significant adverse impacts outside the local area in which the single generating unit is located. As a result, there remains a need to subject those GPSs that are important to the Bulk Power System, such as generator underfrequency trip settings, to the maintenance testing intervals to be derived in these standards.

4. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided for delays in the testing process.

5. However, the SAR team needs to also consider,as part of its scope, assurance that the asset owner has taken all appropriate steps to assure that required outages are appropriately planned and can be reasonably accommodated and approved by the TOP or RC.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to improve the requirements in this set of standards?

☒ Yes

☐ No

Comments: This SAR proposes to revise several standards to eliminate ambiguities and to provide requirements that are measurable. In addition, the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" indicates the need to differentiate between the different technologies used and insure the standard applies to all in the appropriate way (i.e. electromechanicals, microprocessor-based, solid-state). Southwest Transmission Cooperative, Inc. also recognizes this deficit in the existing standards.

2. Do you agree with the proposed scope of this SAR?

☒ Yes

☐ No

Comments: Since most protection schemes are maintained and tested in a similar manner regardless of scheme type, we agree that combining the (4) PRC standards related to maintenance and testing of different types of systems into one standard will create a that is more streamlined and less burdensome standard with easily understood measurable compliance elements.

The most exciting part of the proposed modifications is the inclusion of condition-based and performance-based maintenance and testing and not just time-based criteria. Presently Southwest Transmission Cooperative, Inc. uses this type of maintenance and testing criteria (maintenance data server) which is the current system protection industry technology.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

☒ Yes

☐ No

Consideration of Comments on 1st Draft of Protection System Maintenance and Testing SAR (Project 2007-17)

The Protection System Maintenance and Testing SAR requesters thank all commenters who submitted comments on the first draft of SAR. This SAR was posted for a 30-day public comment period from June 11 through July 10, 2007. The requesters asked stakeholders to provide feedback on the standard through a special SAR Comment Form. There were 18 sets of comments, including comments from 85 different people from more than 50 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

The SAR drafting team made no changes to the SAR based on stakeholder comments.

Based on the comments received, the drafting team is recommending that the Standards Committee authorize moving the SAR forward to the standard drafting stage of the standards development process.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

http://www.nerc.com/~filez/standards/Protection_System_Maintenance_Project_2007-17.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 – Regional Reliability Organizations, Regional Entities

Index to Questions, Comments, and Responses

1. Do you agree that there is a reliability-related need to improve the requirements in this standard?

Summary Consideration: Most commentators indicated they do believe there is a reliability-related need to improve the requirements in this set of standards.

Question #1			
Commenter	**Yes**	**No**	**Comment**
AEP		☑	AEP has not had an event, due to deficiencies in protection maintenance, in it's long existence that jeopardized the reliability or availability of Bulk Power transfers. Simply combining multiple standards into one, does nothing for improving reliability.
Response: The proposed changes will improve clarity which should benefit reliability. While AEP may have an excellent record of maintenance, the existing standards are quite vague and allow an entity that performs maintenance once every 100 years to be fully compliant.			
Manitoba Hydro		☑	There is a need to better define and explain the terms "maintenance" and "testing" as they relate to this standard. Also a tighter definition as to which systems are considered to affect the BES is required. The need to improve the standard is driven by the administration of the standard rather than reliability.
Response: As envisioned, the SDT will work with stake holders to define the terms 'maintenance' and 'testing.' The SAR DT disagrees that the standard changes are driven by "administration". The existing requirements are vague enough to allow an entity to perform maintenance once every 100 years and still be compliant.			
SWTC	☑		This SAR proposes to revise several standards to eliminate ambiguities and to provide requirements that are measurable. In addition, the SPCTF report "Assessment of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing; with implications for PRC-008-0, PRC-011-0, and PRC-017-0" indicates the need to differentiate between the different technologies used and insure the standard applies to all in the appropriate way (i.e. electro-mechanicals, microprocessor-based, solid-state). Southwest Transmission Cooperative, Inc. also recognizes this deficit in the existing standards.
Response: The SAR DT agrees and appreciates your support.			
SERC EC PCS	☑		Consolidation of the maintenance and testing standards is appropriate. Separate definitions for maintenance and testing are needed.
Response: The SAR DT agrees and appreciates your support.			
FRCC	☑		Centralizing System Protection equipment maintenance and testing requirements in a single standard will add clarity, minimize synchronization issues across standards, help provide consistent terminology and improve understanding of system protection standards.
Response: The SAR DT agrees and appreciates your support.			

Question #1			
Commenter	**Yes**	**No**	**Comment**
PSC SC	☑		
BPA	☑		
Consumers Energy	☑		
IESO	☑		
SRP	☑		
SOCO Transmission	☑		
NPCC CP9 RSWG	☑		
MRO	☑		
IRC	☑		
FirstEnergy	☑		
HQT	☑		
Pepco Holdings	☑		
Duke Energy	☑		

2. Do you agree with the proposed scope of this SAR?

Summary Consideration: Some entities objected to the use of 'maximum allowable intervals,' however, FERC has ordered that maximum allowable intervals be developed. No changes to the SAR were made in response to these comments.

Question #2			
Commenter	**Yes**	**No**	**Comment**
AEP		☑	On the surface, the premise of reducing costs and improving efficiencies by combining multiple standards sounds excellent. Having to only keep up with one standard instead of four will not generate significant savings due to the fact that the maintenance will still have to be performed. But what lies hidden, is the fact that prescribed maximum allowable maintenance intervals will result from the revisions. They may require more frequent testing to be performed. Is there evidence that increasing the interval frequency results in a measurable increase in reliability and availability? Development of prescribed maximum intervals that are vastly different than the utility's existing practices may actual increase their O&M costs and reduce efficiencies. The function of the protective system needs to be taken into account. The purpose of the line protection is very different than the purpose of UFLS/UVLS and SPS's. The UFLS program is there as the last line of defense against a decaying system after all other measures have failed. The combination of all the different relaying systems places them on equal ground. Shouldn't the reliability and dependability for one be more important than the others?
Response: In order to develop a measurable standard and conform to the direction from FERC regarding allowable maintenance intervals, the SDT, working with stakeholders, will develop requirements for maximum allowable maintenance intervals for protection systems. Combining these 4 standards into 1 does not preclude the SDT from developing different criteria for different types of protection systems. Your concerns regarding the different purposes of protection systems and your question regarding varying importance of different protection systems will be forwarded to the SDT.			
Manitoba Hydro		☑	We disagree that there is a need to change the standard to include more specificity for maintenance and test procedures. We also disagree with mandating minimum maintenance intervals for protection system equipment.
Response: FERC has directed NERC as the ERO to specify maximum allowable maintenance intervals.			
Duke Energy		☑	Combining PRC-005, 008, 011 and 017 into one new standard does not seem to be the best approach. Duke Energy does not have UVLS systems or Special Protection Systems. Furthermore, Duke Energy's Underfrequency Load Shedding system is on the transmission system in the Carolinas, but on the distribution system in the Midwest.

Question #2			
Commenter	**Yes**	**No**	**Comment**
			Combining these standards would likely create confusion and compliance issues for us and others as well. Also, combining the standards is unlikely to result in simplification, as different requirements associated with the different protection systems could have different Violation Risk Factors and levels of non-compliance, which would necessitate keeping them separate in the combined standard, which would defeat the purpose of combining them in the first place.
Response: Combining these 4 standards into 1 does not preclude the SDT from developing different criteria for different types of protection systems (concerns about different voltage levels remain regardless if there is one standard or more than one).			
SWTC	☑		Since most protection schemes are maintained and tested in a similar manner regardless of scheme type, we agree that combining the (4) PRC standards related to maintenance and testing of different types of systems into one standard will create a that is more streamlined and less burdensome standard with easily understood measurable compliance elements. The most exciting part of the proposed modifications is the inclusion of condition-based and performance-based maintenance and testing and not just time-based criteria. Presently Southwest Transmission Cooperative, Inc. uses this type of maintenance and testing criteria (maintenance data server) which is the current system protection industry technology.
Response: Thank you for your support.			
FirstEnergy	☑		Bullet #5 of the "Detailed Description" on page SAR-2 indicates the following: "Applicable to all four standards — The requirements of the existing standards, as stated, support time-based maintenance and testing, and should be expanded to include condition-based and performance-based maintenance and testing. The requirements for maintenance and testing procedures need to have more specificity to insure that the stated intent of the standards is met to support review by the compliance monitor." FE supports the scope of the SAR to consider adding the ability for condition-based and performance-based testing, as suggested by the System Protection and Control Task Force. Additionally, the SDT should consider the need to perform some level of preventative maintenance on a periodic basis at an established maximum interval length, that would vary per the equipment being maintained. The interval established would be based on established guidelines from vendors, EPRI, industry experts, etc.

Question #2			
Commenter	**Yes**	**No**	**Comment**
Response: Thank you- The SDT will develop maximum allowable maintenance intervals for protection systems, working with stakeholders.			
FRCC	☑	☑	Use of subject matter experts (NERC SPCTF) along with the NERC Planning Committee review of the assessment is an effective and efficient way to supplement project SARs and provides critical input at the front-end of the standards process. Attachment A is described as the SPCTF assessment, but attachment A to the SAR is the SPCTF roster. The assessment referenced in the scope of the SAR should include "Draft 1.0" if the full assessment is not included as part of the SAR.
Response: The attachments and supporting material references will be posted.

3. Do you agree with the applicability of the proposed SAR (Transmission Owners, Generator Owners and Distribution Providers - Distribution Providers may own the devices that must be tested and maintained)?

Summary Consideration: Based on comments received no changes were made to the SAR

Question #3			
Commenter	**Yes**	**No**	**Comment**
FRCC			This question may be better addressed as the standards are integrated.
Response: The SAR DT is obligated to address the applicability,			
MRO		☑	FERC Order 693 in both paragraph 1466 and in footnote 384, indicates that in some areas of the country, Load Serving Entities (LSE) and Transmission Operators (TOP) may individually or jointly own and operate a protection system. Thus, these additional entities should be subject to the resulting consolidated standard. The MRO believes that the following caveat should be added to the LSE where it is listed as an Applicable Entity, (where operation of the protection system can affect the Bulk Electric System). 2. The MRO requests that the SDT review whether or not the Reliability Coordinator (RC) should be added to the list of Applicable Entities given their wide area view-for example, the RC may need to be involved in determining which protection systems below 100kV will affect the BES.
Response: FERC Order 693 in both paragraph 1466 and in footnote 384 reiterates IESO-NE comments on the NOPPR. The FERC directive was to consider this comment. According to the NERC Functional Model, Load-serving Entities, Transmission Operators and Reliability Coordinators are not owners of protection systems – and the entity responsible for maintenance is the facility owner.			
NPCC CP9 RSWG HQT	☑	☑	Each requirement needs to specifically address what protection systems need to comply with the standard - i.e. a generator not connected to the BPS with under frequency trip relay should only be subject to under frequency relay maintenance requirements.
Response: Your comment will be referred to the SDT for consideration when convened.			
FirstEnergy	☑		The inclusion of the Distribution Provider is generally needed for UFLS and UVLS relays. The confusion that previously existed in PRC-005 by including the DP entity should be mitigated by the proposed consolidation of the four maintenance standards.
Response: Thank you for your comment.

4. If you know of a Regional Variance that should be developed as part of this SAR, please identify that for us. If not, please explain in the comment area.

Summary Consideration: No regional variances were identified by the commentators

Question #4		
Commenter	**Regional Variance**	**Comment**
NPCC CP9 RSWG	None	Certain unavoidable delays like the inability to schedule outages for reliability reasons or labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude, with the "appropriate approvals", needs to be provided for delays in the testing process.
Response: This is a compliance issue not a regional variance – The compliance enforcement program does give the compliance monitor latitude to consider extenuating circumstances.		
PSC SC	N/A	
SERC EC PCS	None	
AEP	None	
BPA	No known regional variance.	
Consumers Energy	N/A	
SWTC	N/A	Not aware of any Regional Variance requirements.
MRO	None	
FirstEnergy		Not aware of any.
HQT	None	

5. If you are aware of a Business Practice that needs to be developed to support the proposed SAR, please identify that for us.

Summary Consideration: No needs for development of Business Practices were identified by the commentators.

Question #5		
Commenter	**Business Practice**	**Comment**
AEP	Possibly	AEP and other utilities, with many years of experience serving customers and supporting the electric grid, have voluntarily integrated maintenance and testing programs into the core of their work practices and processes. AEP fully supports improvements if they truly foster reliability and availability benefits to bulk power transfers. More Standards, Requirements and Business Practices are not always better. If Standards create burdens on a utility's physical resources and budgets, then some mechanism must be available to allow for the needed changes.
Response: Please monitor the work of the SDT and advise the team if added burdens are created by any of the proposed requirement and advise the team of the need for any business practice or other mechanism necessary to support the proposed requirements.		
PSC SC	N/A	
SERC EC PCS	None	
Consumers Energy	N/A	
SWTC	N/A	Not aware of any Business Practice needs.
NPCC CP9 RSWG	None that we know of.	
MRO	None	
IRC	None	
FirstEnergy		Not aware of any.
HQT		None that we know of.

6. If you have any other comments on this SAR that you haven't provided above, please provide them here.

Question #6	
Commenter	**Comment**
SERC EC PCS	The SERC EC PCS supports the work of the NERC SPCTF in their assessments of these standards.
Response: Thank you for your support	
AEP	The standard should not use the term Bulk Electric System, but should instead specify a voltage threshold for impacts to bulk system transfers - specifically; 'Facilities operated 200 kV and above and Regionally-defined, Operationally Significant facilities operated greater than 100 kV, but less than 199 kV'. The term 'affects' also needs to be clarified. Inclusion of all facilities greater than 100 kV does not benefit the reliability of national bulk power transfers. For example, the loss or misoperation of a 138 kV line serving a localized load center would not be detrimental to bulk power transfers multiple busses away.
Response: Your comment will be referred to the drafting team when convened for consideration when drafting the standard.	
BPA	In the "Detailed Description" section of the SAR, it states: "Part of the stated purpose in PRC-017 is: "To ensure that maintenance and testing programs are developed and misoperations are analyzed and corrected." The phrase "and misoperations are analyzed and corrected" is not clearly appropriate in a maintenance and testing standard. That is the purpose is more appropriate in PRC-003 and PRC-004, which relate to the analysis and mitigation of protection system misoperations. Analysis of correct operations or misoperations may be an integral part of condition-based maintenance processes, but need not be mandated in a maintenance standard." The analysis of SPS misoperations is handled in PRC-016 (SPS Misoperations) and PRC 012 (SPS review Procedure) not in PRC-003 or PRC-004. Therefore, if the phrase is removed from PRC-017, it does not need to be added to PRC-003 or PRC-004.
Response: We agree. Please see the purpose statement as stated in the SAR.	
SOCO Transmission	In the SAR you state "The revised PRC-005 standard should address the issues raised in the FERC Order 693". With the exception of mentioning the consolidation of the standards into one standard, the SAR drafting team didn't provide readers with the exact language from FERC that would be useful to know with respect to PRC-005 in the directive below: The Commission directs the ERO to develop a modification to PRC-005-1 through the Reliability Standards development process that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System. We further direct the ERO to consider FirstEnergy's and ISO-NE's suggestion to combine PRC-005-1, PRC-008-0,

Question #6	
Commenter	**Comment**
	PRC-011-0 and PRC-017-0 into a single Reliability Standard through the Reliability Standards development process.
Response: The SAR DT Agrees – the SAR DT will make sure that all appropriate documents are included in its next posting of the SAR.	
MRO	1. The MRO commends NERC and the SDT for taking steps to remove some of the redundancy that currently exists among many of the standards today. The consolidation of the protection system maintenance and testing standards is a good first step. 2. The MRO requests that the following be considered during the initial drafting of the Requirements for this new protection and maintenance standard. A minimum set of evidence to be included in a maintenance and testing program should be established in the measures for R1.2. 3. In the SPCTF Assessment of PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0, the clarification for R2 states that documentation is available to its Regional Reliability Organization and NERC during audits or upon request within 30 days but paragraph 1545 of FERC Order 693 states "be routinely provided to the ERO or Regional Entity and not only when it is requested." The MRO believes that the FERC request would be satisfied if the standard were to state: "the applicable entities shall provide testing records to the Regional Entity on a periodic basis e.g. (annually). 4. In the event that the SAR DT does not become the SDT, the MRO requests that these comments be forwarded on to the group that will do tha actual drafting of the Standard.
Response: The SAR DT will forward your comments to the SDT for consideration as required by the process	
IRC IESO	1. The SRC (IESO) commends NERC, the SDT and the SPCTF for providing clarity and for efforts to reduce the costs of compliance. 2 In the Standard PRC-008-0, Generation Owners were not included in the applicable entities. Generation Owners may have underfrequency tripping devices for protection of their units. It would be appropriate to include these devices for maintenance and testing requirements also. 3. Further, there is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes ("GPS") that are critical to bulk power system operation, as distinct from generator operation. For example, a single generating unit may experience contingency events that would not result in any significant adverse impacts outside the local area in which the single generating unit is located. As a result, there remains a need to subject those GPSs that are important to the Bulk Power System, such as generator underfrequency trip settings, to the maintenance testing intervals to be derived in these standards. 4. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor

Question #6	
Commenter	**Comment**
	disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided for delays in the testing process. 5. However, the SAR team needs to also consider, as part of its scope, assurance that the asset owner has taken all appropriate steps to assure that required outages are appropriately planned and can be reasonably accommodated and approved by the TOP or RC.
Response: 1.Thank you **2.** Generator owners are included in the SAR **3.** This comment will be forwarded to the SDT **4.** The compliance enforcement program does give the compliance monitor latitude to consider extenuating circumstances. **5.** There are other standards that require coordination of comments	
FRCC	There are many standards being addressed (Disturbance Monitoring, System Protection Coordination, Reliability Coordination, along with Regional standard developments). As these standards are integrated into PRC-005, the existing and new terminology should be consistently applied in all system protection standards (with respect to defined terms). Where terms are undefined or being revised, the drafting team should carefully consider the terms used to ensure coordination of revised or new definitions with other Reliability standards or flag conflicts within the implementation plan.
Response: Thank you for your comment, your observation will be forwarded to the SDT for consideration.	
NPCC CP9 RSWG HQT	Due consideration should be given to potential difficulties in obtaining required outages. System reliability concerns may preclude performing maintenance at the intervals required. Certain unavoidable delays like the inability to schedule outages for reliability reasons, labor disputes, or force-majeure conditions could affect testing period requirements. These factors should be considered and certain latitude needs to be provided, with "appropriate" approvals, for delays in the testing process. There is need to specify which types of relays will be covered by the new standard. The SAR Team needs to focus on better defining the Generator Protection Schemes ("GPS") that would be subject to this Standard – i.e., what subset of GPS are critical to bulk power system operation, as distinct from generator operation. For example, typically there is no single generating unit that would, if a contingency event occurs on that generating unit, result in significant adverse impacts outside of the local area in which the single generating unit is located. As a result, if these NERC Standards are to apply to all NERC-registered Generators, only a subset of the GPS need to be subjected to the maintenance testing intervals.
Response: 1. The compliance enforcement program does give the compliance monitor latitude to consider extenuating circumstances.	

Question #6	
Commenter	**Comment**
2 Your second comment will be forwarded to the SDT for consideration	
Manitoba Hydro	Manitoba Hydro takes exception to the prescriptive nature of the proposed changes to the maintenance procedures and maintenance intervals. The type of maintenance performed and the minimum maintenance intervals should be determined by the utility within the operating context of the protection system. There is no need for the standard to reflect the inherent difference between various protection system technologies as the utility would account for differences within their stated maintenance practices.
Response: The proposed changes will improve clarity which should benefit reliability. While Manitoba Hydro may have an excellent record of maintenance, the existing standards are quite vague and allow an entity that performs maintenance once every 100 years to be fully compliant.	
Pepco Holdings	This SAR will bring needed coherence to what are now several related standards.
Response: Thank you	
SRP	None.
PSC SC	N/A
Consumers Energy	None.
SWTC	N/A
FirstEnergy	None.

NERC
NORTH AMERICAN ELECTRIC

Maureen E. Long
Standards Process Manager

August 15, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Nomination Periods Open for Three Drafting Teams

The Standards Committee announces the following standards actions:

Nominations for Project 2006-01 System Personnel Training Standard Drafting Team (August 15–29, 2007)

The Standards Committee is seeking additional industry experts to serve on the System Personnel Training Standard Drafting Team. The new members will join the already-formed drafting team in developing the following standard:

- PER-005 — System Personnel Training

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by August 29, 2007 with "System Personnel Training SDT" in the subject line. For questions, please contact Linda Clarke at 610-310-7210 or linclrke@msn.com.

Nominations for Project 2007-06 System Protection Coordination Standard Drafting Team (August 15–29, 2007)

The Standards Committee is seeking industry experts to serve on the System Protection Coordination Standard Drafting Team. The drafting team will work on modifications to the following standard:

- PRC-001 — System Protection Coordination

If you are interested in serving on this standard drafting team, please complete this nomination form and return it to sarcomm@nerc.net by August 29, 2007 with "System Protection Coordination SDT" in the subject line. For questions, please contact Al Calafiore at 678-524-1188 or at al.calafiore@nerc.net.

Nominations for Project 2007-17 Protection System Maintenance and Testing Standard Drafting Team (August 15–29, 2007)

The Standards Committee is seeking industry experts to serve on the Protection System Maintenance and Testing Standard Drafting Team. If you are interested in serving on this team, please complete this nomination form and return it to sarcomm@nerc.net with "Protection System Maintenance SDT" in the subject line by August 29, 2007. For questions, please contact Al Calafiore at 678-524-1188 or at al.calafiore@nerc.net.

The drafting team will work on revising the following standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Nomination Form for Protection System Maintenance and Testing Standard Drafting Team (Project 2007-17)

Please return this form to sarcomm@nerc.net by August 29, 2007 with the words "Protection System Maintenance SDT" in the subject line. If you have questions please contact al.calafiore@nerc.net or at 678-524-1188.

All candidates should be prepared to participate actively at these meetings.

Name: Organization: Address: Office Telephone: E-mail:
Please briefly describe your experience and qualifications to serve on the Protection System Maintenance and Testing Standard Drafting Team. Candidates should have experience in developing, managing or supporting a maintenance program or a testing program for one or more of the following: - **Generator protection systems** - **Transmission protection systems** - **Underfrequency load shedding equipment** - **Undervoltage load shedding equipment** - **Special protection systems** **Previous experience working on or applying NERC or IEEE standards is beneficial, but not a requirement.**

I represent the following NERC Reliability Region(s) (check all that apply):	**I represent the following Industry Segment (check one):**	
☐ ERCOT ☐ FRCC ☐ MRO ☐ NPCC ☐ RFC ☐ SERC ☐ SPP ☐ WECC ☐ NA – Not Applicable	☐	1 — Transmission Owners
	☐	2 — RTOs, ISOs
	☐	3 — Load-serving Entities
	☐	4 — Transmission-dependent Utilities
	☐	5 — Electric Generators
	☐	6 — Electricity Brokers, Aggregators, and Marketers
	☐	7 — Large Electricity End Users
	☐	8 — Small Electricity End Users
	☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
	☐	10 — Regional Reliability Organizations and Regional Entities

Which of the following Function(s)[1] do you have expertise or responsibilities:

☐ Balancing Authority	☐ Planning Coordinator
☐ Compliance Monitor	☐ Transmission Operator
☐ Distribution Provider	☐ Transmission Owner
☐ Generator Operator	☐ Transmission Planner
☐ Generator Owner	☐ Transmission Service Provider
☐ Interchange Authority	☐ Purchasing-selling Entity
☐ Load-serving Entity	☐ Resource Planner
☐ Market Operator	☐ Reliability Coordinator

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. Drafting team posts first draft for comments (July 23, 2009).

Description of Current Draft:
This is the initial draft of the Standard. This standard merges previous standards PRC-005-0, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post response to comments and second draft of standard and associated documents.	To be determined.

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program can include:

- Verification — A means of determining that the component is functioning correctly.
- Monitoring — Observation of the routine in-service operation of the component.
- Testing — Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Physical inspection — To detect visible signs of component failure, reduced performance and degradation.
- Calibration — Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Upkeep — Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.
- Restoration — The actions to restore proper operation of malfunctioning components.

Protection System (modification) — Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** **PRC-005-2**

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owners

   4.1.2 Generator Owners

   4.1.3 Distribution Providers

   4.2. Facilities:

   4.2.1 Protection Systems that are applied on, or are designed to provide protection for the BES.

   4.2.2 Protection System components used for underfrequency load-shedding systems which are installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection System components used for undervoltage load-shedding systems which are installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection System components which is installed as a Special Protection System for BES reliability.

   4.2.5 Protection Systems for Generator Facilities that are part of the BES, including:

   4.2.5.1 Protection system components that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

   4.2.5.2 Protection systems for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

   4.2.5.4 Protection systems for generator-connected station service transformers for generators that are part of the BES.

   4.2.5.5 Protection systems for system-connected station service transformers for generators that are part of the BES.

5. **(Proposed) Effective Date:** **TBD**

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES[1] and that are applied on, or are designed to provide protection for the BES. The PSMP shall meet the following criteria: *[Violation Risk Factor: TBD] [Time Horizon: Long Term Planning]*

1.1. For each component used in each Protection System, include all maintenance activities specified in Tables 1a, 1b, and 1c.

1.2. Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods and identify the associated maintenance interval.

1.3. Include all batteries associated with a Protection System in a time-based program.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses condition-based maintenance intervals in its PSMP for partially or fully monitored Protection Systems shall ensure the components to which the condition-based criteria are applied (as specified in Tables 1b or 1c), possess the necessary monitoring attributes. *[Violation Risk Factor: TBD] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A. *[Violation Risk Factor: TBD] [Time Horizon: Long Term Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctible issues[2] as follows: *[Violation Risk Factor: TBD] [Time Horizon: Long Term Planning]*

4.1. For time-based or condition-based maintenance programs perform the Maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System components within maximum allowable intervals not to exceed those established in Tables 1a, 1b, and 1c.

4.2. For performance-based maintenance programs perform the maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System components in accordance within the maximum allowable intervals established per Requirement R3.

C. Measures (TBD)

[1] Devices that sense non-electrical conditions, such as thermal or transformer sudden pressure relays, are not included within the scope of this standard**.**

[2] A maintenance correctable issue is a failure of a device to operate within design parameters that can be restored to functional order by calibration, repair or replacement.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring Period and Reset Time Frame

Not Applicable.

1.3. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation for two maintenance intervals for the Protection System components.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.5. Additional Compliance Information

2. Violation Severity Levels — TBD

E. Regional Differences

None

F. Supplemental Reference Documents

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference — July 2009.
2. NERC Protection System Maintenance Standard PRC-005-2 FREQUENTLY ASKED QUESTIONS — Practical Compliance and Implementation DRAFT 1.0 — June 2009

Version History

Version	Date	Action	Change Tracking

Table 1a — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.		
Type of Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Protective Relays	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify proper functioning of the relay trip outputs. For microprocessor relays verify proper functioning of the A/D converters (Note 2) Verify that settings are as specified.
Voltage and Current Sensing Devices Inputs to Protective Relays	12 Calendar Years	Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays
Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS)	3 Months	Verify the continuity of the breaker trip circuit including trip coil (except for protection system control circuitry associated with breakers that remain open for the entire "maintenance interval" period")
Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS)	6 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System.
Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only)	(when the associated UVLS or UFLS system is maintained)	Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System.

Table 1a — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.		
Type of Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component any type of battery)	3 Months	Verify proper electrolyte level (excluding valve-regulated lead acid batteries). Verify proper voltage of the station battery. Verify that no dc supply grounds are present.
Station dc supply (that has as a component any type of battery)	18 Months	Verify proper voltage of each individual cell or unit in the station battery. Verify that station battery charger provides the correct float and equalize voltages. Verify continuity and cell integrity of entire battery. Perform a visual cell inspection of all cells for "cell condition" (where cells are visible) or measurement of cell/unit internal ohmic values (where cells are not visible). Measure that specific gravity and temperature of each cell is within tolerance(where applicable) Verify cell to cell and terminal connection resistance is within tolerance Inspect the structural integrity of the battery rack.
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	3 Calendar Years - or - 3 Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)

Table 1a — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.		
Type of Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Vented Lead-Acid Batteries)	6 Calendar Years - or - 18 Months	Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc supply (that uses a battery and charger)	6 Calendar Years	Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit.
Station dc Supply (battery is not used)	18 Months	Verify proper voltage of the station dc supply Verify that no dc supply grounds are present. Perform a visual inspection, of all components of the station dc supply to verify that the physical condition of the station dc supply is as desired and any visual inspection if required by the manufacturer on the condition of the dc supply that is the source of dc power when ac power is unavailable. Verify where applicable the proper voltage level of each component of the station dc supply. Verify the correct operation of ac powered dc power supplies. Verify the continuity of all circuit connections that can be affected by wear or corrosion.
Station dc Supply (used only for UVLS or UFLS)	(when the associated UVLS or UFLS system is maintained)	Verify proper voltage of the dc supply.

Table 1a — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.		
Type of Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection system communications equipment and channels.	3 Months	Verify that the Protection System communications monitoring and alarms reflect the intended communications system condition by means of a substation inspection.
Protection system communications equipment and channels.	6 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment outputs.
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify proper functioning of the relay trip outputs. For microprocessor relays verify the proper functioning of the A/D converters (Note 2) Verify that settings are as specified.
Relay sensing for Centralized UFLS or UVLS systems	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring **Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components** **General Description:** Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Protective Relays	Includes internal self diagnosis and alarm capability, which must assert for power supply failures. Includes input voltage or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.	12 Calendar Years	Verify the status of relays is normal with no alarms indicated. Verify the proper functioning of the A/D converters within the relay by testing or comparing values against other devices. Verify proper functioning of the relay trip outputs. Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken. See Note 2.
Voltage and Current Sensing Devices - Inputs to Protective Relays	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	12 Calendar Years	Verify the proper functioning of current and voltage circuit inputs from the voltage and current sensing devices to the protective relays
Protection System Control Circuitry (Trip Coils and Auxiliary Relays)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	6 Calendar Years	Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval.
Protection System Control Circuitry (Trip Circuits) (except for UFLS/UVLS)	Monitoring and alarming of continuity of trip coil(s)	12 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System. Verify that the relay alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components

General Description: Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component.

Type of Component	Level 2 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only)	Monitoring and alarming of continuity of trip coil(s)	(when the associated UVLS or UFLS system is maintained)	Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System. (Verification does not require actual tripping of circuit breakers or interrupting devices.) Verify that the relay alarms will be received at the location where action can be taken.
Station dc supply (that has as a component any type of battery)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	3 Months	Verify proper electrolyte level (excluding Valve-Regulated Lead Acid batteries).
Station dc supply (that has as a component any type of battery)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	18 Months	Verify proper voltage of each individual cell or unit in the station battery. Verify that station battery charger provides the correct float and equalize voltages. Verify electrical continuity of the entire battery. Perform a visual cell inspection of all cells for “cell condition” (where cells are visible) or measurement of cell/unit internal ohmic values. (where cells are not visible) Measure that specific gravity and temperature of each cell is within tolerance. (where applicable) Verify cell to cell and terminal connection resistance is within tolerance. Inspect the structural integrity of the battery rack. Verify that the battery voltage and dc supply ground alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	3 Calendar Years - or - 3 Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)
Station dc supply (that has as a component Vented Lead-Acid batteries)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	6 Calendar Years - or - 18 Months	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc supply (that uses a battery and charger)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	6 Calendar Years	Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (battery is not used)	Monitoring and alarming of the station dc supply voltage. Detection and alarming of dc grounds.	18 Months	Verify proper voltage of the station dc supply, and where applicable, of each component of the station dc supply. Verify the proper operation of ac powered dc power supplies. Verify the continuity of all circuit connections that can be affected by wear or corrosion. Perform a visual inspection, of all components of the station dc supply to verify that the physical condition of the station dc supply is as desired and any visual inspection if required by the manufacturer on the condition of the dc supply that is the source of dc power when ac power is unavailable. Verify that the station dc supply voltage and dc supply ground alarms will be received at a location where action can be taken.
Station dc Supply (used only for UVLS or UFLS)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	(when the associated UVLS or UFLS system is maintained)	Verify proper voltage of the dc supply
Protection system communications equipment and channels.	Monitoring and alarming of protection communications system by mechanisms that check for presence of the communications channel.	12 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment outputs. Verify proper functioning of alarm notification.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
UVLS and UFLS relays that comprise a protection scheme distributed over the power system.	Includes internal self diagnosis and alarm capability, which must assert for power supply failures. Includes input voltage or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.	12 Calendar Years	Verify the status of relays as in service with no alarms. Verify the proper function of the A/D converters (if included in relay). Verify proper functioning of the relay trip outputs. Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken.
Relay sensing for centralized UFLS or UVLS systems.	See the attributes of Level 1 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the UFLS/UVLS	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See the attributes of Level 1 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the SPS	Perform all of the Maintenance activities listed above as established for components of the SPS, at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1c — Condition-based Maintenance — Level 3 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems

General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.

Type of Component	Level 3 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Protective Relays	The relay A/D converters are continuously monitored and alarmed.	Continuous	Continuous verification of the status of the relays. (Note 2) Alarm on change of settings.
Protective Relays with trip contacts	All Level attributes, except relay possesses mechanical output contacts.	12 Calendar Years	Verify proper functioning of the relay trip contacts.
Voltage and Current Sensing Devices Inputs to Protective Relays	Verification of the ac analog values (magnitude and phase angle) measured by the microprocessor relay or comparable device, by comparing against other measurements using other instrument transformers.	Continuous	Continuous verification and comparison of the current and voltage signals from the voltage and current sensing devices of the Protection System.
Protection System Control Circuitry (Trip Coils and Auxiliary Relays)	No Level 3 monitoring attributes are defined – use Level 2 Maintenance Activities and intervals	6 Calendar Years	Each breaker trip coil, each auxiliary relay, and each lockout relay must be electrically operated within this time interval.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Control Circuitry (Trip Circuits)	Monitoring of the continuity of breaker trip circuits (with alarming for non-continuity), along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil, including any auxiliary contacts essential to proper Protection System operation. If a trip circuit comprises multiple paths, each of the paths must be monitored, including monitoring of the operating coil circuit(s) and the tripping circuits of auxiliary tripping relays and lockout relays.	Continuous	Continuous monitoring of trip voltage and trip path integrity of entire trip circuit is provided with alarming to remote terminal unit upon any failure of the trip path.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (any battery technology)	Monitoring and alarming the station dc supply status, including, for station dc supplies that have as a component a battery, the voltage, specific gravity, electrolyte level, temperature and connectivity (cell to cell and terminal connection resistance) of each cell as well as the battery system terminal voltage and electrical continuity of the overall battery system. Monitoring and alarming if the performance capability of the battery is degraded. Monitoring and alarming the ac powered dc power supply status including low and high voltage and charge rate for station dc supplies that have battery systems. Detection and alarming of dc grounds.	18 Months	Verify that station battery charger operation provides the correct float and equalize voltages Perform a visual inspection of the station battery and charger, individual cells (including electrolyte level), connections, and racks to verify that the physical condition of the battery is as desired, and that no associated alarm lamps are illuminated.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that uses a battery and charger)	Monitoring and alarming the station dc supply status, including, for station dc supplies that have as a component a battery, the voltage, specific gravity, electrolyte level, temperature and connectivity (cell to cell and terminal connection resistance) of each cell as well as the battery system terminal voltage and electrical continuity of the overall battery system. Monitoring and alarming if the performance capability of the battery is degraded. Monitoring and alarming the ac powered dc power supply status including low and high voltage and charge rate for station dc supplies that have battery systems. Detection and alarming of dc grounds.	6 Calendar Years	Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (battery is not used)	Monitoring and alarming the station dc supply status, including output voltage of the dc supply. Monitoring and alarming if the performance capability of the dc supply is degraded. Detection and alarming of dc grounds.	Continuous	Continuous verification of the status of the station dc supply and its ability to deliver dc power when required, is provided.
Station dc Supply (used only for UVLS or UFLS)	No Level 3 monitoring attributes are defined – use Level 2 Maintenance Activities and intervals	(when the associated UVLS or UFLS system is maintained)	Verify proper voltage of the dc supply
Protection system telecommunications equipment and channels.	Evaluating the performance of the channel and its interface to protective relays to determine the quality of the channel and alarming if the channel does not meet performance criteria	Continuous	Continuous verification that the performance and quality of the channel meets performance criteria is provided. Continuous verification of the communications equipment alarm system is provided.
UVLS and UFLS relays that comprise a protection scheme distributed over the power system.	The relay A/D converters are continuously monitored and alarmed.	Continuous	Continuous verification of the status of the relays. (Note 2) Alarm on change of settings. Verification does not require actual tripping of circuit breakers or interrupting devices.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection Systems **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken. Level 3 Monitoring includes all elements of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.			
Type of Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Relay sensing for centralized UFLS or UVLS systems.	See the attributes of Level 3 Monitoring for the individual components of the UFLS/UVLS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See the attributes of Level 3 Monitoring for the individual components of the SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Notes for Table 1a, Table 1b, and Table 1c

1. For some Protection System components, adjustment is required to bring measurement accuracy within parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but power system input values must be verified as correct within the Table intervals. The integrity of the digital inputs and outputs will be verified with the Protection System Control Circuitry.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

Segment: In this procedure, the term, "segment" is a grouping of Protection Systems or component devices from a single manufacturer, with common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components.[3]

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Table 1 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events[4] for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and

[3] Entities with smaller populations of component devices may aggregate their populations to define a segment and shall share all attributes of a single performance-based program for that segment.
[4] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.

implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Unofficial Comment Form for Protection System Maintenance and Testing (Project 2007-17)

Please **DO NOT** use this form. Please use the electronic comment form located at the link below to submit comments on the draft Protection System Maintenance and Testing. **Comments must be submitted by September 8, 2009**. If you have questions please contact Al Calafiore at Al.Calafiore@nerc.net or by telephone at 678-524-1188.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:
The draft standard combines the previous standards, PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program, PRC-011-0 — UVLS System Maintenance and Testing, and PRC-017-0 — Special Protection System Maintenance and Testing. It also addresses FERC directives from FERC Order 693, including that NERC establish maximum allowable maintenance intervals.

In accordance with the FERC directive, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices, and for a performance-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

1. The Standard Drafting Team proposes to change the name of the draft standard from "Protection System Maintenance and Testing" to "Protection System Maintenance", and to include testing as one component of "Protection System Maintenance Program", which will be a defined term. Do you agree? If not, please explain in the comment area.

   ☐ Yes
   ☐ No
   Comments:

2. Within Table 1a, Table 1b, and Table 1c, the draft standard establishes specific minimum maintenance activities for the various types of devices defined within the definition of "Protection System". Do you agree with these minimum maintenance activities? If not, please explain in the comment area.

   ☐ Yes
   ☐ No
   Comments:

3. Within Table 1a, the draft standard establishes maximum allowable maintenance intervals for the various types of devices defined within the definition of "Protection System", where nothing is known about the in-service condition of the devices. Do you agree with these intervals? If not, please explain in the comment area.

   ☐ Yes

☐ No

Comments:

4. Within Tables 1b and 1c, the draft standard establishes parameters for condition-based maintenance, where the condition of the devices is known by means of monitoring within the substation or plant and the condition is reported. Do you agree with this approach? If not, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments:

5. Within PRC-005 Attachment A, the draft standard establishes parameters for performance-based maintenance, where the historical performance of the devices is known and analyzed to support adjustment of the maximum intervals. Do you agree with this approach? If not, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments:

6. The Standard Drafting Team has provided a "Supplementary Reference Document" to provide supporting discussion for the Requirements within the standard. Do you have any comments on the Supplementary Reference Document? Please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments:

7. The Standard Drafting Team has provided a "Frequently-asked Questions" document to address anticipated questions relative to the standard. Do you have any comments on the FAQ? Please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments:

8. If you are aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement please identify the conflict here.

   Conflict:

10. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

    Comments:

Draft Implementation Plan for PRC-005-02

Background:
In developing the implementation plan, the Standard Drafting Team considered the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Until an entity is 100% compliant with PRC-005-2, the entity must be in compliance with PRC-005-1 for those components for which the implementation schedule for PRC-005-2 is not yet applicable.
4. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

Implementation plan for R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter three months following Board of Trustees adoption.

Implementation plan for R2, R3, and R4:

1. For Protection System Components with maximum allowable intervals of less than 1 year, as established in Table 1a,
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 12 months following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 months following Board of Trustees adoption.

2. For Protection System Components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Table 1a,
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

3. For Protection System Components with maximum allowable intervals of 6 years, as established in Table 1a,
    a. The entity shall be 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.
    b. The entity shall be 60% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 6 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 6 calendar years following Board of Trustees adoption.

4. For Protection System Components with maximum allowable intervals of 12 years, as established in Table 1a,
    a. The entity shall be 30% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
    b. The entity shall be 60% compliant on the first day of the first calendar quarter following 8 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 8 calendar years following Board of Trustees adoption.
    c. The entity shall be 100% compliant on the first day of the first calendar quarter 12 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

PRC-005-2 Protection — System Maintenance Supplementary Reference (Draft 1)

Protection System Maintenance and Testing Standard Drafting Team

to ensure the reliability of the bulk power system

July, 2009

Table of Contents

This supplementary reference to PRC-005-2 borrows heavily from the technical reference by the System Protection and Control Task Force (SPCTF) Protection System Maintenance Technical Reference paper approved by the Planning Committee in September 2007). Additionally the Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) for PRC-005-2 (Project 2007-17) utilized data available from IEEE, EPRI and maintenance programs from various generation and transmission utilities across the NERC boundaries.

1. Introduction and Summary

NERC currently has four reliability standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of protection and control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults or system problems, the protection systems may not operate for extended periods. A misoperation - a false operation of a protection system or a failure of the protection system to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. A maintenance or testing program is used to determine the performance and availability of protection systems.

Typically, utilities have tested protection systems at fixed time intervals, unless they had some incidental evidence that a particular protection system was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring relays, and correctness of settings. Typically, a protection system must be visited at its installation site and removed from service for this testing.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms Used in Reliability Standards indicates what must be included as a minimum.

Definition of *Protection System* (excerpted from the NERC Standards Glossary of Terms):

Protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation, transmission, and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Proposed Modification to NERC Glossary Definition

The Protection Systems Maintenance and Testing Standard Drafting Team (PSM SDT), proposes changes to the NERC glossary definition of *Protection Systems* as follows:

Protection System (modification) - Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing devices inputs to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:
"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:
"*… and that are applied on, or are designed to provide protection for the BES.*"

The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional definitions of the BES.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those relays that that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

3. Relay Product Generations

The likelihood of failure and the ability to observe the operational state of a critical protection system, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the protection system must be monitored, or else verified periodically.
- Ability to capture fault records showing how the protection system responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of protection system monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the protection system outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior protection system generations.

4. Definitions

Protection System Maintenance Program (PSMP) – An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program can include:

- **Verification** — A means of determining that the component is functioning correctly.
- **Monitoring** — Observation of the routine in-service operation of the component.
- **Testing** — Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- **Physical Inspection** — To detect visible signs of component failure, reduced performance and degradation.
- **Calibration** — Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- **Upkeep** — Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer’s hardware and software service advisories which are relevant to the application of the device.
- **Restoration** — The actions to restore proper operation of malfunctioning components.

5. Time Based Maintenance (TBM) Programs

Time based maintenance is the process in which protection systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on protection system components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire protection system tripping chain is able to operate the breaker.

Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM — time based maintenance — externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may prove that some portion of the protection system has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components.

- PBM — performance based maintenance — maintenance intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM — condition based maintenance — continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics.

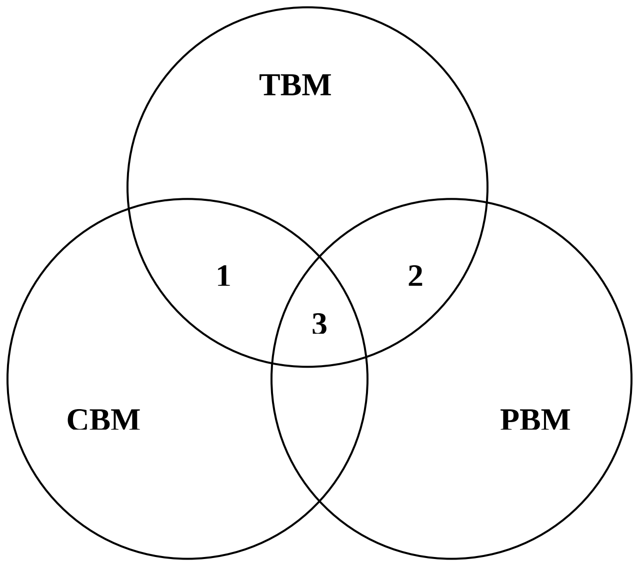
  Microprocessor based protective relays that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include the ac signal inputs, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals. For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM. This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.

- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time based maintenance types

5.1 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the protection system, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relay self monitoring, for example), the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.
- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes also referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot prove correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

6. Condition Based Maintenance (CBM) Programs

Condition based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor protection system elements. These relays and IEDs generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

> Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in relay logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.

> Information can come from event logs, captured files, and/or oscillograph records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the relay front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the protection system.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

> Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.

> Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some relays will show health problems by incorrect relaying before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

7. Time Based versus Condition Based Maintenance

Time based and condition based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time based and condition based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power

System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained device is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification (as specified in the header and the "Monitoring Attributes" column of Tables 1a, 1b and 1c of PRC-005-2), meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system elements as contained in Table 1a.

The result is that:

This NERC standards permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within maximum time intervals specified in Tables 1a, 1b and 1c of PRC-005-2.

8. Maximum Allowable Verification Intervals

The Table of Maintenance Activities and Maximum Interval requirements shows how CBM with newer relay types can reduce the need for many of the tests and site visits that older protection systems require. As explained below, there are some sections of the protection system that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities via data communications, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a period of time of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total protection system functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1 Table of Maximum Allowable Verification Intervals

Table 1, in the standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates verification or testing activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows a typical Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures.

While it is easy to associate protective relays to the three levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables (Tables 1a, 1b and 1c collectively *Tables*) from PRC-005-2:

- First check the table header description to verify that your equipment meets the monitoring requirements. If your equipment does not meet the monitoring requirements of Table 1c then check Table 1b. If your equipment does not meet the requirements of Table 1b then use Table 1a.
- If you find a piece of equipment that meets the monitoring requirements of Table 1b or 1c then you can take advantage of the extended time intervals allowed by Table 1b and 1c. Your maintenance plan must document that this category of equipment can be maintained by the requirements of Table 1b or 1c because it has the necessary attributes required within that Table.
- Once you determine which table applies to your equipment's monitoring requirements then check the Maintenance Activity that is required for that particular category of equipment. This Maintenance Activity is the minimum maintenance activity that must be documented.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this category of your equipment.
- Any given set of Protection System equipment can be maintained with any combination of Tables 1a, 1b and 1c. An entity does not have to stick to Table 1a just because some of its equipment is un-monitored.
- An entity does not have to utilize the extended time intervals in Tables 1b or 1c. An easy choice to make is to simply utilize Table 1a. While the maintenance activities resulting from choosing to use only Table 1a would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for unmonitored, partially monitored and fully monitored protection systems:

Table 1 Maintenance Activities and Maximum Intervals

Level 1 Monitoring (Unmonitored) Table 1a

This table applies to electromechanical, analog solid state and other un-monitored Protection Systems components. This table represents the starting point for all required maintenance activities. The object of this group of requirements is to have specific activities accomplished at maximum set time intervals. From this group of activities it follows that CBM or PBM can increase the time intervals between the hands-on maintenance actions.

Level 2 Monitoring (Partially Monitored) Table 1b

This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process – the monitoring and alarming functions must be shown to work.

Level 3 Monitoring (Fully Monitored) Table 1c

This table applies to microprocessor relays and other associated Protection System components in which every element or function required for correct operation of the Protection System component is monitored continuously and verified, including verification of the means by which failure alarms or indicators are transmitted to a central location for immediate action. This is the highest level of monitoring and if it is available then this gives an entity the ability to have continuous testing of their (Level 3 Monitored) Protection System Component and thus does not have to manually intervene to accomplish routine testing chores. Level 3 Fully Monitored yields continuous monitoring advantages but has substantial technical hurdles that must be overcome; namely that monitoring also verifies the failure of the monitoring and alarming equipment. Without this important ingredient a device that is thought to be continuously monitored could be in an alarm state without the central location being made aware.

Additional Notes for Table 1a, Table 1b, and Table 1c

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.
4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System elements physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner should attempt to use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.
5. Aggregated small entities will naturally distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program.
6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by comparison of known values of other sources on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to prove).

7. Verify the protection system tripping function by performing an operational trip test on all components contained in the trip circuit. This includes circuit breaker or circuit switcher trip coils, auxiliary tripping relays (94), lock-out relays (86), and communications-assisted trip scheme elements. Each control circuit path that carries trip signal must be verified, although each path must be checked only once. A maintenance program may include performing an overall test for the entire system at one time, or several split system tests with overlapping trip verification. Trip coil continuity and aux-contact verification may be accomplished by inspection for the proper control panel light indication. Remote alarm monitoring of the trip coil and aux-contact continuity eliminates the need for tri-monthly inspections of trip coil indications. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test.
8. "End-to-end test" as used in this supplementary reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to prove each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be proven to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.
9. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system will typically be discarded before the next verification, leaving no record of what was done if a misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring that the documentation be retained for two maintenance intervals. Additionally, this requirement assures that the interval between maintenance cycles correctly meets the maintenance interval limits.

8.3 Basis for Table 1 Intervals

SPCTF authors collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the header of Table 1b. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for partial monitoring as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance — A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability — the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability — the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical STvalues are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

PSMT SDT further notes that the SPCTF also allowed 25% extensions to the "maximum time intervals". With a 5 year time interval established between manual maintenance activities and a 25% time extension then this equates to a 6.25 year maximum time interval. It is the belief of the PSMT SDT that the SPCTF understood that 6.25 years was thereby an adequate maximum time interval between manual maintenance activities. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. A 10 year interval with a 25% allowed extension equates to a maximum allowed interval of 12.5 years between manual maintenance activities. The Standard does not allow extensions on any component of the protection system; thus the maximum allowed interval for these devices has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained December 15, 2008; it would be due for maintenance again no later than December 31, 2014.

Section 9 describes a performance-based maintenance process which can be used to justify maintenance intervals other than those described in Table 1.

Section 10 describes sections of the protection system, and overlapping considerations for full verification of the protection system by segments. Segments refer to pieces of the protection system, which can range from a single device to a panel to an entire substation.

Section 11 describes how relay operating records can serve as a basis for verification, reducing the frequency of manual testing.

Section 13 describes how a cooperative effort of relay manufacturers and protection system users can improve the coverage of self-monitoring functions, leading to full monitoring of the bulk of the protection system, and eventual elimination of manual verification or testing.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals. A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance Based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of like devices from the same manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment.

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is “the sampling distribution of the sample mean can be approximated by a normal probability distribution.” The Central Limit Theorem states: “In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> “… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution.” (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> “If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation.” (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> “The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)

> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:
B = bound on the error of distribution (allowable error)
z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation
Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended:

Minimum Population Size to use Performance Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance Based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for Level 1 monitoring, (Table 1a). Time intervals can be lengthened provided the last year's worth of devices tested (or 30 units, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a mis-operation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested-devices (or 30 units whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to 20 years as subsequent analysis might show that an excessive number of countable events could then require that the entire population segment be re-tested and re-evaluated within 3 years.

10. Overlapping the Verification of Sections of the Protection System

Table 1 requires that every protection system element be periodically verified. One approach is to test the entire protection scheme as a unit, from voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Unmonitored, Partially Monitored, or Fully Monitored Tables;
- Full monitoring as described in header of Table 1c;
- A performance-based maintenance program as described in Section 9;
- Opportunistic verification using analysis of fault records as described in Section 11

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent misoperation, as NERC standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity in the record and the associated wiring paths are verified. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.

If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored or partially monitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of full monitoring, the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document full monitoring for some or all sections by:

- Presenting or referencing the product manufacturer’s documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported to remote centers for immediate action, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored elements according to the requirements of Table 1.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-02 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type devices may not be needed.

15.1 Protective Relays

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical input are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, but the relays must meet the calibration requirements of the asset owner.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.2 Voltage & Current Sensing Devices

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these devices. The important thing about these signals is to know that the expected output from these devices actually reaches the protective relay. Therefore, the proof of the proper operation of these devices also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.

- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to prove the circuit to the satisfaction of the asset owner.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to prove that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Other methods that provide documentation that the expected transformer values are applied to the inputs to the protective relays are acceptable.

15.3 DC Control Circuitry

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring from every trip output to every trip coil. In short, every trip path must be verified; the method of verification is optional to the asset owner. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) in any given trip scheme. These electro-mechanical devices must be trip tested. The PSMT SDT considers these devices to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks.

When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.4 Batteries and DC Supplies

IEEE guidelines were used to mandate maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The present NERC definition of a Protection System is "protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry." The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

To insure that there are no open circuits in a lead acid battery string, IEEE 450-2002 recommends that during the monthly inspection "battery float charging current or pilot cell specific gravity" should be measured and recorded. Similarly IEEE 1188-2005 states that during the monthly general inspection, the "dc float current (per string)" should be checked and recorded "using equipment that is accurate at low (typically less than 1 A) currents." These tests are recommended by the IEEE standards for lead acid batteries to detect an open circuit in a battery set that will make a battery unable to deliver dc power.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1 of the standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

Batteries cannot be a unique population segment of a Performance Based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems.

15.5 Tele-protection equipment

This is also known as associated telecommunications equipment. The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.
Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this standard is applied to equipment used to convey both trip signals and block signals.

It was the intent of this standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping occurs locally when the remote action has been asserted.

Evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates is needed.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

Figure 1 and 2 Legend — Components of Protection Systems

Number In Figure	Component of Protection System	Includes	Excludes
1	Protective relays	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Current & voltage sensors	Transformers or other current & voltage sensing devices that produce signals for protective relays as well as the wiring (or other medium) used to convey signal output from the sensor to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	DC Circuitry	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current. Also, it includes auxiliary contacts providing breaker position data that is necessary for the proper operation of the Protection System.	Closing circuits, SCADA circuits
4	DC Supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Associated communications equipment	Tele-protection equipment used to convey remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable)	Any communications equipment that is not used for remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable)

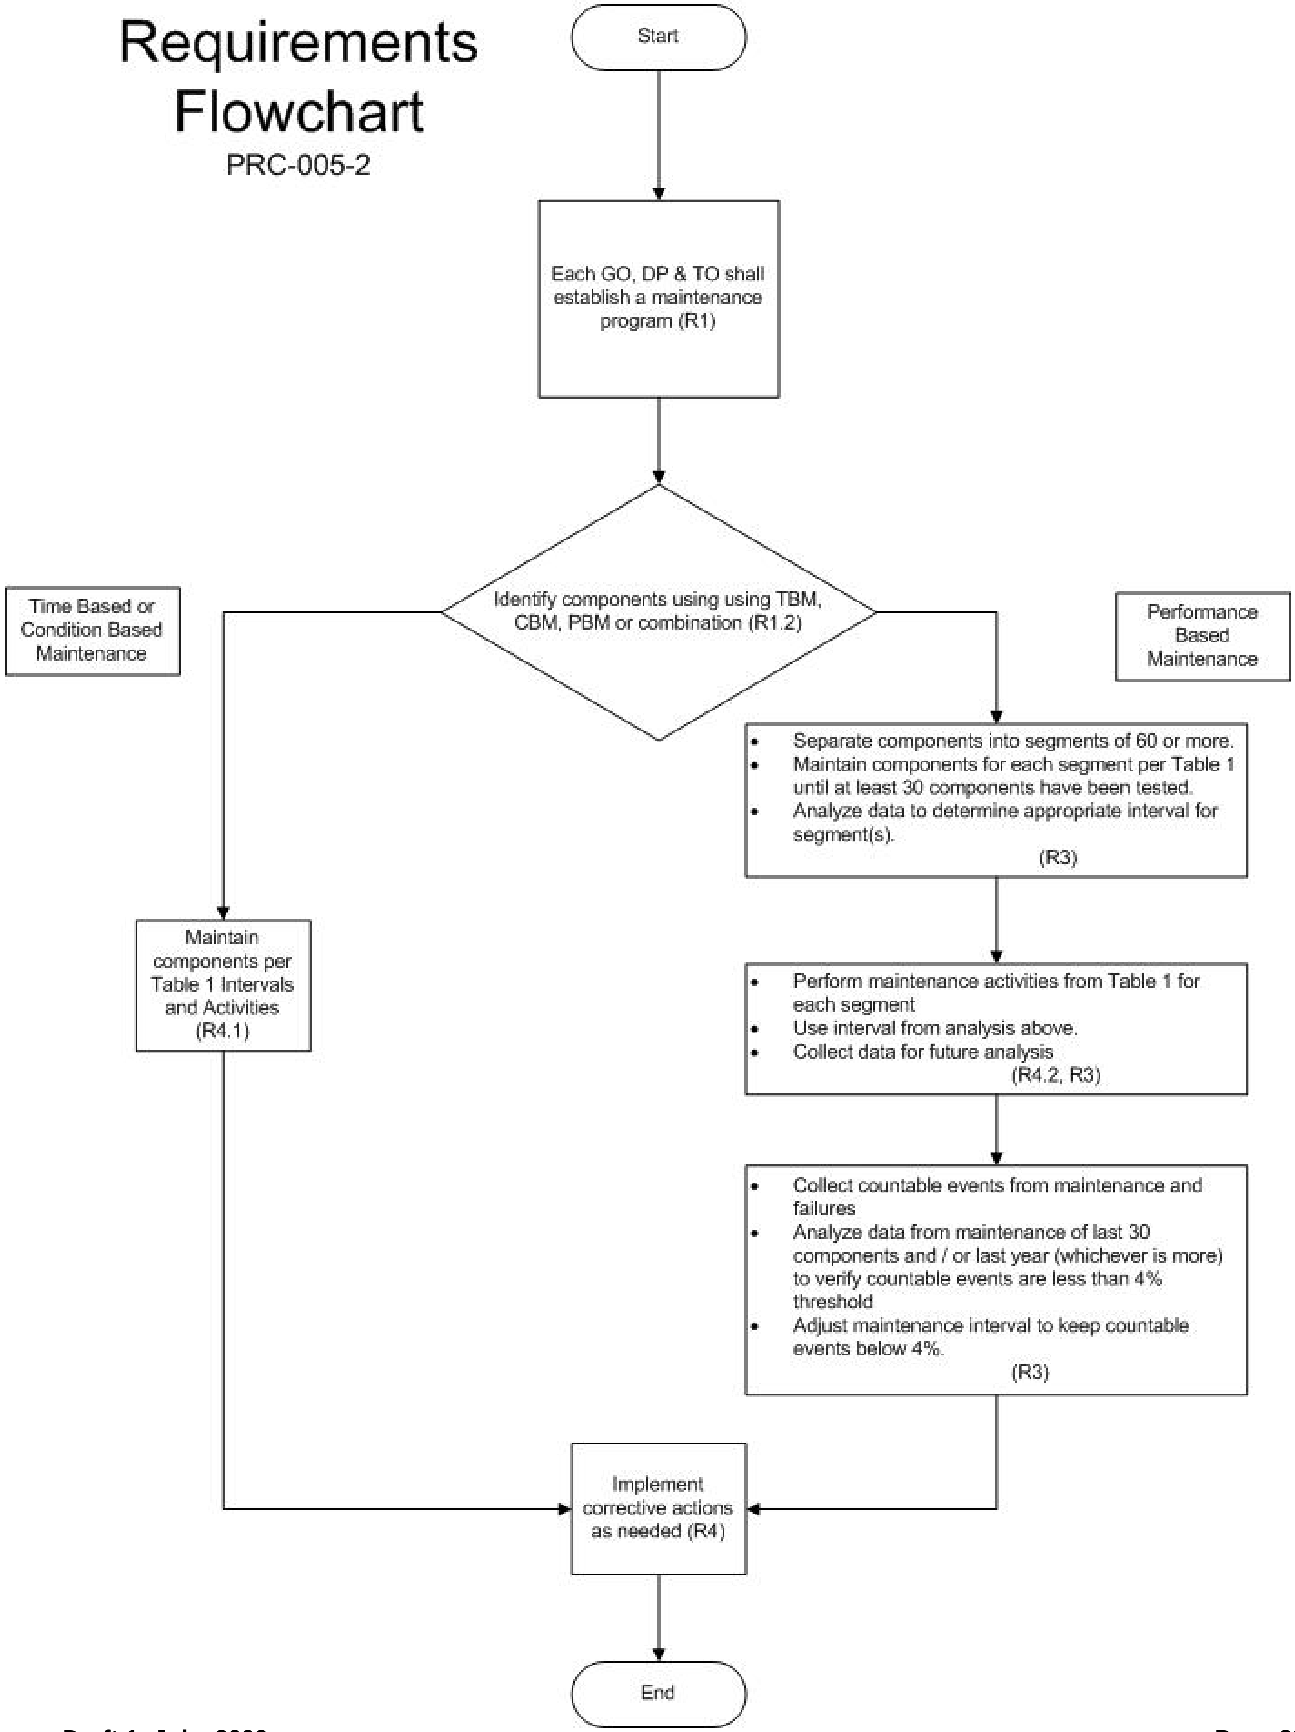
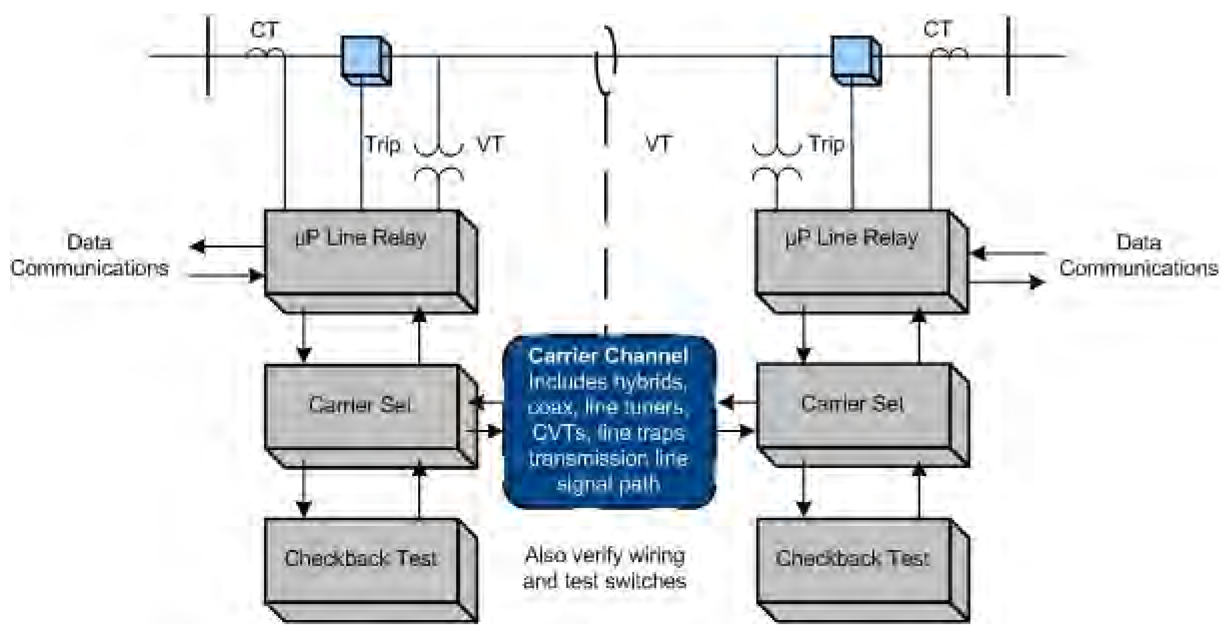
Figure 3: Requirements Flowchart



Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

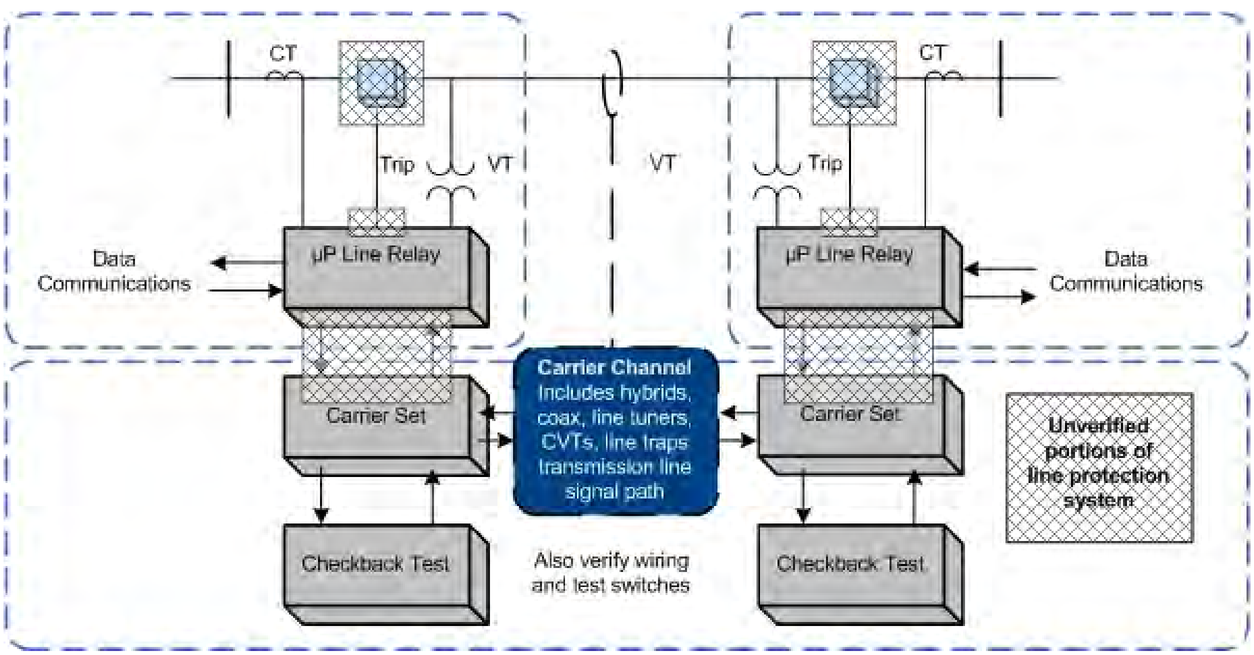
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing Devices, wiring, and analog signal input processing of the relays. One effective way to do

this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Status of Addressing Issues (identified by FERC and stakeholders) Associated with PRC-005-1, PRC-008-0, PRC-011-0 and PRC-017-0

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing		
Source	**Language**	**Drafting Team Resolution**
FERC Order 693	Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.	Specific time intervals are included in the draft standard. The justification for the intervals is provided in the supplemental reference document.
FERC Order 693	Consider FirstEnergy's and ISO-NE's suggestions to combine PRC-005, PRC-008, PRC-011, and PRC-017 into a single standard.	This suggestion is being used.
NERC Audit Observation Team	How do you verify compliance for for cts/pts? How do you audit these within a scheduled maintenance program. As part of the procedure, most have accepted visual inspection. Some entities state that testing of the relays verify functionality of the ct/p	Records must be maintained -- records only means of proof if was done. Verification activities in Table 1 establish the activities required for CTs/PTs.
Version 0 Team	Not a standalone standard	Being combined with three other standards all addressing maintenance of protection systems.
Version 0 Team	Include breakers/switches in list	Breakers are specifically NOT included in the Protection System definition, and therefore are NOT addressed in the draft standard.
Version 0 Team	Define evidence	Requirement R4 established that the program must be implemented. Evidence that the program is implemented is a measure; evidence is not discussed in requirements.

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing		
Source	**Language**	**Drafting Team Resolution**
NERC Audit Observation Team	Determine what on schedule means. Is an entity who maintained/tested 95% of their relays at the same level of non-compliance as an entity who maintained/tested 10% of their relays?	100% compliance is required - violation severity levels to address time. Will consider implementation of this observation when developing compliance elements.
NERC Audit Observation Team	As applicable, each TO, DP and GOP shall have a protection system maintenance and testing program for protection systems that affect the reliability of the BES. Does this include major equipment like circuit breakers and transformers?	Yes – the proposed standard does include protection systems for breakers and transformers. Breakers are specifically NOT included in the Protection System definition, and therefore are NOT addressed as components of Protection Systems.
NERC Audit Observation Team	How do you verify DC control power? All regions require functional testing of the breaker. This should include functional relay & station battery checks, including breaker tripping, not just a visual inspection.	Specific verification activities are established in Table 1 and more details are provided in the supplemental reference.
Phase III/IV Team	All protection systems on the bulk electric system.	The applicability section addresses Protection Systems that are "applied on, or designed to protect the BES", and provides additional specificity regarding applicable generator Protection Systems
Phase III/IV Team	PRC 003 to 005 only address generator (and transmission) protective systems, without defining this term.	The applicability section addresses Protection Systems that are "applied on, or designed to protect the BES", and provides additional specificity regarding applicable generator Protection Systems
Phase III/IV Team	Need to add language to ensure the Regional Requirements focus on the most impactive scenarios	The draft standard established minimum ERO-wide requirements; any Regional requirements would have to exceed the ERO requirements.
Phase III/IV Team	Modify applicability to clarify that the requirements are applicable to the following:	See the applicability section of the standard.

PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing		
Source	**Language**	**Drafting Team Resolution**
Phase III/IV Team	All generation protection systems whose misoperations impact the bulk electric system	Specificity is provided in 4.2.5 addressing generator Protection Systems
Phase III/IV Team	There is no performance requirement or measure of effectiveness of a maintenance program required by the standard	For Time-Based (or Condition-Based) maintenance, minimum activities and maximum intervals are specified; for performance-based maintenance, performance (or effectiveness) goals are established.

PRC-008-0 — Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program		
Source	**Language**	**Drafting Team Resolution**
FERC Order 693	Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.	Specific time intervals are included in the draft standard.
Version 0 Team	Definition of evidence required	Requirement R4 established that the program must be implemented. Evidence that the program is implemented is a measure; evidence is not discussed in requirements.
Version 0 Team	Consistent wording from standard to standard required	Combining maintenance standards and being careful to do this.
Fill in the Blank Team	Okay if PRC-006 is fixed	Applicability section of PRC-005-2 (4.2.2) establishes applicability to UFLS established in accordance with ERO requirements.

PRC-011-0 — Undervoltage Load Shedding System Maintenance and Testing		
Source	**Language**	**Drafting Team Resolution**
FERC Order 693	Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.	Specific time intervals are included in the draft standard.
Version 0 Team	Exemptions for those with shunt reactors	UV Relays on shunt reactors are not UVLS; these relays would be included as pertinent to relays "applied on or to protect the BES".
Version 0 Team	Define evidence	Requirement R4 established that the program must be implemented. Evidence that the program is implemented is a measure; evidence is not discussed in requirements.

PRC-017-0 — Special Protection System Maintenance and Testing		
Source	**Language**	**Drafting Team Resolution**
FERC Order 693	Require that documentation identified in requirement R2 be routinely provided to NERC or the regional entity.	Language to be addressed in the compliance section of the standard.
FERC Order 693	Maintenance and testing of a protection system must be carried out within a maximum allowable time interval that is appropriate for the type of protection system and its impact on the reliability of the bulk power system.	Table 1 establishes maximum allowable maintenance intervals, with different intervals for different technologies of protective system equipment, and for different components defined within "Protection System"
Version 0 Team	Need to retain two dates	Not sure what this is.
Version 0 Team	Define evidence	Requirement R4 established that the program must be implemented. Evidence that the program is implemented is a measure; evidence is not discussed in requirements.

Introduction

The following is a draft collection of questions and answers that the PSMT SDT believes could be helpful to those implementing NERC Standard PRC-005-2 Protection System Maintenance. As the draft standard proceeds through development, this FAQ document will be revised, including responses to key or frequent comments from the posting process. The FAQ will be organized at a later time during the development of the draft Standard.

This FAQ document will support both the Standard and the associated Technical Reference document.

Executive Summary

- To be added later if needed.

Terms Used in PRC-005-2

Maintenance Correctable Issue — As indicated in footnote 2 of the draft standard, a maintenance correctable issue is a failure of a device to operate within design parameters that can be restored to functional order by calibration, repair or replacement

Segment — As indicated in *PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*, a segment is a "A grouping of Protection Systems or component devices of a particular model or type from a single manufacturer, with other common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components."

Component — This equipment is first mentioned in Requirement 1, Part 1.1 of this standard. A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. Types of components are listed in Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems"). For components such as dc circuits, the designation of what constitutes a dc control circuit element is somewhat arbitrary and is very dependent upon how an entity performs and tracks the testing of the dc circuitry. Some entities test their dc circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of "dc control circuit elements." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event — As indicated in footnote 4 of *PRC-005 Attachment A, Criteria for a Performance-based Protection System Maintenance Program*, countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.

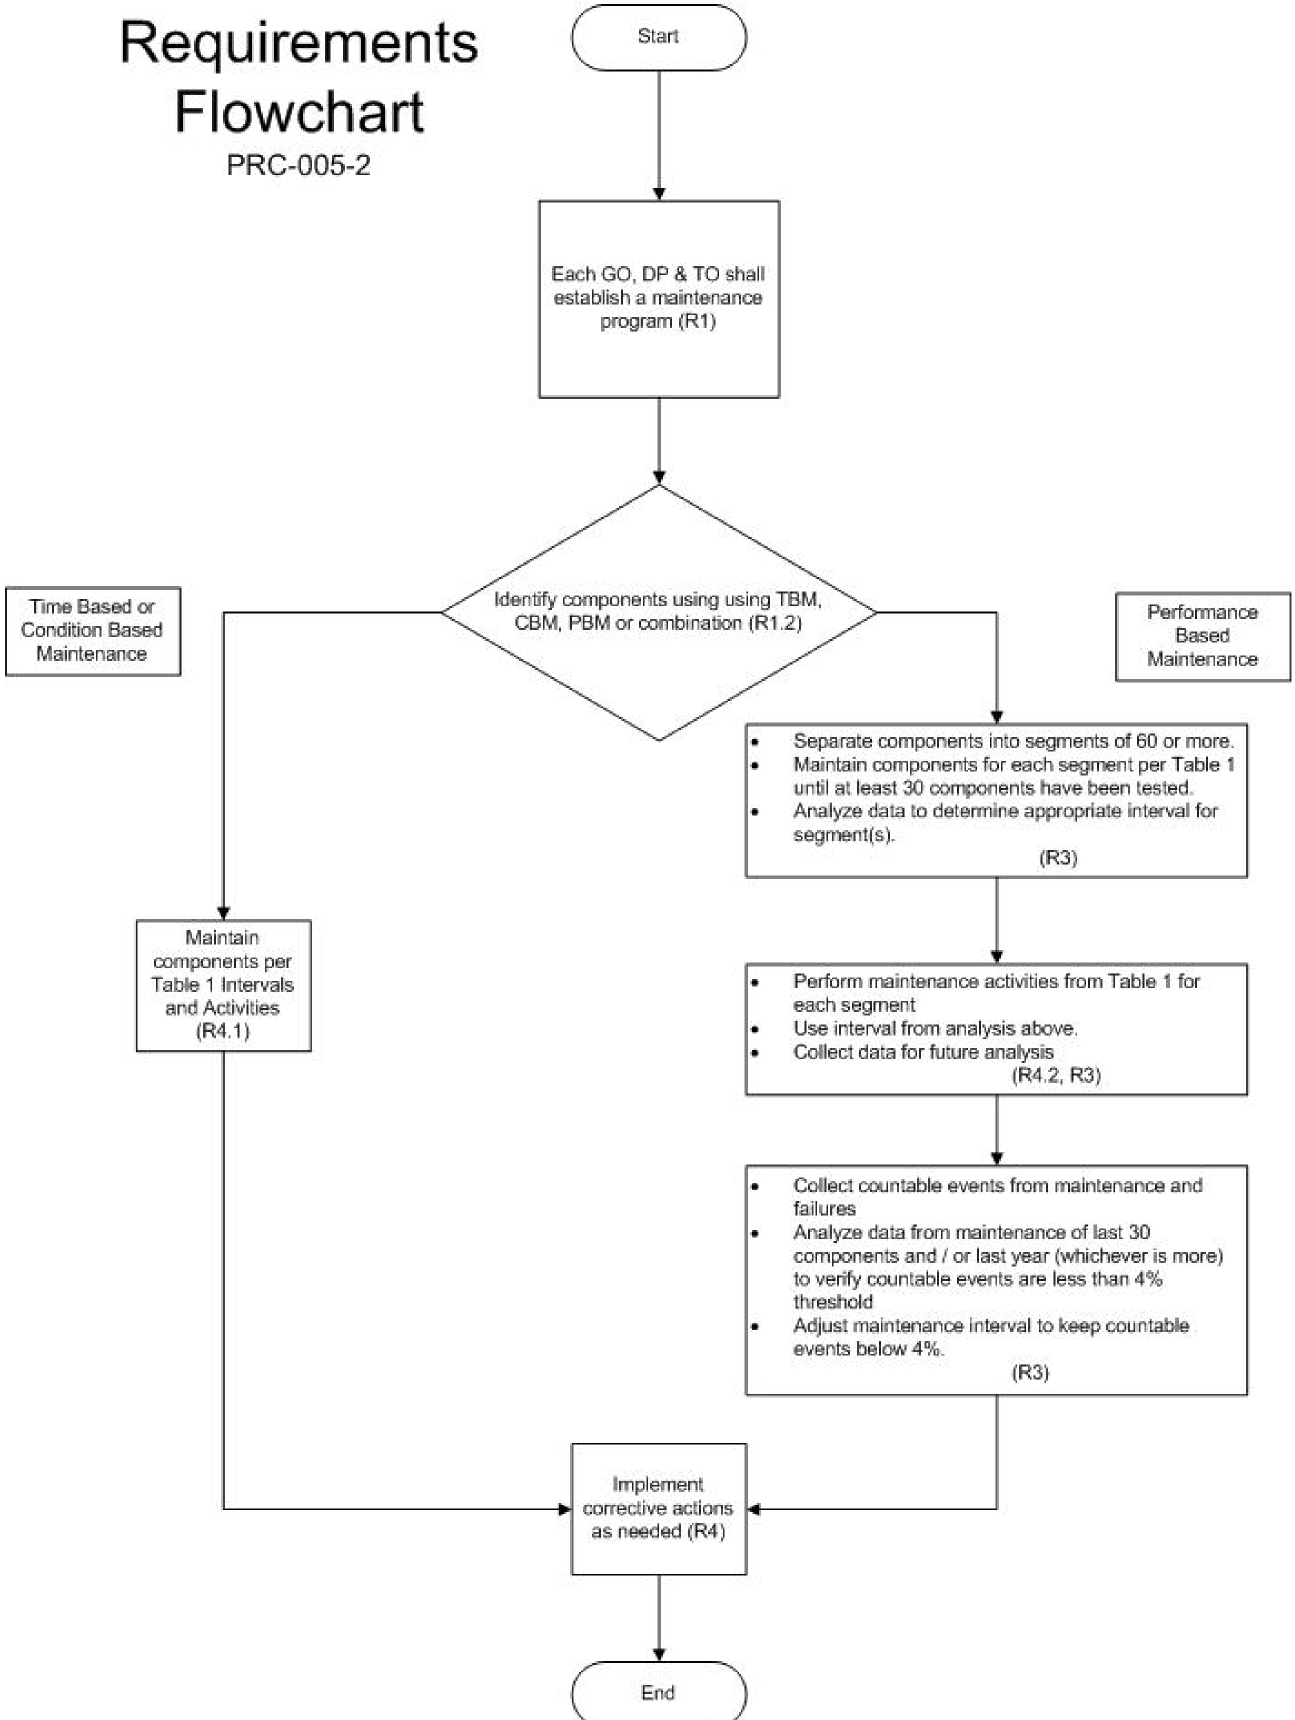
Frequently Asked Questions

General FAQs:

1. **The standard seems very complicated, and is difficult to understand. Can it be simplified?**

   Because the standard is establishing parameters for condition-based Maintenance (R2) and performance-based Maintenance (R3) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to follow R1 and R4 and perform ONLY time-based maintenance according to Table 1a, eliminating R2 and R3 from consideration altogether. If an entity then wishes to take advantage of monitoring on its Protection System components, R2 comes into play, along with Tables 1b and 1c. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, R3 applies.

   Please see the following diagram, which provides a “flow chart” of the standard.



Requirements
Flowchart
PRC-005-2
Start
Each GO, DP & TO shall establish a maintenance program (R1)
Identify components using using TBM, CBM, PBM or combination (R1.2)
Time Based or Condition Based Maintenance
Performance Based Maintenance
Separate components into segments of 60 or more.
Maintain components for each segment per Table 1 until at least 30 components have been tested.
Analyze data to determine appropriate interval for segment(s).
(R3)
Maintain components per Table 1 Intervals and Activities (R4.1)
Perform maintenance activities from Table 1 for each segment
Use interval from analysis above.
Collect data for future analysis
(R4.2, R3)
Collect countable events from maintenance and failures
Analyze data from maintenance of last 30 components and / or last year (whichever is more) to verify countable events are less than 4% threshold
Adjust maintenance interval to keep countable events below 4%.
(R3)
Implement corrective actions as needed (R4)
End

Group by Type of Protection System Component:

1. **All**

   A. Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this standard?

   No. As stated in R1, this standard covers protective relays that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

   B. Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous standard, PRC-005-1?

   PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented Maintenance program, and is focused on establishing Requirements rather than prescribing methodology to meet those Requirements. Between the activities identified in Tables 1a, 1b, and 1c, and the various components of the definition established for a “Protection System Maintenance Program”, PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

2. **Protective Relays**

   A. How do I approach testing when I have to upgrade firmware of a microprocessor relay?

   The component “Upkeep” in the definition of a Protection System Maintenance Program, addresses “Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer’s hardware and software service advisories which are relevant to the application of the device.” The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to Upkeep for Protective Relays. However, the entity should assure that the relay continues to function properly after implementation of firmware changes.

   B. I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

   This standard addresses only devices “that are applied on, or are designed to provide protection for the BES.” Protective relays, providing only the functions mentioned in the question, are not included.

   C. I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are applied on, or are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

3. Voltage and Current Sensing Device Inputs to Protective Relays

A. What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must prove that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. Some examples follow:

◊ Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.

◊ Compare the values, as determined by the questioned relay, to another protective relay monitoring the same line, with currents supplied by different CTs.

◊ Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

◊ Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

B. The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

These values will be zero, or very small, for any reasonably balanced system. To verify these values by comparison, you will need to rely on the normal condition that your system is not perfectly balanced, and there will usually be a small zero-sequence current or voltage, and these values can be measured with instruments having a sufficiently low resolution range. A reading of precisely zero will probably suggest that there is an opening (or some other problem) in the measuring circuit. A finite value of a few percent of the phase quantities, however, may suggest that the measuring circuit is indeed performing properly.

These quantities may be also verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

C. Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not required by the Maintenance Standard.

4. Protection System Control Circuitry

A. Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

B. The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a dc battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

C. How do I test each dc Control Circuit path, as established for level 2 (partially monitored protection systems) monitoring of a "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1b specifies that each breaker trip coil, auxiliary relay, and lockout relay must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

D. What does this standard require for testing an Auxiliary Tripping Relay?

Table 1 requires that the trip test must verify that the auxiliary tripping relay (94) or lockout relay (86) operates electrically and that their trip output(s) perform as expected.

E. What does a functional trip test include?

An operational trip test must be performed on each portion of a trip circuit. Each control circuit path that produces trip signal must be verified; this includes trip coils, auxiliary tripping relays (94), lockout relays (86) and communications-assisted-trip schemes.

A trip test may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip scheme, provided that testing of the various portions of the trip scheme verifies all of the portions, including parallel paths, and overlaps those portions.

A circuit breaker or other interrupting device needs to be trip tested at least once per trip coil. Breaker auxiliary contacts that are essential for the proper operation of the protective relay trip-circuit (or trip-logic) must be verified as providing the correct breaker open/close status information to the Protection System.

Discrete-component auxiliary relays (94) and lock-out relays (86) must be proven by trip test. The trip test must verify that the auxiliary or lock-out relay operates electrically and that the relay's trip output(s) change(s) state. Software latches or control algorithms, including trip logic processing implemented as programming component such as a microprocessor relay that take the place of (conventional) discrete component auxiliary relays or lock-out relays do not have to be routinely trip tested.

Normally-closed auxiliary contacts from other devices (for example, switchyard-voltage-level disconnect switches, interlock switches, or pressure switches) which are in the breaker trip path do not need to be tested.

F. Is a Sudden Pressure Relay an Auxiliary Tripping Relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63, and is excluded from the Standard by footnote 1.

G. The standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as “A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed.”

H. What is a Lock-out Relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

I. My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

5. Station dc Supply

A. What constitutes the station dc supply as mentioned in the definition of Protective System?

The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger — The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery — Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1.

Emerging Technologies — Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

B. In the Maintenance Activities for station dc supply in Table 1, what do you mean by "continuity"?

Because the Standard pertains to maintenance not only of the station battery, but also the whole station dc supply, continuity checks of the station dc supply are required. "Continuity" as used in Table 1 refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal, otherwise there is no way of determining that a station battery is available to supply dc current to the station.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service.

C. Why is it necessary to verify the continuity of the dc supply?

In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

If the battery charger is not sized to handle the maximum dc current required to operate the protective systems, it is sized only to handle the constant dc load of the station and the charging current required to bring the battery back to full charge following a discharge. At those stations, the battery charger would not be able to trip breakers and switches if the battery experiences loss of continuity.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- ◊ Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- ◊ Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

D. How do you verify continuity of the dc supply?

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the substation dc circuitry.

Although the Standard prescribes what must be done during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery.

- ◊ One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- ◊ A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- ◊ Manufacturers of microprocessor based battery chargers have developed methods for their equipment to periodically (or continuously) tested for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1 to insure that the station dc supply will provide the required current to the Protection System at all times.

E. Why is specific gravity testing required?

Specific gravity testing measures the state of the charge for each individual cell, and is performed to determine the condition of the charging system as well as the condition of the individual cell.

Specific gravity measurements can also be used as an indication of loss of continuity over a period of time. Specific gravity measurement is a method of determining the state of charge of a battery. Loss of continuity in the battery circuit will not allow charging current to flow through the battery and the battery cells will eventually self discharge causing the specific gravity to approach the specific gravity value of water which is 1.0.

If the specific gravity measurements taken during an inspection are determined to be low, this indicates that the battery is in a state of discharge. If no recent high discharges of the battery have occurred and the float voltage is normal, then the continuity of the battery circuit can be suspected and other tests such as measuring battery current should be made to determine if the specific gravity readings are an indication of loss of battery continuity.

F. When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium), the maintenance activity chosen, and the type of time based monitoring level selected.

For example, if you have a Valve Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every three months.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

G. Why in Table 1 are there two Maintenance Activities with different Maximum Maintenance Intervals listed to verify that the station battery can perform as designed?

The two acceptable methods for proving that a station battery can perform as designed are based on two different philosophies. The first activity requires a capacitive discharge test of the entire battery set to prove that degradation of one or several components (cells) in the set has not deteriorated to a point where the total capacity of the battery system falls below its designed rating. The second maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the battery set to determine that each component can perform as designed and therefore the entire battery set can be proven to perform as designed.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a battery set may degrade to an unacceptable level without causing the total battery set to fall below its designed rating under capacity testing. However, since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be proven to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

H. What is the justification for having two different Maintenance Activities listed in Table 1 to verify that the station battery can perform as designed?

IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid (VRLA), and nickel-cadmium batteries, respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed.

The first maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries.

The second maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement (taken at the time of the battery set's acceptance capacity test), low-capacity cells can be identified and eliminated to keep the battery set capable of performing as designed. This maintenance activity is applicable only for vented lead-acid and VRLA batteries.

I. Why in Table 1 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, vented lead-acid, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to prove that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity. Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

6. Protection System Communications Equipment

A. What are some examples of mechanisms to check communications equipment functioning?

For Level 1 unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are:

- ◊ On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier checkback test from one terminal.
- ◊ Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing a loss-of-guard indication or alarm. For frequency-shift power line power-line carrier systems, the guard signal level meter can also be checked.
- ◊ Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- ◊ Digital communications systems have some sort of data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For Level 2 partially monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are:

- ◊ On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier checkback tests, with remote alarming of failures.
- ◊ Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- ◊ Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- ◊ Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.

For Level 3 fully monitored Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- ◊ In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.

◊ Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

B. What is needed for the 3-month inspection of communication-assisted trip scheme equipment?

The 3-month inspection applies to Level 1 (Unmonitored) equipment. With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied.

C. Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communication system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communication equipment.

D. In Table 1b, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting “performance criteria”. What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For Level 1 systems this alarm will probably be on the panel. For Level 2 and Level 3 systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance criteria:

◊ For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.

◊ An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use checkback testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.

◊ Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.

◊ Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

7. UVLS and UFLS Relays that Comprise a Protection System Distributed Over the Power System

A. We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage for a transmission system that was intact except for the line that was out of service.

This Standard is not applicable to this UVLS.

UVLS installed to prevent system voltage collapse or voltage instability for BES reliability is covered by this standard.

8. SPS or Relay Sensing for Centralized UFLS or UVLS

A. Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test.

B. What about SPS interfaces between different entities or owners?

All SPS owners should have maintenance agreements that state which owner will perform specific tasks. SPS segments can be tested individually, but must overlap.

C. What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

D. How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?

Components of the SPS, UFLS, or UVLS should be maintained like similar components used for other Protection System functions.

The output action verification may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS, UFLS, or UVLS components whose operation leads to that control action must each be verified.

Group by Type of BES Facility:

1. All BES Facilities

A. What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms Used in Reliability Standards, and is not being modified within this draft Standard.

NERC's approved definition of Bulk Electric System is:

> As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 16, 2007 Informational Filing*.

2. Generation

A. Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays

- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

A loss of a system connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source. Thus, operation of any of the following relays associated with system connected station auxiliary transformers would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit.

3. Transmission

A. Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

Group by Type of Maintenance Program:

1. All Protection System Maintenance Programs

A. I can't figure out how to demonstrate compliance with the requirements for level 3 (fully monitored) Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for level 3 (fully monitored) Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be comprehensive.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c. However, even if there is no equipment available today that can meet this level of monitoring, the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

B. What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database screen shots that demonstrate compliance information
- Diagrams, engineering prints, schematics, maintenance and testing records, etc.
- Logs (operator, substation, and other types of log)
- U.S. or Canadian mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Database lists

C. If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

The replacement component must be tested to a degree that assures that it will perform as intended. If it is desired to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

2. Time-Based Protection System Maintenance (TBM) Programs

A. What does this Maintenance Standard say about commissioning?

Commissioning tests are regarded as a construction activity, not a maintenance activity.

B. The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals.

C. If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this standard.

The NERC Sanction Guidelines provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.[1]

D. What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

Any entity can choose to test some or all of their Protection System more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently.

3. Performance-Based Protection System Maintenance (PBM) Programs

A. I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

B. Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they can not prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

C. When establishing a perfomance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

D. What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM) Program?

1 Sanction Guidelines of the North American Electric Reliability Corporation. Effective January 15, 2008.

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

Human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation.

Certain types of Protection System component errors that cause Misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

E. What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

F. If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed count as a maintenance activity, and “reset the clock” on everything you’ve done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group.

G. Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition based maintenance program using Level 3 monitoring of the battery used in a station dc supply can not do so. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, Level 3 monitoring of a battery can eliminate the requirement for periodic testing and some inspections (see Level 3 Monitoring Attributes for Component of table 1c).

Group by Monitoring Level:

1. **All Monitoring Levels**

   A. Please provide an example of the level 1 monitored (unmonitored) versus other levels of monitoring available?

   A level 1 (Unmonitored) Protection System has no monitoring and alarm circuits on the Protection System components.

   A level 2 (Partially) monitored Protection System or an individual component of a level 2 (Partially) monitored Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert a 24-hr staffed operations center.

   There can be a combination of monitored and unmonitored Protection Systems within any given substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of level 2 (Partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
◊ Instrumentation transformers, with no monitoring, connected as inputs to that relay. (level 1)
◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
◊ A circuit breaker with a trip coil, with no monitor circuit. (level 1)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum test intervals of:

◊ The microprocessor relay is verified every 12 calendar years.
◊ The instrumentation transformers are verified every 12 calendar years.
◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #2: A combination of level 2 (partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with integral alarm that is not connected to SCADA. (level 1)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (level 1)
◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
◊ A circuit breaker with a trip coil, with no circuits monitored. (level 1)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum test intervals of:

◊ The microprocessor relay is verified every 6 calendar years.
◊ The instrumentation transformers are verified every 12 calendar years.
◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #3: A combination of level 2 (partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay (level 1)
◊ Battery without any alarms connected to SCADA (level 1)
◊ Circuit breaker with a trip coil, with no circuits monitored (level 1)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components have maximum test intervals of:

- ◊ The microprocessor relay is verified every 12 calendar years.
- ◊ The instrument transformers are verified every 12 calendar years.
- ◊ The battery is verified every 3 months, every 18 months, plus, depending upon the type of battery used it may be verified at other maximum test intervals, as well.
- ◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

B. What is the intent behind the different levels of monitoring?

The intent behind different levels of monitoring is to allow less frequent manual intervention when more information is known about the condition of Protection System components.

C. Do all monitoring levels apply to all components in a protection system?

No. For some components in a protection system, certain levels of monitoring will not be relevant. See table below:

Monitoring Level Applicability Table

(See related definition and decision tree for various level requirements)

Protection Component	Level 1 (Unmonitored)	Level 2 (Partially Monitored)	Level 3 (Fully Monitored)
Protective relays	Y	Y	Y
Instrument transformer Inputs to Protective Relays	Y	N	Y
Protection System control circuitry (Other than aux-relays & lock-out relays)	Y	Y	Y
Aux-relays & lock-out relays	Y	N	N
DC supply (other than station batteries)	Y	Y	Y
Station batteries	Y	N	N
Protection system communications equipment and channels	Y	Y	Y
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	Y	Y	Y
SPS, including verification of end-to-end performance, or relay sensing for centralized UFLS or UVLS systems	Y	Y	Y

Y = Monitoring Level Applies
N = Monitoring Level Not Applicable

D. When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R2 of the standard, is it necessary to provide this documentation via a device by device listing of components and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc systems are Level 2 - Partially Monitored by stating the following within the program description:

> "All substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc systems of Substation X, Substation Y, and Substation Z are considered Level 1 - Unmonitored and subject to Table 1a requirements as they are not equipped with ground detection capability."

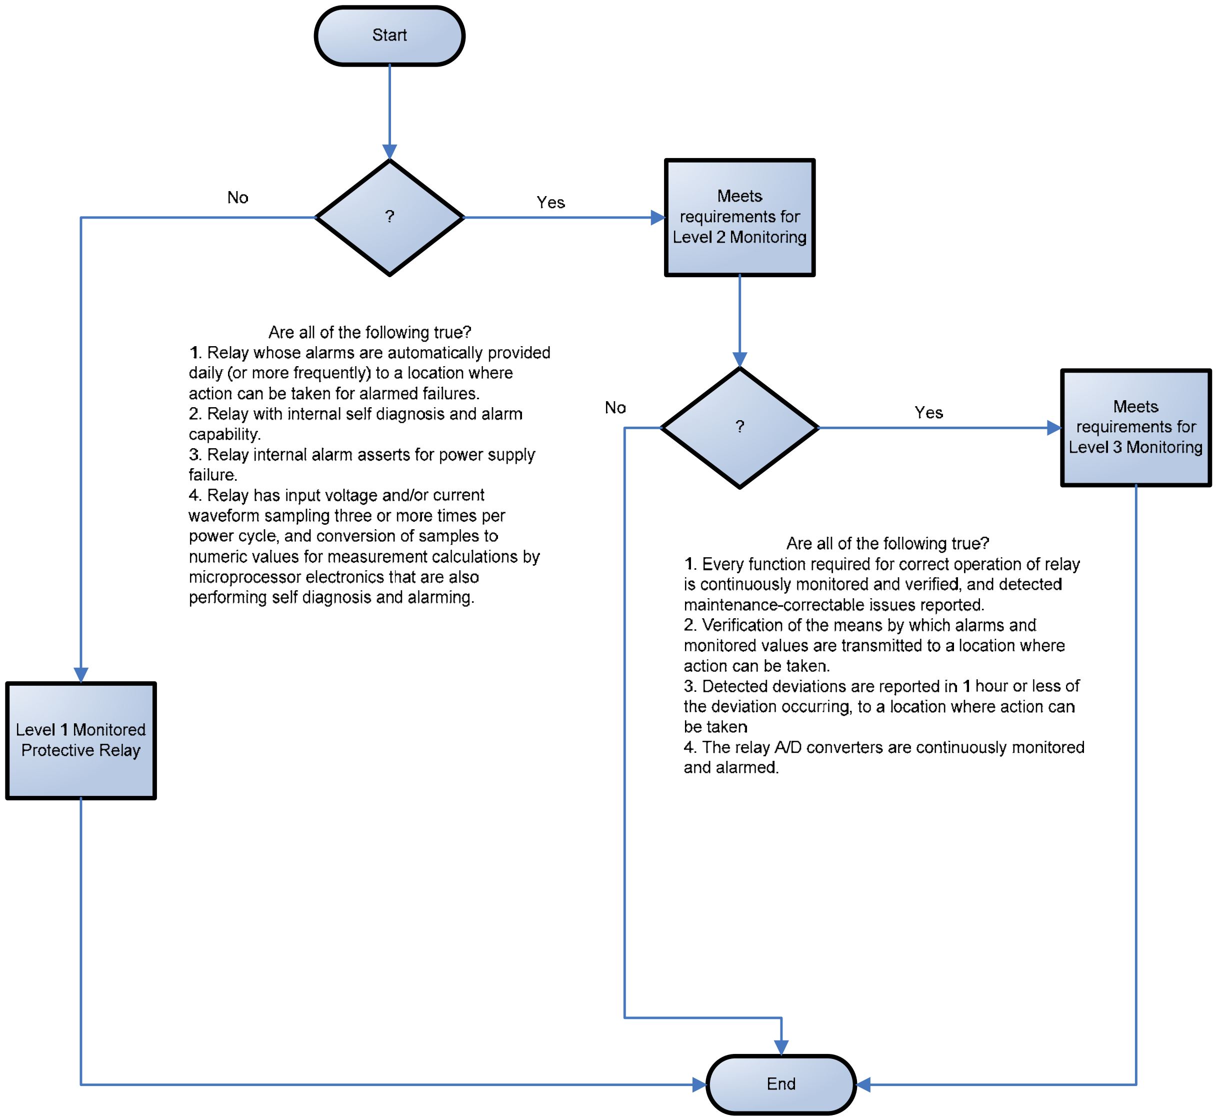
Regardless whether this documentation is provided via a device by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

E. How do I know what monitoring level I am under? – Include Decision Trees

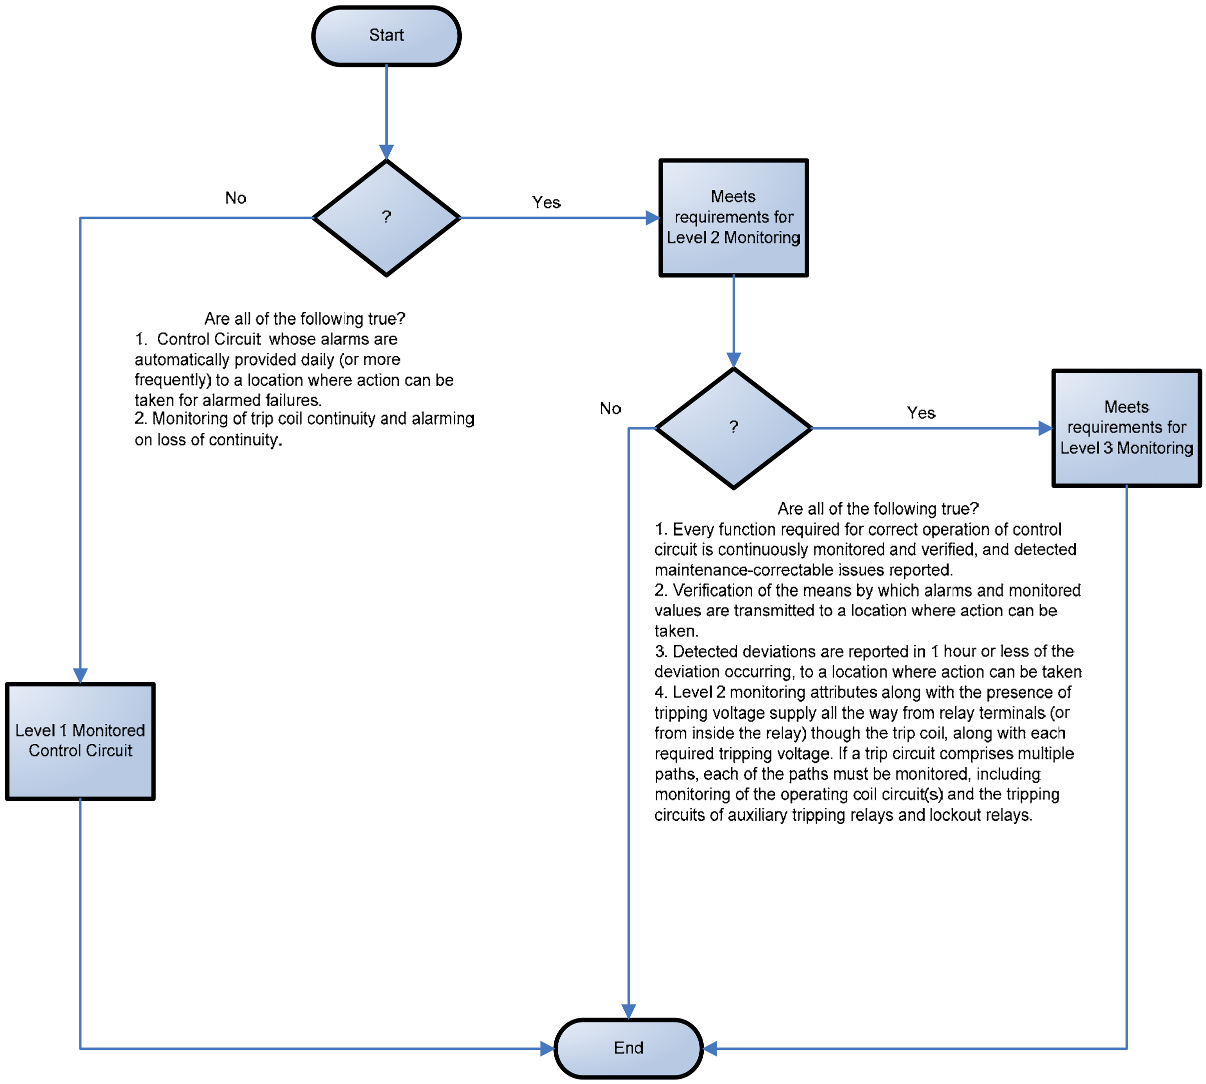
Decision Trees are provided below for each of the following categories of equipment to assist in the determination of the level of monitoring.

- ◊ Protective Relays
- ◊ Protection System Control Circuitry
- ◊ Station dc Supply
- ◊ Protection System Communications Equipment and Channels

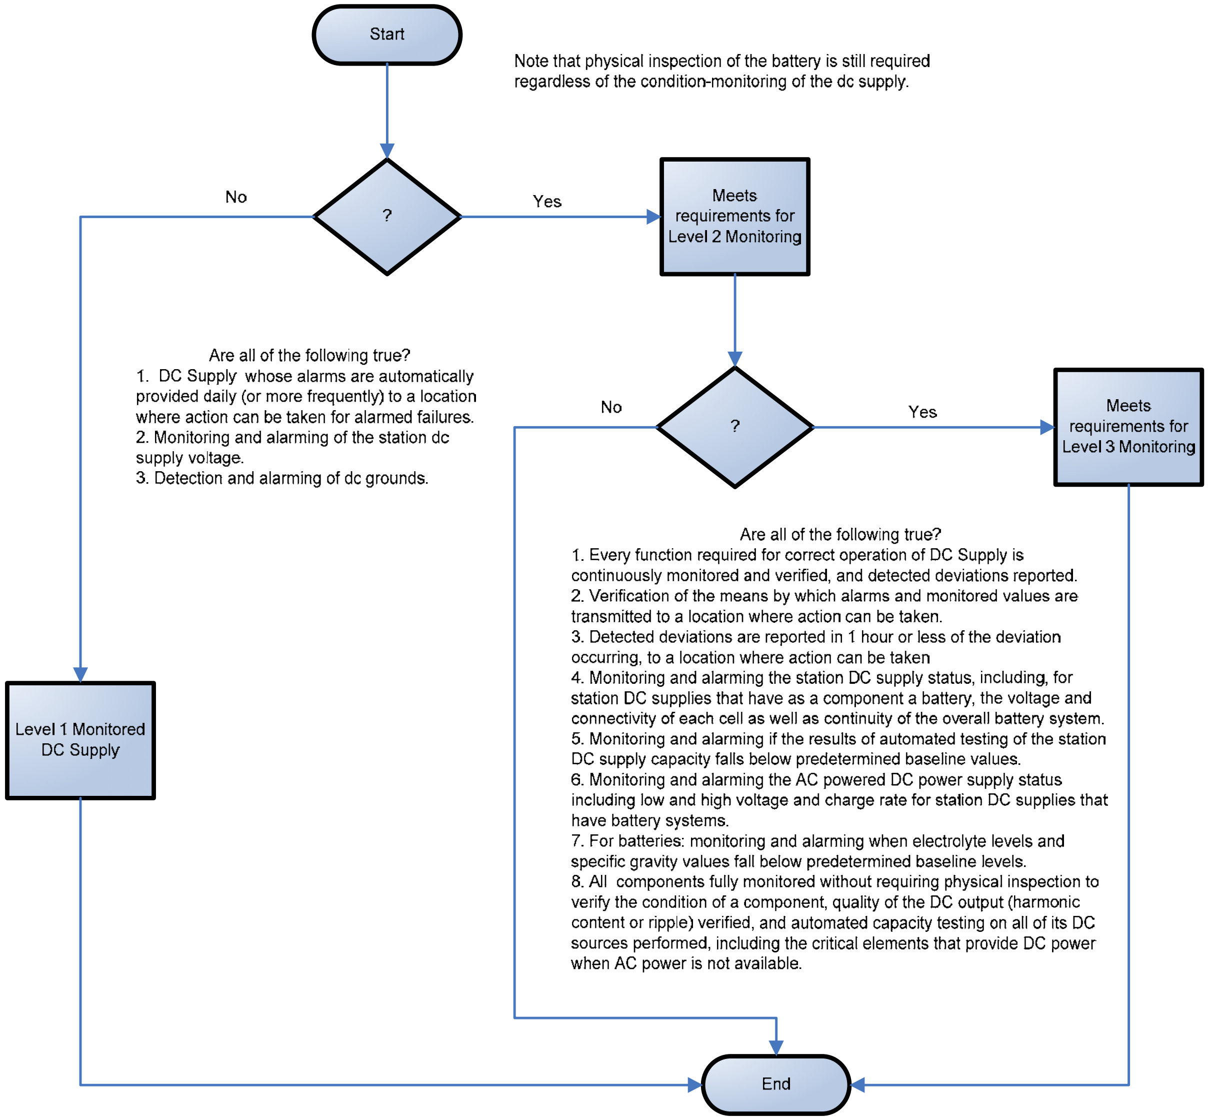
RELAY - MONITOR LEVEL DECISION TREE

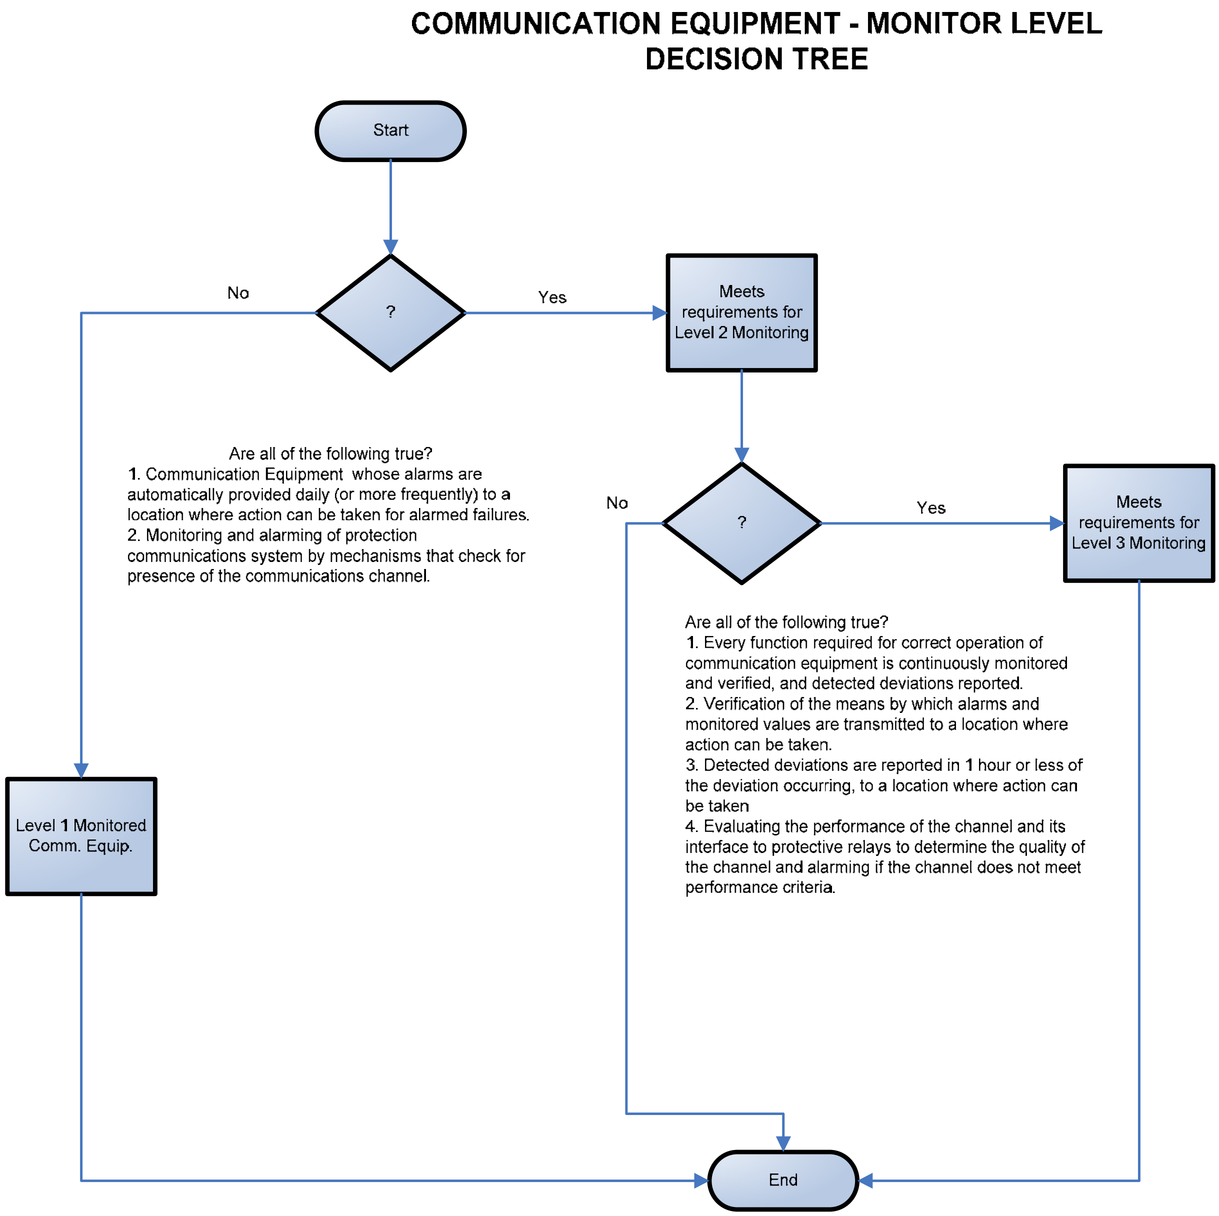


CONTROL CIRCUIT - MONITOR LEVEL DECISION TREE



DC SUPPLY - MONITOR LEVEL DECISION TREE





2. **Level 1 Monitored Protection Systems (Unmonitored Protection Systems)**

A. **We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?**

This system is made up of components that are level 1 (unmonitored). Assuming a time-based protection system maintenance program schedule, each component must be maintained per Table 1a – Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities.

3. Level 2 Monitored Protection Systems (Partially Monitored Protection Systems)

A. We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Is this an unmonitored or a partially-monitored system? How often must I perform maintenance?

The protective relay is a level 2 (partially) monitored component of your protection system and can be maintained every 12 years or when a maintenance correctable issue arises. Assuming a time-based protection system maintenance program schedule, this component must be maintained per Table 1b – Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities

The rest of your protection system contains components that are level 1 (unmonitored) and must be maintained within at least the maximum verification intervals of Table 1a.

B. How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Examples include using values gathered via data communications and automatically comparing these values with values from other sources, and using groupings of other measurements (such as vector summation of bus feeder currents) for comparison if calibration requirements assure acceptable measurement of power system input values. Other methods are possible.

C. For a level 2 monitored Protection System (Partially Monitored Protection System) pertaining to Protection System communications equipment and channels, how is the performance criteria involved in the maintenance program?

The entity determines the performance criteria for each installation, depending on the technology implemented. If the communication channel performance of a Protection System varies from the pre-determined performance criteria for that system, these results should be investigated and resolved.

4. Level 3 Monitored Protection Systems (Fully Monitored Protection Systems)

A. Why are there activities defined for a level-3 monitored Protection System? The technology does not seem to exist at this time to implement this monitoring level.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c.

However, even if there is no equipment available today that can meet this level of monitoring, the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

Assessment of Impact of Proposed Modification to the Definition of "Protection System"

Existing Definition:

Protection System — Protective relays, associated communication systems, voltage and current sensing devices, station batteries, and DC control circuitry.

Proposed Definition (Clean):

Protection System - Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

General Description of Definition Change

The proposed definition of Protection System modifies the existing definition to

1) More precisely define the applicable communication systems

2) More precisely define the involved voltage and current sensing inputs

3) Expand the existing definition to include the entire station DC supply

4) More expansively and precisely define the applicable DC control circuitry.

General Assessment of Impact of Change

After adoption of the proposed change, the definition remains consistent with the existing uses. The modifications make it more useful and lead to an increased ability to monitor compliance of some of the standards using the definition. The following table illustrates each use of the term, "Protective System" in the existing FERC-approved standards, whether the term is capitalized (indicating that the intent is to use the defined term) or not. The modifications, though, address ambiguities that have been identified within the existing approved definition, and are important for the detailed use of the definition within the draft PRC-005-2 Standard.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
NUC-001-1 — Nuclear Plant Interface Coordination	R7. Per the Agreements developed in accordance with this standard, the Nuclear Plant Generator Operator shall inform the applicable Transmission Entities of actual or proposed changes to nuclear plant design, configuration, operations, limits, **protection systems**, or capabilities that may impact the ability of the electric system to meet the NPIRs.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
NUC-001-1 — Nuclear Plant Interface Coordination	R8. Per the Agreements developed in accordance with this standard, the applicable Transmission Entities shall inform the Nuclear Plant Generator Operator of actual or proposed changes to electric system design, configuration, operations, limits, **protection systems**, or capabilities that may impact the ability of the electric system to meet the NPIRs.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PER-005-1 — System Personnel Training	R3.1. Each Reliability Coordinator, Balancing Authority and Transmission Operator that has operational authority or control over Facilities with established IROLs or has established operating guides or **protection systems** to mitigate IROL violations shall provide each System Operator with emergency operations training using simulation technology such as a simulator, virtual technology, or other technology that replicates the operational behavior of the BES during normal and emergency conditions.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-001-1 — System Protection Coordination	R1. Each Transmission Operator, Balancing Authority, and Generator Operator shall be familiar with the purpose and limitations of **protection system** schemes applied in its area.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-001-1 —– System Protection Coordination	R4. Each Transmission Operator shall coordinate **protection systems** on major transmission lines and interconnections with neighboring Generator Operators, Transmission Operators, and Balancing Authorities.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
PRC-001-1 — System Protection Coordination	R5. A Generator Operator or Transmission Operator shall coordinate changes in generation, transmission, load or operating conditions that could require changes in the **protection systems** of others: R5.1. Each Generator Operator shall notify its Transmission Operator in advance of changes in generation or operating conditions that could require changes in the Transmission Operator's **protection systems**. R5.2. Each Transmission Operator shall notify neighboring Transmission Operators in advance of changes in generation, transmission, load, or operating conditions that could require changes in the other Transmission Operators' **protection systems**.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-003-1 — Regional Procedure for Analysis of Misoperations of Transmission and Generation Protection Systems	Purpose - To ensure all transmission and generation **Protection System** Misoperations affecting the reliability of the Bulk Electric System (BES) are analyzed and mitigated.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-003-1 — Regional Procedure for Analysis of Misoperations of Transmission and Generation Protection Systems	R1. Each Regional Reliability Organization shall establish, document and maintain its procedures for, review, analysis, reporting and mitigation of transmission and generation **Protection System** Misoperations. These procedures shall include the following elements: R1.1. The **Protection Systems** to be reviewed and analyzed for Misoperations (due to their potential impact on BES reliability).	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
PRC-003-1 — Regional Procedure for Analysis of Misoperations of Transmission and Generation Protection Systems	R2. Each Regional Reliability Organization shall maintain and periodically update documentation of its procedures for review, analysis, reporting, and mitigation of transmission and generation **Protection System** Misoperations.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-003-1 — Regional Procedure for Analysis of Misoperations of Transmission and Generation Protection Systems	R3. Each Regional Reliability Organization shall distribute procedures in Requirement 1 and any changes to those procedures, to the affected Transmission Owners, Distribution Providers that own transmission **Protection Systems**, and Generator Owners within 30 calendar days of approval of those procedures.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-004-1 — Analysis and Mitigation of Transmission and Generation Protection System Misoperations	Purpose - Ensure all transmission and generation **Protection System** Misoperations affecting the reliability of the Bulk Electric System (BES) are analyzed and mitigated.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-004-1 — Analysis and Mitigation of Transmission and Generation Protection System Misoperations	R1. The Transmission Owner and any Distribution Provider that owns a transmission **Protection System** shall each analyze its transmission **Protection System** Misoperations and shall develop and implement a Corrective Action Plan to avoid future Misoperations of a similar nature according to the Regional Reliability Organization's procedures developed for Reliability Standard PRC-003 Requirement 1.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
PRC-004-1 — Analysis and Mitigation of Transmission and Generation Protection System Misoperations	R2. The Generator Owner shall analyze its generator **Protection System** Misoperations, and shall develop and implement a Corrective Action Plan to avoid future Misoperations of a similar nature according to the Regional Reliability Organization's procedures developed for PRC-003 R1.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
PRC-004-1 — Analysis and Mitigation of Transmission and Generation Protection System Misoperations	R3. The Transmission Owner, any Distribution Provider that owns a transmission **Protection System**, and the Generator Owner shall each provide to its Regional Reliability Organization, documentation of its Misoperations analyses and Corrective Action Plans according to the Regional Reliability Organization's procedures developed for PRC-003 R1.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
WECC Standard PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation	Purpose - Regional Reliability Standard to ensure all transmission and generation **Protection System** and Remedial Action Scheme (RAS) Misoperations on Transmission Paths and RAS defined in section 4 are analyzed and/or mitigated.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
WECC Standard PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation	R1. System Operators and System Protection personnel of the Transmission Owners and Generator Owners shall analyze all **Protection System** and RAS operations. R1.2. System Protection personnel shall analyze all operations of **Protection Systems** and RAS within 20 business days for correctness to characterize whether a Misoperation has occurred that may not have been identified by System Operators.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
WECC Standard PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation	R2. Transmission Owners and Generator Owners shall perform the following actions for each Misoperation of the **Protection System** or RAS. It is not intended that Requirements R2.1 through R2.4 apply to **Protection System** and/or RAS actions that appear to be entirely reasonable and correct at the time of occurrence and associated system performance is fully compliant with NERC Reliability Standards. If the Transmission Owner or Generator Owner later finds the **Protection System** or RAS operation to be incorrect through System Protection personnel analysis, the requirements of R2.1 through R2.4 become applicable at the time the Transmission Owner or Generator Owner identifies the Misoperation: R2.1 If the **Protection System** or RAS has a Security-Based Misoperation and two or more Functionally Equivalent **Protection Systems** (FEPS) or Functionally Equivalent RAS (FERAS) remain in service to ensure Bulk Electric System (BES) reliability, the Transmission Owners or Generator Owners shall remove from service the **Protection System** or RAS that misoperated within 22 hours following identification of the Misoperation. Repair or replacement of the failed Protection System or RAS is at the Transmission Owners' and Generator Owners' discretion. R2.2. If the **Protection System** or RAS has a Security-Based Misoperation and only one FEPS or FERAS remains in service to ensure BES reliability, the Transmission Owner or Generator Owner shall perform the following. R2.2.1. Following identification of the **Protection System** or RAS Misoperation, Transmission Owners and Generator Owners shall remove from service within 22 hours for repair or modification the **Protection System** or RAS that misoperated. R2.2.2. The Transmission Owner or Generator Owner shall repair or replace any **Protection System** or RAS that misoperated with a FEPS or FERAS within 20 business days of the date of removal. The Transmission Owner or Generator Owner shall remove the Element from service or disable the RAS if repair or replacement is not completed within 20 business days.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
WECC Standard PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation	R2.3. If the **Protection System** or RAS has a Security-Based or Dependability-Based Misoperation and a FEPS and FERAS is not in service to ensure BES reliability, Transmission Owners or Generator Owners shall repair and place back in service within 22 hours the **Protection System** or RAS that misoperated. If this cannot be done, then Transmission Owners and Generator Owners shall perform the following. R2.3.1. When a FEPS is not available, the Transmission Owners shall remove the associated Element from service. R2.4. If the **Protection System** or RAS has a Dependability-Based Misoperation but has one or more FEPS or FERAS that operated correctly, the associated Element or transmission path may remain in service without removing from service the **Protection System** or RAS that failed, provided one of the following is performed. R2.4.1. Transmission Owners or Generator Owners shall repair or replace any **Protection System** or RAS that misoperated with FEPS and FERAS within 20 business days of the date of the Misoperation identification, or R2.4.2. Transmission Owners or Generator Owners shall remove from service the associated Element or RAS.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
WECC Standard PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation	R3. Transmission Owners and Generation Owners shall submit Misoperation incident reports to WECC within 10 business days for the following. R3.1. Identification of a Misoperation of a **Protection System** and/or RAS, R3.2. Completion of repairs or the replacement of **Protection System** and/or RAS that misoperated.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
WECC Standard PRC-STD-003-1 — Protective Relay and Remedial Action Scheme Misoperation	Purpose - Regional Reliability Standard to ensure all transmission and generation **Protection System** Misoperations affecting the reliability of the Bulk Electric System (BES) are analyzed and mitigated. PRC-STD-003-1 is a Regional Reliability Standard that meets Requirement 1 of the NERC Standard PRC-003-1.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
TPL-001-0.1 — System Performance Under Normal Conditions (also TPL-002-0, TPL-003-0, and TPL-004-0)	Table 1C - SLG Fault, with Delayed Clearing (stuck breaker or **protection system** failure):	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
TPL-001-0.1 — System Performance Under Normal Conditions (also TPL-002-0, TPL-003-0, and TPL-004-0)	Table 1D - 3Ø Fault, with Delayed Clearing (stuck breaker or **protection system** failure):	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
TPL-001-0.1 — System Performance Under Normal Conditions (also TPL-002-0, TPL-003-0, and TPL-004-0)	Table 1 – Footnote e. Normal clearing is when the protection system operates as designed and the Fault is cleared in the time normally expected with proper functioning of the installed **protection systems**. Delayed clearing of a Fault is due to failure of any **protection system** component such as a relay, circuit breaker, or current transformer, and not because of an intentional design delay.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
TPL-002-0a — System Performance Following Loss of a Single BES Element	R1. The Planning Authority and Transmission Planner shall each demonstrate through a valid assessment that its portion of the interconnected transmission system is planned such that the Network can be operated to supply projected customer demands and projected Firm (nonrecallable reserved) Transmission Services, at all demand levels over the range of forecast system demands, under the contingency conditions as defined in Category B of Table I. To be valid, the Planning Authority and Transmission Planner assessments shall: R1.3. Be supported by a current or past study and/or system simulation testing that addresses each of the following categories,, showing system performance following Category B of Table 1 (single contingencies). The specific elements selected (from each of the following categories) for inclusion in these studies and simulations shall be acceptable to the associated Regional Reliability Organization(s). R1.3.10. Include the effects of existing and planned **protection systems**, including any backup or redundant systems. R1.3.12. Include the planned (including maintenance) outage of any bulk electric equipment (including **protection systems** or their components) at those demand levels for which planned (including maintenance) outages are performed.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
TPL-003-0a — System Performance Following Loss Two or More BES Elements	R1. The Planning Authority and Transmission Planner shall each demonstrate through a valid assessment that its portion of the interconnected transmission systems is planned such that the network can be operated to supply projected customer demands and projected Firm (nonrecallable reserved) Transmission Services, at all demand Levels over the range of forecast system demands, under the contingency conditions as defined in Category C of Table I (attached). The controlled interruption of customer Demand, the planned removal of generators, or the Curtailment of firm (non-recallable reserved) power transfers may be necessary to meet this standard. To be valid, the Planning Authority and Transmission Planner assessments shall: R1.3. Be supported by a current or past study and/or system simulation testing that addresses each of the following categories, showing system performance following Category C of Table 1 (multiple contingencies). The specific elements selected (from each of the following categories) for inclusion in these studies and simulations shall be acceptable to the associated Regional Reliability Organization(s). R1.3.10. Include the effects of existing and planned **protection systems**, including any backup or redundant systems. R1.3.12. Include the planned (including maintenance) outage of any bulk electric equipment (including **protection systems** or their components) at those Demand levels for which planned (including maintenance) outages are performed.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
TPL-004 — System Performance Following Extreme BES Events	R1. The Planning Authority and Transmission Planner shall each demonstrate through a valid assessment that its portion of the interconnected transmission system is evaluated for the risks and consequences of a number of each of the extreme contingencies that are listed under Category D of Table I. To be valid, the Planning Authority's and Transmission Planner's assessment shall: R1.3. Be supported by a current or past study and/or system simulation testing that addresses each of the following categories, showing system performance following Category D contingencies of Table I. The specific elements selected (from within each of the following categories) for inclusion in these studies and simulations shall be acceptable to the associated Regional Reliability Organization(s). R1.3.7. Include the effects of existing and planned **protection systems**, including any backup or redundant systems. R1.3.9. Include the planned (including maintenance) outage of any bulk electric equipment (including **protection systems** or their components) at those demand levels for which planned (including maintenance) outages are performed.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
TPL-006-0 — Assessment Data from Regional Reliability Organizations	R1. Each Regional Reliability Organization shall provide, as requested (seasonally, annually, or as otherwise specified) by NERC, system data, including past, existing, and future facility and Bulk Electric System data, reports, and system performance information, necessary to assess reliability and compliance with the NERC Reliability Standards and the respective Regional planning criteria. The facility and Bulk Electric System data, reports, and system performance information shall include, but not be limited to, one or more of the following types of information as outlined below: R1.5. Transmission system and supporting information (thermal, voltage, and Stability Limits, contingency analyses, system restoration, system modeling and data requirements, and **protection systems**.)	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Assessment of Impact on Existing Standards – Based on May 20, 2009 Revision of NERC Standards		
Standard Number and Name	**Clause (excluding Measures and compliance elements)**	**Impact**
Glossary of Terms Definition — Delayed Fault Clearing	Fault clearing consistent with correct operation of a breaker failure protection system and its associated breakers, or of a backup **protection system** with an intentional time delay.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
Glossary of Terms Definition — Misoperation	• Any failure of a **Protection System** element to operate within the specified time when a fault or abnormal condition occurs within a zone of protection. • Any operation for a fault not within a zone of protection (other than operation as backup protection for a fault in an adjacent zone that is not cleared within a specified time for the protection for that zone). • Any unintentional **Protection System** operation when no fault or other abnormal condition has occurred unrelated to on-site maintenance and testing activity.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
Glossary of Terms Definition — Normal Clearing	A **protection system** operates as designed and the fault is cleared in the time normally expected with proper functioning of the installed **protection systems**.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.
Glossary of Terms Definition — Planning Authority	The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and **protection systems**.	The proposed revisions to the definition are consistent with this use, and do not affect the applicability of the definition.

Standards Announcement

Comment Period Open
July 24–September 8, 2009

Now available at:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Project Name:
Project 2007-17: Transmission and Generation Protection System Maintenance and Testing

Due Date and Submittal Information:
The comment period is open **until 8 p.m. EDT on September 8, 2009**. Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at Lauren.Koller@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Content for Comment Period:
The Transmission and Generation Protection System Maintenance and Testing Standard Drafting Team is seeking comments on its first draft of proposed standard PRC-005-2 — Protection System Maintenance.

Other Documents Posted:

- Implementation plan
- Table showing how the team addressed issues and input from FERC and stakeholders
- Frequently asked questions
- Supplemental reference
- Evaluation of the impact of changing the definition of Protection System

Project Background:
The draft standard combines the following previous standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing.

The proposed standard addresses FERC directives from FERC Order 693 as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices, and for a performance-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Applicability of Standards in Project:

Transmission Owners
Generator Owners
Distribution Providers

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

The SDT is to be commended for developing a clear and well documented draft. Overall it provides a balanced view of Protection System Maintenance, and good justification for its maximum intervals.
No
Table 1a – Level 1 Monitoring has a requirement to “Verify the continuity of the breaker trip circuit including trip coil” at least every 3 months. This is interpreted to be applicable to both the low-side generator output breaker and the high-side breaker for the GSU. The generator output breaker has 3 separate trip coils (one for each pole) that are connected in a parallel configuration and there is no means available to verify continuity of each of these coils INDIVIDUALLY in this arrangement. Is the intent of this requirement to have each trip signal parallel leg verified every three months even though the trip contacts are normally open (these circuits are functionally checked during LOR Functional Verification)? Also, is the Red Indication Light (RIL), which includes the trip coil in the power circuit, adequate for verification (note that the breaker does not include the parallel legs that contain the tripping sensor contacts)? Also, more clarification is needed on the section “Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays” under “Voltage and Current Sensing Devices Inputs to Protective Relays.” How would this be done if no redundancy is available for cross-checking voltage and current sources? In certain situations, “verify proper functioning” is not clear enough. Documentation of verification consistent with the entities procedures should be adequate to indicate compliance.
No
Several maximum maintenance intervals are 3 months. Since this is an absolute maximum period, entities would need to schedule on a 2 month basis to assure the 3 month maximum is

met, i.e., 6 times per year. We recommend that 3 month periods be increased to 4 months which allows scheduling every 3 months. Other methods of achieving the same result is to state periodic requirements of quarterly or 4 times per year.
No
Several maximum maintenance intervals are 3 months. Since this is an absolute maximum period, entities would need to schedule on a 2 month basis to assure the 3 month maximum is met, i.e., 6 times per year. We recommend that 3 month periods be increased to 4 months which allows scheduling every 3 months. An alternate method of achieving the same result is to state periodic requirements of quarterly or 4 times per year.
Yes
No
The FAQ should be expanded to address the issues raised above with verification of trip circuits as to what is an acceptable method meeting the intent of the standard We also suggest changing “prove” to “verify” on FAQ 3a to be consistent with the wording of the requirement. Also, for a single bus with one set of bus potential transformers, how does one verify proper functioning of the potentials? Is a reasonableness criterion adequate?
Individual
Rick Koch
Nebraska Public Power District
Yes
No
Table 1a, for Protective Relays identifies the following Maintenance Activities: Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. Verify proper functioning of the relay trip outputs. What is the difference between these two requirements? They appear to be practically equivalent. Tables 1a & 1b, for Station DC supply identify the following Maintenance Activity: Measure that specific gravity and temperature of each cell is within tolerance (where applicable). What is the advantage of testing the SG in every cell compared to using a pilot cell as representative sample of the entire bank? NPPD has not experienced any problems using a pilot cell compared to testing every individual cell. Typically, if the SG is low the cell voltage will be low, which is detected by the voltage test. This seems to be an excessive requirement and does increase personnel exposure to hazardous fluid. What unique information is provided by this test that other tests do not provide?
No
Table 1a, for Station DC supply (that has as a component Valve Regulated Lead-Acid batteries) establishes a Maximum Maintenance Interval of 3 Calendar Years for the following Maintenance Activity: Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. What is the basis for this interval? NPPD’s experience indicates that a 5 Year interval is adequate, especially during the early service life of the battery bank, with increasing frequency as the bank ages.
Yes
Yes
No
Yes
On page 17, the answers to questions 2B and 2C indicate that there is no allowance or provision to exceed the Maximum Maintenance Interval under any circumstances, except that natural disasters or other events of force majeure will receive special consideration when determining sanctions. The rigidity of this performance requirement could conceivably require equipment to be tested even though it is out of service in order to remain compliant, adding unnecessary cost and waste to the PSMP of the regulated entities. We believe that a prescriptive process for deferring testing and maintenance beyond the stated interval would be beneficial to allow the necessary flexibility to manage the PSMP effectively.
None
None
Definition of Terms: Footnote 2 for R4 defines a "maintenance correctable issue". This should be

added to the Definition of Terms section. Sections 4.2.5.4 and 4.2.5.5 inappropriately extends Generator Protection Systems to Station Service Transformers. These are components necessary for plant operation however they are not part of the generator protection scheme. This conclusion is supported by the explanations on page 16 of the FAQ. The FAQ states the operation of the listed station auxiliary transforms protective relays would result in the trip of the generating unit and, as such, would be included in the program. The FAQ goes on to state that relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of those loades could result in a trip of the generating unit. The FAQ appears to be inconsistent. Station auxiliary transformers are included because they would result in the trip of the generating unit while other loads such as pumps, fans, etc., are excluded even if their trip could result in a trip of the generating unit. In my opinion, the station service transformers like pumps, fans, etc. are components necessary for plant operation but not necessary for generator protection and should therefore be excluded from PRC-005-2 by removing Sections 4.2.5.4 and 4.2.5.5 from the Standard and modifying the FAQ accordingly. R1 (1.1) First sentence: "For each component used in each Protection System,..." is ambiguous. The sentence should be revised to say..."For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, and 1c." This limits the components to only those identified by the definition of a Protection System. R2 End of sentence: "possess the necessary monitoring attributes." is ambiguous. The sentence should be revised to say..."possess the monitoring attributes identified in Tables 1b or 1c." This specifically defines which attributes are necessary. R4 I am concerned with including the phrase "including identification of the resolution of all maintenance correctible issues". Providing evidence of implementation of the PSMP will require the collection and submittal of all work documents that restored a device to functional order by calibration, repair, or replacement. It is reasonable to assume that appropriate corrective actions were taken for each specific situation. Identification of the resolution will add a significant documentation burden without adding to the reliability of the BES. Implementation of the PSMP may be evidenced without including identification of the resolution of all maintenance correctible issues. It is interesting to note that nowhere in PRC-005-2 does it state that you have to take corrective actions to return a component to normal operating conditions. "No action taken" can be the resolution taken by the utility of a maintenance correctible issue.

What documentation or evidence is required to prove that the Protection System Control Circuitry has been maintained every three months, if just a visual inspection of the breaker control trip circuit RED panel light has been completed, to verify continuity of breaker trip coil? How do we handle breakers with dual trip coils and only one RED light for trip coil continuity? What do the terms DISTRIBUTED and CENTRALIZED with respect to UFLS mean? In Table 1C under the heading "Maximum Maintenance Interval" some of the entries are stated as being "Continuous". In the case of other maintenance activities the descriptor for Maintenance Interval indentifies the maximum period of time that may elapse before action must be taken. "Continuous" implies continuous action; however, in reality continuous monitoring enables no maintenance action to be taken until such time as trends indicate the need to do so. Therefore we recommend that where the maintenance interval is stated as "Continuous" it should be changed to read "Never" or "Not Applicable". The Table 1A requirement of 3 months for Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) should be omitted as it is not realistic. Recommend following the Table 1B requirement of 6 years (Trip testing) for this. Does 27 undervoltage monitoring of this circuit qualify as self monitoring?
No
When we have redundant digital relay system that would fall under Level 1c category with a 12 year mtce cycle, but the Protection System Control Circuitry is non-monitored so it falls under Level 1a, with a 6 year mtce cycle. We will have to complete relay mtce and trip testing every 12 years and trip testing only every 6 years, therefore we must complete trip testing twice as often as we are doing the maintenance. We feel that relay maintenance and trip testing should be completed at the same frequency. The Protection System Control Circuitry (Breaker Trip Coil) checks every three months is too excessive. These circuits are checked during trip testing of the Protection scheme, at the 6 or 12 year interval. If we have a redundant digital relay system, using a IEC61850 communication from the relay to a common breaker aux trip relay, what level does this system fall under?

Table 1A, protective replays for 6 calendar years, Testing and calibrating the relays other than microprocessors relays with simulated electrical inputs... does that mean that micro processor relays do not need to be checked? Verify proper function of the relay trip outputs... Does this involve both electro AND micro processors? Then when mentioning the verifying microprocessor relays, does that include the trip output.
Yes

Yes

Yes

No

No

On Table 1A, the maximum time lengths are too long, especially for electro relays. A prime example is when testing a KD relay on a yearly basis and most of the time needs to be adjusted because of how far off it comes out. Allowing entities to take their time up to six calendar years may be too long.

Station DC supply - (Maintenance Activity) As a company we do not think that measuring specific gravity and temperature of each cell is necessary. Their is a better test that we use with the Bite Impedance Test. We have had good success with the impedance test for determining the batteries condition. See article (Impedance Testing Is The Coming Thing For Substation Battery Maintenance)written in Transmission & Distribution 11/1991 by Ritchard Kelleher, Test & Maintenance Specialist, Northeast Utilities.

1. Minimum maintenance activities should be on a yearly multiplier verses a monthly multiplier. Nuclear generating stations are typically on an 18-month or 24-month refueling cycle. The draft standard does not take into consideration a nuclear generators refueling cycle. Specifically, most Boiling Water Reactors (BWRs) are on a 24-month refueling cycle and may run continuously between refueling outages. Performing maintenance on-line puts the generating unit at risk without any commensurate increase in reliability to the bulk electric system. 2. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 3. Activities that begin with "verify" should be modified to "Validate_________are/is within acceptable limits. Initiate corrective actions as required." For example, some level of DC grounds are acceptable based on circuit design and component installation. Troubleshooting or ground isolation may increase the risk to the system depending on ground magnitude and conditions. 4. Please provide clarification on "verify that no dc supply grounds are present" most stations have some level of ground current. Should this be interpreted to be a measure of resistance or current values? Suggest rewording to say "Check and record unintentional battery grounds" 5. "Verify Station Battery Chargers provides the correct float and equalize voltage" should be deleted. Equalizing a battery is a maintenance function and should only be performed as needed. Suggest rewording to say "Check and record charger output current and voltage." 6. Activities associated with Battery Charger performance should be deleted. The ability of the Battery Charger to maintain the battery at full charge state is verified by checking proper "float voltage." The ability to provide full rated current only affects the ability to recharge a battery AFTER an event has occurred. 7. In Table 1a does the requirement to "verify proper electrolyte level" refer to all batteries or only a sampling? Current practice is to use the "pilot cell" as the monitoring cell as this cell is usually the least healthy of the battery bank from a specific gravity and/or voltage standpoint. If the pilot cell continues to degrade then the other batteries will be monitored more often. Suggest rewording to "Check electrolyte level." 8. In Table 1a the 18-month requirement to measure that the specific gravity and temperature of each cell is within tolerance is "where applicable" – what does "where applicable" mean? 9. For the Station dc supply (battery is not used) 18-month interval – should this be interpreted that it is just the battery charger with no attached battery? Or a dc supply system that does not contain a battery? 10. Table 1a Station dc supply 18-month interval to verify cell-to-cell and terminal connection resistance is within "tolerance" should be revised to say "tolerance or acceptable limits." 11. Table 1a Station dc supply (that has as a component valve regulated lead-acid batteries) should provide an additional optional activity for "Total replacement of battery at an interval of four (4) years" in lieu of not conducting performance or service capacity test at maximum maintenance interval.
No
1. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 2. Table 1a – page 6 regarding the 3 Month "Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS)" states that the maintenance activity shall verify the continuity of the breaker trip circuit including the trip coil. There is unclear guidance on how this activity is to be performed, particular on generator output breakers. Does this activity imply actual trip testing of the breaker itself? If so, performing this type of activity with the generator on-line puts the unit at risk without any commensurate increase in reliability to the bulk electric system. If this is the case it is requested that this particular test is extended from 3 months to 24 months to align with nuclear generating units refueling cycle. If not, and this activity is simply verification of continuity by means of light indication, then please clarify in Table 1a.
No
1. Please provide more clarification on what constitutes "partially monitoring." For example, is a computer auxiliary contact alarm count as partial monitoring? Would a common alarm between relays meet the definition of partial monitoring? 2. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 3. Table 1b Station dc supply (that has as a component valve regulated lead-acid batteries) should provide an additional optional activity for "Total replacement of battery at an interval of four (4) years. 4. There seems to be a disconnect between the monitoring attribute and maintenance activity. For example, the monitoring attribute "Monitoring and alarming of the station dc supply voltage/detection and alarming of dc grounds" has the maintenance activity

"verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire batter bank. (3 calendar years) – or – Verify that the station battery can perform as designed by evaluating the measure cell/unit internal ohmic values to station battery baseline (3 months)." The maintenance activity does not support the monitoring attribute. 5. If an entity has implemented Table 1b and/ or Table 1c, is there an acceptable length of time that the monitoring equipment can be out of service without falling back to Table 1a requirements?
Yes
None
No
None
No

Conflict 1. Nuclear generators are licensed to operate and regulated by the Nuclear Regulatory Commission (NRC). Each licensee operates in accordance with plant specific Technical Specifications (TSs) issued by the NRC. TS allow for a 25% grace period may be applied to TS Surveillance Requirements (SRs). Referencing NRC issued NUREGs for Standard Issued Technical Specifications (NUREG-143 through NUREG-1434) Section 3.0, "Surveillance Requirement (SR) Applicability, SR 3.02 states the following: " The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." 2. Battery Charger Testing 3. All conditions (grounds, voltages etc) should be compared to "acceptable limits" as specified in nuclear station design basis documents, industry standards or vendor data. 4. IEEE 450 does not use the word "proper" as utilized in Table 1a (e.g., "record voltage of each cell v/s verify proper voltage of each individual cell….") 5. The NRC Maintenance Rule (10 CFR 50.65) requires monitoring the effectiveness of maintenance to ensure reliable operation of equipment within the scope of the Rule. Adjustments are made to the PM (preventative maintenance) program based on equipment performance. The Maintenance Rule program should provide an acceptable level of reliability and availability for equipment within its scope. Comments: 1. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 2. The 3-month maximum interval should be extended to include a grace period to ensure that a 25% grace period is included to align with current nuclear templates that implement NRC TS SRs are documented in the response to Question 8.
Business Practice
Business Practice: Nuclear Electric Insurance Limited (NEIL) variance allowance.
1. Battery testing should be added to Table 1c for Station dc supply (that uses a battery and charger) 2. Table 1c – Condition based maintenance. Consider adding Battery Capacity Test on a 6-year interval regardless of other condition based maintenance performed. 3. Evaluating the measured cell/unit internal ohmic values to station battery baseline does not provide an evaluation of battery capacity – please explain rational for maintenance activity. 4. If the Table 1a maintenance interval is reached and the entity is unable to perform the maintenance task, is it acceptable to install temporary external monitoring or other measures to defer the maintenance to Table 1b or Table 1c interval? Is it acceptable in Table 1b to substitute additional or augmented maintenance activities or operator rounds to extend intervals? 5. Table 1c for equipment with "continuous monitoring" states the maximum maintenance interval of "continuous" – this does not seem correct wording – consider revising to state "not required." 6. The NERC Standard should be revised to include a specific allowance for a deferral or variances of a maintenance activity based on a formal technical evaluation. Nuclear generating units allow for deferrals and/or variances on certain equipment based on emergent conditions that would prevent safe isolation and/or testing of function. It should be noted that any deferrals and/or variances if justified are to be based on a formal evaluation and not based on work management or resource issues. 7. The maintenance intervals and maintenance activities should be referenced directly to a basis document to ensure guidelines have a specific technical basis (e.g., IEEE-450).
Group
SERC Protection and Controls Sub-committee (PCS)

Yes
We commend the SDT for developing such a clear and well documented first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals.
Yes

We agree with the majority of the activities. Below is an example where clarification is needed. “Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays” under “Voltage and Current Sensing Devices Inputs to Protective Relays.” How would this be done if no redundancy is available for cross-checking voltage and current sources? In certain situations, “verify proper functioning” is not clear enough. Documentation of verification consistent with the entities procedures should be adequate to indicate compliance.
No
Recommend that all Level 1 three-month maintenance intervals be changed from 3 months to quarterly. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. This would result in six inspections per year. In the experience of many of our utilities, four inspections per year have proven to be successful.
No
Recommend that all Level 2 three-month maintenance intervals be changed from 3 months to quarterly. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. This would result in six inspections per year. In the experience of many of our utilities, four inspections per year have proven to be successful.
Yes
No
Yes
Change “prove” to “verify” on FAQ 3a (under Voltage and Current Sensing Devise Inputs to Protective Relays) to be consistent with the wording of the requirement.
None known.
Regional Variance
It is our understanding that once Project 2009-17: “Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State” is approved, that the definition of a “Transmission Protection System” would be included within PRC-005-2 or included within the NERC Glossary of Terms. However, the specific protection that would be considered part of the “Transmission Protection System” would also depend on the regional definition of the BES. We suggest that the regions develop a supplement that provides further clarification on what constitutes a “Transmission Protection System” given the regional definition of the BES.
The “zero tolerance” structure proposed combined with the large volume and complexity of Protection System components forces an entity to shorten their intervals well below maximum. We instead propose a calendar increment carryover period in which a small percentage of carryover components would be tracked and addressed. For example, up to 1% of an entity’s communication channel 6 year verifications could carryover into the next year. These carryover components would be addressed with high priority in that next calendar increment. There are many barriers to 100% completion or zero tolerance. Some utilities have over ten thousand components.

Yes
No
a. Tables 1a, 1b & 1c should offer as an alternative, measuring battery float voltages and float currents in lieu of measuring specific gravities as described in Annex A4 of IEEE Std 450-2002. b. Inspection of CVT gaps, MOVs and gas tubes should be added to the communications equipment time based maintenance tables. Failure of the CVT protective devices may cause failure of the Protection System. c. Maintenance Activities for UVLS or UFLS station dc supplies shows “Verify proper voltage of dc supply”. Does this imply that, except for voltage readings of the dc supply, distribution battery banks are not maintained? d. Why does the Maintenance Activities for UVLS or UFLS relays state that verification does not require actual tripping of circuit breakers? e. Please clarify the Maintenance Activities for Voltage and Current Sensing Devices. Must voltage, current and their respective phase angles be measured at each discrete electromechanical relay? f. NextEra Energy concurs with other entities comments concerning this question: This entity believes the approach taken by the SDT is overly prescriptive and too complex to be practically implemented. The inflexible “minimum maintenance activities” approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. In particular, the loss of maintenance flexibility embodied in this approach would have perverse consequences for entities with redundant systems. Entities with redundant systems have less need for maintenance of individual components (due to redundancy) yet have twice the maintenance requirements

under the "minimum maintenance activities" approach. For example, Table 1A calls for performing a specific gravity test on "each cell' of lead acid batteries. Our company believes such a requirement is dubious for entities that do not have redundant batteries, and absurd for entities that do. We have installed redundant batteries in most locations and has had an excellent operating history with batteries by using a combination of internal resistance testing and specific gravity testing of a single "pilot cell". This practice, combined with DC system alarming capability, has worked well. We are opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would "fix" non-existent problems. To clarify this last point, we are not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. Arguably, an entity could possibly return to its existing practices, if those practices are working well, by navigating through the complex set of options and supporting documentation that the SDT has crafted in this proposal. However, like many entities, we have an army of substation technicians with various ranges of experience to perform maintenance on protective systems and other substation components. It is unrealistic to expect most entities making a good faith effort to comply with this proposal to have a full understanding throughout the entire organization of all the nuances crafted into this complex proposal. For the reasons outlined above, we do not agree with the proposal to specify minimum maintenance activities. However, if the majority of industry commenters agree with the SDT's proposal, we have concerns about some of the proposed minimum tasks. For Protection System control circuitry (trip circuits), Table 1A calls for performing a complete functional trip test. The "Frequently-asked Questions" document states that this "may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip scheme". Such a requirement creates its own set of reliability risks, especially when monitoring already mitigates risks. We are concerned with this standard promoting an overall functional trip test for transmission Protection Systems. This type of testing can negatively impact reliability with the outages that are required and by exposing the electric system to incorrect tripping. Our company views overall functional trip testing as a commissioning task, not a preventive maintenance task. We perform such testing on new stations and whenever expansion or modification of existing stations dictates such testing.
No
a. (i) Protective relays, (ii) Protection Control Circuitry (Trip Circuits) and (iii) Protection System Communications Equipment and Channels should be changed from 6 calendar years to 8 calendar years. Based on FPL Group's experience and Reliability Centered Maintenance (RCM) program, FPL Group has established an 8 year program and has found that an aggressive 6 year program would not substantially increase the effectiveness of a preventative maintenance program. b. Battery visuals should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. c. The maximum maintenance interval for communications equipment should be changed from 3 months to 12 months. Based on FPL Group's experience and RCM program, FPL Group has established a 12 month program that is effective. d. Additionally, NextEra Energy concurs with other entities comments concerning this question: Imposing inflexible maximum interval requirements has the same basic problems as imposing inflexible minimum task requirements. The inflexible "maximum interval" approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. The maximum interval approach also has same perverse consequences for entities with redundant systems as the minimum interval approach. Furthermore, the rigid maximum interval approach embodied herein does not sufficiently take into consideration common natural disaster situations. Several of the preventive maintenance tasks proposed in this standard have a maximum interval of 3 months, which is problematic under normal circumstances and unworkable when routine maintenance activities have a much lower priority than emergency repair and restoration. An interval as short as this does not provide a sufficient maintenance scheduling horizon to complete the tasks. The SDT could attempt to address this shortfall by modifying the draft to account for natural disaster situations. For example, the FERC-approved NERC reliability standard FAC-003 for Vegetation Management does include such allowances for natural disasters, such as tornados and hurricanes. However, even if that specific problem is addressed, the fundamental problems created by an overly prescriptive maximum interval approach remains.
Yes
Yes
No

Yes
a. NextEra Energy believes the need for an extensive "Supplementary Reference Document", in addition to 13 pages of tables and an attachment in the standard itself, illustrates that the proposal is too prescriptive and complex for most entities to practically implement. NextEra Energy would prefer the SDT leave the existing requirements substantially intact or, if most industry commenters prefer the SDT's approach, that the SDT attempt to simplify it. 7. The Standard Drafting Team has provided a "Frequently-asked Questions" document to address anticipated questions relative to the standard. Do you have any comments on the FAQ? Please explain in the comment area. 1 Yes 0 No Comments: a. An alternative to measuring battery specific gravity is to measure float voltage and float current as described in Annex A4 of IEEE Std 450-2002. b. FAQ Page 17 (#1B): It is outside the jurisdiction of the standards development team to determine acceptable forms of evidence. This should be decided by the Regional Entities. c. FAQ Page 15 (#1A): This question should not have been included since it is addressing the definition of BES, which is currently being addressed by another NERC Group. d. FAQ Page 15 (#2): Although the FAQ is not enforceable, the answer provided may be interpreted as enforceable. This should be included in the standard and not in the FAQ.
a. The level of effort that will be required to be in compliance in accordance to PRC-005-2 is substantial. Also, it will be difficult to create one maintenance program for all NextEra Energy sites that establishes maintenance intervals based the implementation of a combination of the three allowable types of maintenance programs (time-based, condition based, and/or performance based maintenance). As a result, a high risk exists that something will be missed or carried out incorrectly. b. What is the implementation period? How will the standard be implemented in relation to the entity's maintenance scheduled in accordance with existing intervals specified in the current Protection System Maintenance and Testing Procedure that meets the requirements of PRC-005-1 but will exceed PRC-005-2's established maximum intervals? Once PRC-005-2 becomes mandatory, entities should not be required to re-do testing in accordance with the new intervals. Instead, entities should be allowed to implement the newly established intervals after the last known cycle. c. Protection System Maintenance Program (PSMP): (c1) The PSMP definition would be better defined if the first sentence was changed to "An ongoing program by which Protection System components are kept in working order and where malfunctioning components are restored to working order." (c2) Please clarify what is meant by "relevant" under the definition of Upkeep. Should "relevant" be changed to "necessary"? (c3) The definition of Restoration would also be more explicit if changed to "The actions to return malfunctioning components back to working order by calibration, repair or replacement. (c4) Please clarify the definition of Restoration. For example, if a direct transfer trip system has dual channels for extra security even though only one channel is required to protect the reliability of the BES and one channel fails, must both be restored to be compliant? d. Protection System (modification): (d1) "Voltage and current sensing inputs to protective relays" should be changed to "voltage and current sensors for protective relays." Voltage and current sensors are components that produce voltage and current inputs to protective relays. (d2) "Auxiliary relays" should be changed to "auxiliary tripping relays" throughout PRC-005-2, FAQ and the Draft Supplementary Reference. (d3) The word "proper" should be removed from the standard. It is ambiguous and should be replaced with a word or words that are clear and concise. e. Additionaly, NextEra Energy concurs with the following comments made by other entities: (e1) PRC-005 Sect B (R2): More clarity needs to be provided. Does this requirement require the utility to document the capabilities of its various protection components to determine fully and partially monitored protection systems? If so the requirement for such documentation should be clearly spelled out. Usually each requirement has a measurement (of compliance) and I'm not clear how this will be done. (e2) PRC-005 Sect B (R4.1): A "grace period" similar to the NPCC Criteria should be considered in case it is not possible to obtain necessary outages.

IMPA does not agree with the battery charger testing requirements. Per the battery charger manual, the manufacturer sets the current limit at the factory, and it only needs to be adjusted if a lower current limit is desired. The manufacturer gives directions on how to lower the current limiter, and the directions seem to be for this purpose only (not for the sole purpose of performing a current limiter test). The manufacturer also does not give directions on how to perform a full load current test and does not give any recommendation to the user that such test is needed. IMPA believes that both of these maintenance items are not needed to maintain the

battery charger and that only the manufacturer's recommendations on maintenance and testing need to be followed.

No
We agree there is a need for minimum maintenance activities; however, the standard does not clearly define the differences between Table 1a, 1b, and 1c. It is recommended that the drafting team develop definitions for the equipment listed in these tables. For example, Table 1a equipment consists of mechanical and solid state equipment without monitoring capability, Table 1b consists of mechanical and solid state equipment with monitoring capability, and Table 1c consists of equipment capable of self monitoring. In addition, all battery, charger and power supply maintenance activities should be removed from Table 1a, 1b, and 1c, and summarized in a separate Table (i.e. Table 2). Tables 1a and 1b for 'Station dc supply (that has as a component any type of battery) and Table 1c for 'Station dc Supply (any battery technology) for an 18 Month 'Maximum Maintenance Interval' identifies the need to 'Measure that the specific gravity and temperature of each cell is within tolerance (where applicable).' Following industry best

practices, we would recommend using the MBRITE diagnostic test. MBRITE testing provides more information than a specific gravity test while reducing the risk of injury to testing personnel. In Table 1a, the Type of Component "Protection system communications equipment and channels." has a 3 month "Maximum Maintenance Interval". Clarification needs to be provided as to how an unmonitored (do not have self-monitoring alarms) will be tested. Table 1a refers to "Unmonitored Protection Systems". The "6 Calendar Years" "Maximum Maintenance Interval" "Maintenance Activities" is excessive.
No
We question whether any maintenance activity should be as long as 12 years. Considering the rate of change in personnel and technology, the working group should reduce the time period by redefining the requirement if necessary, or eliminate the standard requirement. In addition, the DC components have too many tests at confusing intervals. Confusion will make it difficult to implement or follow the exact method used.
Yes
No
The concept is acceptable, but the requirements to follow in Appendix A seem to be a deterrent from attempting to use this process. Is the term "common factors" meant to take into account variables at locations that can affect the components' performance (lightning, water damage, humidity, heat, cold)?
No
Yes
The FAQ is helpful in answering many of the obvious questions.
Yes--NPCC Directory #3, NPCC Key Facility Maintenance Tables. All areas must implement changes at the same time.
Not aware of any regional variance or business practice.
• Requirements 4.2.5.4 and 4.2.5.5 require clarification. It is recommended that the drafting team provide a schematic diagram to provide clarity as to which generator and system connected transformers are included in this facility identification. • When Measures are added to the Standard, the Standard Drafting Team must consider how the owner will be required to assess and document the decision of which table will apply to each protection. While this is a compliance element, the Standard should provide clarity on this matter. As written, the requirement does not seem to be measurable. • Requirement R4 requires clarification on what is meant by "including identification of the resolution of all maintenance correctible issues as follows:" Correctible issues should not be combined in the same sentence with the layout of the tables. • Table 1b: In the section for "Protection system communication equipment and channels", there needs to be clarification on "verify that the performance of the channel and the quality of the channel meets the performance criteria, such as via measurement of signal level, reflected power, or data error rate." This may be done as a pass fail test during trip checks. If the communication line successfully sends proper signals for the trip checks, then the communication line is acceptable and no additional measurement are taken. • Table 1c: There is some confusion on what is expected on items that have a Maximum Maintenance Interval reported as "Continuous". For example, a component in the "Protection System telecommunication equipment and channels" how would one provide documentation or proof of the continuous verification of the two items listed in the maintenance activities? In other words how does one prove "Continuous verification of the communication equipment alarm system is provided" and "Continuous verification that the performance and the quality of the channel meet the performance criteria is provided". These activities appear to be "monitoring attributes" more so than they are maintenance activities. Additionally, the Continuous "Maximum Maintenance Interval" needs clarification because: o the interval is a monitoring interval and not a maintenance interval o a strict interpretation of "Continuous" could require redundant monitoring systems be installed or locations staffed by personnel to monitor equipment in the event remote monitoring capabilities are unavailable o It is unclear how to provide proof to an auditor that continuous monitoring has occurred over a given interval • Table 1a, 1b, and 1c: The maintenance activity for battery chargers are to perform testing of the charger at full rated current and verify current-limit performance. The drafting team should provide an industry standard as how to perform this check, or specify an industry equivalent test. • The Table 1b Level 2 Monitoring Attributes for Component "Monitoring and alarming of continuity of trip coil(s)" should be changed to read "Monitoring and alarming of continuity of all DC circuits including the trip coil(s)". The present wording is confusing and can be interpreted to mean that the DC control circuitry needs to be checked every 12 years, as opposed to what we perceive to be the intended 6 years. • The Maintenance Activities in Table 1c are not consistent with the Level 3 Monitoring Attributes for Component "Protection system telecommunications equipment and channels." "Continuous verification of interface to protective relays" should be added as a third activity should be added under the Maintenance Activities column. • In Section A. Introduction, 4.2.4 should be made to read "Protection System

components which are installed as a Special Protection System for BES reliability." • For Requirement 4.1, a "grace period" similar to the NPCC criteria should be considered in case it is not possible to obtain any necessary outages to get the prescribed maintenance done. • Requirement R1 should be modified to read "Each Transmission Owner, Generator Owner, and Distribution Provider shall develop, document, and implement a Protection System Maintenance Program (PSMP) for its Protection Systems that use… This revision reinforces what is necessary to ensure proper compliance with the program. • The standard has multiple component tests required at different and conflicting intervals, some interdependent. Preference is to have the component listed with a common maintenance and testing interval assigned (list the testing required at 2, 4 and 6 years). This same interval should apply to all areas in the table. • Life span of PC's, software and software license's are much less than 12 years or asset life. This presents a problem during an audit where proof is required. The components in modern relays have not been proven over these extended time periods, users are dependent on proper functions of the alarm output of IED's. Prefer more frequent maintenance cycles over having to continuously document proof of a robust CBM or PBM program. • The burden placed to provide proof of compliance with a CBM or PBM maintenance program seems to outweigh any benefit in maintenance costs or reliability.

Many preventive maintenance programs have testing tolerances which are tighter than the manufacturer's tolerances. This practice is used to force an action prior to falling outside of the manufacture's tolerances and accounts for slight variations in test equipment and environment. Maintenance correctable issues should not be reportable unless the test failure falls outside of the manufacturer's published tolerances. In tables 1a through 1c the "Type of Component" columns in each table do not have consistent listings from one 1a to 1b to 1c. The type of component should be identified consistently in each table. By doing so this would eliminate confusion in moving from one table to the other. The maintenance activities for some types of components specifies how (ie Test and calibrate the relays….with simulated electrical inputs) while other maintenance activities do not specify how. The maintenance activities should either all be specific or all be generic. For Station dc Supply (that has as a component any type of battery) the maintenance activity of "verify that no dc supply grounds are present" there is a problem of tolerance. It is impossible to have "no dc supply grounds present". There has to be some tolerance given here such as a voltage measurement form each battery terminal to ground +- 15 volts of nominal for example. For the type of component of "Protection System Control Circuitry (trip circuits) (UFLS/UVLS Systems only), the maintenance activity requires a complete functional trip test….of the Protection System. This suggests that a breaker trip test is required at each maintenance interval. This requires tripping breakers that supply customers. It is impossible to trip each individual distribution feeder without forcing an outage on some customers as when there are no other usable circuits to tie the load off to. A failure to trip of a single distribution circuit in the overall scheme of a UVLS or UFLS scheme would have little effect on the BES. Trip testing BES breakers and verifying correct operation of breaker auxiliary contacts could become very difficult to accomplish since opening a breaker on a line might adversely affect the BES. ISOs may prohibit such an activity at any time. Allowances should be made for BES circuit breakers that can not be operated for such reasons if documented sufficiently.

While I agree for the most part, there are some activities that are unclear. Specifically, the testing of voltage and current sensing devices, some of the trip coil testing, and some of the communications testing. If the trip coil is now going to be included in the definition of the protective system, is the testing defined adequate? The testing of the voltage and current sensing devices is not entirely clear.
No
The first problem that I have is the 3 Months for the Protection system communications equipment and channels component. My main concern with this interval is that it is so extremely short and I am concerned that there may not be any rational behind it. What studies, surveys, or statistical data were used to determine that 3 months is necessary to protect the reliability of the BES? It doesn't make sense that a communications signal needs to be checked every 3 months but the protective relay that utilizes that scheme needs to be checked at most only every 6 years. What concerns me the most with the 3 month interval for my company is with on-off power line carrier DCB schemes. We only have these schemes on tie lines, and it can be difficult to implement a checkback system with another utility who might utilize different carrier equipment. This type of scheme is also intended to be inheritantly insecure and is frequently more or less tested with faults in the system. The SPCTF should do surveys to determine what is presently done with these type of systems or provide some other rationale for the communication requirements. It is not totally clear from the documents, but it appears that the only way to avoid the 3 month check for an on-off power-line carried DCB scheme is to have an automated check back scheme. Is this correct? Or is alarming from the carrier equipment adequate? My second problem is with the 6 year maximum maintenance interval for the breaker trip coil in tables 1b and 1c. By having to verify that each breaker trip coil is electrically operated, you might as well perform a functional test to test the protection system control circuitry. Electrically operating the trip coil tests the breaker as much as it test the actual trip coil. Also, if you have a primary and secondary trip coil, is it really necessary to test this often? What studies or statistical data were used to determine that testing the breaker trip coils every 6 years is necessary to protect the reliability of the BES? My third problem is with the intervals requirements for the UVLS/UFLS systems. Other than testing and calibration of electromechanical UVLS/UFLS, most other tests probably should require at most 10 years for these type of systems. These systems don't require the performance level of most other systems as stated in the supplementary reference. The testing and calibration of electromechanical UFLS should possibly be even shorter than the 6 year requirement due to problems with drift with these type of relays. What studies, surveys, or statistical data were used to determine the intervals in related to UFLS/UVLS.?
Yes
Yes
Yes
Adds to the confusion with the standard, FAQ, and Supplemental. The three documents at times describe things a little differently.
Yes
Adds to the confusion with the standard, FAQ, and Supplemental. The three documents at times describe things a little differently.
Have several comments and questions: 1. I think that the way that the tables are done is confusing. My biggest complaint is that the "breakdown" of the Type of Component varies between the tables. For example, in tables 1a and 1B, you have Protective Relays, but in table 1c, you have Protective Relays and Protective Relays with trip contacts. This is a little confusing at times. 2. I also find the UFLS/UVLS requirments confusing as well. It can be confusing to figure out when the UFLS/UVLS has a separate requirement. Would prefer to see the UVLS/UFLS in separate tables; e.g. 2a, 2b, 2c. 3. SPCTF should provide the basis for how the intervals in table 1 were derived. While the supplemental describes that a survey of its members with a weighted average was used to determine the maintenance intervals. However, what is not clear is what exactly was surveyed in terms of components. Was it just relay calibration testing? Functional testing? What about communications, voltage and current sensing devices, trip coils, etc? Was UVLS and UFLS looked at separately from transmission? Was generation also considered as well? Why did values change from the SPCTF technical reference "Relay

Maintenance Technical Reference" dated September 13, 2007. For example, UVLS/UFLS testing and calibration went from 10 years to 6 years for un-monitored, communications went from 6 months to 3 months for un-monitored, and instrument transformer testing went from 7 years to 12 years for un-monitored systems. What are the basis for the intervals? 4. The committee should reconsider the use of the term "A/D converters". The point of the requirement is to assure that the analog signal from the instrument transformer is correct to the processor. Two problems with just saying "A/D converters". One, it ignores the digital relay input transformers of microprocessor relays. The SEL-4000 test set can bypass these transformers. Would using this test set be adequate to test the "A/D converters"? Two, some relays, such as the SEL-311L, perform an A/D self-test. I do not think that the A/D self-test performs the testing that is being sought by the document. 5. Could a better example of "Calendar Year" be provided? Is it simply the years difference, or should the days be included as well? I your example in the reference document, you show that December 15, 2008 and December 31, 2014 as meeting the requirement of 6 calendar years. Woudl like to see a more exaggerated example. Would an unmonitored protective relay is calibrated on January 1, 2008 and then again on December 31, 2014 meet the "Maximum Maintenance Interval" of "6 Calendar Years"? 6. Does the standard address breakers and other switching devices that do not have "trip coils". Magnetic actuated circuit breakers, reclosers, and possibly other devices do not have trip coils to monitor or test. Do the trip coil testing and requirements fully take this account? If a breaker does not have a trip coil, is some other type of test required? Does not having a trip coil prevent extending the Protection System Control Circuitry inteval to 12 years? 7. The requirement for testing Voltage and Current Sensing devices should be better thought out as to what is trying to be accomplished. On page 11 of the reference document, item 6 under "Additional Notes for Table...", it states that "phase value and phase relationships are both equally important to prove". In both the FAQ document (page 6, 3A) and the reference document (page 21, 15.2), several methods to verify the voltage and current sensing inputs to the protective relays and satisfy the requirement are given. However, these methods do not all seem to verify the same thing. Totalizing watts and vars on the bus verifies that the current transformers are correctly and providing correct signals to the relays, but do not necessarily verify that the voltage sensing device is necessarily correct if the same PT is used for all relays on the bus. Performing a saturation test on a CT and a ratio test on the PT does not verify the phase angle relationships, which is stated as important on page 11 of the reference document. What exactly needs to be accomplished by the Voltage and Current Sensing devices testing? That an analog signal is getting from the instrument transformer to the device? That the signal is an accurate representation of the measured quantity? What about frequency for UFLS relays, where voltage magnitude may not be that important? Do CT's need to be verified for multiple CT grounds? Do the any examples described necessarily find multiple ct grounds? 8. This standard should also address the ramifications of RRO's not allowing for equipment to be removed from service for testing. Either RRO's should be required to allow outages in some time frame or leeway should be given to entities that cannot get equipment out for maintenance because RRO's will not grant reasonable outage times for testing and maintenance. 9. Page 13 of the reference document states that the 3-month inspection should include checking that "equipment is free of alarms, check any metered signal levels, and that power is still applied." What is meant by "metered signal levels"? What does the term "metered" mean, specifically in terms of an on-off power line carrier scheme. 10. It appears that if a company on a TBM plan has shorter intervals than the maximum allowable of this proposed standard, the company would not be in violation if they did not meet their own plan but still met the intervals required by this proposed standard. Is this true? Could this actually reduce reliability of the BES if companies are now allowed to extend intervals to those listed in this document without any justification?

The “Supplementary Reference Document” provides good technical justification for the various approaches to a maintenance program (Time Based, Performance Based, and Condition Based) or combinations of these programs that an owner of a Protection System can follow.

Yes
The FAQ document is an excellent resource document for Protection System Owners to understand why the maintenance activities listed in the proposed standard were chosen.
The drafting team is to be commended for taking the Technical Paper and Draft Standard that was prepared by the NERC System Protection and Control Taskforce (SPCTF) and the recommendations of the SAR drafting team to create PRC-005-2. This draft standard allows the owners of Protection Systems several options in establishing a maintenance program tailored to their equipment and the topography of their system.

What is the definiton of "Calendar Year"? Does the term "Six calendar years" include any date in 2004 to any date in 2010?
Individual
Armin Klusman
CenterPoint Energy
No
a. CenterPoint Energy believes the approach taken by the SDT is overly prescriptive and too complex to be practically implemented. The inflexible minimum “maintenance activities” approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. In particular, the loss of maintenance flexibility embodied in this approach would have perverse consequences for entities with redundant systems. Entities with redundant systems have less need for maintenance of individual components (due to redundancy) yet have twice the maintenance requirements under the minimum “maintenance activities” approach. For example, Table 1A calls for performing a specific gravity test on “each cell’ of vented lead-acid batteries. CenterPoint Energy believes such a requirement is dubious for entities that do not have redundant batteries, and absurd for entities that do. CenterPoint Energy has installed redundant batteries in most locations and has had an excellent operating history with batteries by using a combination of internal resistance testing and specific gravity testing of a single “pilot cell”. This practice, combined with DC system alarming capability, has worked well. b. CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would “fix” non-existent problems. To clarify this last point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. c. Arguably, an entity could possibly return to its existing practices, if those practices are working well, by navigating through the complex set of options and supporting documentation that the SDT has crafted in this proposal. However, most entities, have an army of substation technicians with various ranges of experience to perform maintenance on protection systems and other substation components. It is unrealistic to expect most entities making a good

faith effort to comply with this proposal to have a full understanding throughout the entire organization of all the nuances crafted into this complex proposal. d. For the reasons outlined above, CenterPoint Energy does not agree with the proposal to specify minimum maintenance activities. However, if the majority of industry commenters agree with the SDT's proposal, CenterPoint Energy has concerns about some of the proposed tasks. For Protection System control circuitry (trip circuits), Table 1A calls for performing a complete functional trip test. The "Frequently-asked Questions" document states that this "may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip scheme". Such a requirement creates its own set of reliability risks, especially when monitoring already mitigates risks. CenterPoint Energy is concerned with this standard promoting an overall functional trip test for transmission protection systems. This type of testing can negatively impact reliability with the outages that are required and by exposing the electric system to incorrect tripping. CenterPoint Energy views overall functional trip testing as a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such testing on new stations and whenever expansion or modification of existing stations dictates such testing. Overall, CenterPoint Energy recommends minimizing, to the extent possible, maintenance activities that disturb the protection system; that is, placing the protection system in an abnormal state in order to perform a test. e. For Protection System control circuitry (breaker trip coils only), Table 1A calls for verifying the continuity of the trip circuit every 3 months. CenterPoint Energy is not sure what would be the expected task to meet this requirement (it is not addressed in the "Frequently-asked Questions' document).
No
a. See CenterPoint Energy's comments made in response to question 2. Imposing inflexible maximum interval requirements has the same basic problems as imposing inflexible minimum task requirements. The inflexible "maximum interval" approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. The maximum interval approach also has same perverse consequences for entities with redundant systems as the minimum interval approach. b. Furthermore, the rigid maximum interval approach embodied herein does not sufficiently take into consideration common natural disaster situations. Several of the preventive maintenance tasks proposed in this standard have a maximum interval of 3 months, which is problematic under normal circumstances and unworkable when routine maintenance activities have a much lower priority than emergency repair and restoration. An interval as short as this does not provide a sufficient maintenance scheduling horizon to complete the tasks. The SDT could attempt to address this shortfall by modifying the draft to account for natural disaster situations. For example, the FERC-approved NERC reliability standard FAC-003 for Vegetation Management does include such allowances for natural disasters, such as tornados and hurricanes. However, even if that specific problem is addressed, the fundamental problems created by an overly prescriptive maximum interval approach remains.
No
a. CenterPoint Energy lauds the SDT for recognizing that strict imposition of the maximum interval approach creates problems which the SDT attempts to correct by allowing performance-based adjustments. CenterPoint Energy believes the majority of industry commenters will agree with CenterPoint Energy's assessment that the maximum interval approach is problematic and should be dropped from the proposal. However, if the majority of industry commenters agree with the SDT's approach, then a performance-based option to correct the problems introduced by the maximum interval requirements should remain. b. CenterPoint Energy answered "No" to question 5 because CenterPoint Energy believes the arduous path of creating a new set of problems with a rigid approach (maximum interval requirements) and then introducing a complex set of auditable requirements to provide an option (performance-based maintenance) to mitigate the harm of the rigid approach is ill-advised and fraught with pitfalls. Stated otherwise, using performance-based adjustments to correct inappropriate maximum intervals would not be necessary if the inappropriate maximum intervals were not imposed. CenterPoint Energy believes a better approach is to avoid introducing the new set of problems that then have to be mitigated by not imposing problematic maximum intervals. c. Followed to its logical conclusion, using performance-based adjustments to correct inappropriate maximum intervals is a contorted way of arriving at the philosophy embodied in the current set of standards in which entities determine the maximum intervals appropriate for their circumstances and performance. CenterPoint Energy's concern is that the contortions needed to arrive at the same point, in addition to being unnecessary, will be difficult for most entities to navigate. An entity making a good faith effort to comply with the performance-based adjustments will have to navigate through the complexities and nuances of the approach, as illustrated by the extensive set of documents the SDT has provided in an attempt to explain all the requirements and nuances. As an entity attempts to manage this hurdle, the entity will likely have to deal with the reality that the granularity of performance metrics do not exist in most cases to justify to an auditor the rationale for the adjustments to the inappropriate maximum intervals. For example, CenterPoint Energy has asserted that it has had good battery performance using existing practices. However, the

assertion is anecdotal. CenterPoint Energy cannot recall any instances where it had a relay misoperation due to battery failure in over twenty five years. CenterPoint Energy does not attempt to keep performance metrics on events that historically occur less than four times a century and CenterPoint Energy believes most entities will be in the same situation. d. If an entity is somehow able to overcome these hurdles, the entity will almost certainly encounter skepticism for what will be viewed as an exception to the default requirement embodied in the standard. Even if an entity can overcome likely skepticism in an audit, the entity will be in a severely disadvantaged situation if a protection system component for which the maintenance interval has been adjusted, based on the entity's good faith effort and reasoned judgment, nevertheless is a contributing factor in a major reliability event investigation, regardless of whether the maintenance interval adjustment contributed to the failure. No matter what maintenance intervals are used, protection system components could fail. If the maintenance interval has been adjusted and if failure occurs, it will likely be unknown whether the interval adjustment was in fact a contributing factor or whether the failure would have occurred anyway. e. Faced with this dilemma, in addition to all the other hurdles to overcome in attempting to adjust an inappropriate maximum interval, the reality is that most entities will accept the inappropriate maximum interval and over-maintain their protection system components, and introduce a new set of reliability risks from such over-maintenance. For these reasons, CenterPoint Energy advises against creating a new set of problem by imposing rigid maximum intervals and then attempting to correct the problems through a performance-based mechanism that in actual practice would likely be illusory.
Yes
CenterPoint Energy believes the need for an extensive "Supplementary Reference Document", in addition to 13 pages of tables and an attachment in the standard itself, illustrates that the proposal is too prescriptive and complex for most entities to practically implement. CenterPoint Energy would prefer the SDT leave the existing requirements substantially intact or, if most industry commenters prefer the SDT's approach, that the SDT attempt to simplify it.
Yes
See CenterPoint Energy's response to question 6. The need for an FAQ document in addition to an extensive "Supplementary Reference Document" further illustrates the complexity and impracticality of the proposed standard revisions.
a. CenterPoint Energy believes the existing maintenance standards are preferable to the approach embodied in this proposal. However, if most entities agree with the SDT's approach, CenterPoint Energy recommends deleting Under-Frequency Load Shedding (UFLS) and Under-Voltage Load Shedding (UVLS) system equipment from the scope of this proposal because the performance requirements for UVLS and UFLS are substantially different from transmission and generation protection schemes. Few would argue that protection schemes that clear faults on the Bulk Electric System must be very reliable, much more reliable than schemes that shed distribution load for under-voltage or under-frequency situations. If an entity plans to shed a contemplated level of load for a contemplated set of circumstances based upon planning simulations, that plan would translate into a certain number of distribution feeders that are reasonably predicted to shed a load amount that is reasonably close, but not exactly equal (unless by chance) to the contemplated amount of load shed. For example, if a certain number of distribution circuits equals 10% of the entity's load during one time (such as system peak), that same amount of distribution circuits will almost certainly equal a different percentage of the entity's load at other times. So, if hypothetically 100 distribution circuits are armed with UVLS or UFLS relays set a given trip point, the actual percentage of load that will be shed will vary under different system conditions. Therefore, if 95 of the distribution circuits actually trip on one occasion and 98 trip on another occasion, the difference in system performance is immaterial because the exercise is not that precise, especially when planning simulation uncertainties are also introduced into the picture. For these reasons, CenterPoint Energy believes it is unreasonable to impose a high level of rigidity into load shedding schemes when the designs of the schemes inherently do not depend on such rigidity. If the SDT agrees, then the revised standard would not be applicable to Distribution Providers, and 4.1.3 can be deleted. b. CenterPoint Energy also disagrees with the proposed expansion of the Protection System definition. The present definition does not include trip coils; and correctly so, as trip coils are part of the circuit breaker. A protection system has correctly performed its function if it provides tripping voltage up to the breaker's trip coils. From that point, the breaker can fail to timely interrupt fault current due to several factors such as a binding mechanism that affects breaker clearing time, a broken pull rod, a bad insulating medium, or bad trip coils. Local breaker failure protection is installed to address the various possible causes of circuit breaker failure. Planning standard TPL-001 tables 1C and 1D specifically support the present definition, as Delayed Clearing is noted as due to "stuck breaker or protection system failure".

Progress Energy
Yes
No
Progress Energy does not agree with the activity “Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit.” We are unclear how this test should be performed.
No
The rational for microprocessor-based relay intervals is examined, but all others are strictly based on industry weighted average of survey results. We believe the team should use a more empirical, documented approach to determining these intervals, as many companies have longer intervals that they currently have documented for their basis. If these have been accepted as satisfactory in previous audits, why should they be required to change just to meet an arbitrary number?
Yes
Progress Energy is concerned that separating this document from the standard may lead to issues down the road. If the desire is to consolidate and clarify existing standards, then the two documents should be merged. Otherwise the reference document may get lost from the standard, or might get changed without due process, or might not even be recognized by FERC.
Yes
Progress Energy is unclear how a new/revised standard can have a 30 page FAQ document associated with it. If questions need to be addressed, the answers should be incorporated into the existing standard. During this stage of the draft, all questions should be addressed, not left to the side in an “interpretation” paper.
Comments: 1- Requirement R4 “Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctible issues as follows: “ Based on the definition provided (A maintenance correctable issue is a failure of a device to operate within design parameters that can be restored to functional order by calibration, repair or replacement.) Pr ogress Energy believes that this will become a potential tracking issue. To maintain all of the data required to meet this definition can be onerous. 2- The biggest concern with the proposed PRC is that for many entities, the proposed maintenance and intervals will greatly increase the entities’ workloads. There are not enough relay technicians available to handle this increased workload across the country. 3- The Implementation Plan for R2, R3, and R4 identified in the Draft Implementation Plan for PRC-005-02, dated July 21, 2009, is very reasonable. This plan recognizes that it is unrealistic to expect entities that are presently using intervals that exceed the maximum allowable intervals to immediately be in compliance with the new intervals. It allows implementation to be implemented across the maximum allowable interval. This is a reasonable approach for the following reasons: a. Sufficient resources are not available to perform the additional maintenance proposed on an accelerated basis. b. It allows the staggering of the PMs so that resource loading can be balanced. Without the ability to stagger the PMs, there would be an initial “bow-wave” of PMs and future “bow-waves” each time the interval is up. 4- The Implementation Plan for R1 identified in the Draft Implementation Plan for PRC-005-02, dated July 21, 2009, is not reasonable. The implementation plan requires entities to be 100% compliant three months following approval of the PRC. This is not a reasonable timeframe given the program changes required, including: a. A massive effort to review circuit schematics to determine whether equipment meets the definition of partial-monitored or unmonitored. b. Many procedures, basis documents, and job plans will need to be revised or created. c. The work management tool will have to be modified to reflect the new intervals. 5- PRC-008-1 placed only the relays associated with UFLS in the compliance program. Contrary to PRC-008-1, the draft PRC-005-02 places all components (relays, instrument transformers, dc supply, breaker trip paths) in the compliance program. This forces much of the distribution-level components to be placed in the compliance program. 6- The response to Item 2A of the FAQ Document, page 17, seems to indicate that commissioning test results do not have to be captured as the initial test record, only the in-service date. Is this a correct interpretation of the response? 7- Table 1a (Unmonitored Protection Systems) seems to indicate that a complete functional trip test must be performed for the UFLS/UVLS protection system control circuitry. This wording is identical with the wording for the protection system control circuitry (except UFLS/UVLS) table entry. This implies that UFLS/UVLS functional testing should include tripping of the feeder breakers for these unmonitored systems. Table 1b (Partially-Monitored Protection Systems) indicates that actual tripping of circuit breakers is not required under the UFLS/UVLS control circuit functional testing. Is this because trip coil continuity is being monitored and alarmed under Level 2 Monitoring?

Must feeder breakers be tripped during the functional testing if the trip coil continuity is not monitored and alarmed (unmonitored protection system)? 8- All standards to be retired should be specifically listed in the Implementation Plan.
Individual
John Moraski
BGE
PRC-005-2 R1 1.2 “Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods and identify the associated maintenance interval.” Comment: The existing standard PRC-005-1 requirement R1.1 says a maintenance program must include the maintenance and testing intervals and their basis. PRC-005-2 does not have a similar requirement, and the associated FAQ indicates the standard “establishes the time-basis for a Protection System Maintenance Program to a level of detail not previously required”. Does PRC-005-2 require evidence to support the basis for a defined maintenance interval, or is the basis now purely defined by PRC-005-2? R2 “ Each transmission owner …….shall ensure the components to which condition-based criteria are applied….possess the necessary monitoring attributes” Comment: Depending on the evidence requirements that are enforced this could be a very large undertaking offsetting the benefit of extending intervals with CBM. It would be helpful to understand what the drafting team or other stakeholders would envision as appropriate evidence supporting this requirement. R4 “Each transmission owner …….shall implement its PSMP, including the identification of the resolution of all maintenance correctable issues as follows : 4.1 ….within the maximum allowable intervals not to exceed those established in table 1a, 1b, 1c Comment: It’s inferred that this requirement applies to maintenance correctable issues that are discovered as a consequence of scheduled maintenance and not as a consequence of monitoring or misoperations. If that inference is incorrect the requirement imposes an unequal playing field for the resolution of known correctable issues depending on the monitoring being employed, not to mention an unreasonably long allowance for the correction of some serious problems. On the other hand, the requirement imposes an unreasonably short period of time for the resolution of some issues that may be associated with short interval maintenance/inspection intervals, such as battery grounds. Section D 1.4 Data Retention “The Transmission Owner..shall...retain documentation for two maintenance intervals….” Comment: Recognizing that in order to achieve compliance PS owners will execute scheduled maintenance on shorter intervals than the maximum requirement it’s uncertain what this means. Example: Max interval for instrument transformers is 12 years, we maintain every six. Is the requirement for 24 years of data or 12. It seems like there ought to be an upper limit. 24 years is a very long time. Table 1a Protection System Control Circuitry (Breaker trip coil only) ; 3 month maximum interval ; “verify the continuity….of the trip circuit …..except for breakers that remain open for the entire maintenance interval.” Comments: What’s the failure-probability justification for this requirement when other similar dc control components have a maximum interval of 6 years? It seems like the SDT made an assumption that all trip coils are monitored by red lights and could be verified by inspection and said somewhat arbitrarily, “do it because you can”. “Remaining open for the entire maintenance interval” is a poorly reasoned effort to arrive at a necessary exception. Even if the red-light-through-the-trip-coil assumption is accurate for a normally open breaker, it’s unreasonable to demand that an inspection take place if its closed at anytime during the interval. The actual time that its closed might be seconds or a few minutes, but that time would make the exception moot and put the owner out of compliance. On the subject of three month maximum intervals in general: One can agree that three months is about the right time for some of these inspections, batteries in particular. However as written, three months and a day is “out of compliance”. More flexibility would avoid a lot of meaningless “technical fouls”. How about four times a year not more than four months between each…or something like that. Table 1a Station DC supply (that has as a component any type of battery); “verify that no dc supply grounds are present” Comment: All grounds are not created equal. No guidance for acceptance criteria is given, nor is evaluation/acceptance criteria explicitly made the responsibility of the battery owner (as it is for relay calibration) . Without any guidance the requirement of “no” grounds is open to unreasonable interpretation (there is always a ground if one considers a high enough resistance) and high impedance grounds that do not present a risk to the PS will consume effort and attention unnecessarily. Station DC supply (that has as a component any type of battery);

“Measure the specific gravity and temperature of each cell is within tolerance” Comment: It is not clear that a specific gravity test provides any better data concerning battery health than an impedance test, but specific gravity testing is a requirement. Can the impedance test be performed as routine maintenance in lieu of a specific gravity test? General Comment: It is not clear whether Communications batteries should be held to the same testing/maintenance requirements as the station battery. Communications batteries are in place to supply relatively low power electronic equipment and do not have to provide energy to trip a breaker. Simple monitoring of the channel may be sufficient to assure battery availability, and a less rigorous maintenance plan may be appropriate based on the continuous monitoring and low duty of the battery. FAQ Group by Monitoring Level A level 2 (partially) monitored Protection System or an individual component of a level 2 monitored Protection System has monitoring and Alarm circuits on the Protection System components. The alarm circuits must alert a 24-hour staffed operations center. Comment: The Standard Table 1b, General Description for Level 2 monitoring is simply described as Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed features. This appears to be a conflict between the FAQ and the standard. The more stringent requirement of the FAQ, for the reporting facility to be manned 24 hours per day, could be read to imply a requirement for a specific time to respond to an alarm. Is there such a requirement? Is there an implied requirement to document the alarm condition and the response time?
Individual
Dale Fredrickson
Wisconsin Electric
Yes
No
1. Page 7 Station DC Supply (Batteries): The activity to verify proper electrolyte level should only apply to unstaffed (unmanned) stations; checking battery electrolyte levels is routinely done in generating stations, which are staffed with personnel continuously (24 x 7). In addition, the three activities listed here with a 3 month interval for batteries (electrolyte, voltage, grounds)should NOT require documentation for compliance purposes. It should be sufficient that these routine and recurring activities (every 3 months) are identified in the Maintenance Plan. Otherwise the administrative burden to provide documentation will become excessive and counterproductive to assuring BES reliability. 2. Page 7 Station DC Supply (Batteries): The 18 month interval includes an activity to verify the battery charger equalize voltage. This activity is normally done only when the bank is load tested. Therefore the activity to verify equalize voltage of a charger should have a 6 year interval along with the other battery charger activities to verify full rated current and current-limiting. 3. Page 9 Communications Equipment: Similar to #1 above, the activity to verify monitoring and alarms should NOT require documentation in order to demonstrate compliance. Having these routine 3 month activities in the Maintenance Plan is sufficient. This needs to be clarified in the standard. Also, this requirement should be re-worded to refer to generating stations also, not just substations. 4. Page 11 Station DC Supply (Batteries): Like #1 above, the similar requirement in Table 1b for verifying battery electrolyte levels should be revised to indicate that documentation is NOT required. 5. Page 6 Prot System Control Circuitry: Like #1 above, the 3 month activity to verify continuity of breaker trip circuits is fine, but there should be no requirement to document the readings or observations; it is sufficient that this activity be addressed in the Maintenance Plan, especially for staffed generating stations. 6. Page 6 Prot System Control Circuitry: For the 6 year activity to "perform a functional trip test...": is this a requirement to actually trip the circuit breaker ? If yes, this should be stated clearly in the Maintenance Activity description. 7. We are concerned that the Maintenance Activities are not appropriate for certain equipment. The RFC definition of Bulk Electric System includes any protection equipment that can trip a BES facility independent of voltage level. As an LSE, this includes distribution-level equipment that was not designed to the same level of redundancy as Transmission equipment. Complying with the requirements for control circuitry functional testing and current sensing device testing will actually decrease system reliability since this often cannot be accomplished without requiring outages to major distribution system components and/or temporarily breaking protection circuits. We propose that this type of testing on distribution systems which fall under the definition of BES Protection Systems should be addressed separately from the rest of the BES Protection Systems in this standard. The intervals and/or maintenance activities should reflect the differences in how these distribution protection systems are designed and operated.
No
Similar to comments in #7 above: It is our practice on distribution-level protection systems to utilize a 6 year interval plus/minus 1 year to accomodate potential scheduling conflicts. This is consistent with other LSE's relay testing practices as well. Thus the potential 7 year maintenance interval would be a violation of the draft requirements. The maintenance intervals in this standard should be increased accordingly for distribution protection system equipment.

Regional Variance
See above Question 2, Item 7: There needs to be some recognition that Protection System's applied on distribution-voltage systems may be included in a regional definition of a BES Protection System. These systems are not designed or operated in the same way as Transmission or Generation Protection Systems. Therefore, it is reasonable that these systems be subject to less rigorous requirements.
1. In the definition of a Protection System Maintenance Program, the statement is made that "A maintenance program CAN include...", with a list of seven attributes following. Is it the intent that the PSMP "SHALL include one or more of the following" ? What is to prevent Compliance staff from concluding that all seven of these attributes MUST be included in the PSMP ? 2. The standard should more clearly describe what is meant by "verify..." when used in a Maintenance Activity description. Does this require actual paper or electronic documentation? If so, then this should be explicitly stated in the Maintenance Activity description. We maintain above that the recurring and routine maintenance activities having a 3 month interval should be revised to use alternate words such as "Check" or "Observe". For example, "Check the continuity of the breaker trip circuit...", or "Observe the voltage of the station battery". This activity should not be required to have paper or electronic documentation or evidence. It should be sufficient to have these activities included in the PSMP. 3. It is stated in the Supplementary Reference that actual event data from fault records may be used to satisfy certain Maintenance Activities, yet the standard itself does not appear to allow for this. Will such evidence be accepted by Compliance staff?

Yes
No
FMPA does not believe that maintenance of each UFLS / UFLS systems are as important as maintenance of BES protection systems. The fundamental reason is that delayed or uncleared faults on the BES can cause system “instability, uncontrolled separation, and cascading outages”; therefore, BES protection systems are very important; however, if a small percentage of UFLS / UVLS relays mis-operate as a result of a frequency or voltage event, the impact of the mis-operation is much smaller, if even measurable. As a result, FMPA believes that the emphasis of the maintenance activities ought to be placed on those systems that can have the most impact on what the standards are all about, as Section 215(a)(4) of the Federal Power Act says, “avoiding instability, uncontrolled separation, and cascading outages”. As a result, FMPA believes that full functional testing, while important for BES protection systems, is not necessary for UFLS and UVLS systems (Table 1a, page 6 and Table 1b, page 11). Because most UFLS / UVLS are on radial distribution feeders, such testing will cause outages to customers fed on radial distribution circuits and transmission lines without sufficient cause, in other words, the maintenance itself will reduce the reliability the customer experiences. In addition, distribution tripping circuits are more regularly exercised by distribution faults than are transmission tripping circuits; therefore, full functional testing of distribution tripping circuits is far less valuable than testing trip circuits of transmission elements which are exercised less frequently due to actual system events. FMPA is confused with the wording of Table 1a, page 6, row 3 that talks about breaker trip coils. In the “Type of Component” column, the subject says “Breaker Trip Coils Only (except for UFLS or UVLS)”, yet the maintenance activity described states “Verify the continuity of the breaker trip circuit including trip coil”. These two statements are inconsistent because the first statement limits the applicability to just the trip coil and the second statement goes beyond the trip coil. And, FMPA believes the second statement should only apply to the trip coil, e.g., the second statement should say: “Verify the continuity of the trip coil”. In addition, the parenthetical is confusing, is it meant to say that the continuity of the trip coil only needs to be verified when the breaker operates during the 3 month interval, or that the intended continuity check is from the relay contacts through the trip coil, and not from the relay contacts back to the batteries?

FMPA is also confused concerning station DC supply testing. There are multiple rows in Table 1a concerning various types of testing for various types of batteries and chargers that do not exclude UVLS and UFLS, yet on page 8, on the bottom row, the row is exclusive to UVLS and UFLS yet overlaps other rows discussing station DC supply testing. Is it intended that the other rows that are silent as to what they apply to exclude UVLS and UFLS? FMPA believes that should be the case. The same comment applies to Table 1b. FMPA also has concern over the battery charger testing requirements. Per the charger manufacturers recommendations there is no reason to test the chargers as proposed in PRC-005-2. It is their opinion that the chargers are self diagnostic and do not require these tests (full load current and current limiting tests). The charger O&M manuals do not even provide instructions for such tests as optional. Therefore, FMPA takes exception to this requirement and suggests that battery chargers be maintained and tested in accordance with manufacturerâ€™s recommendations
No
FMPA agrees in general with many of the maximum maintenance intervals; however we have been unable to determine what basis was used to arrive at the time based intervals provided in the tables. Further explanation would be appreciated FMPA is concerned with the use of the term “continuous” in Table 1c. As stated, it would seem that, on loss of communications that would communicate the alarm, thereby causing a loss of “continuous” monitoring and alarming, the entity who invested in a reliability improving monitoring system would be found non-compliant with an infinitesimal maintenance period required for “continuous” monitoring. Therefore, FMPA recommends using “not applicable” or some other term in this column.
Yes
FMPA agrees with the approach, but, may not agree with the exact wording in the tables. For instance, the use of the word “every” in table 1c in “Protection System components in which every function required for correct operation of that component is continuously monitored and verified” may be overstating the level of monitoring that would realistically enable a Protection System to use table 1c.
No
FMPA believes that the documented process outlined in Attachment A; "Criteria for Performance Based Protection System Maintenance Program" is biased towards larger entities. The requirement that the minimum population of 60 individual components of a particular segment is required to make a component applicable to this program automatically eliminates most of the small or medium sized entities. Further the need to first test a minimum of 30 indivudual components in any segment reinforces the same size limitation. FMPA suggests that the Performance-Based Protection System Maintenance Program allow for regional shared databases applicable towards meeting the establishment and testing criteria of similar individual components. This practice will allow for the inclusion of entities of all sizes. This will also provide a greater format for the discussion of lessons learned and improvements to the testing database on a regional basis.

FMPA is not aware of any conflicts
FMPA is not aware of a need for a regional variance
Facilities applicability 4.2.2, due to the changes in applicability of the draft PRC-006, ought to refer say something like UFLS which are installed per requirements of PRC-006 rather than per ERO requirements. In requirement R1, bullet 1.1 ought to state “For each component used in each Protection System, include all “applicable” maintenance activities specified in Tables 1a, 1b and 1c”. For instance, if every component has continuous monitoring, why should the program include 1a and 1b?

We commend the SDT for developing such a clear and well documented first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. Our existing M&T Program has and continues to yield a very reliable BES with mostly similar intervals, though some are longer and others shorter. We strongly support the almost all of the applicability revision, which clarifies the boundary of NERC maintenance and testing oversight. We question the addition of UFLS station DC Supply, auxiliary relays, and Generating facility system-connected station service transformers. Have these components been a significant source of problems leading to cascading outages? The SDT also modifies the Protection System definition, mostly clarifying the boundaries. We generally agree except that we recommend adding “fault” before “interrupting devices”.
No
We agree with the vast majority of them, listed below are our few concerns, questions, and pleas for clarification. 1) We disagree with doing specific gravity and temperature of every cell in the 18 month test because the other tests being done are already comprehensive. 2) FAQ 3B p 29 digital relay A/D verification should include simply comparing digital relay displayed metered values to another metered source. 3) FAQ 3A p6 Change “prove that” to “verify”. For single CT or VT, this can be challenging and some measure of reasonableness in determining an expected value comparable to the measured value must be acceptable. 4) FAQ 1B p17 Combining evidence forms of “Process documentation or plans” and “Data” or “screen shots” shows compliance. Please add an example or verbiage to clarify that a field technician’s (or operator) recorded check-off combined with a company’s process is sufficient evidence. Otherwise documentation alone could consume considerable field personnel time. 5) FAQ p2 Add FAQ to clarify “verify settings”. If EM relays are included, explain that minor tap or time dial differences of the order of relay tolerances are acceptable. For digital relays state that software compare functions are a sufficient means to “verify settings.” 6) Omit Table 1b row 3 because row 4 actually applies to Monitoring Level 2 Trip Circuits. Row 3 already appears in Table 1a, and repeating it in Table 1b is confusing. 7) FAQ 4D p 7 then defines auxiliary relays as device 86 and 94. Does device number nomenclature or function determine and restrict inclusion? 8) Please state that “a location where action can be taken for alarmed failures” would include a dispatch center or control room. From there the custodial authority would be called out to take action. 9) Please explain the expansion from station battery to station DC supply, specifically the addition of the charger, an AC to DC device. The charger load test up to its current limiter would add a significant amount of work with little known benefit. Have charger problems been a significant cause of cascading outages? 10) We oppose your expansion of Station DC Supply to UFLS (the last row on page 8.) PRC-008-0 is restricted to UFLS equipment. UFLS is often applied in distribution substations to trip feeders directly serving load. Your scope expansion has the potential to greatly increase the number of substation DC Supplies covered by NERC standards. ,. While we agree that UFLS is BES applicable, and those substations are included in our overall maintenance program, this expansion to NERC scrutiny is not warranted. Have there been UF events in which a material amount of load was not shed because of DC problems? UFLS is spread out amongst many distribution stations, and even if a couple did fail to trip in an underfrequency event, it would have little effect. 11) FAQ 2 p 17 expands the scope at Generating Facilities so that system connected station auxiliary transformers would be included. We oppose this expansion as these are radially served loads, and they often do not result in generation loss. Even if they did, the BES can readily tolerate the loss of a single generator.
No
1) The “zero tolerance” structure proposed combined with the large volume and complexity of Protection System components forces an entity to shorten their intervals well below maximum. We instead propose a calendar increment grace period in which a small percentage of carryover components would be tracked and addressed. For example, up to 10% of all breaker trip coils subject to the 3 month “verify breaker trip coil continuity” could carry over into the first month of

the next period. And for example, up to 5% of an entity's communication channel 6 year verifications could carryover into the next year. These carryover components would be addressed with high priority in that next calendar increment. There are many barriers to 100% completion or zero tolerance. Barriers include sheer volume, obtaining outages, resource availability, coordination, and documentation (over ten thousand components in our utility alone; taking a BES outage to permit maintenance can incur a greater reliability risk than delaying the maintenance; emergent issues such as major storms impact resource availability; coordination with interconnected neighbors, their resources and maintenance timing; record keeping errors or oversights; etc.) 2) Alternatively, components with intervals less than a year should be stated in terms of the number of times annually it should be performed, rather than a short duration interval. The expectation is that they would be roughly equally spaced throughout the year; for example quarterly instead of 3 months. Comment 1 grace period would still apply to components with maximum intervals of 1 year or greater. 3) Some of our maintenance intervals are shorter than maximum. Please confirm that documentation is only to be kept for two of the entity's intervals, not two of the maximum interval. 4) Please add standard language or FAQ near 2D on p 18 that an entity can validly use an interval with % tolerance to achieve maintenance goals, as long as the applicable maximum interval is honored.
Yes
We agree with the condition-based approach. Our comments in 3 above apply to Tables 1b and 1c as well. We note that Table 1b Station dc supply intervals are the same as Table 1a. Why doesn't the monitoring cause 1b intervals to be longer than 1a?
Yes
While we agree with the approach, batteries should be allowed, not excluded.
Yes
1) We disagree with the page 22 statement that batteries cannot be a unique population segment of a PBM. 2) What role does the Supplement play in Compliance Monitoring and Enforcement?
Yes
1) We don't think an Executive Summary is needed. 2) Please include the Supplement's explanation of A/D verification method from Supplement page 9. 3) What role does the FAQ play in Compliance Monitoring and Enforcement? 4) Refer to question 2 and add our items # 2, 3, 4, 5, 7, and 11 to FAQ. 5) Please add FAQ that provides the NERC Compliance Reqistry Criteria for Generating Facilities, to clarify applicability to >20MVA direct BES connection, aggregate >75MVA etc. 6) FAQ 2A p17 states that commissioning is construction, not maintenance. It seems like you're ignoring the significant verification, testing, inspection, and calibration activities that occur in commissioning. Should the in-service date be assigned to these components for determining their next maintenance? 7) Refer to question 3 and add our items # 4 to FAQ.
1) Documentation could be a monumental task. Although FAQ 1B allows a comprehensive set of forms of documentation, a very large number of people are involved across this set at most utilities. Producing a particular needle in the haystack may take longer than an auditor would expect. Inspection forms can be structured to capture abnormal conditions, and thus normal conditions are not recorded. Some items, like the red light monitoring a trip coil, may only be reported by exception (i.e., "red light out, replaced bulb" but if the red light is on an operator may not report that). 2) We presume that the SDT would expect transmission facilities to be switched out of service if maintenance would result in those facilities being unprotected. We think this should be stated or clarified, as there may be entities that still use differential cutoff switches or other means of disabling protection for testing and have not considered the consequences of a concurrent fault.

We agree with all stated intervals except for the maximum stated interval of 6 years for Protection System Control Circuitry (Trip Coils and Auxiliary Relays) in tables 1b and 1c. What was the intent of separating this interval out from the Protection System Control Circuitry (Trip Circuits), which is 12 years for monitored components? Monitoring of the trip coils should be enough to justify a maximum interval of 12 years. As stated these requirements will put an undue financial and resource burden on utilities that have updated their protective relay systems with state-of –the art components and monitoring. In addition to the expense and effort of scheduling the additional maintenance, the additional validation of lockouts and auxiliary relays,

separate from the full function testing could lead to additional human errors and accidental tripping of circuits while testing. We believe there should be one stated activity “Protection System Control Circuitry and have a maximum interval of 12 years for monitored systems.
Yes
Yes
We commend the drafting team for recognizing the advantages of using monitored systems and a condition-based approach. This approach recognizes the benefits of using newer technologies and will give utilities added incentive to update their relay systems.
Yes
Yes
The Supplementary Reference is well written and helpful in explaining the drafting teams thought process.
Yes
The Frequently-asked Questions document is very well written and very helpful. The decision trees are a good addition.
Conflict: Potential conflict with PRC-023 as to which PRS systems are applicable per this standard. Comments:PRC-005-2 requires compliance for this standard for all non-radial systems over 100 kV; while, PRC-023-1 prescribes it as below: 1. Title: Transmission Relay Loadability 2. Number: PRC-023-1 3. Purpose: Protective relay settings shall not limit transmission loadability; not interfere with system operators’ ability to take remedial action to protect system reliability and; be set to reliably detect all fault conditions and protect the electrical network from these faults. 4. Applicability: 4.1. Transmission Owners with load-responsive phase protection systems as described in Attachment A, applied to facilities defined below: 4.1.1 Transmission lines operated at 200 kV and above. 4.1.2 Transmission lines operated at 100 kV to 200 kV as designated by the Planning Coordinator as critical to the reliability of the Bulk Electric System. 4.1.3 Transformers with low voltage terminals connected at 200 kV and above. 4.1.4 Transformers with low voltage terminals connected at 100 kV to 200 kV as designated by the Planning Coordinator as critical to the reliability of the Bulk Electric System. 4.2. Generator Owners with load-responsive phase protection systems as described in Attachment A, applied to facilities defined in 4.1.1 through 4.1.4. 4.3. Distribution Providers with load-responsive phase protection systems as described in Attachment A, applied according to facilities defined in 4.1.1 through 4.1.4., provided that those facilities have bi-directional flow capabilities. 4.4. Planning Coordinators. We believe Bulk Electric System (BES) owners’ resources would be better utilized by focusing on relay systems as defined in the above PRC-023-1 and this would still provide high level of reliability for the BES, since not all facilities operating between 100 – 200KV are critical to the BES. This would not preclude any utilities from applying this standard to other facilities operating at the lower voltage range. Why did the drafting team not use the application language sited in the “Protection System Maintenance - A NERC Technical Reference” which is similar to what is described above from PRC-023-1?
We commend the work done by the Standard Drafting team. In particular, the merging of previous standards PRC-005-0, PRC-008-0, PRC-011-0, and PRC-017-0 which will help with the efficient management of these standards.

Regional Variance
It is our understanding that once Project 2009-17: “Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State” is approved, that the definition of a “Transmission Protection System” would be included within PRC-005-2 or included within the NERC Glossary of Terms. However, the specific protection that would be considered part of the “Transmission Protection System” would also depend on the regional definition of the BES. We suggest that the regions develop a supplement that provides further clarification on what constitutes a “Transmission Protection System” given the regional definition of the BES.
The “zero tolerance” structure proposed within this standard combined with the large volume and complexity of Protection System components requires a utilities processes and built-in grace periods to perform to perfection. Although this is a worthy goal for our industry, this can result in a large number of non-compliances for minor documentation issues or slightly missed

maintenance schedules on an insignificant percentage of relays. The processing of these non-compliances can be costly in terms of resources that could be better utilized to address other transmission reliability matters. To provide a better approach, we suggest an incremental carryover system be permitted that would allow up to 0.5 percent of the PRC-005 maintenance task to be carried over to the next period, provided they are random events (not repetitive). As an example, a small percentage of our Protective System Control Trip tests on a 6-year interval could be carried over into the next calendar year when a generator outage is rescheduled. With this provision, these few tests could be handled without risk of a generator trip and without a compliance consequence. These carryover tasks could be addressed through an action plan with a defined completion date, and could be documented through a regional web portal. There are many barriers to 100% completion at a zero tolerance level with this volume of tasks.

No
Tables 1a and 1b require entities to verify the proper operation of voltage and current inputs to sensing devices on a 12 year interval. The Protection System Supplementary Reference (Draft 1), in section 15.2, describes several methods that may be used for such verification efforts. In order to perform this type of verification the circuit in question would need to be in operation. This verification introduces a possible unit trip due to the need to connect test equipment to live potential and current circuits at each relay, which has the potential to trip the circuit under test. This could result in the loss of critical transmission lines or generating units. The System Maintenance Supplementary Reference also allows saturation tests or circuit commissioning tests to satisfy this requirement; however, these types of tests require the circuit in question to be removed from service. For generating plants, removing the circuit from service requires that the station be shut down. We do not feel that the value obtained from this requirement is equal to the risk or maintenance burden associated with it. Such testing and verification should not be required periodically, but only if new instrument transformers, cabling or protective devices are installed or if the instrument transformers are replaced. Table 1b: Protection System Control Circuitry (Trip Coils and Auxiliary Relays) – Experience has shown that electrically operating partially monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend eliminating this maintenance requirement. Protection System Control Circuitry (Trip Circuits) (UFLS or UVLS Systems Only) - Table 1b includes the statement "Verification does not require actual tripping of circuit breakers or interrupting devices." This statement should be included in Table 1a. In Table 1a – Station DC Supply (that has as a component any type of battery), we recommend changing the maximum maintenance interval from 3 months to 6 months as described below Verify Proper Electrolyte Level – 3 Months The 3 months interval for verifying proper electrolyte level is excessive for current battery designs that are properly maintained. The interval in which the electrolyte must be replenished is affected by many factors. These include temperature, float voltage, grid material, age of the battery, flame arrester design, frequency of equalization, and electrolyte volume in the battery jar. Manufacturers are aware that their customers want to extend the interval in which their batteries require water and this has lead to jar designs that have a wide min-max band with a high volume of electrolyte to allow for extended watering intervals. Understanding all the factors and proper maintenance will extend watering intervals. A battery should go a year or more between watering intervals and some as many as 3 years. Being conservative the Southern Company Substation Maintenance Standards require that we check the electrolyte level twice yearly. Experience has shown this has worked well. We propose that the “3 Months” interval be changed to “6 months”. • Verify proper voltage of the station battery – 3 Months Being conservative, the Southern Company Substation Maintenance Standards require that we check the station battery voltage twice yearly. Experience has shown this has worked well. We propose that the “3 Months” interval be changed to “6 months”. • Verify that no dc supply grounds are present – 3 Months Being conservative, the Southern Company Substation Maintenance Standards require that we check for dc supply grounds twice yearly. Experience has shown this has worked well. We propose that the “3 Months” interval be changed to “6 months”. Measurement of Specific Gravity – 18 Months The measurement of specific gravity and temperature every 18 months is not necessary as a regular part of maintenance. Specific gravity can provide information as to the health of a cell; however, taking specific gravity readings is a messy process no matter how careful you are and will result in acid being dripped on top of the battery jars as the hydrometer is moved from cell to cell. Should a drop of acid end up on an external connection, it will result in corrosion and problems later. Voltage reading of cells can be substituted for specific gravity readings under normal conditions. Specific gravity is equal to the cell voltage minus 0.85. A cell with low voltage will have a low specific gravity. If cell voltage becomes a problem that can not be addressed through equalization then specific gravity readings are justified as a follow-up test. Since measurement of specific gravity could lead to

problems and reading cell voltage is a viable alternative, we propose that it be removed from the battery maintenance activities. Verify Cell to Cell and Terminal Connection Resistance – 18 Months Clarification is needed on the expected method for verifying cell to cell and terminal connection resistance. This could easily be interpreted as requiring the use of an ohmic value (impedance/conductive/resistance) test device. If this is the case then basically it eliminates the need for the activity to “Verify that the substation battery can perform as designed by performing a capacity test every 6-Calendar Years or performing an ohmic value test every 18 Months”, because the practical thing to do is go ahead and perform the ohmic value test while you have your device connected to the battery. In table 1a and 1 b - Station dc supply (that has as a component Vented Lead-Acid batteries. Verify that the Substation Battery can Perform as Designed – 6 Calendar Years/18 Months Southern Company Transmission has approximately 570 batteries that are covered by this proposed standard. These batteries currently have ohmic value testing performed every “4 Years” as required by the Southern Company Substation Maintenance Standards. The “4 Years” interval has been utilized for over 10 years and has not experienced a failure of any of the 570 batteries to perform as designed Having to perform ohmic value testing on an “18 Months” interval will significantly increase our costs and manpower requirements with no anticipated improvement in reliability. We propose that the “18 Months” interval for ohmic value testing be changed to “4 Calendar Years”. This proposal also applies to verifying cell to cell and terminal connection resistance if an ohmic value test device is required as discussed above. In table 1a and 1b – Station dc supply (that uses a battery and charger). Verify that the Battery Charger can Perform as Designed – 6 Calendar Years Clarification is needed on an acceptable method for verifying that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current limit, especially the part about “will properly current limit”. On Table 1b – Station DC Supply (that has a component any type of battery) we recommend changing the maximum maintenance interval from 3 months to 6 months as described below • Verify Proper Electrolyte Level – 3 Months The 3 months interval for verifying proper electrolyte level is excessive for current battery designs that are properly maintained. The interval in which the electrolyte must be replenished is affected by many factors. These include temperature, float voltage, grid material, age of the battery, flame arrester design, frequency of equalization, and electrolyte volume in the battery jar. Manufacturers are aware that their customers want to extend the interval in which their batteries require water and this has lead to jar designs that have a wide min-max band with a high volume of electrolyte to allow for extended watering intervals. Understanding all the factors and proper maintenance will extend watering intervals. A battery should go a year or more between watering intervals and some as many as 3 years. Being conservative the Southern Company Substation Maintenance Standards require that we check the electrolyte level twice yearly. Experience has shown this has worked well. We propose that the “3 Months” interval be changed to “6 months”. We recommend removing the “Detection and alarming of dc grounds” monitoring attribute. Note that this applies to every “Station dc supply” section where it is listed. Experience has shown that there have been no significant problems discovered via alarms that would not have been discovered by 6 month inspection cycles. We propose to add “verify no dc grounds are present” as a maintenance activity on a 6 months inspection cycle. Experience has shown that there have been no significant problems discovered via alarms that would not have been discovered by 6 month inspection cycles. Table 1a, p. 7, Station dc supply, 3 month interval: need to add ‘unintentional” to the sentence “Verify that no dc supply grounds are present.” because most dc systems have ground detection systems which place an intentional ground on the battery. “No grounds” is not practical and is unacceptable since most dc systems have some high resistance ground paths. Some criteria should be established to determine the acceptable ground resistance on a dc system. Table 1a, p. 8: For the vented, lead-acid battery, there is no basis for the 18 month activity option (internal ohmic value measurement) in place of the 6 year performance test. The activities for trip checks for Level 1A and Level 1B should be the same. Currently, they read: Level 1a: “Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System. “ Level 1b: “Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval.” The Level 1a text is adequate for 1b also. Table 1c, p 16: Monitoring of single or parallel trip circuits is not practical where multiple normally open contacts are in series to trip. Monitoring of the trip coils is practical and useful. How would one monitor several normally open contacts which are in series to trip a breaker? Table 1c, p. 15, 16, 19: The use of “continuous” under “Maximum Maintenance Interval” in Table 1c should be changed to “N/A” and the Maintenance Activity should be “NONE”. Verification of the various monitoring (automated notification) systems is not specified anywhere in the requirements. This, too, should be required.
No
The 3 month intervals specified for the trip coil monitoring and communication circuit testing are too frequent. Our experience is that trip coils rarely burn open and don’t need to be checked this often. If no monitoring currently exists, manually checking the circuit (until a time where monitoring can be installed) may inadvertently cause a trip. This adds risk to the reliability. Thus, requiring the trip circuits to be tested every 3 months may reduce the reliability of the BES. Protection System Control Circuitry (Breaker Trip Coil Only) (Except for UFLS or UVLS) In order

to reduce the risk of reducing Bulk Electric System reliability a better time interval for testing un-monitored trip coils would be 12 months. This may need to be 24 months for Nuclear Generating units. Some allowance for a grace period (beyond the specified intervals) should be considered for all classifications. Outage schedules are known to change unexpectedly due to unforeseen circumstances. A grace period tolerance of +25% for specified maintenance intervals less than 12 months and of +1yr for those intervals specified as greater than 12 months is recommended. Typically at a nuclear plant a grace period is allowed by plant procedures. This grace period is defined as an additional 25 percent of the original schedule interval for the task. The grace period is provided as reasonable flexibility to allow for alignment with surveillance activities and equipment maintenance outages and to better manage the use of station resources. Some maintenance activities will require an outage to perform the work. Refueling outages are typically performed on an 18 month or 24 month refueling cycle. However, refueling outages do not always fall exactly on that interval. It is possible that the duration between one outage to the next may exceed 18 or 24 months. For activities that are required to be complete on a calendar year cycle this should not be an issue since the outages are normally scheduled several months prior to the end of the year. However, if the interval is a monthly interval there could be a problem with scheduling the maintenance such that it does not impact planned maintenance activities, surveillance requirements, and station resources. Tables 1a, 1b and 1c have several instances where inspection and testing of DC circuits or components has a specified interval of 18 months. At nuclear generating stations, such tests on station battery banks and associated chargers incur unacceptable risk if performed with the unit on line and a unit outage is required for this testing. A number of nuclear plants are on two-year shutdown cycles and we request that the 18 month intervals be changed to two (2) (calendar) year intervals to accommodate this. Protection System Control Circuitry (Breaker Trip Coil Only) (Except for UFLS or UVLS) – Based on past performance, a complete functional test trip every 6 years is not warranted. This complete functional test introduces additional risk to our maintenance program, not only from a human error perspective, but also from the additional frequency of switching and outages required. Our experience has shown that 12 years is an appropriate maximum time interval (rather than 6 years.)
No
Table 1b should allow self-monitored circuits that are not alarmed but are monitored and logged by personnel daily or more often. Many plants and substations have personnel that do in person checks of unmanned control rooms. This is the equivalent of “Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures.” For example, dc system ground potential lights and dc system volt meters exist on most control room bench boards or exist in the digital control systems at generating stations. These devices are monitored by operators in manned control rooms. On Table 1b, Protection System Control Circuitry (Trip Coils and Auxiliary Relays), the monitoring component calls for “Monitoring and alarming of continuity of trip coil(s).” Clarify that “trip coil(s)” excludes Breaker Failure Initiate relay coil(s). On Table 1b, Protection System Control Circuitry (Trip Coils and Auxiliary Relays) – Experience has shown that electrically operating fully monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend eliminating this maintenance requirement from Table 1b. On Table 1c, Protection System Control Circuitry (Trip Coils and Auxiliary Relays) – Experience has shown that electrically operating fully monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend changing this maximum maintenance interval to 12 years. Component monitoring attributes need to be defined for all components in table 1b and 1c. For example, the attributes for voltage and current sensing devices could be that "Voltage and current input circuits are monitored and alarmed". Based on past performance, the requirement to electrically operate trip coils, auxiliary relays, and lockout relays every 6 years in Table 1b is not warranted. We recommend complete functional testing including electrical operation of breaker trip coils, auxiliary trip relays, and lockout relays every 12 years in tables 1b and 1c.
Yes
Yes
Section 15.3 DC Control Circuitry: Although we agree with the premise that auxiliary trip relays and lock-out relays are similar in nature to EM relays and breakers, we believe that based on past performance, a complete functional test trip every 6 years is not warranted. This complete functional test introduces additional risk to our maintenance program not only from a human error perspective but also from the additional frequency of switching and outages required. Our experience has shown that 12 years is an appropriate maximum time interval (rather than 6 years.) The Protection System Maintenance Supplementary Reference (Draft 1), section 8.4, states that the intervals using the term “calendar” are allowed to be completed by the end of the applicable period, not necessarily exactly at the interval specified. The only intervals specified in the PRC-005-2 tables are “calendar years” and “months”. We believe that the “calendar”

description should be extended to the "months" designator also to also provide some maintenance flexibility (i.e. if an inspection were performed March 1st and was on a three month interval, it would not be required until the end of June). This section should remove the term "calendar" and use "months" and "years" with an appropriate explanation of the intent of the durations.
Yes
Part of the responses could be more correctly stated: Page 11E, "why is specific gravity testing required?" The specific gravity measurements do not reflect accurate state of charge for lead-calcium batteries. (Float current is a better parameter for this indication)
We presently utilize a UFLS system distributed across many transmission and distribution substations. Are the station batteries located in stations with no network transmission protection schemes (other than UFLS) subject to the requirements of PRC-005-2? This was not addressed in previous revisions. We presently utilize a UVLS system distributed across many transmission and distribution substations. Are the station batteries located in stations with no network transmission protection schemes (other than UVLS) subject to the requirements of PRC-005-2? In the applicability section, there is no exception for smaller units and those with very low capacity factors. Rather, those that "are part of the BES" are in the scope. We recommend that smaller units and low capacity factor units be exempt from the requirements of this standard or have extended maintenance intervals. Refer to the current SERC supplement for PRC-005-1. Section II.A. of the May 29, 2008: SERC Supplement Maintenance & Testing – Protection Systems (Transmission, Generation, UFLS, UVLS, & SPS) NERC Reliability Standards PRC-005-1, PRC-008, PRC-011, & PRC-017. The applicability section paragraph 4.2.4 should read "are installed" rather than "is installed". Note 2 at the bottom of the table (1c) implies that one has to apply voltage and inject current into the microprocessor relay to perform trip checks. Is this the intent of the statement? If so, Note 2 should be revised to make clear the intention. We don't think this is necessary with microprocessor relays since they monitor inputs Why is the Violation Severity Level Matrix not a part of this standard revision? In cases where a common dc system exists between a generator owner and transmission owner, who is the responsible entity? We appreciate the work that went into the implementation plan. We agree with the concept of phasing in mandatory compliance and the timing of the implemetation. Consider defining the Monitoring Levels once and reformatting the information contained within Tables 1a, 1b, and 1c to regroup the information by component type rather than by Monitor Level. When considering the various monitoring levels for the protection system components, each entity will consider each component type apart from the others when determining the Monitor Level to apply, so this reorganization will assist the end user to understand and apply the levels. See samples attached as a separate document:

Yes
No
It is recommended to change the wording of the Maintenance Activities to the activity itself, not the resolved state of the maintenance correctable issue (i.e. "For microprocessor relay, check for proper operation of the A/D converters" instead of "For microprocessor relays, verify proper functioning of the A/D converters"). The wording of the standard effectively sets the end date for the correction of maintenance identified issues. In other words, maintenance has not taken place until all maintenance correctible issues have been completely resolved. The wording in the standard have set non-compliance "traps" for those performing the maintenance but have not completed correctable issues for legitimate reasons which may not be allowed by the no-exception approach of the standard. For example, rewording of the Battery Supply 3 month activities are recommended as follows: "Check for proper electrolyte level. Check for proper voltage. Check for dc supply grounds." As inspection activities, any issue not corrected during the interval should become a maintenance correctible issue. For generating stations, the judgments to locate and remove a ground are based upon criteria not accounted for in the requirements of this standard. An activity to locate and clear a ground requires the judgment of station maintenance and operational management depending upon the operating conditions of the unit and the level of the ground (solid or high-resistance). Inspections (3 month requirement activities) although good practices, should not be standard requirements. The practice of verifying the continuity of breaker trip circuits does not belong as an auditable NERC standard requirement; it becomes more of a documentation requirement rather than a reliability improvement. Otherwise, it will ultimately require the expending of resources in an unproductive manner primarily on the development, storage, and production of excessive records for compliance purposes. The elimination of this requirement is recommended. For Table 1a –

Protection System Control Circuitry - rewording is suggested as follows: “Perform functional trip tests of Protection System trip circuits, including auxiliary relays essential to the proper functioning of the Protection System.” The requirement, as presently worded “that includes all sections of the Protection System,” is overly prescriptive and will create non-compliances for miniscule oversights, given the very large scope of components in protection systems that are spread out far and wide in a system. The requirement opens the door, allowing the compliance process itself to be punitive in nature. When pursued to the extreme under audit conditions, this requirement will be very difficult to demonstrate on a large scale. For Table 1a – Station dc supply: The ability of a battery charger to correctly supply equalize voltage to a battery has no direct correlation to reliability of the BES and does not belong in this standard. The objective is that the battery get an equalize charge when it needs it, not the maintenance of the equalize function of a battery charger. How the battery gets equalized is not important to this standard, especially since a battery and the equalize source are usually disconnected from the protection system during the process. For Table 1a – Station dc supply: The use of the term “in tolerance,” for the measurement of specific gravity, is an inconsistency in stating the standard requirements. There are multiple activities that will necessitate the measurement of a quantity “in tolerance” whether it is battery charger output, individual cell voltages, connection resistances, or internal ohmic values. The suggested rewording is as follows: “Measure the specific gravity and temperature of each cell.” For Table 1a – Station dc supply: Referring to the requirement to “verify that the station battery can perform as designed…” very little of a generating station battery sizing is related to BES protection. Verification of a generating station to design conditions is outside the scope of BES protection and does not belong in this standard. Nearly all protection system operations operate without reliance upon the battery to do so, and the separation of the generating unit from the BES will take place within cycles, if called upon to do so. The remainder of the battery duty cycle is outside the scope of BES protection.

No

The intervals need to be defined on a calendar quarters or calendar years, especially for intervals listed as 3 months. The demonstration of maintenance on rolling three-month intervals will be an onerous record keeping task, particularly when relying upon planning and tracking software that scheduled recurring tasks on the same day of an interval. Given the magnitude of the number of trip circuits, the requirements set an un-acceptable trap of non-compliance from a record keeping perspective. The resources required to keep and maintain flawless records are too much to justify the intervals. A non-compliance is the result if the breakers that happen to be in an open state when the officially “documented” inspection is recorded and is missed by accidental oversight on follow-up. If the requirement remains, it should be waived for any breaker that is operated during the defined interval.

Yes

Yes

No

Yes

Reverse power relays do not belong in the list of devices within the scope of this standard; reverse power is not used for generator protection or protection of a BES element. Aside from the protection of reverse power for other non-BES equipment, a generator can operate continuously as a generator, synchronous condenser, or a synchronous motor. Reverse power relays (or reverse power elements in multi-function relays) is commonly used as a control function for automatic shut-down purposes, which is not a protective function. Other reverse power protection, with longer time delays, is provided for turbine protection, which is not within the scope of the NERC Standards.

The standard was written to implement generally accepted practices, but has developed requirements that are overly prescriptive relative to what will be required to demonstration compliance. The standard should not assume the need to write all aspects of a maintenance program into the standard or that maintenance programs will only consist of the standard requirements. Protection systems of the BES have and will continue to perform very reliably with the basic elements of a maintenance program without the need to divert resources for the development of excessive documentation to demonstrate compliance. PRC-005-1 is the most violated standard in the industry; not because of the lack of maintenance to protection systems, but because the documentation requirements of the standard, given the large magnitude of components that fall within the scope of the standard. This standard significantly increases the administrative burden for additional documentation, without corresponding improvements to the reliability of the BES. Recommend rewording A.4.2.5.1 as follows: “Generator Protection system components that trip the generator circuit breakers to separate and isolate the generator from

the BES either directly in the breaker trip coil circuit or through interposing lockout or auxiliary tripping relays.” This document should not expand the compliance scope beyond the definition of the BES. The generator protection systems that “trip the generator” also perform additional control functions that extend beyond the electrical isolation of the generating unit from the BES. These additional circuits do not protect the BES and do not belong in the scope of this document. Recommend rewording A.4.2.5.4 as follows: “Protection systems for generator-connected station service transformers that trip the generator circuit breakers to separate and isolate the generator from the BES.” This document should not expand the compliance scope beyond the definition of the BES. Related protection circuits of the transformer not involved with the electrical isolation of the generating unit from the BES does not belong in the scope of this document. Recommend rewording A.4.2.5.5 as follows: “Protection systems for BES elements connecting to the station service transformers of generating stations.” This document should not expand the compliance scope beyond the definition of the BES. The requirement incorporates radial feeds (with dedicated breakers) into the scope of the standard that are not necessarily a part of the BES as defined by some RRO’s. Station service transformers are not necessarily required for generating unit operation. In some cases there are redundant sources for startup or back-up power. Protection of these transformers does not belong in the scope of the standard if they are not a part of the BES. The suggested rewording of R1.2 is as follows: “Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods.” The requirement for the registered entity to list the interval of maintenance does not belong in the standard, especially since the maximum intervals are listed in the standard tables. The registered entity may have internal documents that intentionally target a shorter duration than the maximum interval of Table 1a. The failure to meeting those internally established targets can be a violation of the standard by the wording of this requirement. Allow R4 of the standard to identify the maximum allowable intervals. In R4, the requirement for “identification of the resolution of all maintenance correctible issues” should be separated from the maintenance intervals; which define the maximum intervals of maintenance activities. The requirement should be eliminated to remove the overly prescriptive requirements of auditable documentation. If retained, a rewording of the requirement is as follows: “Each Transmission Owner, Generator Owner, and Distribution Provider shall identify the resolution of all issues identified and not corrected at the time the maintenance is initiated and the protected element is returned to service.” The documented resolution of maintenance correctible issues (if retained) should apply only to activities that are unresolved and incomplete during the normal maintenance process. The standard should not micromanage the documentation process by creating requirements for excessive auditable records needed to demonstrate compliance of routine maintenance activities. In R4, the requirements for Generator Owners which establish the durations of maximum allowable intervals should be separated from the Transmission Owners, even if the intervals are the same. The reason is to allow for the assignment of different Violation Risk Factors. The Violation Risk Factor for the application of a 20 MVA generating unit with an operating capacity factor of less than 5%, and connected to a 138 kV system, should not be the same as those applied to a 500kV transmission line. The violation risks factors for these two applications are significantly different, and the ability to recognize this is not permitted by the standard presently. Similarly, the criteria used for the sizing of station batteries for a large generating station is very different than those used for transmission facilities. Very little of the generating station battery sizing is related to BES protection, and nearly all generator protection system operations occur without reliance upon the battery. Without NERC Standard requirements, Generator Owners have their own natural incentives to maintain batteries for the protection of the turbine generator bearings on the loss of AC power. With the most basic requirements of an inspection and maintenance program, there is an extremely high degree of reliability given the typical design of DC systems within a generating station, even without documented compliance to a rigid set of standards. With very basic, elementary maintenance (documented or not), the statistical probability for the random and simultaneous failure of multiple battery cells to disable the protection system of a generating station for the milliseconds of time required to separate a generating unit from the BES is insignificant (well in excess of 1 billion to 1 across an entire calendar quarter). Violation risk factors and the resulting penalties for non-compliance need to be realistic.

Tables 1a, 1b & 1c should offer as an alternative, measuring battery float voltages and float currents in lieu of measuring specific gravities as described in Annex A4 of IEEE Std 450-2002. b. Inspection of CVT gaps, MOVs and gas tubes should be added to the communications equipment time based maintenance tables. Failure of the CVT protective devices may cause failure of the Protection System. c. Maintenance Activities for UVLS or UFLS station dc supplies shows “Verify proper voltage of dc supply”. Does this imply that, except for voltage readings of the dc supply,

distribution battery banks are not maintained? d. Why does the Maintenance Activities for UVLS or UFLS relays state that verification does not require actual tripping of circuit breakers? e. Please clarify the Maintenance Activities for Voltage and Current Sensing Devices. Must voltage, current and their respective phase angles be measured at each discrete electromechanical relay?
No
i) Protective relays, ii) Protection Control Circuitry (Trip Circuits) and iii) Protection System Communications Equipment and Channels should be changed from 6 calendar years to 8 calendar years. Based on FPL's experience and Reliability Centered Maintenance (RCM) program, FPL has established an 8 year program and has found that an aggressive 6 year program would not substantially increase the effectiveness of a preventative maintenance program. b. Battery visuals should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. c. The maximum maintenance interval for communications equipment should be changed from 3 months to 12 months. Based on FPL's experience and RCM program, FPL has established a 12 month program that is effective.

No
Yes
An alternative to measuring battery specific gravity is to measure float voltage and float current as described in Annex A4 of IEEE Std 450-2002.
Protection System Maintenance Program (PSMP) The PSMP definition would be better defined if the first sentence was changed to "An ongoing program by which Protection System components are kept in working order and where malfunctioning components are restored to working order." b. Please clarify what is meant by "relevant" under the definition of Upkeep. Should "relevant" be changed to "necessary"? c. The definition of Restoration would also be more explicit if changed to "The actions to return malfunctioning components back to working order by calibration, repair or replacement. d. Please clarify the definition of Restoration. For example, if a direct transfer trip system has dual channels for extra security even though only one channel is required to protect the reliability of the BES and one channel fails, must both be restored to be compliant? e. Protection System (modification) "Voltage and current sensing inputs to protective relays" should be changed to "voltage and current sensors for protective relays." Voltage and current sensors are components that produce voltage and current inputs to protective relays. f. "Auxiliary relays" should be changed to "auxiliary tripping relays" throughout PRC-005-2, FAQ and the Draft Supplementary Reference. g. The word "proper" should be removed from the standard. It is ambiguous and should be replaced with a word or words that are clear and concise.

Table 1a requires entities to "verify the continuity of of the breaker trip circuit including trip coil..." The term "verify" needs clarification. For example, we beieve verifying red and green" lights during routine inspection should be sufficient. On the other hand, actual testing is not feasible and is risky to reliability.
No
The 3 month interval in Table 1a for verification of the continuity of the breaker trip circuit is only feasible if this verification can be done by inspection versus testing (see Response to Question 2).
Yes
Yes
Yes
Suggest including operational verification (i.e. analysis of protection system operation after a system event) as an acceptable method of verification.

No
1. The proposed definition of Protection System needs further clarification. Suggest changing wording around DC supply to read as follows: "..and DC control circuitry associated with protective devices from the station DC supply". 2. Suggest revising Section 4.2 to separate time based program as its own item under R4. 3. Change title on Table 1a to clarify level 1 monitoring as time based.

• (FAQ 3C) What is the technical justification for omitting insulation testing of the wiring for DC control, potential and current circuits between the station-yard equipment and the relay schemes? We feel this wiring is susceptible to transients which, over time, may compromise the insulation, and therefore should be tested. • Table 1a (Page 6) Improve wording. Suggestion: “Verify proper functioning of the current and voltage circuits from the voltage and current sensing devices to the protective relay inputs” • On Page 6: The red light monitors trip circuit not only trip coil. With only one circuit going to three parallel single-pole trip coils a red light will not detect a single open trip coil. Is a station inspection that verifies the red light is “on” an acceptable activity? • On Page 9: The 3 month communications maintenance activities should say that the channel needs to be checked. For example: initiate a manual checkback test of the carrier system. • On Page 10: Not clear on level 2 monitoring attributes for protective relay component description. As written it notes two separate requirements which are ambiguous. We assume that all monitoring noted is required (internal self diagnosis and waveform sampling) • On Page7: The standard should note that battery testing must include all batteries that are used in protective relay systems (for example pilot wire batteries).
No
• Does the standard require that time or condition based maintenance programs monitor countable events to identify significant problems in particular relay segments, and then adjust the maintenance interval accordingly? • On page 6: Please clarify the use of “Calendar Year” Our understanding is that if a relay is maintained on August 31, 2003 on a 6 year interval, it will not be overdue until January 1, 2010. Is this correct? • On Page 7: What is the basis for 18 months? We believe 2 calendar years would be more appropriate. • On Pages 6,10: What is the basis of the 6 calendar year interval for functional trip tests? We request that this be changed to a 10 calendar year interval. We follow a 10 calendar year interval that has proven to be satisfactory. Decreasing the interval to 6 calendar years will result in a major increase in our maintenance expenses without a corresponding increase in reliability. • On Page 9: If it is being verified ok every 3 months, what is the basis of the 6 calendar year interval for Communication equipment? ITC communications systems are partially monitored and therefore required to perform this testing every 12 years. However, ITC would like to know the basis of the 6 year interval for informational purposes. • On pages 6, 8, 11, 13, 14 and 19: The maximum maintenance interval “(when the associated UVLS or UFLS system is maintained)” should be shown as the actual “6 Calendar Years”. • On Page 1 of Attachment A: Please provide an example in the reference of the proper way of adjusting the interval based on test results. • On Pages 7, 8, 12: It is our understanding that adequate maintenance can be achieved by performing either one of the two maintenance activities in cases where there is an “or”, is that correct? • On Page 14: For the bottom two rows on page 14 we believe there is a typo and it should read “Level 2” not “Level 1”. • On Page 13: Do powerline carrier schemes that provide a remote alarm if a daily checkback test fails, meet level 2 monitoring requirements? • In Table 1: What is the basis for the 6 year interval for the battery systems? This test would be an additional test for ITC. We would prefer to perform this additional test with the relay periodic maintenance on a 10 year interval.
Yes
• We agree with the approach. We have several issues with the details of Maintenance Issues, Interval and Monitoring Attributes. See previous comments for Questions 2 and 3.
No
• Appendix A fixes a 4% level of “countable events”. Is this number the industry average for countable events? Has the industry average actually been determined? The basis for the 4% requirement noted in Paragraph 5 of Appendix A should be included in the reference document. Also a sample calculation for adjusting the interval is needed to clarify the requirement.
Yes
• Will clarifications in the Reference Document be enforceable with the standard? For example

page 11 of the reference document notes "Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by comparison of known values of other sources on live circuits or by using test currents and voltages on equipment out of service for maintenance." Can a maintenance program be confidently established using this or other testing methods included in the reference document? • A condensed definition of "Condition Based Maintenance" as described in Section 6 of the Reference document should be included in the standard document itself.
Yes
• FAQ page 6 question 3C should be clarified in the standard document itself. What is the technical justification for omitting insulation testing of the wiring for DC control, potential and current circuits between the station-yard equipment and the relay schemes? We feel this wiring is susceptible to transients which, over time, may compromise the insulation, and therefore should be tested. • FAQ page 17 question 2A the standard should define when the first maintenance activity is to be performed. We include our maintenance activities during commissioning, and set the next maintenance due date based on the testing interval. • Will clarifications in the FAQs be enforceable with the standard? Can a maintenance program be confidently established using this or other answers included in the FAQ's?
Comments: We are not aware of any conflicts.
Comment: We are not aware of any regional variance or business practice that should be considered with this project.
In the Definitions of Terms, the Protection System (modification) should include control circuits up to and including the trip coil of ground switches used in protection schemes. Footnote 2 (Maintenance correctable issue) should be included in the Definition of Terms in the body of the standard.
Individual
Robert Waugh
Ohio Valley Electric Corp.
Yes
No
In general, all maintenance activities that are verifications of proper function imply that problems found must be resolved within the maximum interval. For some activities, that is an unreasonable expectation. A temporary resolution may reliably correct an adverse situation but may not address the original verification requirement within the maximum interval. Routine substation inspections should not fall under NERC standards. The documentation for quarterly inspections would be oppresive. It is unreasonable to require there to be no DC grounds. All DC grounds do not rise to the level of a reliability concern. In some cases, attempting to resolve a relatively minor DC problem may rise to the level of negatively affecting reliability. The value of capacity testing battery banks and chargers in the context of a protection system reliability standard is questionable.
No
The documentation requirements for the inspection activities with three month intervals is oppressive and should not be a part of the protection system maintenance standard.
R1.2 seems to require owners to establish there own intervals and basis. Compliance with these requirements should be based on the intervals that are in tables 1a, 1b and 1c. R4 implies that all maintenance correctible issues must be resolved within the Maintenance Activity Intervals. A diligent effort to restore proper function of a system should not be penalized if it does not fall within the prescribed maintenance interval.
Individual
Brent Ingebrigtson
E.ON U.S.
No
Capacity or AC impedance only needs to be done to determine service life and therefore periodic testing of station DC supply does not seem necessary or prudent. If a company checks overall battery bank voltages quarterly then periodic testing of the battery bank charger should not be required.

No
Generally, E.ON U.S. requests that the SDT provide the basis for the proposed changes in maintenance time lines. E ON U.S.'s existing maintenance intervals are based on actual operating experience. Not having been provided with the basis for the proposed intervals, the time lines appear arbitrary. E.ON U.S. currently has an 8-year interval for combustion turbines vs. the 6-year interval provided here. The E.ON U.S. interval is based on the Company's experience with this equipment. E.ON U.S. suggests that the SDT provide some consideration to individual entities' historic practices. It is difficult to track "18 months". Maintenance intervals should be in expressed in number of years. E ON U.S. also does not understand the basis for the 3 months maintenance schedule on breaker trip coils. Typically, the circuit breaker closed indication is wired through the breaker trip coil. Thus there could not be a breaker closed indication without a good breaker trip coil. So, this test should be considered continuous monitoring which may not even require documentation except in case of failure.
Yes
No
E.ON U.S. recommends keeping with time-based intervals (and the improvement thereof) and staying clear of condition-based performance for the generating stations. But that is not meant to preclude other companies from doing condition-based, if they so prefer.
Yes
With reference to Section 8.1., under additional notes is the following bullet: 5. Aggregated small entities will naturally distribute the testing of the population of UFLS/UVLS systems and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. This implies that incorrect performance of a "relatively small quantity" of UFLS relays is acceptable but with the understanding that it is not optimal. E.ON U.S. agrees with this statement in principle, in that the UFLS program is spread out across the system, and there is not a one to one performance expectation as there is with a transmission line or generation protection system. This calls into question the required intervals for testing of these types of relays, and the performance expectations in a PBM program. Given the number of relays spread out across the distribution system, the testing requirements of UFLS relays require longer testing intervals than other bulk transmission system components. 8.2 Is this requirement expected to be retroactive? That is, if the previous retention policy was followed to the letter, an entity could be fully in compliance based on the previous standard, but not be in compliance if PRC-005-2 were retroactive. 8.3 And 8.4 This discussion explains how time based maintenance intervals were determined. The conclusion is based upon surveys of SPCTF members and their existing practices, and seemed to arrive at a maintenance interval based upon a simple average weighed by the size of the reporting utility. No consideration appears to have been given to utilities who have successfully operated with longer test and calibration intervals. In section 5 of the Supplementary Reference it is stated that "excessive maintenance can actually decrease the reliability of the component or system." With that in mind, some of the intervals defined in the table seem too aggressive. With the proposed PRC-005-2, the Drafting Team has effectively shortened the recommendation for UFLS relays from 10 years to 6 years, with reference to the recommendations of the Protection System Maintenance Technical Reference. E.ON U.S. believes that this is inconsistent with previous comments in Section 8.1, bullet 5 of the notes. Consistent with the comments above and based on E ON U.S.'s internal testing, calibration and verification experience, E.ON U.S. recommends maintenance on UFLS relays that comprise a protection scheme distributed over the power system to be no less than 10 years for Level 1 monitoring and no less than 15 years for Level 2 monitoring. For a PBM program, require the number of countable events within a segment to be no more than 10%, not 4% as proposed.
No
E.ON U.S. disagrees with commissioning tests not being considered as a baseline for subsequent maintenance activities. Commissioning tests should be counted as the initial testing in the scheme of a maintenance program
Recently, NERC made an interpretation on PRC-005-1 which stated that battery chargers were not to be included as part of the standard. This version of the standard seems to be in direct conflict with that interpretation, and for the reasons stated above E.ON U.S. recommends that battery chargers not be included in the standard. E.ON U.S. believes that capacity or AC impedance only needs to be done to determine service life, and therefore a periodic testing of station DC supply does not seem necessary or prudent. Regarding the "Retention of Records", retaining records of the latest test seems adequate. E.ON U.S. does not understand the point of retaining records for the past two test results. This is particularly true for equipment for which there are relatively long testing intervals, for example, 12 years. Retaining result documents from 24 years ago seems unnecessary and impractical. With regard to NERC's PRC-005-2

Supplementary Reference Section 2.4 on Applicable Relays, E.ON U.S. offers the following comments: 1. This section extends the applicable relay coverage to IEEE type # 86 and IEEE type # 94. Some utilities define their turbine trip relay as an IEEE type #94. E.ON U.S. interprets that the NERC scope of applicable relays is that the turbine trip relays would be excluded; however, it would further clarify this exclusion if it were mentioned as an example in the last sentence. 2. The Tables in proposed Standard PRC-005-2 require additional clarity. E.ON U.S. suggests renaming tables to 1, 2 and 3 to match Level 1, 2 and 3 monitoring. The wording and format of text is not consistent between tables. 3. The fields in the tables are incoherent. E.ON U.S.' interpretation is that intervals and activities for UFLS and UVLS are different than other relay systems and components, but this is unclear. E.ON U.S. believes a separate table or sections for UFLS and UVLS would provide more clarity. In section 7 of the Supplementary Reference the SDT refers to the Bulk Power System instead of the Bulk Electric System. These are not interchangeable and the SDT needs to explain the need to use the term in this case. The phrase "support from protection equipment manufacturers" is used several times in the technical reference (Section 8 and Section 13) yet there is no manufacturer represented on the SDT. Rather than developing one size fits all requirements applicable to all equipment, E.ON U.S. suggests that the SDT pursue comments from manufacturers to obtain recommendations on what they believe is required to maintain and test their equipment.

Austin Energy is meticulous in adhering to the current maintenance standard and is convinced that its current maintenance and documentation program is adequate to maintain its reliable electric power system. Austin Energy appreciates the good intentions of the SDT but believes that the approach taken increases complexities to the maintenance process, introduces unwarranted workload in excessive documentation, is inflexible towards system configuration and experience, and is over prescriptive in nature. The approach also fails to distinguish the harmful effects of over-maintenance, increasing reliability risk due to human error and ultimately affecting the overall performance and reliability of the system. Another concerning issue is the addition of the breaker trip coil to the protection system definition. Our position is that the trip coil should be part of the breaker. The protection system would be considered operating correctly if it provided the output signal for the trip coil when expected. Hence the trip coil should be excluded from the new protection system definition. Performance based maintenance as specified in the attachment is extremely difficult and cumbersome to navigate. The intricate requirements are difficult to comprehend and will entrap entities making a good faith effort to comply. We believe this approach may become burdened with undesirable consequences. Last but not least, Austin Energy believes that under-frequency load shedding (UFLS) and under-voltage load shedding (UVLS) systems should not be included in the scope of this new proposal. UFLS and UVLS are a wholly different entity as compared to the Bulk Electric System (BES). Rigidity imposed onto distribution system equipment, operating schemes and performance is uncalled for and overreaching.

CU has concern over the battery charger testing requirements. Per the charger manufacturers recommendations there is no reason to test the chargers as proposed in PRC-005-2. It is their opinion that the chargers are self diagnostic and do not require these tests (full load current and current limiting tests). The charger O&M manuals do not even provide instructions for such tests as optional. Therefore, CU takes exception to this requirement and suggests that battery chargers be maintained and tested in accordance with manufacturer's recommendations. Additionally, CU is concerned with the wording in Table 1a concerning Protection system communication equipment and channels. We are unsure what the maintenance activity actually means. If this is an unmonitored system, how can you verify the condition of the communication system? Is the Standard referring to local monitoring such as annunciators? Please provide clarification.
No
CU agrees in general with many of the maximum maintenance intervals. However, we disagree with the necessity to verify the continuity of trip coils every 3 months. We would be interested to know what basis the committee used to arrive at all intervals. Furthermore, it is our opinion that even if a component is unmonitored, the interval should not surpass the manufacturer's recommendations.
Yes
CU agrees with the approach, but, may not agree with the exact wording in the tables. For instance, the use of the word "every" in table 1c in "Protection System components in which every function required for correct operation of that component is continuously monitored and verified" may be overstating the level of monitoring that would realistically enable a Protection System to use table 1c.
No
It appears that Attachment A was written for large utilities. Some allocation needs to be made for utilities with smaller numbers of components.
No
No
CU is unaware of any conflicts.
CU is not aware of a need for a regional variance.
As proposed, this Standard is very long and complex. Additionally,in requirement R1, bullet 1.1 ought to state "For each component used in each Protection System, include all "applicable" maintenance activities specified in Tables 1a, 1b and 1c". For instance, if every component has continuous monitoring, why should the program include 1a and 1b?

Richard Kafka
Yes

No
Tables 1a, 1b and 1c all require measuring specific gravity and temperature of battery cells. This invasive test provides no information regarding battery health that cannot be obtained from cell impedance testing. Recommend requiring cell impedance OR specific gravity & cell temperature testing. Tables 1a, 1b and 1c all require testing the battery charger every 6 years to verify that it can provide full rated current and will properly current limit. In order to perform this (unnecessary) test the battery would be subjected to a deep discharge. Whatever benefits may be derived from this test are dwarfed by the negative effect on the battery. Recommend removing this requirement.
No
Table 1a requires verification of the continuity of the breaker trip circuit every three months in the absence of a trip coil monitor. Recommend maintenance interval to match that for other protection system control circuitry (6 years).
No
Monitoring and alarming of the station dc supply and detection and alarming of dc grounds are required to qualify for Level 2 monitoring of battery / dc systems. While the presence of dc ground may affect protection and control operations, they do not affect any of the systems for which dc ground alarming is listed as a monitoring criteria. Recommend removing this criterion from the battery & dc system monitoring criteria and adding it as a maintenance activity, with frequency of testing based on presence of detection / alarming.
Yes
No
No
Item 3.B. (Page 6) claims that a small measurable quantity in 3I0 and 3V0 inputs to relays -may- be evidence that the circuit is performing properly. This statement is weak at best, and incorrect at worst. A balanced transmission system may exhibit 3I0 and 3V0 quantities that are not measurable, and those that are measurable cannot be compared to other readings, since CT/PT error often exceeds system imbalance. Since these inputs are verified at commissioning, recommend that maintenance verification require ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.
Individual
Charles J. Jensen
JEA
Yes
Generally agree; however, some suggestions for possible changes: 1) change "associated communication systems necessary for correct operation of protective devices" to "protective relays", 2) add a PSMP glossary defintion for an acceptable type of monitored alarm, either to the proposed "PSMP monitor" or another definition for "PSMP monitored and alarmed." The SDT did a good job of making the overall Protection System definition clearer.
Yes
If a communication system relies on a battery system independent of the "station battery", is this communication system battery under the same requirements as the "station battery"?
Yes
Is it possible that for coil monitored equipment, such as LOR coils, that they were left out, of this Table allowing for a longer maintenance interval. Certainly LOR continuous coil monitoring with alarming to a 24 hour 7 day a week manned location, with emergency dispatch, would allow for a longer maintenance interval for continuously monitored LORs. Suggestion here might be alignment with continuously self-tested, monitored and alarmed microprocessor relays at 12 years.
Yes
Approach appears to be well explained. Only one are of concern and that would be delaying the advancement of replacement of EM relay systems with microprocessor, if the PBM population were to decrease below the 60, resulting in not meeting the sample minimum population criteria. Falling below this 60 population sample minimum, might result in an immediate compliance violation.
No

Yes
The FAQ is a well written document and the team should take pride in its clarity and informative content. One area that would be good to have further clarification, is if the SDT could provide a current industry product or example of the "software latches or control algorithms, including trip logic processing implemented as programming components, such as a microprocessor relay that takes the place of (conventional) discrete componenet auxilary relays or lockout relays that do not have to be routinely tested." Is this a microprocessor lockout relay (that does not require trip testing?)
Regional Variance
Regional variances in the Bulk Electric System defintion as applied across regions allows for PSMP to vary possibly even for the same region crossing tie lines. Also, accepted maintenance practices by one region vary from accepted maintenance practices from another region. In the case of lower kV non-redundant bus lockout protection systems, one region may allow for the prtoection system to be taken out of service to perform maintenance, while another region may specifically prohibit this practice (don't leave energized equipment protected by delayed clearing, etc.)
Implementation Plan - Stongly encourage keeping the implementation plan and allow for an extension of the implementation plan for the time required to fund, design, procure, install and commission redundant protection systems for current non-redundant lockout systems at the lower kV levels of the BES. Our present and past performance of LOR and auxilary relays will support a PBM/CBM program that allows for a much longer time than the six years proposed for EM LOR trip testing. To use a TBM for LORs of six years, may in fact, lower the reliability of the BES due to the complete outages required, along with the detailed procedures that must be created and rigourously followed to perform these tests without subsequent load loss on the BES.

Suggest that under “Maintenance Activities” for “Protective Relays” add the following: Verify proper functioning of the microprocessor relay external logic inputs (carrier block, etc.) We recommend not requiring specific gravity and temperature readings for batteries. We have found from experience that the time and difficulty to obtain specific gravity readings are not justified. We have found that utilizing visual inspections, voltage and internal/intercell resistance readings gives a good picture of the health of the battery. We use specific gravity readings on occasion for troubleshooting purposes. It is recommended that the sections about verifying battery charger performance be eliminated if there are low voltage alarms that go to a monitored location. We recommend changing the maximum maintenance interval for DC supplies with no battery from 18 months to 3 years. If there is no battery, you do not have the risk of failure of chemical processes and such that would require an interval as short as 18 months.
No
What is the basis for the three month interval for verifying breaker trip coil continuity? Will the investment required to facilitate this really result in the presumed expected increased reliability?
No
Table 1b indicates that this (level 2) includes all elements of level 1 monitoring. However, level 1 is constantly referred to as unmonitored in other places.
Yes
No
Yes
Example #1 on page 21 states “A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)”. However, Table 1b indicates that detection and alarming of dc grounds is also required for level 2.
Suggest that the term “alarmed failures” in the table headings be changed to “alarmed abnormalities” to better indicate that the monitored parameter may be in an abnormal state or out of range but not necessarily failed. Does “system-connected” station service transformers

refer to transformers connected to the BES or transformers connected to a system at any voltage level? Is the intent of R1.1.2 that each Protection System component (specific relay at specific location) be listed individually with its associated maintenance method and interval or can the general component category be listed as such? Regarding R4, further clarification would be helpful in understanding the intent of the term “resolution of all maintenance correctible issues” as it applies to R4.1 and R4.2. Is it intended that “maintenance correctible issues” be completed within the interval? It is recommended that each line in the tables be given a number or letter designation to make reference to that row easier.

No
Our comments are limited to activities in Table 1a. • Protective Relays – okay • Voltage and Current Sensing Devices Inputs to Protective Relays – Proper functioning should be verified at commissioning, and then anytime thereafter if changes are made in a PT or CT circuit. Additional periodic checks may be warranted as suggested in Table 1A, however no additional checking should be required where circuit configuration will inherently detect problems with a PT or CT. For example, PTs & CTs that are monitored through EMS or microprocessor relays will be alarmed when they are out of specification. • Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) – Need more clarity on exactly what this activity is expected to include. In some cases we have a red light on a control panel monitoring the circuit path to the trip coil. In locations where there is not a red light, verifying the continuity of the breaker trip circuit including the trip coil will be complicated. There is no straightforward way to do it without potentially impacting reliability, and we would have to consider modifying these installations to include a red light. • Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) – Need more clarity on exactly what the activity is. We believe testing one output all the way to the coil is sufficient to prove the trip path. The activity states that “all auxiliary contacts” must be tested. We propose that all protection control circuitry should be tested at initial commissioning, and then again if any changes are made. Ongoing routine testing is complicated and could pose reliability challenges to the BES. As stated on page 8 of the System Maintenance Supplementary Reference document: “Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs. In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.” • Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only) – Need additional clarity on exactly what the test includes. “Complete functional trip test” should not include tripping the breaker. Proving the output of the relay should be sufficient. Systems that have all load shed on distribution circuits should require that trip output be confirmed but should not be required through to the trip coil due to constraints in tying distribution load. • Station dc supply (that has as a component any type of battery) – Under the 3 month interval activities, we disagree with the wording of the activity “Verify that no dc supply grounds are present.” The activity should instead read “Check for dc supply grounds and if any are found, initiate action to repair.” • Station dc supply (that has as a component any type of battery) – Under the 18 month interval activities, what is meant by “Verify continuity and cell integrity of the entire battery”? Also what is required to “Inspect the structural integrity of the battery rack”? The “Supplementary Reference Document” and “Frequently asked Questions” document should be made part of the standard to provide clarity to the requirements. • Station dc supply (that has as a component Valve Regulated Lead-Acid batteries) – Need more clarity on exactly what is required for a “performance or service capacity test of the entire battery bank”. The “Supplementary Reference Document” and “Frequently asked Questions” document should be made part of the standard to provide clarity to the requirement. • Station dc supply (that has as a component Vented Lead-Acid batteries) – Need more clarity on exactly what is required for a “performance, service, or modified performance capacity test of the entire battery bank”. The “Supplementary Reference Document” and “Frequently asked Questions” document should be made part of the standard to provide clarity to the requirement. • Protection system communication equipment and channels – Need additional clarity on exactly what is required for the substation inspection. What is required for power-line carrier systems? • UVLS and UFLS relays that comprise a protection scheme distributed over the power system – Need more clarity regarding the meaning of “distributed over the power system”.
No
Our comments are limited to Table 1a. More clarity is needed for many of the Maintenance Activities before assessing whether or not the intervals are reasonable. But as a general

comment we would like to understand the basis used to develop all of the intervals, and how that basis compares with research done by the Electric Power Research Institute (EPRI). It is our understanding that NERC did an industry survey of maintenance intervals and we would like to see the results of that survey as well. Specific comments: • Protective Relays – 6 calendar years is okay. • Voltage and Current Sensing Devices Inputs to Protective Relays – We question the logic for a 12-year interval. Proper functioning should be verified at commissioning, and then anytime thereafter if changes are made in a PT or CT circuit. Additional periodic checks may be warranted as suggested in Table 1A, however no additional checking should be required where circuit configuration will inherently detect problems with a PT or CT. For example, PTs & CTs that are monitored through EMS or microprocessor relays will be alarmed when they are out of specification. • Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) – In locations where the continuity of the circuit is not monitored (via a light in the path or through a microprocessor relay) this would be a very complicated test, which could impact reliability, especially if done every three months. • Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) – Need clarity on exactly what the activity is to include. We believe proving one output all the way to the trip coil is appropriate. Proving every output and every auxiliary contact, to the trip coil would be unnecessarily invasive and could impact reliability, even if done every 6 calendar years. • Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only) – Interval is okay, but we disagree with tripping the breakers – proving the output of the relay should be sufficient. Systems that have all load shed on distribution circuits should require trip output be confirmed but should not be required through to the trip coil due to constraints in tying distribution load. • Station dc supply (that has as a component any type of battery) – 3 month and 18 month intervals are probably okay, depending on what is required to "verify continuity and cell integrity of the entire battery" and "inspect the structural integrity of the battery rack". • Station dc supply (that has as a component Valve Regulated Lead-Acid batteries) – 3 calendar years and 3 month intervals are probably okay, depending on what is required for the "performance or service capacity test". • Station dc supply (that has as a component Vented Lead-Acid batteries) – 6 calendar year and 18 month intervals are probably okay, depending on what is required for the "performance, service or modified performance capacity test". • Protection system communication equipment and channels – 3 months and 6 calendar years seem reasonable, depending upon what is included in the substation inspection, and what is required for power-line carrier systems. • UVLS and UFLS relays that comprise a protection scheme distributed over the power system – Can't comment on the 6 calendar year interval until we get more clarity regarding the meaning of "distributed over the power system".
No
For utilities like us with large numbers of relays it's too complicated, which drives us back to Table 1a.
No
For utilities like us with large numbers of relays it's too complicated, which drives us back to Table 1a.
Yes
We strongly believe that this document should be made a part of the standard, either as an Attachment or worked into the requirements and tables. This will bring clarity to PRC-005 that is needed to get away from all the past problems that were due to a lack of clarity with the previous PRC-005 standards. Also, all the explanations and guidance lose force if they are not part of the standard. Auditors will only be bound by the standard.
Yes

None
Regional Variance
Regions with ISO's and RTO's - Where the independent system operator (ISO) is not the same company as the entity doing testing and maintenance, the independent system operator could prevent the entity from performing scheduled maintenance and testing due to outage request constraints. There should be no violation in such a situation, and the maintenance and testing just rescheduled.
• Regarding the Implementation Plan, R1 compliance should be the first day of the first calendar quarter 18 months following applicable regulatory approvals. Entities will need this time to change monitoring equipment and develop extensive new work practices and procedures to assure time frames and documentation of practices comply with the wording of the revised standard. The time frames for R2, R3 and R4 are adequate except in cases where upgrades have to be developed and implemented in order to be able to meet the intervals (such as breaker trip

coil verification every three months). • FAQ 2C "If I am unable to complete the maintenance as required due to a major natural disaster, how will this effect my compliance with the standard." Response is the Compliance monitor will consider extenuating circumstances...We would like to see this statement clarified as to the time frame extensions that result in non compliance or fines. • R4 – States "each transmission owner...shall implement its PSPM, including identification of the resolution of all maintenance correctable issues". If the intent is to document resolution to misoperations this is a reasonable request. If the intent is to document that a relay was found out of calibration on a routine test, which was corrected by recalibration we need some clarity on expectations of how that would be recorded and tracked. As written this statement is vague and somewhat confusing since % of allowable error may vary utility to utility. • R4 doesn't appear to allow any time beyond the stated intervals for repairs or replacements that may take additional time. PRC-005-2 is a maintenance and testing standard, and R4 inappropriately requires a replacement strategy and an obsolescence strategy. Is R4 intended to apply to all equipment in Table 1?

1) Table 1a – Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only). Currently, we test our UFLS relays on a 2 year maintenance interval. We test the relays and associated DC circuitry up to the DC lockout relays. It would require extraordinary effort to trip the breakers directly when performing these tests. Usually, each UFLS relay will trip several feeder breakers. This requirement states that we need to check the trip coil for each of those breakers each time we perform relay maintenance. This will add an unreasonable amount of time and effort to reliably switch out several 4kV or 13kV feeder every time we perform UFLS maintenance. For UFLS and UVLS schemes, we feel the requirement for DC control testing should not go past the lockout relay. The standard says to perform trip checks at the same time as UF maintenance. We test the relays on a 2 year interval right now. It is unreasonable to perform trip checks this often. The trip checks should follow a 6 year span (or longer) just like the BES equipment. 2) Table 1a – DC supply. The 18 month inspection requires a measurement of specific gravity and temperature. We believe that if a battery owner opts to perform an 18 month ohmic value test, this combined with the cell voltage readings and continuity tests will give a good indication of battery health. We do not feel that the measurement of specific gravity is required in conjunction with the tests performed above.
No
1) Table 1a – Station dc supply (that uses a battery and charger). The 6 year test requires that the charger perform as designed. PSE&G usually applies redundant battery chargers. PSE&G would like the drafting team to consider if it is appropriate to not require the 6 year battery charger tests if a battery owner uses primary and backup battery chargers. PSEG believes that the use of a redundant charger will maintain reliability at the same level or better level as provided by testing a single charger. 2) For protection system control circuits components (breaker trip coil only), suggest that a sub category with redundant trip coils be added with longer maintenance interval to allow for the reliability provided by redundancy.
Yes
Figure 2 “typical generation system” shows a typical auxiliary medium voltage bus, suggest that a line of distinction (dotted line) be added to the figure that defines the element connected to the BES (station Aux Transformer - SAT) and equipment not associated with protection of the SAT be shown as not part of the BES- PSMP.
Yes
1) R1 - PRC-005-1 required the protection owner to supply a “basis” for the chosen maintenance intervals. Is it intended that the new standard will no longer require the protection owners to provide a basis for their intervals as long as they meet (or better) the published required intervals? 2) Compliance 1.4 Data Retention – Needs more clarity. Some items require 12 years maximum maintenance interval. However, we may perform the same maintenance in 6 years. The requirement for data retention is 2 maintenance intervals. In this example, does this mean 12 years or 24 years? Are we required to maintain records for the maximum maintenance intervals allowed by the Standard or only for the two shorter maintenance intervals that we actually use? 3) Compliance – will need some guidance on to what is required for “proper documentation”. Generally, the relay technicians will scribe the actual test values for a given tests requiring the application of AC voltage and current. However, as an example, when performing DC checks (DC aux relay), the technician may simply state that the aux relay is “OK” without stating the DC coil pickup value in volts. Is this acceptable? Another example may be when performing battery inspections (ie verify proper voltage of station battery, verify that no DC grounds exist, etc), the inspector may simply indicate/document that the battery is “Ok”. This would indicate that appropriate 3 month inspections (as per table 1a) were completed and found to be within tolerances. Is this acceptable? If specific details are required to be stored on test media (paper test sheets, computer based data storage, etc), then please make some comments as such. 4) Table 1a – DC supply. The 3 month inspection requires “verify that no dc supply grounds are present”. This needs further clarification. What is the defined “limit” to determine whether we have a DC ground? The detection methods for determining the presence of a DC

ground will vary from indicating light balance to actual DC ammeters or voltmeters. It is assumed that the intent of this requirement is to ensure that there are no full DC grounds (dead shorts) in the DC terminals. Please clarify. 5) In the group by type of BES facility descriptions on pages 15 and 16 there is discussion about generation station auxiliary transformers and associated protection devices. It also cites examples of relays which need not be included even though they could result in tripping of the generating station. The line of demarcation is not well defined in the FAQs or in the standard itself. Suggest that verbiage be added that clearly defines the element (transformer) directly connected to the BES and it's associated protection is what is included in the PSMP requirements, items connected at lower voltage (down stream) are not within the PSMP requirement. 6) On page 15, the sample list of what is included in the standard, suggest that the list be expanded to show what is not included (a relay that monitors parameters and is used for control/ alarm but not protection); generator excitation controls that trip an auxiliary exciter. The list of items not included in the PSMP but that could trip the unit should be further defined and expanded.
1) R4 requires all maintenance correctable issues identified as part of a time based maintenance plan to be resolved in that same maintenance period. This places a burden on some items (for example, 3 month battery inspections) to achieve adequate resolution for problems that are not an immediate threat. For example, if a battery with a somewhat out of allowable range specific gravity is found near the end of the maintenance period, scheduling and performing the work to replace the battery could reasonably extend somewhat beyond the end of maintenance period. PSE&G requests that the drafting team revisit this requirement and allow flexibility for corrections to be made within a specified reasonable timeframe when correctible issues are identified that for practical reasons require extension for work completion beyond the end of the current maintenance interval. 2) Section 4.2.5.5 of the standard should define provide an example that just the transformer connected to the BES is included and specifically exclude connected equipment beyond the LV terminals. 3) Draft implementation plan for requirements R2, R3 & R4 discusses table 1a as basis, should also address tables 1b and 1c.

The second sentence in Note 1 on page 20 should be changed to "A calibration failure is when the relay is inoperable and cannot be brought within acceptable parameters." Note 2 should be changed to "Microprocessor relays typically are specified by manufacturers as not requiring calibration. The integrity of the digital inputs and outputs will be verified by applying the inputs and verifying proper response of the relay. The A/D converter must be verified by inputting test values and determining if the relay measurements are correct."
No
The interval for Protection System Control Circuitry (breakers trip coil) should be set at 12 years since this is a scheme test. This test requires testing of the circuit and not just the coil. The interval for Protection System Control Circuitry (trip circuit) should be set at 12 years since this is a scheme test. The Protection System Control Circuitry (trip circuit) test would require tripping off customers on radial distribution circuits which is not acceptable. The interval for a station battery service test (lead acid) should be set at 5 years based on NFPA 70B.
In Table 1a for Station dc supply it requires verification that no dc supply grounds are present. DC grounds are common occurrences and the activity should be to document if dc grounds are present. Please specify how cell to cell connection resistance is measured. For station dc supply (battery is not used) change "Verify the continuity of all circuit connections that can be affected by wear and corrosion" to "Inspect all circuit connections that can be affected by wear and corrosion." Is "metered and monitored" equivalent to "alarming"? If a component failure causes the unit to trip, what is the purpose of testing it? It will always test positive until the point of failure and that point is identified when the unit trips. In the Facilities Section 4.2.5.4 "station service transformer" should be changed to "unit connected auxiliary transformer" to be consistent with Figure 2 of the Supplement Reference Document. Facilities Section 4.2.5.5 should also include "System connected auxiliary transformers are excluded when only used for unit

start-up." There should be an allow variance period (grace period) for the testing intervals. The maximum allowable time periods should be in calendar years, defined as "occurring anytime during the calendar year." The following statement should be added to Requirement 1.2: "Identification at a program level is permissible if all components use the same maintenance method."

Will this document be a part of the standard? Are its explanations the official interpretation of the standard?
Will this document be a part of the standard? Are its explanations the official interpretation of the standard?
1. Tables 1a, 1b, and 1c were cumbersome to use because we found ourselves flipping back and forth to compare the requirements for the different levels of monitoring. Also, in some cases, the types of components were slightly different between the tables, which created confusion. We believe that it would be much easier to decipher a single table that listed each type of component only once and showed the requirements and maintenance intervals for the different levels of monitoring on a single page. Even if it took an entire page for each component, it would be very useful to see all of the options for that component without having to flip back and forth between tables. 2. Please clarify the requirements for trip coils. Table 1a has as a component type "breaker trip coil only", with a maximum maintenance interval of 3 months, while Table 1b has as a component type "trip coils and auxiliary relays". Table 1b say that there are no monitoring attributes for this component and to use the level 1 intervals, but then gives a

maximum maintenance interval of 6 years, which doesn't agree with the 3 month interval given in Table 1a. 3. The terminology used to describe the secondary currents and voltages provided to the relay is confusing. Under the modified definition of a protection system, it includes the term "voltage and current sensing inputs to protective relays", and in the tables it uses the term "current and voltage circuit inputs". These terms, especially the use of the word input, give the impression that the actual input circuitry of the protective relay is what is being described, but we believe that these terms are really meant to describe the secondary currents and voltages from the instrument transformers (or other devices). BPA suggests revising the terminology to describe the secondary currents and voltages. For example, in the maintenance activities section of the tables, you could say, "Verify that the secondary current and voltages provided to the relay are correct". 4. There is no mention to what the thresholds are when performing these maintenance activities or what corrective actions must take place and by when they need to be carried out. Is this something we should expect to see soon? 5. The need to measure the cell/unit internal ohmic value every 18 months can be argued. BPA's Substation Maintenance crew performs these measurements once every 24 months and with the Operators monthly inspections, we have been able to effectively catch any problems before a severe event/failure. 6. Communications: It is not clear specifically what equipment is included in "communications". The test interval of 12 years in table 1b is too long to verify continued proper operation of transfer trip tone equipment. Monitoring the presence of the channel does not provide any indication of whether the equipment can initiate a trip. Consequently, a required minimum interval of 12 calendar years is too long and does not do anything to verify proper communications support of the relay scheme. A shorter interval of 6 years, such as that in table 1a makes more sense from a functionality standpoint.

In the process of performing maintenance, some protection systems may need to be taken out of service on in-service equipment (bus differential protection for example) where redundant protection systems do not exist. This action seems counter to NERC recommendations, presenting a scenario for expanding outages during a simultaneous fault. Would the implementation plan include time for the additions of redundant protection systems? Comments expanded in question 10 response.
No
The availability to perform maintenance of many protection systems is dictated by the load or customer that is connected. Many of these industrial customers, who are outside the jurisdiction of NERC requirements, operate 24X7 and see the outages required for maintenance as a nuisance and a loss of revenue. How can the owner be held non- compliant for not meeting the intervals when they may not control the timing? Comments expanded in question 10 response.
No
How would the failure of a SCADA system affect the ability to take advantage of monitoring?
Yes
Although helpful in understanding and clarifying intent, the requirements of a standard should be clearly written so that multiple, lengthy supporting documents are not needed. These supporting documents do not get recorded into the registry as part of the standard and may or may not be used by auditors during compliance audits which could lead to different interpretations.
Yes
Although helpful in understanding and clarifying intent, the requirements of a standard should be clearly written so that multiple, lengthy supporting documents are not needed. These supporting documents do not get recorded into the registry as part of the standard and may or may not be used by auditors during compliance audits which could lead to different interpretations.
No known conflicts.
No none regional or business practice variances known.
Monitoring and tracking the activities prescribed in the standard seem too complex to manage at a level needed for auditable compliance. The activities prescribed seem to lean toward conventional protection systems and do not take into account newer special technology devices (High Voltage DC, Static Var Compensator and Phase Shifting transformer controls) and how there are to included. R1 1.2 Does the draft standard require a basis for an entities' defined time based maintenance intervals or can an entity just move directly to the intervals prescribed and use the standard as its basis? R4. This requirement seems to refer to failed equipment and its' reporting. This corrective maintenance activity is outside of the interpreted preventative maintenance theme of the standard and adds another layer of complexity in compliance data

retention. It also implies that a failed piece of equipment or segment could remain failed for the entire maintenance interval. Tables 1a & 1b. Station dc supply (that has as a component any type of battery) Interval: 18 months This requirement incorporates specific gravity testing (where applicable). Although (where applicable) is not defined, it seems it refers to all non-sealed batteries. For sealed batteries, a more frequent internal ohmic test is prescribed. The same 18 month requirement incorporates ohmic testing which is essentially equivalent to specific gravity. Specific gravity and measure of internal temperature are invasive tests which subject personnel to handling acid and subject the battery to damage. If the logic for sealed batteries is to do more frequent ohmic testing why not allow more frequent ohmic testing as a substitute for specific gravity? We would suggest ohmic testing every 6 months with any questionable results rechecked using specific gravity. This eliminates excessive intervention into all cells and gives a validity check on the ohmic testing. For Ni-Cad the performance service test has no option (6 year intervals). Typically, the Ni-Cad can yield a low voltage indication; however testing the cells in pairs allows testing and finding bad cells. Why not offer a more frequent ohmic test for the Ni-Cads? Facilities 4.2.1 and R1 '…. applied on, or are designed to provide protection for the BES.' This may be in conflict with Regional Entity (RE) BES definitions. There needs to a clear understanding of what is included and what is not without regional differences. There should be no responsibilities or requirements of the RE. BES also takes on different meanings depending upon which of the many standards it is applied. Data Retention 1.4 Data retention for two intervals could mean that records would need to be kept for 24 years. This seems impractical. Could audit evidence be used in lieu of actual data for long intervals? Tables: Where the interval is in months, the term 'calendar' months should be used for clarification. Table 1a '….verify the continuity of the breaker trip coil…..' The SDT assumed that Trip Coil Monitoring (TCM) could be accomplished by verifying/inspecting red lights. This may be true in most cases, but there are designs that do not incorporate this type of TCM and the breaker would have to be exercised every 3 months if not operated by natural events unless the scheme gets replaced. This seems counter productive to the reliability of the BES. The implementation plan does not take the time required for upgraded systems into consideration. Table 1a DC Supply, 3 month interval 'Verify no dc supply grounds are present.' Does this mean that you are non-compliant if you have a DC ground? This also needs to be clarified as to the amount of acceptable ground that could be present. Table 1a PS communications equipment channels 3 month interval: Do the activities imply that only alarms be verified and that no channel 'playback' be performed? If SPR relay or similar auxiliary relay is excluded as a protective relay, then do we not have to verify its tripping contact as part of the DC system? Table 1a The exclusion of UVLS/UFLS from certain activities is confusing. Does trip coil monitoring not have to be performed on these systems? Tables: Since PT and CT devices themselves are not included in the PS definition, then the word 'devices' should be removed from the type of component column describing inputs to the relay. Table 1a. Even though an entity may be on time-based intervals, would a natural occurring fault event reset the maintenance clock for the protection segment involved? Assessment of Impact of Proposed Modification to the Definition of Protection System: Reclosing and certain auxiliary relays have been excluded from protection system definition. This new definition would have an impact on other PRC standards that use this term in its requirements, specifically the misoperations investigation and reporting standards. These other standards, as written today, are not clearly written as to the application and assumptions as to what is included in a protection system. Trip coil Monitoring: If the trip coil is actually part of the DC circuitry, then why is there a differing (shorter) interval for this series connected element?

Yes
No
The Standard should focus on identifying the types of components to be tested but should not identify the specific maintenance activities that must be performed. Entities should be allowed the flexibility to develop and implement the appropriate maintenance activities necessary for each identified component. ATC is also concerned with the expressed identification of maintenance intervals. We do not believe that the standard should identify specific maintenance intervals but that it should require entities to identify their maintenance intervals appropriate for their system. If the team continues to pursue specific maintenance intervals it will be establishing the industries practices. Specific Concern: The standard identifies that entities should perform complete functional testing as part of its maintenance activities, but we are concerned that this could lead to reduced levels of reliability, because it requires entities to remove elements from service and then requires entities to perform tests that are inherently prone to human errors. We believe that the perceived benefits do not match the anticipated costs or improve system reliability.
No
ATC is concerned that the proposed standard would result in entities being required to use

outdated testing techniques and or practices. We believe that the standard should identify the "what" and not the "how". The identification of specific testing techniques and/or practices would likely result in entities being prevented from implementing improved techniques and/or practices. (The standard would have to be updated and receive FERC approval before entities could test/implement improved testing techniques and/or practices.) And example of the standard directing the how is with station batteries. The "specific gravity" test, proposed in the standard, is being used less or not at all by some registered entities because a more accurate method that is less intrusive and provides more accurate results has been developed. (This standard would basically require entities to go backwards in testing practices.) This standard should not prevent the use of improved techniques and/or practices.
No
ATC does not believe that there is a relay, on the market today, that has the ability to fully monitor itself as described in Table 1c. We believe that Table 1c should be deleted. (Table 1b could cover any device that has the ability to fully monitor if such a device is developed in the future.) ATC does not believe that NERC Reliability Standards should be used as an enticement for manufacturers to develop specific devices. Under the "General Description" in Table 1c, there is a reporting requirement identifying a 1 hour window. ("... must be reported within 1 hour or less of the maintenance-correctable issue occurring, to the location where action can be taken.") ATC believes that the team needs to define if this action is a phone call or physically verify the maintenance correctable issue which is occurring.
No
ATC agrees with this approach but is concerned that Attachment A does not contain enough language to support an entity that implements this practice. This attachment needs to clearly state that following your performance-based maintenance practices satisfies an entity's compliance obligations. Entities should not be subject to non-compliance over disagreements with their performance-based maintenance methodology.
No
No
Overall, the FAQ's are helpful. Explanations for questions dealing with the maintenance activities (e.g., battery testing) indicate an attempt to line up the requirement with IEEE standards. While commendable to attempt alignment with the industry, it is further justification that maintenance activities should not be included in the standard. Over the long term, technology or IEEE standards could change making the compliance standard inconsistent.
Order 672 says that standards should be clear and unambiguous This proposed standard is very complex. While the standard allows entities to select the appropriate maintenance strategy (time based, performance based or conditioned based) for their system the amount of data and tracking required to demonstrate compliance will be overwhelming.
Business Practice
Jointly-owned facilities should be a component of this standard. Comments: ATC shares services at Substations; consider dividing the services, i.e. batteries and PTs.
General Comment: The requirements section of the standard seems acceptable. NOTE: Why does R1.3 identify the inclusion of batteries? We believe that this should be part of the definition. We believe that the team needs to define the term "condition-based". Does the Protection System definition in PRC-005-2 or interpretation of the standard and the tables line up with other NERC Standards? The table formats (1a through 1b) are confusing and should be reconsidered. We found is difficult to relate one table to another. (No consistency in the Type of components)

Yes
No
A 3 month interval activity is likely to drive an entity to perform that activity every 2 months in a zero tolerance, 100% completion, mandatory compliance environment. There should be an allowance for a grace period on monthly designated activities, for instance a one month grace period, unless the intention is to have the activity performed more frequently than indicated. Additional guidance is needed on the monthly interval designations. Is it okay, for instance, to do all four tasks (3 month interval) at one time? Instinctively the answer should be "no", but if following the "calendar year" allowance, then maybe it is. Are we non-compliant on a 3 month interval task if we go one single day over the due date? Instinctively the answer should be "no", but some additional guidance should be provided. For example, the standard might be more understandable if it indicated that if the interval is "four per year" (or 3 month interval), then it

is allowed to perform these tasks no less than 45 days apart from each other as long as four are done within a calendar year, etc. We believe the 3 month trip coil task activity could actually shorten the life of the trip coil, introduce unpredictable trip coil failures, and increase the risk of an in-service failure of the trip coil if the verification is done by tripping the breaker each time. Increasing the risk of failure is counter-productive the intent of the standard.
Yes
Yes
No
Regarding Section 2.3, Applicability of New Protection System Maintenance Standards, there needs to be clarification and examples of applicable relaying associated with the language: "… and that are applied on, or are designed to provide protection for the BES." For example, is the application of reverse power schemes and directional overcurrent schemes considered applicable when considering the impact to the protection of the BES? We agree with the application of the term "calendar" in the PRC-005-2 Protection — System Maintenance Supplementary Reference document. There should be enough flexibility in interval assignments to allow for annual maintenance planning, scheduling and implementation.
Yes
It would be beneficial to also include an explanation or definition of the term "calendar year" in the standard. It is not readily apparent in the draft standard, especially in light of the new maximum interval requirements, that a task can be performed anytime between 1/1 and 12/31. Although addressed in the FAQ and Supplement, the terms "Upkeep" and "Restoration" are referenced in the definitions section of the standard but are not used anywhere else in the document, or with regard to routine activities. They should be eliminated from the standard unless there are upkeep or restoration requirements.
Individual
W. Guttormson
Saskatchewan Power Corporation
Yes
Saskatchewan would like clarification of what the expectations and rationale are for including Restoration in the PSMP. The other terms listed under the PSMP definition represent what we would consider as typical relay maintenance activities. We would typically consider Restoration as an Operational activity. The existing NERC standards seem to treat this an Operator concern addressed in PRC-001 R2.1 and R2.2 (The Operator shall take corrective action as soon as possible). If Restoration is included in PRC-005 doesn't PRC-001 have to be modified as well to remove these references? Saskatchewan would also like clarification on the term upkeep. Is the standard prescriptive and mandate the application of the latest firmware upgrades within a defined period, or is it flexible and can upgrades be applied as the utility deems necessary?
Yes
Yes
Yes
No
Saskatchewan agrees with the approach, but requires clarification in the definition of segment. The definition uses a population of 60 or more individual components but in the establishment of a PSMP, it only asks for a population of 30 or more. Which number will be used to define the segment?
Yes
The supplementary reference document is useful information if properly explained and justified. Are the suggestions in the reference document to become part of the standard, or simply recommendations of best practice from industry and serve as a document to reduce the number of interpretations requested?
Yes
The FAQ section is beneficial, but would suggest reviewing it to determine if it can be integrated within the reference document.

Saskatchewan recommends that the PC's and RC's designate what equipment is applied to protect the BES and should be included in the protection maintenance program. It is questionable whether the facility owners or Distribution Providers will know. What are the impacts on the BES from the protection systems identifed in Facilities 4.2.5 and the FAQ? For example there is an impact on the BES from generator under-frequency protection not being properly coordinated, but assuming it is and if it is not maintained isn't the impact to the unit itself? Inadvertent energization protection also seems to be an impact to the unit itself not the BES? The standard should be concerned with protection systems that impact the BES not equipment protection that has localized impacts however important they may be. Change Facilities 4.2.2 to “Protection System components used for under-frequency load-shedding systems which are installed to prevent system under-frequency collapse for BES reliability.” The reference to ERO is unnecessary and inappropriate.
Group
FirstEnergy
Sam Ciccone
Yes
Although we agree with the change in the title of the standard, as well as the proposed definition of "Protection System Maintenance Program", we feel that the definition could be clarified. With regard to "Restoration", which at present is described as "The actions to restore proper operation of malfunctioning components", it may be helpful to add examples of acceptable actions to restore operations, such as calibration, repair, replacement, etc.
No
In general we agree with the maintenance activities, except for the specific gravity and temperature testing included in the "Station dc Supply (that has as a component any type of battery)" of the tables 1a and 1b. We only perform this testing at nuclear facilities for insurance requirements. In transmission substation applications it has been eliminated due to the variability of results due to recharging/equalizing, water addition, temperature correction requirements, etc. In the Supplementary reference, section 15.4 Batteries and DC Supplies, third paragraph, the SDT indicates these tests are recommended in IEEE 450-2002 to ensure that there are no open circuits in the battery string. This is essentially a continuity check of the battery string. In the fourth paragraph, the SDT states that "…"continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards." The SDT in Table 1a, the Maintenance Activity "Verify continuity and cell integrity of the entire battery", and in Table 1b, the Maintenance Activity "Verify electrical continuity of the entire battery". Based on the information in the Supplementary reference, the owner has to choose a method to verify continuity and the measurement of specific gravity and cell temperatures could be the selected method, however it should not be a required maintenance activity as shown in Tables 1a and 1b.
No
Although we agree with the proposed maintenance intervals, there may be extenuating circumstances beyond an entity’s control that could delay maintenance on a particular protection system. We ask the SDT to consider adding a footnote to these intervals that allows a grace period of up to three months when outages necessary for maintenance must be delayed due to unusual system conditions or other issues where an outage would be detrimental to the entity's system.
Yes
Yes
Although we agree with the parameters of the proposed PBM, we have the following comments: 1. We question the inclusion of misoperations in countable events as described in footnote 4. Since standard PRC-004 already requires analysis and mitigation of Protection System Misoperations through a Corrective Action Plan, entities should not be required to repeat this analysis and mitigation in PRC-005. We ask that the SDT clarify the requirements to allow a tie between PRC-005 and PRC-004 so as to assure work is not duplicated. 2. We are not receptive to using this methodology to develop intervals due to the detailed tracking and analysis that will be required to establish maximum intervals. The approach may suit other utilities and thus, we are not opposed to the methodology being contained within the standard.
Yes
1. Sec. 2.3 (pg. 4) – This section appears to be discussing the purpose of the standard and not the applicability. We suggest changing the title of Sec. 2.3 to "Purpose of New Protection System Maintenance Standard." Also, in Sec. 2.3 it states: "The applicability language has been changed from the original PRC-005: '... affecting the reliability of the Bulk Electric System (BES) ...' To the present language: '... and that are applied on, or are designed to provide protection for the BES.' However, the posted Draft 1 of PRC-005-2 still has the original Purpose statement. Is the SDT planning to revise the Purpose statement as discussed in Sec. 2.3 of the Ref. document? It

appears that this statement is included in the applicability section 4.2.1 but believe it is more appropriate as a general purpose statement applying to the whole standard. 2. Sec. 2.4 (pg. 4) – Remove the extra word "that" from the second sentence of this section. 3. In the Supplementary reference, section 15.4 Batteries and DC Supplies, third paragraph, the SDT indicates these tests are recommended in IEEE 450-2002 to ensure that there are no open circuits in the battery string. This is essentially a continuity check of the battery string. In the fourth paragraph, the SDT states that "..."continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards." The SDT in Table 1a, the Maintenance Activity "Verify continuity and cell integrity of the entire battery", and in Table 1b, the Maintenance Activity "Verify electrical continuity of the entire battery". Based on the information in the Supplementary reference, the owner has to choose a method to verify continuity and the measurement of specific gravity and cell temperatures could be the selected method, however it should not be a required maintenance activity as shown in Tables 1a and 1b.
Yes
Pg. 17 (What forms of evidence are acceptable) – Although Measures are not yet developed and posted with the standard, we wanted to point out that the SDT should consider adding these acceptable forms of evidence in the measures of the standard.
1. BES reclosing schemes were recently questioned in a PRC-005-1 interpretation but there is no mention of reclosing schemes in the draft standard. This interpretation should be integrated into the requirements of PRC-005-2. 2. Lack of Exception Process - The standard as written does not reflect the fact that any one group, such as a TO performing maintenance on a BES, does not have full control over when an outage can be taken to perform maintenance activities. Especially regarding functional testing, where the equipment needs to be exercised resulting in some BES components being de-energized, it can be very difficult in certain parts of the T&D system to obtain the necessary outage to complete these tasks. Even with proper planning, changes in system conditions and unforeseen equipment problems in other areas can impact the ability to schedule an equipment outage appropriately. Accordingly, a TO can be penalized for not completing prescribed maintenance within prescribed limits due to factors outside of their control. This type of scenario has already been experienced where maintenance activities are scheduled upwards of a year in advance, and then inclement weather or system conditions outside of a TO’s service territory (e.g. unanticipated generating unit shutdown) prevent the work from taking place. The standard should provide some specific guidance to allow relief for such situations, or that properly incents or even requires independent system operators (ISOs) and other outside groups to also ensure maintenance is completed within prescribed intervals. If a TO properly considers factors such as weather (not scheduling critical outage during middle of summer), resource commitment, schedule (the requested outage window is at least one year before maximum interval is met), time of day (performing work during after hours period when load is down) etc. then if outages are still denied, that the TO is not penalized for being out of compliance as maximum intervals are exceeded. This suggested "exception process" should provide requirements for all parties involved, both those performing the maintenance as well as those controlling and overseeing the system. There should be required documentation to prove that the parties on both sides made proper efforts to complete the required maintenance, as well as discuss conflict resolution. 3. With regard to the phrase "including identification of the resolution of all maintenance correctible issues" in Req. R4, we feel that this requirement should be a subset of R4 since it is part of the implementation of the PSMP. We suggest removing the phrase from the main requirement of R4 and creating a new 4.3 as follows: "4.3. For all maintenance programs, identify resolutions for all encountered maintenance correctible issues and take corrective action within a time period suitable for maintaining reliability of the affected protection system." 4. With regard to the proposed modification of "Protection System", we suggest adding the word "devices" after "voltage and current sensing". This would also match what appears to be the SDT’s intended wording as shown in the Supplementary Reference Document sec. 2.2. Also, we suggest modifications to the proposed definition to add clarity to the types of communications system protection and the voltage and current sensing devices. The following is our suggestion for wording of the definition: "Protective relays, communication systems used in communications aided (or pilot) protection, voltage and current sensing devices and their secondary circuits to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices." 5. Protection System Communication Equipment and Channels - Some power line carrier equipment has automatic testing and remote alarming and some that does not. For other relay communication schemes (e.g., tone transfer trip ckts), if the circuit travels over our private communications network (fiber or microwave radio), the communication equipment is remotely monitored/alarmed. In other cases it is not remote monitored. We ask for clarification as follows: As part of our maintenance program, we check that signal level, reflected power, and data error rate are all within tolerance at the interface between the end equipment and the communication link. Our question is: Does this meet the intent of the proposed requirements in PRC-005-2 for

maintenance activities for Protection System Communication Equipment and Channels? Or do the requirements ask for something beyond this? 6. We suggest combining 4.2.2, 4.2.3 and 4.2.4 to read as a new 4.2.2 "Protection System components which are installed as a underfrequency load shedding, underfrequency generation shedding, under voltage load shedding or Special Protection System for BES reliability."

Regarding battery chargers, does the SDT propose that OEM-type tests be performed to validate the rated full current output and current limiting capabilities? It has been proposed that simply turning off the charger and allowing the batteries to drain for a period of several hours, then returning the charger to service, will validate these items. It is not clear that an auditor would come to the same conclusion, since it appears open to interpretation. Please modify to make this clear. If an entity has an over-sized battery charger, they can (and should) only test to the max capacity of the battery bank. Suggest changing “full rated current” to “designed charging rate”.
No
Within the tables, several components related to UFLS/UVLS systems have an interval of “when the associated UVLS or UFLS system is maintained.” Yet, there is no maximum interval established for a UVLS or UFLS system. We feel this item should be clarified. If the intent of the SDT is to tie the testing to when the UFLS/UVLS relays are maintained, so that all components are tested at the same time, then this should be made clear. One possible resolution would be to change the interval to read: “when the associated UVLS/UFLS relays are maintained”.
Yes
Yes
Yes
The information in the supplementary reference document is very helpful and valuable. Yet, it is not clear how the document would be managed/revised, nor what role it plays in compliance monitoring. There needs to be a clear understanding if everything in the document is required for compliance, e.g. criteria for monitored systems, etc. Additionally, we feel that evidence should be addressed within the supplementary reference document.
Yes
The Frequently-asked Questions seem to act as interpretations to the standard. What roll will they play in determining compliance? On table 1b (page 11) the UFLS and UVLS maintenance activities indicate that tripping of the interrupting device is not required, but it uses the term ‘functional trip test’. The FAQ indicates that a ‘functional trip test’ does require tripping the interrupting device. This conflicts with what is in the table and should be corrected in the FAQ to reflect that no trip is required.
Please clarify if the following are subject to PRC-005-2 requirements: 1) a battery that is in a station where the only BES element is a UFLS scheme 2) batteries used only to support communication elements (microwave houses)

NERC Standards Review Subcommittte
Carol Gerou
Yes
N/A
No
A. In the tables, the term “verification” should be switched with “check”. B. The verification activities include testing for “specific gravity” in batteries. Since “impedance testing” will give you the same results or similar results; revise the tables to reflect this, as well. C. Another question deals with the table title verbiage. Table 1a and 1c are labeled as Protection Systems, while Table 1b is Protection System Components. One could interpret table 1c as saying that if any one component of the protection system in question is not in compliance with level 3 monitoring stipulations, then every component must be degraded to level 2 monitoring as so forth. This needs to be clarified. D. Some activities, such as complete functional testing, could lead to reduced levels of reliability, because [1] it requires removing elements of the transmission system from service and [2] it requires performing tests that are inherently prone to human

errors. The MRO NSRS does not believe the perceived benefits justify the anticipated costs. E. In the tables, under Table 1a and Protection system communications equipment and channels, a technical justification should be provided to show that performance and quality channel testing would result in the reduction of regional disturbances and blackouts. Quality and performance testing is subjective. Subjective tests are inherently poor compliance measures. The requirements to measure, document, store, and prove channel quality data is a poor use of limited compliance resources. F. In the tables, under Table 1a and Station DC supply (and anywhere else), equalize (battery) voltages should be eliminated. Equalizing battery voltages reduces battery life and do not provide a significant gain in overall system reliability to offset the loss of battery life. G. In the tables, under Table 1a and Station DC supply (and anywhere else), delete the reference to measuring the fluid temperature of "each cell". A technical basis should be demonstrated that shows why individual cell fluid temperature measurement would reduce the occurrence of regional disturbances. If fluid temperature measurement remains in the standard, a single fluid temperature measurement per battery bank should be sufficient to demonstrate that the battery bank was performing within normal parameters. The compliance burden to add fluid temperature measurements for each cell is unwarranted and reduces compliance personnel resources that could be utilized on more important reliability activities.
No
A. It looks like for unmonitored systems, breaker trip coils are to be checked for continuity every 3 months. There is no mention of auxiliary relays. In the partially monitored and fully monitored sections, trip coils and auxiliary relays are lumped in the same category at 6 calendar years each. What happened to the aux relays in the unmonitored section? Also, note that the term "trip coils" is used, not "breaker trip coils" in the type of component category. B. The maintenance interval for Protection System Control Circuitry (Trip coils and Auxiliary relays) is 6 years, but the interval for relay output contacts is 12 years when these components are partially monitored. It seems that these things all have a similar reliability. If commissioning tests are done diligently, the trip DC availability is continuously monitored and the trip coil itself is continuously monitored, no functional tests should be needed. The only thing that would be done at PM time would be to ensure that the alarming method is still functional.
Yes
A. The MRO NSRS agrees with this approach; however, I think most entities will not see the advantage of condition-based maintenance until they can resolve any gaps in data retention. If an entity was retaining a set of maintenance records but failed to include all the needed information as specified in this standard so they would need to adjust their maintenance procedure to collect all information and then they would need to wait for the entire retention period until they could start using the extended maintenance interval. If an entity had a collateral set of records which verified the information that lacked in the original maintenance record then could the entity start using the extended maintenance interval? For example, an entity has records showing that they have maintained a voltage or current transformer within the prescribed maintenance interval listed in level 1 monitoring (which is a maximum 12 year maintenance interval). Could this same entity go to level 3 monitoring (which is a continuous maintenance interval) immediately if it can query their SCADA and produce detailed records indicating the accuracy of the PT or CT for the maintenance records already retained? B. For lockout relays, if commissioning tests are done diligently, the trip DC availability is continuously monitored and the trip coil itself is continuously monitored, is it necessary to operate these relays for functional testing? For breaker failure lockout relays, re-verifying the operation of the coil and all the contacts could mean taking multiple breakers and line terminals out of service at the same time. Functional trip tests could cause unintentional tripping of equipment, cause equipment damage and interruption of service to customers. It's hard to see how the reliability of the BES is significantly improved by doing this test. The MRO NSRS feels the risk of adverse impact could be greatly reduced by a longer interval such as 12 years. C. In table 1c, the word "continuous or continuously monitored" is used. Please clarify the "within 1 hour" time frame takes into account that there may be a communication outage (failover) that will prevent an entity to "continuously" monitor a device.
No
A. The MRO NSRS is concerned that this approach could lead to non-compliance if the company follows this process and a Compliance Auditor disagrees with the method that was used. An applicable entity should be protected if they follow the standard appropriately. There should be some assurance of a grace period for mitigation if this selected approach was not accepted. B. Please provide the basis for having at least 60, then taking 30 (50%) for testing/maintenance. This may give an unfair advantage to larger companies rather than being fair across the board. This places an undue burden on smaller companies by having to team up with other asset owners.
No
N/A
No
Overall, the FAQ's are helpful toward understand what the SDT was thinking. Explanations for

questions dealing with the maintenance activities (e.g., battery testing) indicate an attempt to line up the requirement with IEEE standards. While it is commendable to attempt alignment reliability standards with other industry standards, it also begs the question of why requirements that are already covered by other standards should be repeated in reliability standards. In addition, if the other standards are changed, then they could become inconsistent with or contradictory to the reliability standard.
Conflict: Order 672 says that standards should be clear and unambiguous.
A. In the applicability section 4.2.5.5, change the statement to say, “Protection systems for BES connected station-service transformers for generators that are part of the BES.” B. In the applicability section 4.2.5, change the statement to replace “are part of” with “directly connected to”. The “are part of” will be left to interpretation. Please indicate the added reliability benefit by collecting this in Table 1a Page 9 protection system communication equipment and channels. C. If a breaker failure relay is also being used for sync-check, is it required to verify the voltage inputs since they are used for a closing function and not a tripping function? It is understood that the current inputs would have to be verified since these are used for breaker failure tripping. D. Please clarify requirement R1-1.1, does one have to individually list out each Protection System and its associated maintenance activities or can the PSMP be a generalized procedure that covers each of the components in all of a utility's Protection Systems? E. All references to breakers should be eliminated; thus, eliminate breaker trip coils. Breakers are primarily mechanical in nature and should be excluded similar to mechanical relay systems such as sudden pressure relays. F. Clarify that trip coils checks or tests can be verified through alternate means other than physically tripping the coil or potentially requiring system outages to physically trip a coil. Alternate tests could consist of checking self monitoring relays, continuity lights, etc. Trip coil tests could require transmission line outages which can be denied by regulatory authorities due to system conditions beyond an entity’s control. Significant delays of months or longer could occur to obtain a transmission line outage. Further, potentially requiring transmission line outages for trip coil test could harm BES reliability by increase the number of force transmission line outages due to testing. System reliability could be significantly negatively impacted anytime testing on trip circuits is performed due to human errors causing outages or regional disturbances. G. One item R1.3 (inclusion of batteries) was questioned as why this was specifically called out. It should be part of the definition. H. Define the term “condition-based”. I. The format of the tables is poor with 17 line items addressed in each. It is difficult to relate one table to another because they are not consistent with regard to the type of components. For example table 1a references of components a “breaker trip coil (only)” and the 1b references “trip coils and auxiliary relays”. J. R1.1 please add “… as they apply to the applicable entity”. As stated now, all three tables must be accomplished. K. Please add the words “time based maintenance methods” to table 1a for clarity in the heading. L. Table 1b under general description, last sentence the word “elements” should be replaced with “maintenance activities” which will provide exactly what is intended. M. Table 1b, if maintenance activities for level 2 monitoring include level 1 maintenance activities, then redundant activities in table 2 that are contained in table 1 should be removed (the same for table 3 to table 2 to table 1). N. If an entity maintenances a protective relay such that it is included in level 2 monitoring (a Condition Based Maintenance program) and this relay is considered to have a maximum interval of 12 years, does the entity need to also perform the maintenance activities for level 1 monitoring since the table 1b header indicates, “General Description: Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component?”
Group
Platte River Power Authority Maintenance Group
Deborah Schaneman
Yes
No
Minimum maintenance activites should be based on categorization of relays and defined maintenance actions system by system using historical and definitively known data entity by entity. By establishing specific minimum maintenance activities you risk entites changing currently effective maintenance programs to programs that match minimum maintenance activities to meet requirements in the Standard which could be less effective for their system.
No
Electro-mechanical relays are historically out of tolerance well before the 6 year maximum allowable maintenance intervals defined witin table 1a.
Yes
Yes

Yes
It isn't clear in the Supplementary Reference Document why lock-out relays (86) are included as a component of Protection Systems that require a 6 year maximum interval. Historically we haven't experienced any failures with lock-out relays and feel the risk of causing a system reliabiliy issue by removing it from service and restroing it far out weghts the benefits of testing it. What, if any evidence, i.e. equipment failure, does the standard drafting team use to mandate routine testing of 86 devices? Are we fixing something that isn't broke here? The FERC order directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the BPS. It would seem more appropriate to allow each entity to set their own maximum allowable interval based on studies and historical data of their specific protection system and impact on the reliability of the BPS opposed to a blanket approach that covers all systems regardless of their size or system confirguration.
No
Individual
Martin Bauer
US Buereau of Reclamation
No
The alteration of the program to include testing as a component does not add value to system reliability. The existing requirement can only be completed with procedures that some of the elements listed under the program. The proposed program is far too restrictive in the manner in which it requires specific actions and thereby excludes others. The program element for monitoring is listed; however, the monitoring is intended to be used through an electronic subsystem and does not allow for observations by experienced technical staff. Testing is listed; however, the definition is limited to the application of signals and precludes other procedures. Further, the definition of Protection System proposed is a nested definition which tends to expand the number of devices covered (any device that has voltage and current sensing inputs) irrespective of their impact on the BPS.
No
2. The basis for developing the maintenance intervals was adequately explained. It is understood that FERC would like uniform intervals; the intervals do not recognize the tremendous variation in installation and equipment and possibly manufacturer recommendation. Point in fact is the interval for listed for electromechanical relays. Some of these relays must be calibrated every year or three years on the outside. Relays that have a history of stable performance based on consistently good test results. The intervals for battery maintenance are not reasonable. The capacity testing at 3 years is higher than the 5 year which battery manufactures require.
No
The definition of Protection System components does not add clarity. The standard proposes including stations service transformers for generation facilities, however, the protection system definition does not include those elements. The inclusion of station service transformers would only be appropriate if the protection associated with the transformer results in the tripping of a transmission element.
No
The condition based monitoring only provides for a very narrow process and excludes sound judgment in determining maintenance intervals. As long as the registered entity establishes parameters by which variation in the prescribed maintenance intervals are determined, justified variation should be allowed.
No
The parameters established can only be implemented with documentation that defined in the document but is not readily available.
No
6. The document will require revisions. Performance based maintenance is establishing a strategy to achieve a desired performance. The document limits strategy to statistical analysis of failure rates. The document assumes a modern protection system with a high level of monitoring. Facilities which barely qualify would not have high end monitoring installed. The document also refers to “exercising a circuit breaker through t relay tripping circuits using remote control capabilities via data communication.” This repeated several times throughout the document as a means of increasing the TBM. This function, if indeed used, would require maintenance. This

function is very dangerous and could introduce a cyber vulnerability.
No
The significance of this issue is not relfected in the period of time needed to review the documents. The supplement has many good ideas; however, the concept is going further than needed for establishing consistent maintenance intervals.

Consideration of Comments on Draft Standard Version 1 Protection System Maintenance and Testing — Project 2007-17

The Protection System Maintenance and Testing SDT thanks all commenters who submitted comments on PRC-005-2 — Protection System Maintenance standard. This standard was posted for a 45-day public comment period from July 24, 2009 through September 8, 2009. Stakeholders were asked to provide feedback on the Standard through a special electronic comment form. There were 57 sets of comments, including comments from more than 130 different people from over 75 companies representing all of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

The SDT proposed to change the name of the draft standard from "Protection System Maintenance and Testing" to "Protection System Maintenance", and to include testing as one component of "Protection System Maintenance Program", which will be a defined term. The majority of stakeholders agreed with both the change in the name of the draft standard and with the definition of Protection System Maintenance Program. Only two respondents disagreed and their comments were addressed. Hence, the draft standard will now be referred to as "Protection System Maintenance."

Stakeholders generally disagreed with the minimum maintenance activities as well as the maximum allowable intervals included in Tables 1a, 1b, and 1c in the draft standard. As a result, the SDT made extensive changes to the standard and tables regarding the maintenance activities, and made minor changes relative to the associated maintenance intervals.

A majority of the respondents agreed with the general approaches regarding condition-based and performance based maintenance programs but provided suggestions on improving the clarity of the provisions within the tables and expressed concerns about perceived administrative issues in establishing the programs. The SDT responded by revising the tables to improve clarity and addressing the administrative concerns in its responses to comments.

Stakeholders expressed appreciation for the "Supplementary Reference Document" and the "Frequently-asked Questions" (FAQs) document. In its responses to the comments, the SDT explained the relationship between the Standard and the two documents. Additionally, the SDT addressed many of the comments in Questions 1-5 by developing additional FAQ content, and referring the respondents to the FAQs document.

Most stakeholders were unaware of any conflicts between the proposed standard and any business practices; however, a few commented that conflicts possibly existed with existing business practices or with other organizations such as the Nuclear Regulatory Commission. The SDT provided clarifying explanations to illustrate that conflicts are not actually present.

Stakeholders made numerous comments and suggestions resulting in substantial changes to the draft Standard, the Supplemental Reference Document, the FAQs, and minor changes to the draft Implementation Plan.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards,

Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. The SDT proposes to change the name of the draft standard from "Protection System Maintenance and Testing" to "Protection System Maintenance", and to include testing as one component of "Protection System Maintenance Program", which will be a defined term. Do you agree? If not, please explain in the comment area.

Summary Consideration: The majority of the respondents agreed with both the change in the name of the draft standard and with the definition of Protection System Maintenance Program. Some comments were offered, most of which were answered by explanation of the rationale of the SDT.

Organization	Yes or No	Question 1 Comment
US Bureau of Reclamation	No	1. The alteration of the program to include testing as a component does not add value to system reliability. The existing requirement can only be completed with procedures that some of the elements listed under the program. The proposed program is far too restrictive in the manner in which it requires specific actions and thereby excludes others. 2. The program element for monitoring is listed; however, the monitoring is intended to be used through an electronic subsystem and does not allow for observations by experienced technical staff. 3. Testing is listed; however, the definition is limited to the application of signals and precludes other procedures. 4. Further, the definition of Protection System proposed is a nested definition which tends to expand the number of devices covered (any device that has voltage and current sensing inputs) irrespective of their impact on the BPS.
Response: The SDT thanks you for your comments. **1. Maintenance includes a number of actions, one of which is testing; inspections, etc are also part of maintenance. One option is to separately identify each type of activity, another is to combine the types of activities within the overall Maintenance activity and address the specific activity type where relevant. As for including some activities and excluding others, the listed activities are contemplated as minimum activities and do not preclude an entity from performing additional activities.** **2. If a facility is attended, the observation of locally-alarmed conditions by on-site personnel, within the time intervals expressed in the monitoring attributes, can satisfy these requirements. Adequate documentation should be available that the facility is indeed attended, and that the on-site personnel observe the related items. See FAQ V-1-D (page 30)** **3. Nothing is precluded; minimum activities are specified, and entities may use additional approaches.** **4. This concern is addressed by the applicability of the standard, where the applicability is limited to "Protection Systems that are applied on, or are**		

Organization	Yes or No	Question 1 Comment
designed to provide protection for the BES".		
Wolverine Power Supply Cooperative, Inc.	No	Wolverine Power has concern about the level of "prescription" in this standard draft. The intent of the standards is to define what, not how. This draft gets unnecessarily prescriptive in our opinion, particularly in the table
Response: The SDT thanks you for your comments. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.		
AEP	Yes	
American Transmission Company	Yes	
Austin Energy	Yes	
Bonneville Power Administration	Yes

Transmission Owner	Yes	
TVA	Yes	
Western Area Power Administration	Yes	
Wisconsin Electric	Yes	
Xcel Energy	Yes	
FirstEnergy	Yes	Although we agree with the change in the title of the standard, as well as the proposed definition of "Protection System Maintenance Program", we feel that the definition could be clarified. With regard to "Restoration", which at present is described as "The actions to restore proper operation of malfunctioning components", it may be helpful to add examples of acceptable actions to restore operations, such as calibration, repair, replacement, etc.

Organization	Yes or No	Question 1 Comment
Response: The SDT appreciates your support and comments. An FAQ document is included that addresses your comment related to an example of acceptable operations to restore operations. See FAQ II-2-B. (page 5)		
JEA	Yes	Generally agree; however, some suggestions for possible changes: 1) change "associated communication systems necessary for correct operation of protective devices" to "protective relays", 2) add a PSMP glossary definition for an acceptable type of monitored alarm, either to the proposed "PSMP monitor" or another definition for "PSMP monitored and alarmed." The SDT did a good job of making the overall Protection System definition clearer.
Response: The SDT appreciates your support and comments. **1) "Protective relays" is too specific a term here; it excludes applications such as logic-based direct transfer trip that provides protective functions.** **2) The SDT disagrees that the proposed definition is necessary. Guidance on this issue is included in the FAQ. See FAQ V-1-A (page 28)**		
MRO NERC Standards Review Subcommittee	Yes	N/A
Exelon Generation Company, LLC	Yes	None
Saskatchewan Power Corporation	Yes	Saskatchewan would like clarification of what the expectations and rationale are for including Restoration in the PSMP. The other terms listed under the PSMP definition represent what we would consider as typical relay maintenance activities. We would typically consider Restoration as an Operational activity. The existing NERC standards seem to treat this as an Operator concern addressed in PRC-001 R2.1 and R2.2 (The Operator shall take corrective action as soon as possible). If Restoration is included in PRC-005 doesn't PRC-001 have to be modified as well to remove these references? Saskatchewan would also like clarification on the term upkeep. Is the standard prescriptive and mandate the application of the latest firmware upgrades within a defined period, or is it flexible and can upgrades be applied as the utility deems necessary?
Response FAQ II-2-B (page 5) explains that restoration is the "corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction" and provides extensive discussion contrasting "restoration" in this context from "restoration" in a system operations context. Examples are also discussed. Note that the word, 'restoration' is capitalized in the definition, but this capitalization is for consistent format by capitalizing the first letter of each word in each bulleted phrase – the word was not capitalized to show that		

Organization	Yes or No	Question 1 Comment
the term is using the approved definition of 'Restoration.'		
SCE&G	Yes	The SDT is to be commended for developing a clear and well documented draft. Overall it provides a balanced view of Protection System Maintenance, and good justification for its maximum intervals.
Response: The SDT appreciates your support.		
Ameren	Yes	1. We commend the SDT for developing such a clear and well documented first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. Our existing M&T Program has and continues to yield a very reliable BES with mostly similar intervals, though some are longer and others shorter. We strongly support the almost all of the applicability revision, which clarifies the boundary of NERC maintenance and testing oversight. 2. We question the addition of UFLS station DC Supply, auxiliary relays, and Generating facility system-connected station service transformers. Have these components been a significant source of problems leading to cascading outages? 3. The SDT also modifies the Protection System definition, mostly clarifying the boundaries. We generally agree except that we recommend adding "fault" before "interrupting devices".
Response: **1. The SDT appreciates your support and comments.** **2. The standard is not focused only on causes of "cascading outages"; it is focused on "Protection Systems that are applied on, or are designed to provide protection for the BES" and on maintenance of the UFLS systems. The components addressed in the comment are all part of the BES, or the UFLS. As for the DC supply to the UFLS, it is a component that is necessary for the UFLS to function properly. FAQ II-4-D (page 11) discusses what auxiliary tripping relays are actually included, and FAQ III-2-A (page 20) provides a discussion of station service (auxiliary) transformers and their inclusion in this standard.** **3. The "Interrupting devices" is a term that addresses the actions of UFLS, UVLS, and SPS, as well as the actions to clear faults.**		
Electric Market Policy	Yes	We commend the SDT for developing such a clear and well documented first draft. In general, it provides a well reasoned and balanced view of Protection System Maintenance.
Response: The SDT appreciates your support.		
SERC (PCS)	Yes	We commend the SDT for developing such a clear and well documented first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum

Organization	Yes or No	Question 1 Comment
		intervals.
Response: The SDT appreciates your support		
AECI	Yes	
Puget Sound Energy	Yes	

2. Within Table 1a, Table 1b, and Table 1c, the draft standard establishes specific minimum maintenance activities for the various types of devices defined within the definition of "Protection System". Do you agree with these minimum maintenance activities? If not, please explain in the comment area.

Summary Consideration: Most of the respondents disagreed with the minimum maintenance activities to some degree or another. The disagreement ranged over the full spectrum of activities specified in the Tables, resulting in numerous changes to the standard in response to comments.

Organization	Yes or No	Question 2 Comment
ITC Holdings	No	1. (FAQ 3C) What is the technical justification for omitting insulation testing of the wiring for DC control, potential and current circuits between the station-yard equipment and the relay schemes? We feel this wiring is susceptible to transients which, over time, may compromise the insulation, and therefore should be tested. 2. 2. Table 1a (Page 6) Improve wording. Suggestion: "Verify proper functioning of the current and voltage circuits from the voltage and current sensing devices to the protective relay inputs" 3. On Page 6: The red light monitors trip circuit not only trip coil. With only one circuit going to three parallel single-pole trip coils a red light will not detect a single open trip coil. Is a station inspection that verifies the red light is "on" an acceptable activity? 4. On Page 9: The 3 month communications maintenance activities should say that the channel needs to be checked. For example: initiate a manual checkback test of the carrier system. 5. On Page 10: Not clear on level 2 monitoring attributes for protective relay component description. As written it notes two separate requirements which are ambiguous. We assume that all monitoring noted is required (internal self diagnosis and waveform sampling)? 6. On Page7: The standard should note that battery testing must include all batteries that are used in protective relay systems (for example pilot wire batteries).

Response: The SDT thanks you for your comments.

1. The SDT does not believe that insulation testing needs to be included within the minimum required maintenance activities; the SDT is not aware of a body of evidence that suggests that these tests should be included as a requirement. The proposed standard does not prevent an entity from including such tests in its program if its experience indicates that such testing is needed.

2. The SDT has modified the standard in consideration of your suggestion and the suggestions of others as shown:

Organization	Yes or No	Question 2 Comment
Verify proper functioning of the current and voltage circuit signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays. **3. The SDT has modified the standard to remove the requirement cited in this comment as shown below:** **4. The SDT has modified the standard in consideration of your suggestion as shown below:** Verify that the Protection System communications system is functional. **See FAQ II-6-B for suggestions related to methodology.** **5. Yes. For level 2 monitoring, all attributes must be satisfied. The SDT has modified the standard to clarify as shown below:** Includes: • Internal self diagnosis and alarm capability • Alarm must assert for power supply failures. • Input voltage or current waveform sampling three or more times per power cycle • Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming. **6. The proper functioning of such batteries will be addressed by the verification and monitoring of the communications system, and by addressing maintenance correctable issues related to the communications system.**		
Green Country Energy LLC	No	1) Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) also The maintenance activity causes excessive breaker operation, and the intrusive nature increases the risk of subsequent misoperations on operating units. System configuration of many plants will require an extensive interruption of total plant production to complete the test. 2) Protection System Control Circuitry (Trip Circuits) (UFLS or UVLS systems only) The maintenance activity causes excessive breaker operation, and the intrusive nature increases the risk of subsequent misoperations on operating units. System configuration of many plants will require an extensive interruption of total plant production to complete the test.
Response: The SDT thanks you for your comments. **1. The overall Protection System Control Circuitry can be addressed in segments, as long as all portions are verified or tested as required. Depending on the arrangement of the DC control circuit, it may be necessary to only trip the breaker itself once. See FAQ II-4-E. (page 11)** **2. The overall Protection System Control Circuitry can be addressed in segments, as long as all portions are verified or tested as required.**		

Organization	Yes or No	Question 2 Comment
Depending on the arrangement of the DC control circuit, it may be necessary to only trip the breaker itself once. See FAQ II-4-E. (page 11)		
Public Service Enterprise Group Companies	No	1) Table 1a Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only). Currently, we test our UFLS relays on a 2 year maintenance interval. We test the relays and associated DC circuitry up to the DC lockout relays. It would require extraordinary effort to trip the breakers directly when performing these tests. Usually, each UFLS relay will trip several feeder breakers. This requirement states that we need to check the trip coil for each of those breakers each time we perform relay maintenance. This will add an unreasonable amount of time and effort to reliably switch out several 4kV or 13kV feeders every time we perform UFLS maintenance. For UFLS and UVLS schemes, we feel the requirement for DC control testing should not go past the lockout relay. The standard says to perform trip checks at the same time as UF maintenance. We test the relays on a 2 year interval right now. It is unreasonable to perform trip checks this often. The trip checks should follow a 6 year span (or longer) just like the BES equipment. 2) Table 1a DC supply. The 18 month inspection requires a measurement of specific gravity and temperature. We believe that if a battery owner opts to perform an 18 month ohmic value test, this combined with the cell voltage readings and continuity tests will give a good indication of battery health. We do not feel that the measurement of specific gravity is required in conjunction with the tests performed above.
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard in consideration of your comment as shown below:** Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except that verification does not require actual tripping of circuit breakers or interrupting devices. **See FAQ II-8-D (page 19) for a discussion on this.** **2. The SDT has modified the standard in consideration of your comment and this has been deleted.**		
Wisconsin Electric	No	1. Page 7 Station DC Supply (Batteries): The activity to verify proper electrolyte level should only apply to unstaffed (unmanned) stations; checking battery electrolyte levels is routinely done in generating stations, which are staffed with personnel continuously (24 x 7). In addition, the three activities listed here with a 3 month interval for batteries (electrolyte, voltage, grounds) should NOT require documentation for compliance purposes. It should be sufficient that these routine and recurring activities (every 3 months) are identified in the Maintenance Plan. Otherwise the administrative burden to provide documentation will become excessive and counterproductive to assuring BES reliability. 2. Page 7 Station DC Supply (Batteries): The 18 month interval includes an activity to verify the battery charger equalize voltage. This activity is normally done only when the bank is load tested. Therefore the

Organization	Yes or No	Question 2 Comment
		activity to verify equalize voltage of a charger should have a 6 year interval along with the other battery charger activities to verify full rated current and current-limiting. 3. Page 9 Communications Equipment: Similar to #1 above, the activity to verify monitoring and alarms should NOT require documentation in order to demonstrate compliance. Having these routine 3 month activities in the Maintenance Plan is sufficient. This needs to be clarified in the standard. Also, this requirement should be re-worded to refer to generating stations also, not just substations. 4. Page 11 Station DC Supply (Batteries): Like #1 above, the similar requirement in Table 1b for verifying battery electrolyte levels should be revised to indicate that documentation is NOT required. 5. Page 6 Prot System Control Circuitry: Like #1 above, the 3 month activity to verify continuity of breaker trip circuits is fine, but there should be no requirement to document the readings or observations; it is sufficient that this activity be addressed in the Maintenance Plan, especially for staffed generating stations. 6. Page 6 Prot System Control Circuitry: For the 6 year activity to "perform a functional trip test...": is this a requirement to actually trip the circuit breaker ? If yes, this should be stated clearly in the Maintenance Activity description. 7. We are concerned that the Maintenance Activities are not appropriate for certain equipment. The RFC definition of Bulk Electric System includes any protection equipment that can trip a BES facility independent of voltage level. As an LSE, this includes distribution-level equipment that was not designed to the same level of redundancy as Transmission equipment. Complying with the requirements for control circuitry functional testing and current sensing device testing will actually decrease system reliability since this often cannot be accomplished without requiring outages to major distribution system components and/or temporarily breaking protection circuits. We propose that this type of testing on distribution systems which fall under the definition of BES Protection Systems should be addressed separately from the rest of the BES Protection Systems in this standard. The intervals and/or maintenance activities should reflect the differences in how these distribution protection systems are designed and operated.

Response: The SDT thanks you for your comments.

1. **The SDT has modified the standard in consideration of your comment. The revised standard requires the responsible entity to "check" the following every 3 calendar months:**
   - Electrolyte level (excluding valve-regulated lead acid batteries)
   - Station dc supply voltage
   - Unintentional grounds

2. The SDT has modified the standard in consideration of your comments regarding DC supply and the reference to "equalize voltages" has been

Organization	Yes or No	Question 2 Comment
removed **3. The word "substation" has been removed from this requirement. Documentation of completion of required maintenance activities will likely be necessary to demonstrate compliance.** **4. The SDT has modified the standard in consideration of your comments to require checking of electrolyte levels, instead of verification. Documentation of completion of required maintenance activities will likely be necessary to demonstrate compliance.** **5. The SDT has modified the standard to remove the requirement cited in your comment.** **6. Yes. The intent here is that the entire dc control circuit, including the breaker trip coil, be exercised. This was changed to read as follows:** Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System. **7. As established in 4.2.1, this standard applies to all Protection Systems that are "Protection Systems that are applied on, or are designed to provide protection for the BES".**		
Exelon Generation Company, LLC	No	1. Minimum maintenance activities should be on a yearly multiplier verses a monthly multiplier. Nuclear generating stations are typically on an 18-month or 24-month refueling cycle. The draft standard does not take into consideration a nuclear generators refueling cycle. Specifically, most Boiling Water Reactors (BWRs) are on a 24-month refueling cycle and may run continuously between refueling outages. Performing maintenance on-line puts the generating unit at risk without any commensurate increase in reliability to the bulk electric system. 2. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 3. Activities that begin with "verify" should be modified to "Validate…are/is within acceptable limits. Initiate corrective actions as required." For example, some levels of DC grounds are acceptable based on circuit design and component installation. Troubleshooting or ground isolation may increase the risk to the system depending on ground magnitude and conditions. 4. Please provide clarification on "verify that no dc supply grounds are present" most stations have some level of ground current. Should this be interpreted to be a measure of resistance or current values? Suggest rewording to say "Check and record unintentional battery grounds" 5. "Verify Station Battery Chargers provides the correct float and equalize voltage" should be deleted. Equalizing a battery is a maintenance function and should only be performed as needed. Suggest rewording

Organization	Yes or No	Question 2 Comment
		to say "Check and record charger output current and voltage." 6. Activities associated with Battery Charger performance should be deleted. The ability of the Battery Charger to maintain the battery at full charge state is verified by checking proper "float voltage." The ability to provide full rated current only affects the ability to recharge a battery AFTER an event has occurred. 7. In Table 1a does the requirement to "verify proper electrolyte level" refer to all batteries or only a sampling? Current practice is to use the "pilot cell" as the monitoring cell as this cell is usually the least healthy of the battery bank from a specific gravity and/or voltage standpoint. If the pilot cell continues to degrade then the other batteries will be monitored more often. Suggest rewording to "Check electrolyte level." 8. In Table 1a the 18-month requirement to measure that the specific gravity and temperature of each cell is within tolerance is "where applicable" what does "where applicable" mean? 9. For the Station dc supply (battery is not used) 18-month interval should this be interpreted that it is just the battery charger with no attached battery? Or a dc supply system that does not contain a battery? 10. Table 1a Station dc supply 18-month interval to verify cell-to-cell and terminal connection resistance is within "tolerance" should be revised to say "tolerance or acceptable limits." 11. Table 1a Station dc supply (that has as a component valve regulated lead-acid batteries) should provide an additional optional activity for "Total replacement of battery at an interval of four (4) years" in lieu of not conducting performance or service capacity test at maximum maintenance interval.

Response: The SDT thanks you for your comments.

1. The activities that are on an interval less than one calendar year are all "inspection" type activities, rather than "testing" activities. The SDT requests more specificity as to your concerns.

2. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8.4 of the Supplementary Reference Document (page 13) and FAQ IV-2-D (page 23) for a discussion on this issue.

3. The SDT has modified the standard and Frequently Asked Questions document (See FAQ II-5-I, page 15) in consideration of your comments about dc grounds.

4. The SDT has modified the standard and Frequently Asked Questions document (See FAQ II-5-I, page 15) in consideration of your comments about

Organization	Yes or No	Question 2 Comment
no dc supply grounds being present. The language in the standard was changed to: Check for unintentional grounds 5. The SDT has modified the standard in consideration of your comments – the phrase, “equalize voltages,” was deleted 6. The performance of the battery charger is critical to the performance of the protection system. The SDT has modified the standard to simplify the requirements related to maintenance of the battery charger. 7. The SDT has modified the standard in consideration of your comments. The Maintenance Activity related to electrolyte level of batteries has been changed from “verify proper” to “check” electrolyte levels. This Maintenance Activity refers to every individual cell in a non-VLRA station battery, similar to recommendations in the relevant IEEE Standards. 8. The SDT has modified the standard in consideration of your comments. The requirement to measure that the specific gravity and temperature of each cell is within tolerance is "where applicable" has been deleted. 9. The FAQ II-5-A (page 12) addresses your question concerning “Station dc supply (battery is not used)” by explaining that “a Station dc supply where a battery is not used” is a situation where another energy storage technology besides a battery is used prevent loss of the station dc supply when ac power to the station dc supply is lost. 10. The SDT has modified the standard in consideration of your comments regarding cell-to-cell and terminal connection resistance – the phrase, “within tolerance” was deleted – and the requirement was subdivided to clarify that the entity must “verify battery terminal connection resistance and verify battery cell-to-cell connection resistance.” 11. The SDT believes that the maintenance activities specified in Table 1a for VRLA batteries are necessary to assure that the station battery will perform reliably and that replacement of the battery every four years in lieu of such testing would not provide such assurance. The SDT is providing the option of either capacity testing (every three years) or measuring individual cell/unit ohmic values (every three months) and trending the test results against the station battery’s baseline to allow entities to choose which of these activities best address their facilities. Total replacement of a VRLA battery with a properly-performing new battery, 3 calendar years after installation of the original battery, is in compliance with Table 1a of this standard. See FAQ IV-2-A (page 22) & IV-2-B (page 23) for a discussion about commissioning tests and how they relate to establishing a baseline.		
US Bureau of Reclamation	No	1. The basis for developing the maintenance intervals was adequately explained. It is understood that FERC would like uniform intervals; the intervals do not recognize the tremendous variation in installation and equipment and possibly manufacturer recommendation. Point in fact is the interval for listed for electromechanical relays. Some of these relays must be calibrated every year or three years on the outside. Relays that have a history of stable performance based on consistently good test results. 2. The intervals for battery maintenance are not reasonable. The capacity testing at 3 years is higher than the 5 year which battery manufactures require.
Response: The SDT thanks you for your comments. 1. The proposed standard does not prevent an entity from including such tests in their program if their experience has indicated that such testing is		

Organization	Yes or No	Question 2 Comment
needed. **2. The 3-year capacity test is specifically for Valve Regulated Lead-Acid batteries (VRLA); Vented Lead-Acid batteries require a 6-year capacity test. Due to the failure mode and designed service life of Valve Regulated Lead-Acid (VRLA) batteries compared to a Vented Lead-Acid batteries, the SDT believes that extending capacity testing of a VRLA battery beyond the maximum maintenance interval of 3 calendar years in Table 1a cannot be justified regardless of what the battery manufacturers recommend.**		
MRO NERC Standards Review Subcommittee	No	A. In the tables, the term “verification” should be switched with “check”. B. The verification activities include testing for “specific gravity” in batteries. Since “impedance testing” will give you the same results or similar results; revise the tables to reflect this, as well. C. Another question deals with the table title verbiage. Table 1a and 1c are labeled as Protection Systems, while Table 1b is Protection System Components. One could interpret table 1c as saying that if any one component of the protection system in question is not in compliance with level 3 monitoring stipulations, then every component must be degraded to level 2 monitoring as so forth. This needs to be clarified. D. Some activities, such as complete functional testing, could lead to reduced levels of reliability, because [1] it requires removing elements of the transmission system from service and [2] it requires performing tests that are inherently prone to human errors. The MRO NSRS does not believe the perceived benefits justify the anticipated costs. E. In the tables, under Table 1a and Protection system communications equipment and channels, a technical justification should be provided to show that performance and quality channel testing would result in the reduction of regional disturbances and blackouts. Quality and performance testing is subjective. Subjective tests are inherently poor compliance measures. The requirements to measure, document, store, and prove channel quality data is a poor use of limited compliance resources. F. In the tables, under Table 1a and Station DC supply (and anywhere else), equalize (battery) voltages should be eliminated. Equalizing battery voltages reduces battery life and do not provide a significant gain in overall system reliability to offset the loss of battery life. G. In the tables, under Table 1a and Station DC supply (and anywhere else), delete the reference to measuring the fluid temperature of “each cell”. A technical basis should be demonstrated that shows why individual cell fluid temperature measurement would reduce the occurrence of regional disturbances. If fluid temperature measurement remains in the standard, a single fluid temperature measurement per battery bank should be sufficient to demonstrate that the battery bank was performing within normal parameters. The compliance burden to add fluid temperature measurements for each cell is unwarranted and reduces compliance personnel resources that could be utilized on more important reliability activities.

Organization	Yes or No	Question 2 Comment
Response: The SDT thanks you for your comments. **A. The SDT has modified the tables in consideration of your comments regarding “verification” vs. “checking”.** **B. The SDT has modified the standard in consideration of your comments – the term, “specific gravity” is not used in the revised standard** **C. The SDT has modified Tables 1a and 1c in consideration of your comments. The subheading of Table 1a and 1c were modified, replacing, “Systems” with “System Components.”** **D. To minimize system impact of such maintenance and possible errors, the maintenance necessarily should be scheduled at a time that minimizes the risks.** **E. Many utilities have long history that emphasizes that maintenance of communications systems is critical to assuring the proper performance of these systems. The intervals were determined based on the experiences of SDT and NERC System Protection and Task Force members. Additionally, this standard is not focused only on avoiding regional disturbances or blackouts, but instead on overall Protection System reliability. See Supplementary Reference Document, Section 15.5 (page 23) and FAQ II-6-D (page 17).** **F. The SDT has modified the standard in consideration of your comments. The requirement to “equalize battery voltages” was removed from the revised standard.** **G. The SDT has modified the standard in consideration of your comments and all references to measuring “temperature” have been removed from the revised standard.**		
CenterPoint Energy	No	a. CenterPoint Energy believes the approach taken by the SDT is overly prescriptive and too complex to be practically implemented. The inflexible minimum “maintenance activities” approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. In particular, the loss of maintenance flexibility embodied in this approach would have perverse consequences for entities with redundant systems. Entities with redundant systems have less need for maintenance of individual components (due to redundancy) yet have twice the maintenance requirements under the minimum “maintenance activities” approach. For example, Table 1A calls for performing a specific gravity test on “each cell” of vented lead-acid batteries. CenterPoint Energy believes such a requirement is dubious for entities that do not have redundant batteries, and absurd for entities that do. CenterPoint Energy has installed redundant batteries in most locations and has had an excellent operating history with batteries by using a combination of internal resistance testing and specific gravity testing of a single “pilot cell”. This practice, combined with DC system alarming capability, has worked well. b. CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would “fix” non-existent problems. To clarify this last point, CenterPoint Energy is not asserting that maintenance problems do not exist. However,

Organization	Yes or No	Question 2 Comment
		requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability performance. c. Arguably, an entity could possibly return to its existing practices, if those practices are working well, by navigating through the complex set of options and supporting documentation that the SDT has crafted in this proposal. However, most entities have an army of substation technicians with various ranges of experience to perform maintenance on protection systems and other substation components. It is unrealistic to expect most entities making a good faith effort to comply with this proposal to have a full understanding throughout the entire organization of all the nuances crafted into this complex proposal. d. For the reasons outlined above, CenterPoint Energy does not agree with the proposal to specify minimum maintenance activities. However, if the majority of industry commenters agree with the SDT's proposal, CenterPoint Energy has concerns about some of the proposed tasks. For Protection System control circuitry (trip circuits), Table 1A calls for performing a complete functional trip test. The "Frequently-asked Questions" document states that this "may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip scheme". Such a requirement creates its own set of reliability risks, especially when monitoring already mitigates risks. CenterPoint Energy is concerned with this standard promoting an overall functional trip test for transmission protection systems. This type of testing can negatively impact reliability with the outages that are required and by exposing the electric system to incorrect tripping. CenterPoint Energy views overall functional trip testing as a commissioning task, not a preventive maintenance task. CenterPoint Energy performs such testing on new stations and whenever expansion or modification of existing stations dictates such testing. Overall, CenterPoint Energy recommends minimizing, to the extent possible, maintenance activities that disturb the protection system; that is, placing the protection system in an abnormal state in order to perform a test. e. For Protection System control circuitry (breaker trip coils only), Table 1A calls for verifying the continuity of the trip circuit every 3 months. CenterPoint Energy is not sure what would be the expected task to meet this requirement (it is not addressed in the "Frequently-asked Questions" document).

Response: The SDT thanks you for your comments.

a) The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. Regardless of the level of redundancy provided, all components addressed by this standard must be maintained in accordance with the requirements of the standard. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP. The SDT has modified the standard in consideration of your comments concerning performing a specific gravity test

Organization	Yes or No	Question 2 Comment
and the revised standard does not require a specific gravity test. **b)) The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The opportunities in R3 provide additional flexibilities for entities which desire them.** **c) For those entities which wish the least complex approach, a pure time-based program, using R1, R2, and R4, with Table 1a provides the simplest approach to meeting this standard.** **d) The SDT believes that functional trip testing is a key component of an effective PSMP.** **e) See the Supplemental Reference Document, Section 15.3 (page 22) for a discussion on this topic.**		
NextEra Energy Resources	No	a. Tables 1a, 1b & 1c should offer as an alternative, measuring battery float voltages and float currents in lieu of measuring specific gravities as described in Annex A4 of IEEE Std 450-2002. b. Inspection of CVT gaps, MOVs and gas tubes should be added to the communications equipment time based maintenance tables. Failure of the CVT protective devices may cause failure of the Protection System. c. Maintenance Activities for UVLS or UFLS station dc supplies shows “Verify proper voltage of dc supply”. Does this imply that, except for voltage readings of the dc supply, distribution battery banks are not maintained? d. Why does the Maintenance Activities for UVLS or UFLS relays state that verification does not require actual tripping of circuit breakers? e. Please clarify the Maintenance Activities for Voltage and Current Sensing Devices. Must voltage, current and their respective phase angles be measured at each discrete electromechanical relay? f. NextEra Energy concurs with other entities comments concerning this question: This entity believes the approach taken by the SDT is overly prescriptive and too complex to be practically implemented. The inflexible “minimum maintenance activities” approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. In particular, the loss of maintenance flexibility embodied in this approach would have perverse consequences for entities with redundant systems. Entities with redundant systems have less need for maintenance of individual components (due to redundancy) yet have twice the maintenance requirements under the “minimum maintenance activities” approach. For example, Table 1A calls for performing a specific gravity test on “each cell” of lead acid batteries. Our company believes such a requirement is dubious for entities that do not have redundant batteries, and absurd for entities that do. We have installed redundant batteries in most locations and have had an excellent operating history with batteries

It is unrealistic to expect most entities making a good faith effort to comply with this proposal to have a full understanding throughout the entire organization of all the nuances crafted into this complex proposal. For the reasons outlined above, we do not agree with the proposal to specify minimum maintenance activities. However, if the majority of industry commenters agree with the SDT's proposal, we have concerns about some of the proposed minimum tasks. For Protection System control circuitry (trip circuits), Table 1A calls for performing a complete functional trip test. The "Frequently-asked Questions" document states that this "may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip scheme". Such a requirement creates its own set of reliability risks, especially when monitoring already mitigates risks. We are concerned with this standard promoting an overall functional trip test for transmission Protection Systems. This type of testing can negatively impact reliability with the outages that are required and by exposing the electric system to incorrect tripping. Our company views overall functional trip testing as a commissioning task, not a preventive maintenance task. We perform such testing on new stations and whenever expansion or modification of existing stations dictates such testing.

Response: The SDT thanks you for your comments.

a. The SDT has modified the standard in consideration of your comments. All references to measuring specific gravities have been removed from the revised standard – and for Table 1a for station dc supply, the language was revised to require, "Verify float voltage of battery charger."

b. Power line carrier channels are made up of many components that must be maintained on a periodic basis. This standard indicates that adequate maintenance and testing must be done to keep the performance of the channel at a level that meets the requirements of the relay system. The determination of specific maintenance activities is the responsibility of the Entity.

c. This standard limits the maintenance requirements of distribution system batteries to those used for UVLS and UFLS and constrains those requirements to verification of proper voltage. If "distribution system" batteries are used for any other BES Protection System applications, they must

Organization	Yes or No	Question 2 Comment
be maintained according to the other requirements of this standard. **d. The SDT believes that the UFLS scheme is predominantly based within the distribution sector. As such, there are many circuit interrupting devices that will be operating for any given under-frequency event that require tripping for that event. A failure in the tripping-action of a single distribution breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in the standard.** **e. The requirement is that the proper voltage, current, and phase angle must be delivered to each respective relay. The standard does not prescribe methodology. See FAQ II-3-A (page 8) for further discussion.** **f. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. Regardless of the level of redundancy provided, all components addressed by this standard must be maintained in accordance with the requirements of the standard. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP. The SDT has modified the standard in consideration of your comments concerning specific gravity testing.**		
E.ON U.S.	No	1. Capacity or AC impedance only needs to be done to determine service life and therefore periodic testing of station DC supply does not seem necessary or prudent. 2. If a company checks overall battery bank voltages quarterly then periodic testing of the battery bank charger should not be required.
Response: The SDT thanks you for your comments. 1. **Capacity or Internal Ohmic testing must be periodically performed at the Maximum Maintenance Intervals in Table 1 to verify that a lead acid battery can perform as designed. Periodic testing to ensure that a battery can perform as designed is necessary to ensure that a battery is capable of being a dc source to the station dc loads when required. If a battery fails to perform as designed during test before its designed service life is reached it must be replaced regardless of how many years of service are left on its warranty or its engineered service life.** 2. **Proper functioning of the battery charger is critical to proper performance of the DC supply. The SDT has modified the standard to simplify the battery charger maintenance requirements.**		
City Utilities of Springfield, MO	No	1. CU has concern over the battery charger testing requirements. Per the charger manufacturers recommendations there is no reason to test the chargers as proposed in PRC-005-2. It is their opinion that the chargers are self diagnostic and do not require these tests (full load current and current limiting tests). The charger O&M manuals do not even provide instructions for such tests as optional. Therefore, CU takes exception to this requirement and suggests that battery chargers be maintained and tested in accordance with manufacturer's recommendations.

Organization	Yes or No	Question 2 Comment
		2. Additionally, CU is concerned with the wording in Table 1a concerning Protection system communication equipment and channels. We are unsure what the maintenance activity actually means. If this is an unmonitored system, how can you verify the condition of the communication system? Is the standard referring to local monitoring such as enunciators? Please provide clarification.
Response: The SDT thanks you for your comments. 1. **The SDT has modified the standard in consideration of your comments. If the battery charger is self diagnostic, it may qualify for Table 1b or Table 1c.** 2. **FAQ II-6-A (page 16) provides an extensive discussion about various methods to test communications systems.**		
Florida Municipal Power Agency, and its Member Cities	No	1. FMPA does not believe that maintenance of each UFLS / UFLS systems are as important as maintenance of BES protection systems. The fundamental reason is that delayed or uncleared faults on the BES can cause system “instability, uncontrolled separation, and cascading outages”; therefore, BES protection systems are very important; however, if a small percentage of UFLS / UVLS relays mis-operate as a result of a frequency or voltage event, the impact of the mis-operation is much smaller, if even measurable. As a result, FMPA believes that the emphasis of the maintenance activities ought to be placed on those systems that can have the most impact on what the standards are all about, as Section 215(a)(4) of the Federal Power Act says, “avoiding instability, uncontrolled separation, and cascading outages”. As a result, FMPA believes that full functional testing, while important for BES protection systems, is not necessary for UFLS and UVLS systems (Table 1a, page 6 and Table 1b, page 11). Because most UFLS / UVLS are on radial distribution feeders, such testing will cause outages to customers fed on radial distribution circuits and transmission lines without sufficient cause, in other words, the maintenance itself will reduce the reliability the customer experiences. In addition, distribution tripping circuits are more regularly exercised by distribution faults than are transmission tripping circuits; therefore, full functional testing of distribution tripping circuits is far less valuable than testing trip circuits of transmission elements which are exercised less frequently due to actual system events. 2. FMPA is confused with the wording of Table 1a, page 6, row 3 that talks about breaker trip coils. In the “Type of Component” column, the subject says “Breaker Trip Coils Only (except for UFLS or UVLS)”, yet the maintenance activity described states “Verify the continuity of the breaker trip circuit including trip coil”. These two statements are inconsistent because the first statement limits the applicability to just the trip coil and the second statement goes beyond the trip coil. And, FMPA believes the second statement should only apply to the trip coil, e.g., the second statement should say: “Verify the continuity of the trip coil”. In addition, the parenthetical is confusing, is it meant to say that the continuity of the trip coil only needs to be verified when the breaker operates during the 3 month interval, or that the intended continuity check is from the relay contacts through the trip coil, and not from the relay contacts back to the

Organization	Yes or No	Question 2 Comment
		batteries? 3. FMPA is also confused concerning station DC supply testing. There are multiple rows in Table 1a concerning various types of testing for various types of batteries and chargers that do not exclude UVLS and UFLS, yet on page 8, on the bottom row, the row is exclusive to UVLS and UFLS yet overlaps other rows discussing station DC supply testing. Is it intended that the other rows that are silent as to what they apply to exclude UVLS and UFLS? FMPA believes that should be the case. The same comment applies to Table 1b. 4. FMPA also has concern over the battery charger testing requirements. Per the charger manufacturers recommendations there is no reason to test the chargers as proposed in PRC-005-2. It is their opinion that the chargers are self diagnostic and do not require these tests (full load current and current limiting tests). The charger O&M manuals do not even provide instructions for such tests as optional. Therefore, FMPA takes exception to this requirement and suggests that battery chargers be maintained and tested in accordance with manufacturer's recommendations
Response: The SDT thanks you for your comments. **1. The SDT believes that UFLS and UVLS maintenance needs to be prescriptive for the following reasons:** **a. PRC-008-0 and PRC-011-0 today require maintenance of UFLS and UVLS equipment.** **b. FERC Order 693 directs NERC to develop maximum allowable intervals for UFLS and UVLS equipment, and recommends combining PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0.** **The objectives are not constrained to limiting "instability, uncontrolled separation, and cascading outages", but instead address overall Protection System reliability. The standard has, however, been modified to remove the requirement that the breakers actually be tripped for UFLS and UVLS functional trip testing.** **2. The SDT has modified the standard to remove the requirement cited in your comments.** **3. The SDT has modified the standard to clarify that the only DC Supply requirement relevant to UVLS and UFLS is to verify the DC supply voltage in consideration of your comments.** **4. The SDT has modified the standard in consideration of your comments. If the battery charger is self diagnostic, it may qualify for Table 1b or Table 1c.**		
Indiana Municipal Power Agency	No	IMPA does not agree with the battery charger testing requirements. Per the battery charger manual, the manufacturer sets the current limit at the factory, and it only needs to be adjusted if a lower current limit is desired. The manufacturer gives directions on how to lower the current limiter, and the directions seem to be for this purpose only (not for the sole purpose of performing a current limiter test). The manufacturer also

Organization	Yes or No	Question 2 Comment
		does not give directions on how to perform a full load current test and does not give any recommendation to the user that such test is needed. IMPA believes that both of these maintenance items are not needed to maintain the battery charger and that only the manufacturer's recommendations on maintenance and testing need to be followed.
Response: The SDT thanks you for your comments. The performance of the battery charger is critical to the performance of the protection system. The SDT has modified the standard to simplify the requirements related to maintenance of the battery charger.		
FirstEnergy	No	In general we agree with the maintenance activities, except for the specific gravity and temperature testing included in the "Station dc Supply (that has as a component any type of battery)" of the tables 1a and 1b. We only perform this testing at nuclear facilities for insurance requirements. In transmission substation applications it has been eliminated due to the variability of results due to recharging/equalizing, water addition, temperature correction requirements, etc. In the Supplementary reference, section 15.4 Batteries and DC Supplies, third paragraph, the SDT indicates these tests are recommended in IEEE 450-2002 to ensure that there are no open circuits in the battery string. This is essentially a continuity check of the battery string. In the fourth paragraph, the SDT states that "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards."The SDT in Table 1a, the Maintenance Activity "Verify continuity and cell integrity of the entire battery", and in Table 1b, the Maintenance Activity "Verify electrical continuity of the entire battery". Based on the information in the Supplementary reference, the owner has to choose a method to verify continuity and the measurement of specific gravity and cell temperatures could be the selected method, however it should not be a required maintenance activity as shown in Tables 1a and 1b.
Response: The SDT thanks you for your comments and has modified the standard in consideration of your comments. All references to specific gravity and temperature testing have been removed from the revised standard.		
Ohio Valley Electric Corp.	No	1. In general, all maintenance activities that are verifications of proper function imply that problems found must be resolved within the maximum interval. For some activities, that is an unreasonable expectation. A temporary resolution may reliably correct an adverse situation but may not address the original verification requirement within the maximum interval. 2. Routine substation inspections should not fall under NERC standards. The documentation for quarterly inspections would be oppressive. It is unreasonable to require there to be no DC grounds. All DC grounds do not rise to the level of a reliability concern. In some cases, attempting to resolve a relatively minor DC problem may rise to the level of negatively affecting reliability. 3. The value of capacity testing battery banks and chargers in the context of a protection system reliability

Organization	Yes or No	Question 2 Comment
		standard is questionable.
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard to clarify that corrective actions must be initiated, but intentionally does not identify when they need to be completed, largely for the reasons you cite. See FAQ II-2-I (page 7) for a discussion on this.** **2. The SDT believes that certain verification activities must be performed on a periodic basis via visual inspection. The standard and Frequently Asked Questions document (See FAQ II-5-I, page 15) have been modified in consideration of your comment concerning locating and removal of a dc ground. References to dc grounds have been revised to "unintentional dc grounds."** **3. The SDT believes that the ability of the battery to provide required tripping current is CRITICAL to the reliability of the Protection System; else, the Protection System is unable to react properly when required. Similarly, the SDT believes that the ability of the charger to properly charge the battery is critical to sustain the battery capability.**		
AEP	No	In the process of performing maintenance, some protection systems may need to be taken out of service on in-service equipment (bus differential protection for example) where redundant protection systems do not exist. This action seems counter to NERC recommendations, presenting a scenario for expanding outages during a simultaneous fault. Would the implementation plan include time for the additions of redundant protection systems? Comments expanded in question 10 response.
Response: The SDT thanks you for your comments. To minimize system impact of maintenance, the maintenance necessarily should be scheduled at a time that minimizes the risks. The implementation plan addresses the development of acceptable PSMPs.		
RRI Energy	No	1. It is recommended to change the wording of the Maintenance Activities to the activity itself, not the resolved state of the maintenance correctable issue (i.e. "For microprocessor relay, check for proper operation of the A/D converters" instead of "For microprocessor relays, verify proper functioning of the A/D converters"). The wording of the standard effectively sets the end date for the correction of maintenance identified issues. In other words, maintenance has not taken place until all maintenance correctible issues have been completely resolved. The wording in the standard have set non-compliance "traps" for those performing the maintenance but have not completed correctable issues for legitimate reasons which may not be allowed by the no-exception approach of the standard. For example, rewording of the Battery Supply 3 month activities are recommended as follows: "Check for proper electrolyte level. Check for proper voltage. Check for dc supply grounds." As inspection activities, any issue not corrected during the interval should become a maintenance correctible issue. For generating stations, the judgments to locate and remove a ground are based upon criteria not accounted for in the requirements of this standard. An activity to locate and clear a ground requires the judgment of station maintenance and operational management depending upon the operating conditions of the unit and the level of the ground (solid or high-resistance).Inspections (3 month requirement

Organization	Yes or No	Question 2 Comment
		activities) although good practices, should not be standard requirements. 2. The practice of verifying the continuity of breaker trip circuits does not belong as an auditable NERC standard requirement; it becomes more of a documentation requirement rather than a reliability improvement. Otherwise, it will ultimately require the expending of resources in an unproductive manner primarily on the development, storage, and production of excessive records for compliance purposes. The elimination of this requirement is recommended. 3. For Table 1a Protection System Control Circuitry - rewording is suggested as follows: "Perform functional trip tests of Protection System trip circuits, including auxiliary relays essential to the proper functioning of the Protection System." The requirement, as presently worded "that includes all sections of the Protection System," is overly prescriptive and will create non-compliances for miniscule oversights, given the very large scope of components in protection systems that are spread out far and wide in a system. The requirement opens the door, allowing the compliance process itself to be punitive in nature. When pursued to the extreme under audit conditions, this requirement will be very difficult to demonstrate on a large scale. 4. For Table 1a Station dc supply: The ability of a battery charger to correctly supply equalize voltage to a battery has no direct correlation to reliability of the BES and does not belong in this standard. The objective is that the battery get an equalize charge when it needs it, not the maintenance of the equalize function of a battery charger. How the battery gets equalized is not important to this standard, especially since a battery and the equalize source are usually disconnected from the protection system during the process. 5. For Table 1a Station dc supply: The use of the term "in tolerance," for the measurement of specific gravity, is an inconsistency in stating the standard requirements. There are multiple activities that will necessitate the measurement of a quantity "in tolerance" whether it is battery charger output, individual cell voltages, connection resistances, or internal ohmic values. The suggested rewording is as follows: "Measure the specific gravity and temperature of each cell." 6. For Table 1a Station dc supply: Referring to the requirement to "verify that the station battery can perform as designed" very little of a generating station battery sizing is related to BES protection. Verification of a generating station to design conditions is outside the scope of BES protection and does not belong in this standard. Nearly all protection system operations operate without reliance upon the battery to do so, and the separation of the generating unit from the BES will take place within cycles, if called upon to do so. The remainder of the battery duty cycle is outside the scope of BES protection.

Response: The SDT thanks you for your comments.

The station dc supply 3 month activities section of table 1a has been reworded in consideration of your comment as shown below:

Check:

Organization	Yes or No	Question 2 Comment
• Electrolyte level (excluding valve-regulated lead acid batteries) • Station dc supply voltage • For unintentional grounds **1. Also FAQ II-5-I (page 15) has been modified in consideration of your comment concerning location and removal of dc grounds on a generating station. The following was added to the FAQs:** In most cases, the first ground that appears on a battery pole is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised to demonstrate that a check is routinely done for Unintentional DC Grounds. **Additionally, the Maintenance Activities in Table 1a, Table 1b, and Table 1c have been generally revised as you suggest, to present the activity rather that the resolved state.** **2. The SDT has modified the standard to clarify that this requirement is actually monitoring the trip coil. The SDT believes that verification of breaker trip coil continuity is a vital component of the Protection System performance, and that they must be maintained as specified in the Standard.** **3. The SDT believes that proper functioning of all trip circuit paths is a vital component of the Protection System performance, and that they must be maintained as specified in the Standard.** **4. The SDT has modified the standard in consideration of your comment and the requirement to equalize voltages has been removed from the revised standard** **5. The SDT has modified the standard in consideration of your comment and the comments from others, the reference to measuring specific gravity and temperature has been removed** **6. Thank you for your comments concerning verification that the station battery can perform as designed. Although the SDT agrees with you that very little of a generation station battery sizing is related to BES protection, the majority of a generation station battery duty cycle is for safely operating the station when the other elements of a station dc supply are unavailable and that some Protection System operations can operate using the other elements of the station dc supply besides the station battery. The SDT believes that the station dc supply is such an integral part of the Protection System of a generating station that, at a minimum, it must be maintained using the Maintenance Activities and Maximum Maintenance Intervals of Table 1. It is important to note that the station battery must still be able to perform its vital Protection System functions even if it is simultaneously supplying dc for its myriad of other applications. The required activities include "verify that the station battery can perform as designed."**		
Indianapolis Power & Light Co.	No	1. Many preventive maintenance programs have testing tolerances which are tighter than the manufacturer's tolerances. This practice is used to force an action prior to falling outside of the manufacture's tolerances and

Organization	Yes or No	Question 2 Comment
		accounts for slight variations in test equipment and environment. Maintenance correctable issues should not be reportable unless the test failure falls outside of the manufacturer's published tolerances. 2. In tables 1a through 1c the "Type of Component" columns in each table do not have consistent listings from one 1a to 1b to 1c. The type of component should be identified consistently in each table. By doing so this would eliminate confusion in moving from one table to the other. 3. The maintenance activities for some types of components specifies how (i.e. Test and calibrate the relays. with simulated electrical inputs) while other maintenance activities do not specify how. The maintenance activities should either all be specific or all be generic. 4. For Station dc Supply (that has as a component any type of battery) the maintenance activity of "verify that no dc supply grounds are present" there is a problem of tolerance. It is impossible to have "no dc supply grounds present". There has to be some tolerance given here such as a voltage measurement from each battery terminal to ground +- 15 volts of nominal for example. 5. For the type of component of "Protection System Control Circuitry (trip circuits) (UFLS/UVLS Systems only), the maintenance activity requires a complete functional trip test" of the Protection System. This suggests that a breaker trip test is required at each maintenance interval. This requires tripping breakers that supply customers. It is impossible to trip each individual distribution feeder without forcing an outage on some customers as when there are no other usable circuits to tie the load off to. A failure to trip of a single distribution circuit in the overall scheme of a UVLS or UFLS scheme would have little effect on the BES. Trip testing BES breakers and verifying correct operation of breaker auxiliary contacts could become very difficult to accomplish since opening a breaker on a line might adversely affect the BES. ISOs may prohibit such an activity at any time. Allowances should be made for BES circuit breakers that can not be operated for such reasons if documented sufficiently.

Response: The SDT thanks you for your comments.

1. **The tolerances, per Note 1 to Table 1a, Table 1b, and Table 1c, are defined by the entity according to their application considerations as related to the component. The standard has been revised to exclude minor issues that can be corrected during the on-site maintenance activities from "maintenance correctible issues".**
2. **The variations in the "Type of Component" are a result of the varying maintenance activities that are necessary as there are higher levels of component monitoring. If the "Type of Component" was made consistent among all three tables, there would be additional confusion, because many of the "Types of Component" in Tables 1b and 1c would indicate that no maintenance activities are required.**
3. **Generic activity descriptions have been used except where specific activities are necessary.**
4. **The standard and Frequently Asked Questions document (See FAQ II-5-I, page 15) have been modified in consideration of your comment regarding**

Organization	Yes or No	Question 2 Comment
dc grounds. References to dc grounds have been revised to "unintentional dc grounds." **5. We agree. The minimum activities have been revised in the standard to not require tripping of the breakers for this table entry.**		
Platte River Power Authority Maintenance Group	No	Minimum maintenance activities should be based on categorization of relays and defined maintenance actions system by system using historical and definitively known data entity by entity. By establishing specific minimum maintenance activities you risk entities changing currently effective maintenance programs to programs that match minimum maintenance activities to meet requirements in the standard which could be less effective for their system.
Response: The SDT thanks you for your comments. As for including some activities and excluding others, the listed activities are contemplated as minimum activities and do not preclude an entity from performing additional activities. Your use of historical and definitively known data may be applicable to a Performance-Based maintenance program (R3) for some of your activities.		
PacifiCorp	No	No comment.
Duke Energy	No	Our comments are limited to activities in Table 1a. 1. " Protective Relays " okay 2. " Voltage and Current Sensing Devices Inputs to Protective Relays " Proper functioning should be verified at commissioning, and then anytime thereafter if changes are made in a PT or CT circuit. Additional periodic checks may be warranted as suggested in Table 1A; however no additional checking should be required where circuit configuration will inherently detect problems with a PT or CT. For example, PTs & CTs that are monitored through EMS or microprocessor relays will be alarmed when they are out of specification. 3. "Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) "Need more clarity on exactly what this activity is expected to include. In some cases we have a red light on a control panel monitoring the circuit path to the trip coil. In locations where there is not a red light, verifying the continuity of the breaker trip circuit including the trip coil will be complicated. There is no straightforward way to do it without potentially impacting reliability, and we would have to consider modifying these installations to include a red light. 4." Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) "Need more clarity on exactly what the activity is. We believe testing one output all the way to the coil is sufficient to prove the trip path. The activity states that "all auxiliary contacts" must be tested. We propose that all protection control circuitry should be tested at initial commissioning, and then again if any changes are made. Ongoing routine testing is complicated and could pose reliability challenges to the BES. As stated on page 8 of the System Maintenance Supplementary Reference document: "Excessive maintenance can actually decrease the

Organization	Yes or No	Question 2 Comment
		reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical over current relays, test currents have been known to destroy convolution springs. In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures. 5." Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only) Need additional clarity on exactly what the test includes. "Complete functional trip test" should not include tripping the breaker. Proving the output of the relay should be sufficient. Systems that have all load shed on distribution circuits should require that trip output be confirmed but should not be required through to the trip coil due to constraints in tying distribution load. 6. Station dc supply (that has as a component any type of battery) Under the 3 month interval activities, we disagree with the wording of the activity Verify that no dc supply grounds are present. The activity should instead read "Check for dc supply grounds and if any are found, initiate action to repair. 7. Station dc supply (that has as a component any type of battery) Under the 18 month interval activities, what is meant by "Verify continuity and cell integrity of the entire battery"? Also what is required to "Inspect the structural integrity of the battery rack"? The "Supplementary Reference Document" and "Frequently asked Questions" document should be made part of the standard to provide clarity to the requirements. 8. Station dc supply (that has as a component Valve Regulated Lead-Acid batteries) Need more clarity on exactly what is required for a "performance or service capacity test of the entire battery bank". The "Supplementary Reference Document" and "Frequently asked Questions" document should be made part of the standard to provide clarity to the requirement. 9. Station dc supply (that has as a component Vented Lead-Acid batteries) Need more clarity on exactly what is required for a "performance, service, or modified performance capacity test of the entire battery bank". The "Supplementary Reference Document" and "Frequently asked Questions" document should be made part of the standard to provide clarity to the requirement. 10." Protection system communication equipment and channels Need additional clarity on exactly what is required for the substation inspection. What is required for power-line carrier systems? 11. UVLS and UFLS relays that comprise a protection scheme distributed over the power system Need more clarity regarding the meaning of "distributed over the power system".
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 2 Comment
1. Thank you. **2. Your example describes attributes applicable to Table 1c, and which would not require periodic maintenance. If monitoring, as you've described, is not present, periodic verification is necessary as described in Table 1a.** **3. You are correct. This area of each of the Tables has been extensively revised in response to comments. FAQ II-4-C (page 10) explains that this "may be via targeted maintenance activities or by documented operation of these devices for other purposes such as fault clearing" and Section 15.3 of the Supplementary Reference (page 22) provides discussion on this.** **4. If only one path is tested, this provides no assurance that other paths will perform properly. The cited reference on Page 8 of the Supplementary Reference Document is focused on effective maintenance intervals, not on performing maintenances. There are methods of performing functional testing without injecting damaging test currents.** **5. The requirement has been modified to provide more clarity, and has been modified to remove the requirement to actually trip the breaker.** **6. The SDT has modified the standard in consideration of your comment – it now reads, "Check for unintentional grounds."** **7. The SDT has modified the standard in consideration of your comment on cell integrity of the entire battery. Also, the Protection System Maintenance Frequently Asked Questions document (FAQ II-5-H, page 15) that accompanied the standard for this comment period addresses your question about the battery rack in Station dc Supply section. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.** **8. Methodologies regarding performance and service capacity tests for VLRA batteries are explained in detail in various available references. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.** **9. Your comment is in the nature of a "how to", not a requirement, and therefore the SDT believes it belongs in the supporting discussion. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.** **10. FAQ II-6-A (page 16) presents a variety of methods to maintain Protection System communication equipment.** **11. This refers to the common practice of applying UFLS on the distribution system, with each UFLS individually tripping a relatively low value of load. Therefore, the program is implemented via a large number of relays, and the failure of any individual relay to perform properly will have a minimal effect on the effectiveness of the UFLS program. There are some UVLS systems that are applied similarly.**		
Progress Energy	No	Progress Energy does not agree with the activity "Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit." We are unclear how this test should be performed.
Response: The SDT thanks you for your comments. The SDT has modified the standard in consideration of your comment. The component description was changed to: Station dc supply (which do not use a station battery) And the maintenance activity was changed to: Verify that the dc		

Organization	Yes or No	Question 2 Comment
supply can perform as designed when the ac power from the grid is not present.		
Xcel Energy	No	Regarding battery chargers, does the SDT propose that OEM-type tests be performed to validate the rated full current output and current limiting capabilities? It has been proposed that simply turning off the charger and allowing the batteries to drain for a period of several hours, then returning the charger to service will validate these items. It is not clear that an auditor would come to the same conclusion, since it appears open to interpretation. Please modify to make this clear. If an entity has an over-sized battery charger, they can (and should) only test to the max capacity of the battery bank. Suggest changing “full rated current” to “designed charging rate”.
Response: The SDT thanks you for your comments. The SDT has modified the standard in consideration of your comment. The component description was changed to: Station dc supply (which do not use a station battery) **And the maintenance activity was changed to:** Verify that the dc supply can perform as designed when the ac power from the grid is not present.		
Austin Energy	No	See item # 10 Comments
Response: See #10 Response		
Otter Tail Power	No	Station DC supply - (Maintenance Activity) As a company we do not think that measuring specific gravity and temperature of each cell is necessary. There is a better test that we use with the Bite Impedance Test. We have had good success with the impedance test for determining the batteries condition. See article (Impedance Testing Is The Coming Thing For Substation Battery Maintenance)written in Transmission & Distribution 11/1991 by Richard Kelleher, Test & Maintenance Specialist, Northeast Utilities.
Response: The SDT thanks you for your comments regarding DC supply. Changes have been made to the standard in consideration of your comments. The requirement to measure specific gravity and temperature of each cell has been deleted.		
Detroit Edison	No	1. Suggest that under “Maintenance Activities” for “Protective Relays” add the following: Verify proper functioning of the microprocessor relay external logic inputs (carrier block, etc.) 2. We recommend not requiring specific gravity and temperature readings for batteries. We have found from experience that the time and difficulty to obtain specific gravity readings are not justified. We have found that utilizing visual inspections, voltage and internal/intercell resistance readings gives a good picture of the health of the battery. We use specific gravity readings on occasion for troubleshooting purposes. 3. It is recommended that the sections about verifying battery charger performance be eliminated if there are low voltage alarms that go to a monitored location.

Organization	Yes or No	Question 2 Comment
		4. We recommend changing the maximum maintenance interval for DC supplies with no battery from 18 months to 3 years. If there is no battery, you do not have the risk of failure of chemical processes and such that would require an interval as short as 18 months.
Response: Thank you for your comments 1. **The SDT has modified the standard in consideration of your comment. The revised activity reads as follows:** For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System 2. **Thank you for your comments regarding DC supply. The SDT has modified the standard in consideration of your comment. The requirement to measure specific gravity and temperature of each cell has been deleted.** 3. **Changes have been made to the standard in consideration of your comments regarding verifying battery charger performance. The only requirement relative to battery chargers in the latest draft of the standard (see Table 1a, pg 14) is to verify the float voltage.** 4. **The SDT disagrees; the 18-month interval includes several items that can be verified only by physical inspection; that are independent of chemical processes, and that affect the ability of the dc supply to perform properly.**		
SCE&G	No	1. Table 1a Level 1 Monitoring has a requirement to “Verify the continuity of the breaker trip circuit including trip coil” at least every 3 months. This is interpreted to be applicable to both the low-side generator output breaker and the high-side breaker for the GSU. The generator output breaker has 3 separate trip coils (one for each pole) that are connected in a parallel configuration and there is no means available to verify continuity of each of these coils INDIVIDUALLY in this arrangement. Is the intent of this requirement to have each trip signal parallel leg verified every three months even though the trip contacts are normally open (these circuits are functionally checked during LOR Functional Verification)? 2. Also, is the Red Indication Light (RIL), which includes the trip coil in the power circuit, adequate for verification (note that the breaker does not include the parallel legs that contain the tripping sensor contacts)? 3. Also, more clarification is needed on the section “Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays” under “Voltage and Current Sensing Devices Inputs to Protective Relays.” How would this be done if no redundancy is available for cross-checking voltage and current sources? 4. In certain situations, “verify proper functioning” is not clear enough. Documentation of verification consistent with the entities procedures should be adequate to indicate compliance.
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard to remove the requirement cited in your comment.**		

Organization	Yes or No	Question 2 Comment
2. The SDT has modified the standard to remove the requirement cited in your comment. **3. The Supplementary Reference Document, Section 15.2 (page 21) and FAQ II-3 (page 8) provides several discussions on this item.** **4. Documentation of verification consistent with your procedures is sufficient to "verify proper functioning"**		
Dynegy	No	Table 1a requires entities to "verify the continuity of the breaker trip circuit including trip coil..." The term "verify" needs clarification. For example, we believe verifying red and green" lights during routine inspection should be sufficient. On the other hand, actual testing is not feasible and is risky to reliability.
Response: The SDT thanks you for your comment, and has modified the standard to remove the requirement cited in your comment.		
Nebraska Public Power District	No	1. Table 1a, for Protective Relays identifies the following Maintenance Activities: Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. Verify proper functioning of the relay trip outputs. What is the difference between these two requirements? They appear to be practically equivalent. 2. Tables 1a & 1b, for Station DC supply identify the following Maintenance Activity: Measure that specific gravity and temperature of each cell is within tolerance (where applicable). What is the advantage of testing the SG in every cell compared to using a pilot cell as representative sample of the entire bank? NPPD has not experienced any problems using a pilot cell compared to testing every individual cell. Typically, if the SG is low the cell voltage will be low, which is detected by the voltage test. This seems to be an excessive requirement and does increase personnel exposure to hazardous fluid. What unique information is provided by this test that other tests do not provide?
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard in consideration of your comment. The activity to "verify proper functioning of the relay trip outputs was changed to:** Verify that settings are as specified. **2. The SDT thanks you for your comments regarding DC supply and has made changes to the standard in consideration of your comments. The requirement to measure specific gravity and temperature of each cell has been deleted.**		
ENOSERV	No	1. Table 1A, protective relays for 6 calendar years, Testing and calibrating the relays other than microprocessors relays with simulated electrical inputs... does that mean that micro processor relays do not need to be checked? 2. Verify proper function of the relay trip outputs... Does this involve both electro AND micro processors? Then when mentioning the verifying microprocessor relays, does that include the trip output.

Organization	Yes or No	Question 2 Comment
Response: The SDT thanks you for your comments. **1. Yes. The SDT has modified the standard for clarity. The maintenance activities for microprocessor relays were changed to read as follows:** For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System. For microprocessor relays, verify acceptable measurement of power system input values. **2. Yes. The SDT has modified the standard for clarity. The language for microprocessor relays was changed as noted in response to your first comment; the following modification addresses all protective relays:** Verify that settings are as specified.		
Southern Company	No	1. Tables 1a and 1b require entities to verify the proper operation of voltage and current inputs to sensing devices on a 12 year interval. The Protection System Supplementary Reference (Draft 1), in section 15.2, describes several methods that may be used for such verification efforts. In order to perform this type of verification the circuit in question would need to be in operation. This verification introduces a possible unit trip due to the need to connect test equipment to live potential and current circuits at each relay, which has the potential to trip the circuit under test. This could result in the loss of critical transmission lines or generating units. The System Maintenance Supplementary Reference also allows saturation tests or circuit commissioning tests to satisfy this requirement; however, these types of tests require the circuit in question to be removed from service. For generating plants, removing the circuit from service requires that the station be shut down. We do not feel that the value obtained from this requirement is equal to the risk or maintenance burden associated with it. Such testing and verification should not be required periodically, but only if new instrument transformers, cabling or protective devices are installed or if the instrument transformers are replaced. 2. Table 1b: Protection System Control Circuitry (Trip Coils and Auxiliary Relays) " Experience has shown that electrically operating partially monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend eliminating this maintenance requirement. 3. Protection System Control Circuitry (Trip Circuits) (UFLS or UVLS Systems Only) - Table 1b includes the statement "Verification does not require actual tripping of circuit breakers or interrupting devices." This statement should be included in Table 1a. 4. In Table 1a "Station DC Supply (that has as a component any type of battery), we recommend changing the maximum maintenance interval from 3 months to 6 months as described below. 5. "Verify Proper Electrolyte Level "3 Months - The 3 months interval for verifying proper electrolyte level is excessive for current battery designs that are properly maintained. The interval in which the electrolyte must be replenished is affected by many factors. These include temperature, float voltage, grid material, age of the

Organization	Yes or No	Question 2 Comment
		battery, flame arrester design, frequency of equalization, and electrolyte volume in the battery jar. Manufacturers are aware that their customers want to extend the interval in which their batteries require water and this has lead to jar designs that have a wide min-max band with a high volume of electrolyte to allow for extended watering intervals. Understanding all the factors and proper maintenance will extend watering intervals. A battery should go a year or more between watering intervals and some as many as 3 years. Being conservative the Southern Company Substation Maintenance Standards require that we check the electrolyte level twice yearly. Experience has shown this has worked well. We propose that the "3 Months" interval be changed to "6 months". 6."Verify proper voltage of the station battery "3 Months - Being conservative, the Southern Company Substation Maintenance Standards require that we check the station battery voltage twice yearly. Experience has shown this has worked well. We propose that the "3 Months" interval be changed to "6 months". 7." Verify that no dc supply grounds are present "3 Months Being conservative, the Southern Company Substation Maintenance Standards require that we check for dc supply grounds twice yearly. Experience has shown this has worked well. We propose that the "3 Months" interval be changed to "6 months". 8. Measurement of Specific Gravity 18 Months- The measurement of specific gravity and temperature every 18 months is not necessary as a regular part of maintenance. Specific gravity can provide information as to the health of a cell; however, taking specific gravity readings is a messy process no matter how careful you are and will result in acid being dripped on top of the battery jars as the hydrometer is moved from cell to cell. Should a drop of acid end up on an external connection, it will result in corrosion and problems later. Voltage reading of cells can be substituted for specific gravity readings under normal conditions. Specific gravity is equal to the cell voltage minus 0.85. A cell with low voltage will have a low specific gravity. If cell voltage becomes a problem that cannot be addressed through equalization then specific gravity readings are justified as a follow-up test. Since measurement of specific gravity could lead to problems and reading cell voltage is a viable alternative, we propose that it be removed from the battery maintenance activities. 9. Verify Cell to Cell and Terminal Connection Resistance 18 Months - Clarification is needed on the expected method for verifying cell to cell and terminal connection resistance. This could easily be interpreted as requiring the use of an ohmic value (impedance/conductive/resistance) test device. If this is the case then basically it eliminates the need for the activity to "Verify that the substation battery can perform as designed by performing a capacity test every 6-Calendar Years or performing an ohmic value test every 18 Months", because the practical thing to do is go ahead and perform the ohmic value test while you have your device connected to the battery. 10. In table 1a and 1 b - Station dc supply (that has as a component -Vented Lead-Acid batteries). Verify that the Substation Battery can Perform as Designed 6 Calendar Years/18 Months - Southern Company Transmission has approximately 570 batteries that are covered by this proposed standard. These batteries currently have ohmic value testing performed every "4 Years" as required by the Southern Company

Organization	Yes or No	Question 2 Comment
		Substation Maintenance Standards. The "4 Years" interval has been utilized for over 10 years and has not experienced a failure of any of the 570 batteries to perform as designed Having to perform ohmic value testing on an "18 Months" interval will significantly increase our costs and manpower requirements with no anticipated improvement in reliability. We propose that the "18 Months" interval for ohmic value testing be changed to "4 Calendar Years". This proposal also applies to verifying cell to cell and terminal connection resistance if an ohmic value test device is required as discussed above. 11. In table 1a and 1b Station dc supply (that uses a battery and charger). Verify that the Battery Charger can Perform as Designed 6 Calendar Years - Clarification is needed on an acceptable method for verifying that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current limit, especially the part about "will properly current limit". 12. On Table 1b Station DC Supply (that has a component any type of battery) we recommend changing the maximum maintenance interval from 3 months to 6 months as described below " Verify Proper Electrolyte Level " 3 Months - The 3 months interval for verifying proper electrolyte level is excessive for current battery designs that are properly maintained. The interval in which the electrolyte must be replenished is affected by many factors. These include temperature, float voltage, grid material, age of the battery, flame arrester design, frequency of equalization, and electrolyte volume in the battery jar. Manufacturers are aware that their customers want to extend the interval in which their batteries require water and this has lead to jar designs that have a wide min-max band with a high volume of electrolyte to allow for extended watering intervals. Understanding all the factors and proper maintenance will extend watering intervals. A battery should go a year or more between watering intervals and some as many as 3 years. Being conservative the Southern Company Substation Maintenance Standards require that we check the electrolyte level twice yearly. Experience has shown this has worked well. We propose that the "3 Months" interval be changed to "6 months". 13. We recommend removing the "Detection and alarming of dc grounds" monitoring attribute. Note that this applies to every "Station dc supply" section where it is listed. .Experience has shown that there have been no significant problems discovered via alarms that would not have been discovered by 6 month inspection cycles. We propose to add "verify no dc grounds are present" as a maintenance activity on a 6 months inspection cycle. Experience has shown that there have been no significant problems discovered via alarms that would not have been discovered by 6 month inspection cycles. 14. Table 1a, p. 7, Station dc supply, 3 month interval: need to add "unintentional" to the sentence "Verify that no dc supply grounds are present." Because most dc systems have ground detection systems which place an intentional ground on the battery. "No grounds" is not practical and is unacceptable since most dc systems have some high resistance ground paths. Some criteria should be established to determine the acceptable ground resistance on a dc system. 15. Table 1a, p. 8: For the vented, lead-acid battery, there is no basis for the 18 month activity option

Organization	Yes or No	Question 2 Comment
		(internal ohmic value measurement) in place of the 6 year performance test. 16. The activities for trip checks for Level 1A and Level 1B should be the same. Currently, they read: Level 1a: Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System. Level 1b: Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval. The Level 1a text is adequate for 1b also. 17. Table 1c, p 16: Monitoring of single or parallel trip circuits is not practical where multiple normally open contacts are in series to trip. Monitoring of the trip coils is practical and useful. How would one monitor several normally open contacts which are in series to trip a breaker? 18. Table 1c, p. 15, 16, 19: The use of "continuous" under "Maximum Maintenance Interval" in Table 1c should be changed to "N/A" and the Maintenance Activity should be "NONE". 19. Verification of the various monitoring (automated notification) systems is not specified anywhere in the requirements. This, too, should be required.

Response: The SDT thanks you for your comments.

1. The SDT believes that proper functioning of the sensing devices is a vital component of the Protection System performance, and that they must be maintained as specified in the Standard. To minimize system impact of such maintenance and possible errors, the maintenance necessarily should be scheduled at a time that minimizes the risks.

2. The SDT believes that proper functioning of the Protection System Control Circuitry is a vital component of the Protection System performance and those must be maintained as specified in the standard. To minimize system impact of such maintenance and possible errors, the maintenance necessarily should be scheduled at a time that minimizes the risks

3. The SDT has modified the standard in consideration of your comment. The following was added to Table 1a:

> **Type of Component -** Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only)
>
> **Maximum Maintenance Interval -** 6 Calendar Years
>
> **Maintenance Activity -** Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except .that verification does not require actual tripping of circuit breakers or interrupting devices.

4. Please see responses 5, 6 and 7 (below) for discussion regarding your concern about extending the Maximum Maintenance Intervals for an extra 3 months on activities related the station dc supply.

5. The SDT agrees that a healthy modern lead acid battery can go for extended periods of time beyond 3 months without requiring watering. However, checking cell electrolyte level not only indicates the need for battery watering, it is an indication of an individual cell's health and needs to remain at

Organization	Yes or No	Question 2 Comment

the Maximum Maintenance Interval of 3 months. To avoid the confusion that the Maintenance Activity listed in Table 1 was to water the battery at the specified 3 month interval, the Drafting Team has changed the wording of the Maintenance Activity from "verify proper" to "check" electrolyte level.

6. Thank you for your comment to extend the Maximum Maintenance Interval for checking the station dc supply voltage. The SDT believes that extending the Maximum Maintenance Interval beyond that listed in Table 1 would compromise the performance of the station dc supply.

7. Due to the consequences of unintentional grounds to the station dc control system, the SDT feels that extension of the Maintenance Intervals beyond the 3 month interval is not prudent. See FAQ IV-2-F (Page 23).

8. Changes have been made to the standard in consideration of your comments regarding specific gravity testing, and the revised standard does not include a requirement to perform this maintenance activity.

9. Thank you for your comments concerning performance of ohmic measurement at the same time that connection resistance is measured. As you suggested, these two measurements could be taken at the same time to meet the requirements of their respective Maintenance Activities.

10. Thank you for your comments concerning evaluating internal ohmic values and measurement of battery connection resistance for Vented Lead-Acid (VLA) batteries. As noted in your comment an owner has two different Maintenance Activities with associated different Maximum Maintenance Intervals to choose from in verifying that the VLA station battery can perform as designed.

FAQ II-5-F (page 14) and II-5-G (page 14) provides an explanation of why there are two different intervals for these Maintenance Activities is given. Because trending is an important element of ohmic measurement evaluation, the SDT believes that extending the Maximum Maintenance Interval listed in Table 1 for evaluating internal ohmic values to four years as suggested would not provide the necessary information for proper evaluation of the ability of the station battery to perform as designed.

Concerning verifying cell to cell and terminal connection resistance as part of inspecting the battery, various technical references on Lead-Acid battery maintenance talk about how and why this Maintenance Activity should be performed at the Maximum Maintenance Interval listed in Table 1. The SDT believes that to extend this inspection activity for the connections of a Lead-Acid battery beyond the Maximum Maintenance Interval would compromise the performance of the station dc supply.

11. The SDT has modified the standard in consideration of your comment regarding battery charger performance. The only remaining maintenance activity relevant to the battery charger is to verify the float voltage.

12. The SDT agrees that a healthy modern lead acid battery can go for extended periods of time beyond 3 months without requiring watering. However, checking cell electrolyte level not only indicates the need for battery watering, it is an indication of an individual cell's health and needs to remain at the Maximum Maintenance Interval of 3 months. To avoid the confusion that the Maintenance Activity listed in table 1 was to water the battery at the specified 3 month interval, the Drafting Team has changed the wording of the Maintenance Activity from "verify proper" to "check" electrolyte level.

13. Thank you for your comments concerning the monitoring attribute for unintentional dc grounds on the station dc supply. Due to the consequences of unintentional grounds to the station dc control system (see FAQ II-5-I, page 15), the SDT feels that monitoring for them is an important part of an effective condition based maintenance program and should be an option available for those who want to perform condition based maintenance. Also because the threat to the dc system and the BES that unintentional dc grounds create, the SDT feels that extension of the Maintenance Intervals for

Organization	Yes or No	Question 2 Comment
checking for unintentional dc grounds beyond the 3 month interval is not prudent. See FAQ IV-2-F (page 23). **14. The SDT has modified the standard in consideration of your comment regarding dc grounds – the word, "unintentional" was added as proposed.** **15. The SDT thanks you for your comment concerning ohmic value measurements. The FAQ II-5-F (page14) includes an explanation for the basis of this activity. The SDT believes that this Maintenance Activity is a viable alternative that a Vented Lead-Acid battery owner can perform at the Maximum Maintenance Interval of Table 1 in place of conducting a performance, modified performance or service capacity test.** **16. For Table 1b, much of the DC control circuit is, by definition, being monitored; therefore, the only requirement is that the electromechanical devices be exercised.** **17. With the detail provided in your comment, it appears to the SDT that you would not be able to use Table 1c in this example.** **18. "Continuous" is intended to clarify that the maintenance is being performed continuously via the monitoring system and the Activities portion of the table is intended to state those activities that are being performed by the monitoring system.** **19. This verification is established within the "General Description" at the top of Table 1c as generic criteria to use this table.**		
Transmission Owner	No	a. Tables 1a, 1b & 1c should offer as an alternative, measuring battery float voltages and float currents in lieu of measuring specific gravities as described in Annex A4 of IEEE Std 450-2002. b. Inspection of CVT gaps, MOVs and gas tubes should be added to the communications equipment time based maintenance tables. Failure of the CVT protective devices may cause failure of the Protection System. c. Maintenance Activities for UVLS or UFLS station dc supplies shows "Verify proper voltage of dc supply". Does this imply that, except for voltage readings of the dc supply, distribution battery banks are not maintained? d. Why does the Maintenance Activities for UVLS or UFLS relays state that verification does not require actual tripping of circuit breakers? e. Please clarify the Maintenance Activities for Voltage and Current Sensing Devices. Must voltage, current and their respective phase angles be measured at each discrete electromechanical relay?
Response: The SDT thanks you for your comments. **a. The SDT has modified the standard in consideration of your comment regarding dc supply. All references to measuring specific gravities have been removed from the revised standard – and for Table 1a for station dc supply, the language was revised to require, "Verify float voltage of battery charger."** **b. Power line carrier channels are made up of many components that must be maintained on a periodic basis. This standard indicates that adequate maintenance and testing must be done to keep the performance of the channel at a level that meets the requirements of the relay system. The**		

Organization	Yes or No	Question 2 Comment
determination of specific maintenance activities is the responsibility of the Entity. **c. This standard limits the maintenance requirements of distribution system batteries to those used for UVLS and UFLS and constrains those requirements to verification of proper voltage. If "distribution system" batteries are used for any other BES Protection System applications, they must be maintained according to the other requirements of this standard.** **d. The SDT believes that the UFLS scheme is predominantly based within the distribution sector. As such, there are many circuit interrupting devices that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distribution breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in the standard.** **e. Not exactly. The requirement is that the entity must verify that proper voltage, current, and phase angle is delivered to the relays. The standard does not prescribe methodology. See FAQ II-3-A (page 8) and the Supplementary Reference Document, Section 15.2 (page 21) for a discussion on this topic.**		
Pepco Holdings Inc.	No	1. Tables 1a, 1b and 1c all require measuring specific gravity and temperature of battery cells. This invasive test provides no information regarding battery health that cannot be obtained from cell impedance testing. Recommend requiring cell impedance OR specific gravity & cell temperature testing. 2. Tables 1a, 1b and 1c all require testing the battery charger every 6 years to verify that it can provide full rated current and will properly current limit. In order to perform this (unnecessary) test the battery would be subjected to a deep discharge. Whatever benefits may be derived from this test are dwarfed by the negative effect on the battery. Recommend removing this requirement.
Response: The SDT thanks you for your comments. **1. The SDT has made changes in consideration of your comments regarding measuring of specific gravity and temperature of battery cells and removed this maintenance activity from the revised standard.** **2. The SDT has modified the standard in consideration of your comments regarding battery charger performance. All maintenance activities relating to the battery charger were removed except for verification of the float voltage.**		
Illinois Municipal Electric Agency	No	1. The Illinois Municipal Electric Agency (IMEA) is concerned the minimum maintenance activities may be too prescriptive for transmission subsystems that essentially operate radially. 2. Please see comment under Question 7. 3. Also, IMEA supports comments submitted by Florida Municipal Power Agency regarding applicability to

Organization	Yes or No	Question 2 Comment
		UFLS systems.
Response: The SDT thanks you for your comments. **1. This standard applies Protection Systems that that are applied on, or are designed to provide protection for the BES. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.** **2. Please see our response to your comments under Question 7.** **3. The SDT has responded to the FMPA comments regarding UFLS systems.**		
Consumers Energy Company	No	1. The second sentence in Note 1 on page 20 should be changed to "A calibration failure is when the relay is inoperable and cannot be brought within acceptable parameters." 2. Note 2 should be changed to "Microprocessor relays typically are specified by manufacturers as not requiring calibration. The integrity of the digital inputs and outputs will be verified by applying the inputs and verifying proper response of the relay. The A/D converter must be verified by inputting test values and determining if the relay measurements are correct."
Response: The SDT thanks you for your comments. **1. The standard establishes a calibration failure to be any condition where the relay is found to be out of tolerance, whether or not it can be restored to acceptable parameters. The condition described is a calibration failure that is also a "maintenance correctable issue" as established in revisions to R4 and the resulting footnote, and requires more extensive action to resolve.** **2. Note 2 has been removed and the relevant requirements added to the Tables themselves. There are methods, other than inputting test values, to verify the A/D converter.**		
American Transmission Company	No	1. The Standard should focus on identifying the types of components to be tested but should not identify the specific maintenance activities that must be performed. Entities should be allowed the flexibility to develop and implement the appropriate maintenance activities necessary for each identified component. 2. ATC is also concerned with the expressed identification of maintenance intervals. We do not believe that the standard should identify specific maintenance intervals but that it should require entities to identify their maintenance intervals appropriate for their system. If the team continues to pursue specific maintenance intervals it will be establishing the industries practices. 3. Specific Concern: The standard identifies that entities should perform complete functional testing as part of its maintenance activities, but we are concerned that this could lead to reduced levels of reliability, because it

Organization	Yes or No	Question 2 Comment
		requires entities to remove elements from service and then requires entities to perform tests that are inherently prone to human errors. We believe that the perceived benefits do not match the anticipated costs or improve system reliability.
Response: The SDT thanks you for your comments. As you are probably aware, protection systems have contributed to most major events, indicating a need to provide greater "defense in depth" to the body of standards. While many facility owners do have effective protective system maintenance programs, some do not – which puts the grid at risk. **1. Specific activities are defined where necessary to implement an effective PSMP, and has provided for flexibility where there are multiple methods that will be effective.** **2. FERC Order 693 expressly directs NERC to develop maximum maintenance intervals.** **3. The SDT believes that complete functional testing is a vital component of the Protection System performance, and must be performed as specified in the standard. To minimize system impact of such maintenance and possible errors, the maintenance necessarily should be scheduled at a time that minimizes the risks.**		
Wolverine Power Supply Cooperative, Inc.	No	The tables are too prescriptive - The standards should state what, not how.
Response: The SDT thanks you for your comments. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.		
Northeast Power Coordinating Council	No	1. We agree there is a need for minimum maintenance activities; however, the standard does not clearly define the differences between Table 1a, 1b, and 1c. It is recommended that the drafting team develop definitions for the equipment listed in these tables. For example, Table 1a equipment consists of mechanical and solid state equipment without monitoring capability, Table 1b consists of mechanical and solid state equipment with monitoring capability, and Table 1c consists of equipment capable of self monitoring. 2. In addition, all battery, charger and power supply maintenance activities should be removed from Table 1a, 1b, and 1c, and summarized in a separate Table (i.e. Table 2). Tables 1a and 1b for 'Station dc supply (that has as a component any type of battery) and Table 1c for 'Station dc Supply (any battery technology) for an 18 Month 'Maximum Maintenance Interval' identifies the need to 'Measure that the specific gravity and temperature of each cell is within tolerance (where applicable).' 3. Following industry best practices, we would recommend using the MBRITE diagnostic test. MBRITE testing provides more information than a specific gravity test while reducing the risk of injury to testing

Organization	Yes or No	Question 2 Comment
		personnel. 4. In Table 1a, the Type of Component "Protection system communications equipment and channels." has a 3 month "Maximum Maintenance Interval". Clarification needs to be provided as to how an unmonitored (do not have self-monitoring alarms) will be tested. 5. Table 1a refers to "Unmonitored Protection Systems". The "6 Calendar Years" "Maximum Maintenance Interval" "Maintenance Activities" is excessive.
Response: The SDT thanks you for your comments. **1. The component differences between Table 1a, Table 1b, and Table 1c are described in the header to the Tables and in the specific monitoring attributes for the specific component types. Please see the decision trees near the end of the FAQ document (pages 33-37).** **2. The SDT believes that the Station DC Supply component should be addressed with the other components, and has simplified the Tables in consideration of your comments.** **3. The DC Supply component has been modified, and no longer specifically requires specific gravity testing.** **4. See FAQ II-6-B (page 16) for a discussion of a number of methods to test the communications systems.** **5. Your comment is unclear, and the SDT is unsure how to respond. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities and maximum intervals necessary to implement an effective PSMP. Some entities may feel that they need to maintain Protection System components more frequently.**		
Lower Colorado River Authority	No	We agree with all stated intervals except for the maximum stated interval of 6 years for Protection System Control Circuitry (Trip Coils and Auxiliary Relays) in tables 1b and 1c. What was the intent of separating this interval out from the Protection System Control Circuitry (Trip Circuits), which is 12 years for monitored components? Monitoring of the trip coils should be enough to justify a maximum interval of 12 years. As stated these requirements will put an undue financial and resource burden on utilities that have updated their protective relay systems with state-of "the art components and monitoring. In addition to the expense and effort of scheduling the additional maintenance, the additional validation of lockouts and auxiliary relays, separate from the full function testing could lead to additional human errors and accidental tripping of circuits while testing. We believe there should be one stated activity "Protection System Control Circuitry and have a maximum interval of 12 years for monitored systems.
Response: The SDT thanks you for your comments. **Monitoring of the coil of these devices does not assure that the device will mechanically operate properly. Electromechanical devices such as lockout**		

Organization	Yes or No	Question 2 Comment
relays and auxiliary relays must be exercised periodically to assure proper operation. The monitoring systems cannot perform this. See Supplementary Reference Document Section 15.3 (page 22).		
Ameren	No	We agree with the vast majority of them, listed below are our few concerns, questions, and pleas for clarification. 1) We disagree with doing specific gravity and temperature of every cell in the 18 month test because the other tests being done are already comprehensive. 2) FAQ 3B p 29 digital relay A/D verification should include simply comparing digital relay displayed metered values to another metered source. 3) FAQ 3A p6 Change “prove that” to “verify”. For single CT or VT, this can be challenging and some measure of reasonableness in determining an expected value comparable to the measured value must be acceptable. 4) FAQ 1B p17 Combining evidence forms of “Process documentation or plans” and “Data” or “screen shots” shows compliance. Please add an example or verbiage to clarify that a field technician’s (or operator) recorded check-off combined with a company’s process is sufficient evidence. Otherwise documentation alone could consume considerable field personnel time. 5) FAQ p2 Add FAQ to clarify “verify settings”. If EM relays are included, explain that minor tap or time dial differences of the order of relay tolerances are acceptable. For digital relays state that software compare functions are a sufficient means to “verify settings.” 6) Omit Table 1b row 3 because row 4 actually applies to Monitoring Level 2 Trip Circuits. Row 3 already appears in Table 1a, and repeating it in Table 1b is confusing. 7) FAQ 4D p 7 then defines auxiliary relays as device 86 and 94. Does device number nomenclature or function determine and restrict inclusion? 8) Please state that “a location where action can be taken for alarmed failures” would include a dispatch center or control room. From there the custodial authority would be called out to take action. 9) Please explain the expansion from station battery to station DC supply, specifically the addition of the charger, an AC to DC device. 10. The charger load test up to its current limiter would add a significant amount of work with little known benefit. 11. Have charger problems been a significant cause of cascading outages? 12) We oppose your expansion of Station DC Supply to UFLS (the last row on page 8.) PRC-008-0 is

Organization	Yes or No	Question 2 Comment
		restricted to UFLS equipment. UFLS is often applied in distribution substations to trip feeders directly serving load. Your scope expansion has the potential to greatly increase the number of substation DC Supplies covered by NERC standards. ,. While we agree that UFLS is BES applicable, and those substations are included in our overall maintenance program, this expansion to NERC scrutiny is not warranted. Have there been UF events in which a material amount of load was not shed because of DC problems? UFLS is spread out amongst many distribution stations, and even if a couple did fail to trip in an underfrequency event, it would have little effect. 13) FAQ 2 p 17 expands the scope at Generating Facilities so that system connected station auxiliary transformers would be included. We oppose this expansion as these are radially served loads, and they often do not result in generation loss. Even if they did, the BES can readily tolerate the loss of a single generator.

Response: The SDT thanks you for your comments.

1. **All references to specific gravity and temperature testing have been removed from the revised standard.**
2. **The FAQ has been revised and reorganized in response to many industry comments; see FAQ II-3 (all subsections – pages 8-10) for a discussion of this topic.**
3. **The FAQ has been revised and reorganized in response to many industry comments; see FAQ II-3 (all subsections – pages 8-10) for a discussion of this topic.**
4. **The FAQ has been revised and reorganized in response to many industry comments; see FAQ IV-1-B (page 21)**
5. **See FAQ II-2-D & II-2-E(pages 6-7).**
6. **Table 1a and Table 1b each stand alone; use the table that is relevant to the level of monitoring that is implemented.**
7. **The SDT modified the FAQ to remove references to the IEEE device numbers (page 11) except when essential to respond to the question. Regardless of how the device is described by internal entity nomenclature, the function of the device determines whether it is included within the standard.**
8. **Your suggestion is properly considered as an example. See FAQ V-1-A (page 28).**
9. **The SDT believes that the charger is an integral portion of the Station DC supply; thus it has been added. The SDT has modified the standard to simplify the requirements related to maintenance of the battery charger.**
10. **The SDT modified the standard in consideration of your comment. All maintenance activities pertaining to battery chargers have been removed except verification of the float voltage.**
11. **The standard addresses overall Protection System reliability, not only those issues that may cause cascading outages.**
12. **The SDT believes that verification of the DC supply voltage to the UFLS is not burdensome. The SDT has modified the standard to clarify that the**

Organization	Yes or No	Question 2 Comment
only DC Supply requirement relevant to UFLS is to verify the DC supply voltage. **13. Station service transformers are essential to starting the plant during grid recovery. The FAQ clarifies why these elements are included. The standard addresses overall Protection System reliability, not only those issues that may cause extreme outages.**		
Manitoba Hydro	No	1. What documentation or evidence is required to prove that the Protection System Control Circuitry has been maintained every three months, if just a visual inspection of the breaker control trip circuit RED panel light has been completed, to verify continuity of breaker trip coil? 2. How do we handle breakers with dual trip coils and only one RED light for trip coil continuity? 3. What do the terms DISTRIBUTED and CENTRALIZED with respect to UFLS mean? 4. In Table 1C under the heading "Maximum Maintenance Interval" some of the entries are stated as being "Continuous". In the case of other maintenance activities the descriptor for Maintenance Interval indentifies the maximum period of time that may elapse before action must be taken. "Continuous" implies continuous action; however, in reality continuous monitoring enables no maintenance action to be taken until such time as trends indicate the need to do so. Therefore we recommend that where the maintenance interval is stated as "Continuous" it should be changed to read "Never" or "Not Applicable". 5. The Table 1A requirement of 3 months for Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) should be omitted as it is not realistic. Recommend following the Table 1B requirement of 6 years (Trip testing) for this. Does 27 undervoltage monitoring of this circuit qualify as self monitoring?
Response: The SDT thanks you for your comments. **1. The requirement to which you refer has been removed. See FAQ IV-1-B (page 21) for a general discussion of documentation.** **2. The SDT has modified the standard to remove the requirement cited in your comment.** **3. See FAQ II-7-C (page 18) and FAQ II-8-E (page 19A).** **4. Continuous" is intended to clarify that the maintenance is being performed continuously via the monitoring system and the Activities portion of the table is intended to state those activities that are being performed by the monitoring system.** **5. The SDT has removed this requirement.**		
CPS Energy	No	While I agree for the most part, there are some activities that are unclear. 1. Specifically, the testing of voltage and current sensing devices, some of the trip coil testing, and some of the communications testing. If the trip coil is now going to be included in the definition of the protective

Organization	Yes or No	Question 2 Comment
		system, is the testing defined adequate? 2. The testing of the voltage and current sensing devices is not entirely clear.
Response: The SDT thanks you for your comments. **1. The listed activities are contemplated as minimum activities and do not preclude an entity from performing additional activities.** **2. See the Supplementary Reference Document, Section 15.2 (page 21) and FAQ II-3-A (page 19) for a discussion of this topic.**		
AECI	No	1. Tables 1a and 1b Station DC Supply: Requirement is to measure specific gravity and temperature of every cell. We believe that this test is unnecessary if voltage and internal resistance are measured. This test should only be required if other tests indicate a problem, or if the voltage and internal resistance tests are not performed. 2. Tables 1a and 1b Station DC Supply (Valve Regulated Lead-Acid Batteries): Will a limited discharge test be acceptable as a "performance or service capacity test" or is full discharge required? We believe a full discharge test will decrease battery life and suggest that only a limited discharge test be performed. 3. Tables 1a and 1b Station DC Supply (Vented Lead-Acid Batteries): What is the definition of "modified performance capacity test?"
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard in consideration of your comment concerning station dc supply and has removed the requirement to measure specific gravity and temperature of every cell.** **2. The SDT does not feel that conducting a performance or service capacity test at the intervals prescribed in the standard will cause any appreciable decrease in battery life over the service life of the battery. The Protection System owner is responsible for maintaining a station dc supply that can perform as designed and conducting a performance or service capacity test will verify that a VRLA battery will satisfy the design requirements (battery duty cycle) of the dc system that a limited discharge test might not verify. If you are concerned that such a test may have implications on battery life, the standard provides an option to instead measure and trend internal cell/unit ohmic values on a 3-month interval.** **3. How to conduct a modified performance test for Vented Lead-Acid Batteries is explained in detail in various available reference books. For Vented Lead-Acid Batteries, it is a capacity test where the discharge rate(s) are modified to cover every portion of the battery's duty cycle.**		
Puget Sound Energy	No	For all tables, PSE agrees with the majority of the minimum maintenance activities established. However, the Station DC supply maintenance activities raise concern. The requirement to test that the charger will provide full rated current versus output seems to be excessive. In many cases the charger is rated far in excess of the output needed to perform its function. Also PSE is not aware of a known industry test for these and it is

<table>
<tr><th>Organization</th><th>Yes or No</th><th>Question 2 Comment</th></tr>
<tr><td></td><td></td><td>not an IEEE recommended standard. Finally, PSE is unclear whether this test would diminish the charger.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comments. The SDT modified the standard in consideration of your comment regarding battery chargers. The maintenance activities for battery chargers have been modified to remove all activities except for verification of the float voltage.</td></tr>
<tr><td>SERC (PCS)</td><td>Yes</td><td>We agree with the majority of the activities. Below is an example where clarification is needed.

1. “Verify proper functioning of the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays” under “Voltage and Current Sensing Devices Inputs to Protective Relays.” How would this be done if no redundancy is available for cross-checking voltage and current sources?

2. In certain situations, “verify proper functioning” is not clear enough. Documentation of verification consistent with the entities procedures should be adequate to indicate compliance.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comments.

1. The standard is prescribing what needs to be done, not how. Please refer to the Supplementary Reference Document Section 15.2 (page 21) and FAQ II-3-A (page 19) for examples and additional discussion.

2. Documentation of verification consistent with your procedures is sufficient to “verify proper functioning”</td></tr>
<tr><td>TVA</td><td>Yes</td><td>Add clarifying statement from Table 1b for Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only) to the same section in Table 1a. Statement is “(Verification does not require actual tripping of circuit breakers or interrupting devices.)"</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT has modified the standard in consideration of your comment. The following was added to Table 1a:

Type of Component - Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only)

Maximum Maintenance Interval - 6 Calendar Years

Maintenance Activity - Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except .that verification does not require actual tripping of circuit breakers or interrupting devices.</td></tr>
<tr><td>JEA</td><td>Yes</td><td>If a communication system relies on a battery system independent of the "station battery", is this communication system battery under the same requirements as the "station battery"?</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The proper functioning of such batteries will be addressed by the verification and monitoring of the communications system, and by addressing maintenance correctable issues related to maintenance of communication systems. See FAQ II-5-K (page</td></tr>
</table>

3. Within Table 1a, the draft standard establishes maximum allowable maintenance intervals for the various types of devices defined within the definition of "Protection System", where nothing is known about the in-service condition of the devices. Do you agree with these intervals? If not, please explain in the comment area.

Summary Consideration: Most respondents disagreed with the specified maximum allowable intervals to some degree or another. The disagreements ranged over the full spectrum of activities specified in the Tables, and often corresponded to the disagreements related to the activities. The intervals within Table 1a were reconsidered (with minor changes – eliminating the 3-month control circuit activity) by the SDT when responding to the comments.

Organization	Yes or No	Question 3 Comment
Green Country Energy LLC	No	1) Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) also The maintenance activity causes excessive breaker operation, and the intrusive nature increases the risk of subsequent Misoperations on operating units. System configuration of many plants will require an extensive interruption of total plant production to complete the test. 2) Protection System Control Circuitry (Trip Circuits) (UFLS or UVLS systems only) The maintenance activity causes excessive breaker operation, and the intrusive nature increases the risk of subsequent Misoperations on operating units. System configuration of many plants will require an extensive interruption of total plant production to complete the test.
Response: The SDT thanks you for your comments. **1. The overall Protection System Control Circuitry can be addressed in segments, as long as all portions are verified or tested as required. Depending on the arrangement of the DC control circuit, it may be necessary to only trip the breaker itself once. See FAQ II-4-E (page 11).** **2. The overall Protection System Control Circuitry can be addressed in segments, as long as all portions are verified or tested as required. Depending on the arrangement of the DC control circuit, it may be necessary to only trip the breaker itself once. See FAQ II-4-E (page 11).**		
Public Service Enterprise Group Companies	No	1) Table 1a Station dc supply (that uses a battery and charger). The 6 year test requires that the charger perform as designed. PSE&G usually applies redundant battery chargers. PSE&G would like the drafting team to consider if it is appropriate to not require the 6 year battery charger tests if a battery owner uses primary and backup battery chargers. PSEG believes that the use of a redundant charger will maintain reliability at the same level or better level as provided by testing a single charger. 2) For protection system control circuits components (breaker trip coil only), suggest that a sub category with redundant trip coils be added with longer maintenance interval to allow for the reliability provided by

Organization	Yes or No	Question 3 Comment
		redundancy.
Response: The SDT thanks you for your comments. **1. The performance of the battery charger is critical to the performance of the protection system. The SDT has modified the standard to simplify the requirements related to maintenance of the battery charger. If condition-based maintenance is applied in accordance with Table 1b, the battery alarms could automatically (or manually) switch to the redundant charger. Redundancy may also provide more flexibility in addressing issues discovered during maintenance.** **2. Even with redundant equipment, it is essential that all equipment be tested according to the requirements of this standard to ensure proper function and to support the reliability advantages presented by redundancy. The requirements related to this subject have been extensively modified.**		
Ameren	No	1) The “zero tolerance” structure proposed combined with the large volume and complexity of Protection System components forces an entity to shorten their intervals well below maximum. We instead propose a calendar increment grace period in which a small percentage of carryover components would be tracked and addressed. For example, up to 10% of all breaker trip coils subject to the 3 month “verify breaker trip coil continuity” could carry over into the first month of the next period. And for example, up to 5% of an entity’s communication channel 6 year verifications could carryover into the next year. These carryover components would be addressed with high priority in that next calendar increment. There are many barriers to 100% completion or zero tolerance. Barriers include sheer volume, obtaining outages, resource availability, coordination, and documentation (over ten thousand components in our utility alone; taking a BES outage to permit maintenance can incur a greater reliability risk than delaying the maintenance; emergent issues such as major storms impact resource availability; coordination with interconnected neighbors, their resources and maintenance timing; record keeping errors or oversights; etc.) 2) Alternatively, components with intervals less than a year should be stated in terms of the number of times annually it should be performed, rather than a short duration interval. The expectation is that they would be roughly equally spaced throughout the year; for example quarterly instead of 3 months. Comment 1 grace period would still apply to components with maximum intervals of 1 year or greater. 3) Some of our maintenance intervals are shorter than maximum. Please confirm that documentation is only to be kept for two of the entity’s intervals, not two of the maximum interval. 4) Please add standard language or FAQ near 2D on p 18 that an entity can validly use an interval with % tolerance to achieve maintenance goals, as long as the applicable maximum interval is honored.
Response: The SDT thanks you for your comments. **1. The SDT is concerned that a “grace period”, if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a “grace**		

Organization	Yes or No	Question 3 Comment
period" would not conform to this directive. **2. Simply stating the number of times annually that these devices must be maintained, with a tacit expectation that the maintenance be spaced throughout the year, does not ensure that they will be tested thusly. To achieve the periodicity of the testing, it is essential that the requirement specify such periodicity. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive.** **3. The data retention has been modified in consideration of your comments. The revised language reads as follows:** The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer. **4. You may define your program within the parameters expressed within the standard as long as you adhere both to your program and to the Standard.**		
Exelon Generation Company, LLC	No	1. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 2. Table 1a page 6 regarding the 3 Month "Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS)" states that the maintenance activity shall verify the continuity of the breaker trip circuit including the trip coil. There is unclear guidance on how this activity is to be performed, particular on generator output breakers. Does this activity imply actual trip testing of the breaker itself? If so, performing this type of activity with the generator on-line puts the unit at risk without any commensurate increase in reliability to the bulk electric system. If this is the case it is requested that this particular test is extended from 3 months to 24 months to align with nuclear generating units refueling cycle. If not, and this activity is simply verification of continuity by means of light indication; then please clarify in Table 1a.
Response: The SDT thanks you for your comments. **1. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document for a discussion on this issue.**		

Organization	Yes or No	Question 3 Comment
2. The SDT has removed this requirement.		
Entergy Services, Inc	No	1. A 3 month interval activity is likely to drive an entity to perform that activity every 2 months in a zero tolerance, 100% completion, mandatory compliance environment. There should be an allowance for a grace period on monthly designated activities, for instance a one month grace period, unless the intention is to have the activity performed more frequently than indicated. Additional guidance is needed on the monthly interval designations. Is it okay, for instance, to do all four tasks (3 month interval) at one time? Instinctively the answer should be "no", but if following the "calendar year" allowance, then maybe it is. Are we non-compliant on a 3 month interval task if we go one single day over the due date? Instinctively the answer should be "no", but some additional guidance should be provided. For example, the standard might be more understandable if it indicated that if the interval is "four per year" (or 3 month interval), then it is allowed to perform these tasks no less than 45 days apart from each other as long as four are done within a calendar year, etc. 2. We believe the 3 month trip coil task activity could actually shorten the life of the trip coil, introduce unpredictable trip coil failures, and increase the risk of an in-service failure of the trip coil if the verification is done by tripping the breaker each time. Increasing the risk of failure is counter-productive the intent of the standard.
Response: The SDT thanks you for your comments. **1. The standard specifies MAXIMUM allowable intervals for the various activities; entities must manage their program however they see fit to adhere to those intervals. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive.** **2. The SDT has removed this requirement.**		
MRO NERC Standards Review Subcommittee	No	A. It looks like for unmonitored systems, breaker trip coils are to be checked for continuity every 3 months. There is no mention of auxiliary relays. In the partially monitored and fully monitored sections, trip coils and auxiliary relays are lumped in the same category at 6 calendar years each. What happened to the aux relays in the unmonitored section? Also, note that the term "trip coils" is used, not "breaker trip coils" in the type of component category. B. The maintenance interval for Protection System Control Circuitry (Trip coils and Auxiliary relays) is 6 years, but the interval for relay output contacts is 12 years when these components are partially monitored. It seems that these things all have a similar reliability. If commissioning tests are done diligently, the trip DC availability is continuously monitored and the trip coil itself is continuously monitored, no functional tests should be needed. The only thing that would be done at PM time would be to ensure that the alarming method is still

Organization	Yes or No	Question 3 Comment
		functional.
Response: The SDT thanks you for your comments. **A. The SDT has removed this requirement.** **B. In your discussion (with continuous monitoring of the trip dc and trip coil), you have effectively established most of the monitoring to move to either Table 1b or even Table 1c. You are encouraged to carefully review the Monitoring Attributes for these higher levels of monitoring; if you satisfy the attributes, you may be able to further minimize hands-on maintenance.**		
NextEra Energy Resources	No	a. (i) Protective relays, (ii) Protection Control Circuitry (Trip Circuits) and (iii) Protection System Communications Equipment and Channels should be changed from 6 calendar years to 8 calendar years. Based on FPL Group's experience and Reliability Centered Maintenance (RCM) program, FPL Group has established an 8 year program and has found that an aggressive 6 year program would not substantially increase the effectiveness of a preventative maintenance program. b. Battery visuals should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. c. The maximum maintenance interval for communications equipment should be changed from 3 months to 12 months. Based on FPL Group's experience and RCM program, FPL Group has established a 12 month program that is effective. d. Additionally, NextEra Energy concurs with other entities comments concerning this question: Imposing inflexible maximum interval requirements has the same basic problems as imposing inflexible minimum task requirements. The inflexible "maximum interval" approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. The maximum interval approach also has same perverse consequences for entities with redundant systems as the minimum interval approach. e. Furthermore, the rigid maximum interval approach embodied herein does not sufficiently take into consideration common natural disaster situations. Several of the preventive maintenance tasks proposed in this standard have a maximum interval of 3 months, which is problematic under normal circumstances and unworkable when routine maintenance activities have a much lower priority than emergency repair and restoration. An interval as short as this does not provide a sufficient maintenance scheduling horizon to complete the tasks. The SDT could attempt to address this shortfall by modifying the draft to account for natural disaster situations. For example, the FERC-approved NERC reliability standard FAC-003 for Vegetation Management does include such allowances for natural disasters, such as tornados and hurricanes. However, even if that specific problem is addressed, the fundamental problems created by an

Organization	Yes or No	Question 3 Comment
		overly prescriptive maximum interval approach remains.
Response: The SDT thanks you for your comments. **a. The SDT believes that the 6-year maximum allowable intervals, to which you refer, are appropriate. The intervals within the standard are based on the experience of the SDT and of the NERC System Protection and Control Task Force (SPCTF). The SPCTF also validated these intervals via an informal survey that represented about 2/3 of the net-energy-for-load within NERC, and by comparison to IEEE surveys. See Supplementary Reference Document Section 8 (page 9). An entity may implement a Performance Based maintenance program if they wish to apply their experience.** **b. The SDT agrees that a healthy modern lead acid battery can go for extended periods of time beyond 3 months without requiring watering. However, checking cell electrolyte level not only indicates the need for battery watering, it is an indication of an individual cell's health and needs to remain at the Maximum Maintenance Interval of 3 months. To avoid the confusion that the Maintenance Activity listed in Table 1 was to water the battery at the specified 3 month interval, the Drafting Team has changed the wording of the Maintenance Activity from "verify proper" to "check" electrolyte level.** **c. The 3 month interval is for inspection of unmonitored equipment. The SDT felt that this is appropriate for carrier channels or for leased audio channels that have a chance of failure and would result in an overtrip or failure to trip if ignored. It is possible to extend the interval for performance based systems if the entity has applicable data.** **d. FERC Order 693 directs that NERC establish maximum allowable intervals. For entities that wish to establish a performance-based maintenance program using experience, the standard DOES allow for that.** **e. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.**		
CenterPoint Energy	No	a. See CenterPoint Energy's comments made in response to question 2. Imposing inflexible maximum interval requirements has the same basic problems as imposing inflexible minimum task requirements. The inflexible "maximum interval" approach fails to recognize the harmful effects of over-maintenance and precludes the ability of entities to tailor their maintenance program based on their configurations and operating experience. The maximum interval approach also has same perverse consequences for entities with redundant systems as the minimum interval approach. b. Furthermore, the rigid maximum interval approach embodied herein does not sufficiently take into consideration common natural disaster situations. Several of the preventive maintenance tasks proposed in this standard have a maximum interval of 3 months, which is problematic under normal circumstances and unworkable when routine maintenance activities have a much lower priority than emergency repair and restoration. An interval as short as this does not provide a sufficient maintenance scheduling horizon to complete the tasks. The SDT could attempt to address this shortfall by modifying the draft to account for natural disaster situations. For example, the FERC-approved NERC reliability standard FAC-003 for

Organization	Yes or No	Question 3 Comment
		Vegetation Management does include such allowances for natural disasters, such as tornados and hurricanes. However, even if that specific problem is addressed, the fundamental problems created by an overly prescriptive maximum interval approach remains.
Response: The SDT thanks you for your comments. **a. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.** **b. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.**		
FirstEnergy	No	Although we agree with the proposed maintenance intervals, there may be extenuating circumstances beyond an entity's control that could delay maintenance on a particular protection system. We ask the SDT to consider adding a footnote to these intervals that allows a grace period of up to three months when outages necessary for maintenance must be delayed due to unusual system conditions or other issues where an outage would be detrimental to the entity's system.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.		
American Transmission Company	No	1. ATC is concerned that the proposed standard would result in entities being required to use outdated testing techniques and or practices. We believe that the standard should identify the "what" and not the "how". The identification of specific testing techniques and/or practices would likely result in entities being

Organization	Yes or No	Question 3 Comment
		prevented from implementing improved techniques and/or practices. (The standard would have to be updated and receive FERC approval before entities could test/implement improved testing techniques and/or practices.) 2. An example of the standard directing the how is with station batteries. The "specific gravity" test, proposed in the standard, is being used less or not at all by some registered entities because a more accurate method that is less intrusive and provides more accurate results has been developed. (This standard would basically require entities to go backwards in testing practices.)This standard should not prevent the use of improved techniques and/or practices.
Response: The SDT thanks you for your comments. **1. In consideration for your concern, the Drafting Team has revised Table 1 to identify more of what is required for the station dc supply activities and eliminated most of the "how to do it".** **2. All references to specific gravity and temperature testing have been removed from the revised standard.**		
City Utilities of Springfield, MO	No	CU agrees in general with many of the maximum maintenance intervals. However, we disagree with the necessity to verify the continuity of trip coils every 3 months. We would be interested to know what basis the committee used to arrive at all intervals. Furthermore, it is our opinion that even if a component is unmonitored, the interval should not surpass the manufacturer's recommendations.
Response: The SDT thanks you for your comments and has removed this requirement.		
ITC Holdings	No	1. Does the standard require that time or condition based maintenance programs monitor countable events to identify significant problems in particular relay segments, and then adjust the maintenance interval accordingly? 2. On page 6: Please clarify the use of "Calendar Year" Our understanding is that if a relay is maintained on August 31, 2003 on a 6 year interval, it will not be overdue until January 1, 2010. Is this correct?? 3. On Page 7: What is the basis for 18 months? We believe 2 calendar years would be more appropriate. 4. On Pages 6, 10: What is the basis of the 6 calendar year interval for functional trip tests? We request that this be changed to a 10 calendar year interval. We follow a 10 calendar year interval that has proven to be satisfactory. Decreasing the interval to 6 calendar years will result in a major increase in our maintenance expenses without a corresponding increase in reliability. 5. On Page 9: If it is being verified ok every 3 months, what is the basis of the 6 calendar year interval for Communication equipment? ITC communications systems are partially monitored and therefore required to

Organization	Yes or No	Question 3 Comment
		perform this testing every 12 years. However, ITC would like to know the basis of the 6 year interval for informational purposes. 6. On pages 6, 8, 11, 13, 14 and 19: The maximum maintenance interval (when the associated UVLS or UFLS system is maintained) should be shown as the actual "6 Calendar Years".? 7. On Page 1 of Attachment A: Please provide an example in the reference of the proper way of adjusting the interval based on test results. 8. On Pages 7, 8, 12: It is our understanding that adequate maintenance can be achieved by performing either one of the two maintenance activities in cases where there is an "or", is that correct? 9. On Page 14: For the bottom two rows on page 14 we believe there is a typo and it should read "Level 2" not "Level 1". 10. On Page 13: Do power line carrier schemes that provide a remote alarm if a daily check back test fails, meet level 2 monitoring requirements? 11. In Table 1: What is the basis for the 6 year interval for the battery systems? This test would be an additional test for ITC. We would prefer to perform this additional test with the relay periodic maintenance on a 10 year interval.

Response: The SDT thanks you for your comments.

1. No, the standard does not require that countable events be analyzed for determination of intervals in time-based or condition-based maintenance programs. However, excessive poor operation may trigger additional activities as part of a corrective action plan per PRC-004 in response to Misoperations.

2. Your understanding is incorrect. A maintenance activity last completed in 2003 on a 6-year interval would next need to be maintained sometime in 2009. (See Supplementary Reference Document Section 8.4, page 13)

3. The SDT believes that 18-month is the appropriate interval, based on common industry practice.

4. The SDT believes that 6-years is the appropriate interval, based on common industry practice. For entities that wish to establish a performance-based maintenance program using experience, the standard DOES allow for that.

5. The 6 year interval is mostly driven by the needs of power line carrier channels and the use of analog auxiliary tuning components in the communications systems. The relay communications systems intervals were based on the experiences of SDT and NERC System Protection Committee Task Force members.

6. The SDT has modified the standard in consideration of your comment to include the specific intervals for the various components related to UFLS/UVLS, with the exception of the dc supply. The maintenance for the dc supply for UFLS/UVLS was left related to the maintenance of the

Organization	Yes or No	Question 3 Comment
UVLS/UFLS system because the SDT believed that this activity should be tied to the specific intervals needed for the relays. 7. See FAQ IV-3-H (page 26). 8. You are correct in your statement that the Maintenance Activity of verifying that the station battery can perform as designed can be met by completing either of the two activities listed in Table 1 in the prescribed Maximum Maintenance Interval. 9. Thank you. You are correct; these table entries have been modified accordingly. 10. Yes. A remote alarm daily auto-check back as you describe satisfies the Level 2 monitoring attributes for channel performance in a power line carrier system. 11. The SDT believes that extending the Maximum Maintenance Interval for station batteries beyond that listed in Table 1 would degrade the Protection System by not detecting compromises to the performance of the station dc supply during the extended interval.		
Platte River Power Authority Maintenance Group	No	Electro-mechanical relays are historically out of tolerance well before the 6 year maximum allowable maintenance intervals defined within table 1a.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals.		
Florida Municipal Power Agency, and its Member Cities	No	1. FMPA agrees in general with many of the maximum maintenance intervals; however we have been unable to determine what basis was used to arrive at the time based intervals provided in the tables. Further explanation would be appreciated 2. FMPA is concerned with the use of the term “continuous” in Table 1c. As stated, it would seem that, on loss of communications that would communicate the alarm, thereby causing a loss of “continuous” monitoring and alarming, the entity who invested in a reliability improving monitoring system would be found non-compliant with an infinitesimal maintenance period required for “continuous” monitoring. Therefore, FMPA recommends using “not applicable” or some other term in this column.
Response: The SDT thanks you for your comments. 1. The intervals within the standard are based on the experience of the SDT and of the NERC System Protection and Control Task Force (SPCTF). The SPCTF also validated these intervals via an informal survey that represented about 2/3 of the net-energy-for-load within NERC, and by comparison to IEEE surveys. See Supplementary Reference Document Section 8 (page 9). 2. The SDT believes that the maintenance is indeed being done “continuously”. If the alarming method is not functional, you’ve fundamentally dropped back to Level 1 or Level 2 monitoring, depending on the component.		

Organization	Yes or No	Question 3 Comment
E.ON U.S.	No	1. Generally, E.ON U.S. requests that the SDT provide the basis for the proposed changes in maintenance time lines. E ON U.S.'s existing maintenance intervals are based on actual operating experience. Not having been provided with the basis for the proposed intervals, the time lines appear arbitrary. E.ON U.S. currently has an 8-year interval for combustion turbines vs. the 6-year interval provided here. The E.ON U.S. interval is based on the Company's experience with this equipment. E.ON U.S. suggests that the SDT provide some consideration to individual entities historic practices. 2. It is difficult to track "18 months". Maintenance intervals should be in expressed in number of years. 3. E ON U.S. also does not understand the basis for the 3 months maintenance schedule on breaker trip coils. Typically, the circuit breaker closed indication is wired through the breaker trip coil. Thus there could not be a breaker closed indication without a good breaker trip coil. So, this test should be considered continuous monitoring which may not even require documentation except in case of failure.
Response: The SDT thanks you for your comments. **1. See Supplementary Reference Document, Section 8 (page 9). An entity's historical practices and results can be used to establish a performance-based maintenance program as described within the standard.** **2. The SDT believes that the 18-month interval is appropriate. If you wish, you may do these activities more frequently to aid in your maintenance tracking, as long as you adhere to the requirements within the standard.** **3. If this indication is local (for example, a lamp), 3-month inspections of the lamp state are necessary to satisfy the requirement. If the indication is an alarm to a location such as a control room, control center, etc, this may satisfy for either Level 2 or Level 3 monitoring as you suggest.**		
Transmission Owner	No	a. i) Protective relays, ii) Protection Control Circuitry (Trip Circuits) and iii) Protection System Communications Equipment and Channels should be changed from 6 calendar years to 8 calendar years. Based on FPL's experience and Reliability Centered Maintenance (RCM) program, FPL has established an 8 year program and has found that an aggressive 6 year program would not substantially increase the effectiveness of a preventative maintenance program. b. Battery visuals should be changed from 3 months to 6 months. Electrolyte levels of today's lead-calcium batteries are relatively stable for a 6 month period compared to lead-antimony batteries used in the past. c. The maximum maintenance interval for communications equipment should be changed from 3 months to 12 months. Based on FPL's experience and RCM program, FPL has established a 12 month program that is effective.
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 3 Comment
a. The SDT believes that the 6-year interval is appropriate. An entity may implement a Performance Based maintenance program if they wish to apply their experience. **b. The SDT agrees that a healthy modern lead acid battery can go for extended periods of time beyond 3 months without requiring watering. However, checking cell electrolyte level not only indicates the need for battery watering, it is an indication of an individual cell's health and needs to remain at the Maximum Maintenance Interval of 3 months. To avoid the confusion that the Maintenance Activity listed in Table 1 was to water the battery at the specified 3 month interval, the Drafting Team has changed the wording of the Maintenance Activity from "verify proper" to "check" electrolyte level.** **c. The 3 month interval is for inspection of unmonitored equipment. The SDT felt that this is appropriate for carrier channels or for leased audio channels that have a chance of failure and would result in an overtrip or failure to trip if ignored. It is possible to extend the interval for performance based systems if the entity has applicable data.**		
Illinois Municipal Electric Agency	No	1. IMEA is concerned the maximum allowable maintenance intervals may be too prescriptive for transmission subsystems that essentially operate radially. 2. Please see comment under Question 7. 3. Given the magnitude of reliability-related initiatives currently in progress, additional time is needed to evaluate these intervals, particularly for communications equipment, dc supply, and UFLS relays.
Response: The SDT thanks you for your comments. **1. The intervals are established for Protection Systems on BES components. If you believe that some of your system components are not BES that is an issue relative to your region's BES definition.** **2. See response to comment under Question 7.** **3. An Implementation Plan is provided to allow systematic implementation of these intervals. If you are concerned about the time available to develop comments on posted drafts, be advised that the posting period is determined according to the NERC Reliability Standards Development Process. The SDT is providing the maximum comment time available.**		
PacifiCorp	No	No comment.
Duke Energy	No	1. Our comments are limited to Table 1a. More clarity is needed for many of the Maintenance Activities before assessing whether or not the intervals are reasonable. But as a general comment we would like to understand the basis used to develop all of the intervals, and how that basis compares with research done by the Electric Power Research Institute (EPRI). It is our understanding that NERC did an industry survey of maintenance intervals and we would like to see the results of that survey as well. Specific comments:

Organization	Yes or No	Question 3 Comment
		2. Protective Relays 6 calendar years is okay. 3. Voltage and Current Sensing Devices Inputs to Protective Relays We question the logic for a 12-year interval. Proper functioning should be verified at commissioning, and then anytime thereafter if changes are made in a PT or CT circuit. Additional periodic checks may be warranted as suggested in Table 1A, however no additional checking should be required where circuit configuration will inherently detect problems with a PT or CT. For example, PTs & CTs that are monitored through EMS or microprocessor relays will be alarmed when they are out of specification. 4. Protection System Control Circuitry (Breaker Trip Coil Only) (except for UFLS or UVLS) In locations where the continuity of the circuit is not monitored (via a light in the path or through a microprocessor relay) this would be a very complicated test, which could impact reliability, especially if done every three months. 5. Protection System Control Circuitry (Trip Circuits) (except for UFLS or UVLS) Need clarity on exactly what the activity is to include. We believe proving one output all the way to the trip coil is appropriate. Proving every output and every auxiliary contact, to the trip coil would be unnecessarily invasive and could impact reliability, even if done every 6 calendar years. 6. Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only) Interval is okay, but we disagree with tripping the breakers proving the output of the relay should be sufficient. Systems that have all load shed on distribution circuits should require trip output be confirmed but should not be required through to the trip coil due to constraints in tying distribution load. 7. Station dc supply (that has as a component any type of battery) 3 month and 18 month intervals are probably okay, depending on what is required to “verify continuity and cell integrity of the entire battery” and “inspect the structural integrity of the battery rack”. 8. Station dc supply (that has as a component Valve Regulated Lead-Acid batteries) 3 calendar years and 3 month intervals are probably okay, depending on what is required for the “performance or service capacity test”. 9. Station dc supply (that has as a component Vented Lead-Acid batteries) 6 calendar year and 18 month intervals are probably okay, depending on what is required for the “performance, service or modified performance capacity test”. 10. Protection system communication equipment and channels 3 months and 6 calendar years seem reasonable, depending upon what is included in the substation inspection, and what is required for power-line carrier systems. 11. UVLS and UFLS relays that comprise a protection scheme distributed over the power system Can’t comment on the 6 calendar year interval until we get more clarity regarding the meaning of “distributed over

Organization	Yes or No	Question 3 Comment
		the power system".
Response: The SDT thanks you for your comments. **1. See Supplementary Reference Document, Section 8 (page 9).** **2. The SDT thanks you for your support.** **3. For unmonitored systems, the SDT believes that the interval specified in Table 1a is appropriate. If alarming is available for anomalies, you may be able to use Table 1c with continuous monitoring.** **4. Table 1a has been modified to remove the activities to which you refer.** **5. See Supplementary Reference Document, Section 15.3 (page 22).** **6. The requirements relating to Protection System Control Circuitry for UFLS/UVLS only do not require tripping of the breaker.** **7. Thank you for agreeing with the Maximum Maintenance intervals associated with the Maintenance Activities. The SDT has modified the standard concerning the requirement to verify cell integrity (See FAQ II-5-C, page 12), and continuity (See FAQ II-5-D, page 13) and inspecting for the structural integrity of the battery rack (See FAQ II-5-H, page 15).** **8. How to conduct a performance and service capacity test for Valve Regulated Lead-Acid batteries are explained in detail in various available reference books. One of the options available to the Protection System owner who is responsible for maintaining a station dc supply that can perform as designed is to conduct a performance or service capacity test within the Maximum Maintenance Interval of Table 1 that will verify that a VRLA battery will satisfy the design requirements (battery duty cycle) of the dc system.** **9. How to conduct a performance service or modified performance capacity test for Vented Lead-Acid Batteries is explained in detail in various available reference books.** **10. These intervals are for power line carrier channels as well as other types of communications channels.** **11. See FAQ II-7-C (page 19).**		
Electric Market Policy	No	Recommend that all Level 1 three-month maintenance intervals be changed to a quarterly based system where only 4 inspections are required per year. Given a 3 month maximum interval, activities would need to be scheduled every 2 months, which would result in six inspections per year. Our experience of four inspections per year has proven to be successful.
Response: The SDT thanks you for your comments. The SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		

Organization	Yes or No	Question 3 Comment
SERC (PCS)	No	Recommend that all Level 1 three-month maintenance intervals be changed from 3 months to quarterly. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. This would result in six inspections per year. In the experience of many of our utilities, four inspections per year have proven to be successful.
Response: The SDT thanks you for your comments. The SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		
Indianapolis Power & Light Co.	No	See comments in number 2 above.
Response: The SDT thanks you for your comments. See response to comments in Question 2.		
Austin Energy	No	See item # 10 Comments
Response: The SDT thanks you for your comments. See Question #10 Response		
Wolverine Power Supply Cooperative, Inc.	No	See question 2 response
Response: The SDT thanks you for your comments. See Question #2 Response		
SCE&G	No	Several maximum maintenance intervals are 3 months. Since this is an absolute maximum period, entities would need to schedule on a 2 month basis to assure the 3 month maximum is met, i.e., 6 times per year. We recommend that 3 month periods be increased to 4 months which allows scheduling every 3 months. Other methods of achieving the same result are to state periodic requirements of quarterly or 4 times per year.
Response: The SDT thanks you for your comments. The SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" or "four times per year" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		
Wisconsin Electric	No	Similar to comments in #7 above: It is our practice on distribution-level protection systems to utilize a 6 year interval plus/minus 1 year to accommodate potential scheduling conflicts. This is consistent with other LSE's relay testing practices as well. Thus the potential 7 year maintenance interval would be a violation of the draft

Organization	Yes or No	Question 3 Comment
		requirements. The maintenance intervals in this standard should be increased accordingly for distribution protection system equipment.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a “grace period”, if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a “grace period” would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document for a discussion on this issue.		
Pepco Holdings Inc.	No	Table 1a requires verification of the continuity of the breaker trip circuit every three months in the absence of a trip coil monitor. Recommend maintenance interval to match that for other protection system control circuitry (6 years).
Response: The SDT thanks you for your comments. The SDT has modified the standard to remove the requirement to which you refer.		
Nebraska Public Power District	No	Table 1a, for Station DC supply (that has as a component - Valve Regulated Lead-Acid batteries) establishes a Maximum Maintenance Interval of 3 Calendar Years for the following Maintenance Activity: Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. What is the basis for this interval? NPPD’s experience indicates that a 5 Year interval is adequate, especially during the early service life of the battery bank, with increasing frequency as the bank ages.
Response: Thank you for your comment concerning the Maximum Maintenance Interval for Valve Regulated Lead-Acid batteries (VRLA). Due to the failure mode and designed service life of VRLA batteries compared to a Vented Lead-Acid batteries, the SDT believes that extending capacity testing of a VRLA battery beyond the maximum maintenance interval of 3 calendar years in Table 1 cannot be justified regardless of what the battery manufacturers of VRLA batteries recommend. This is especially true in the later periods of service life beyond 3 calendar years as noted by many utilities requiring total replacement of their VRLA batteries after 4 years of service. It appears that your practices are actually addressing Vented Lead Acid batteries, rather than Valve Regulated Lead-Acid batteries.		
Dynegy	No	The 3 month interval in Table 1a for verification of the continuity of the breaker trip circuit is only feasible if this verification can be done by inspection versus testing (see Response to Question 2).
Response: The SDT thanks you for your comment and has removed the requirement.		

Organization	Yes or No	Question 3 Comment
Southern Company	No	1. The 3 month intervals specified for the trip coil monitoring and communication circuit testing are too frequent. Our experience is that trip coils rarely burn open and don't need to be checked this often. If no monitoring currently exists, manually checking the circuit (until a time where monitoring can be installed) may inadvertently cause a trip. This adds risk to the reliability. Thus, requiring the trip circuits to be tested every 3 months may reduce the reliability of the BES. 2. Protection System Control Circuitry (Breaker Trip Coil Only) (Except for UFLS or UVLS) In order to reduce the risk of reducing Bulk Electric System reliability a better time interval for testing un-monitored trip coils would be 12 months. This may need to be 24 months for Nuclear Generating units. 3. Some allowance for a grace period (beyond the specified intervals) should be considered for all classifications. Outage schedules are known to change unexpectedly due to unforeseen circumstances. A grace period tolerance of +25% for specified maintenance intervals less than 12 months and of +1yr for those intervals specified as greater than 12 months is recommended. Typically at a nuclear plant a grace period is allowed by plant procedures. This grace period is defined as an additional 25 percent of the original schedule interval for the task. The grace period is provided as reasonable flexibility to allow for alignment with surveillance activities and equipment maintenance outages and to better manage the use of station resources. Some maintenance activities will require an outage to perform the work. Refueling outages are typically performed on an 18 month or 24 month refueling cycle. However, refueling outages do not always fall exactly on that interval. It is possible that the duration between one outage to the next may exceed 18 or 24 months. For activities that are required to be complete on a calendar year cycle this should not be an issue since the outages are normally scheduled several months prior to the end of the year. However, if the interval is a monthly interval there could be a problem with scheduling the maintenance such that it does not impact planned maintenance activities, surveillance requirements, and station resources. 4. Tables 1a, 1b and 1c have several instances where inspection and testing of DC circuits or components has a specified interval of 18 months. At nuclear generating stations, such tests on station battery banks and associated chargers incur unacceptable risk if performed with the unit on line and a unit outage is required for this testing. A number of nuclear plants are on two-year shutdown cycles and we request that the 18 month intervals be changed to two (2) (calendar) year intervals to accommodate this. 5. Protection System Control Circuitry (Breaker Trip Coil Only) (Except for UFLS or UVLS) Based on past performance, a complete functional test trip every 6 years is not warranted. This complete functional test introduces additional risk to our maintenance program, not only from a human error perspective, but also from the additional frequency of switching and outages required. Our experience has shown that 12 years is an appropriate maximum time interval (rather than 6 years.)
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 3 Comment
1. The SDT believes that such maintenance of the communications will primarily be performed by inspection monitoring lamps and so forth. The trip coil requirements to which you refer have been removed. 2. This activity is primarily inspection-based, involving no invasive testing. The stated intervals seem appropriate. 3. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 (page 9) of the Supplementary Reference Document for a discussion on this issue. 4. All Maintenance Activities listed in Tables 1a, 1b, and 1c related to the station dc supply that have a Maximum Maintenance Interval shorter than two (2) (calendar) years are necessary inspection, checking or verification activities routinely performed on the station dc supply with it in service and without posing an unacceptable risk. The Drafting team feels that to extend these activities beyond their Maximum Maintenance Intervals listed in Table 1 would jeopardize the station dc supply. 5. The SDT believes that the 6-year interval for this activity is appropriate. If you experience supports a longer interval, the standard permits you to utilize Performance-Based maintenance.		
AEP	No	The availability to perform maintenance of many protection systems is dictated by the load or customer that is connected. Many of these industrial customers, who are outside the jurisdiction of NERC requirements, operate 24X7 and see the outages required for maintenance as a nuisance and a loss of revenue. How can the owner be held non-compliant for not meeting the intervals when they may not control the timing? Comments expanded in question 10 responses.
Response: The SDT thanks you for your comments. This non-compliance would be addressed via contract law; these contracts are described in the Statement of Compliance Registry.		
US Bureau of Reclamation	No	The definition of Protection System components does not add clarity. The standard proposes including stations service transformers for generation facilities, however, the protection system definition does not include those elements. The inclusion of station service transformers would only be appropriate if the protection associated with the transformer results in the tripping of a transmission element.
Response: The SDT thanks you for your comments. The applicability to station service transformers emphasizes the impact of those components on the operability of the associated generator. They are not themselves Protection System components; however, maintenance of the Protection System		

Organization	Yes or No	Question 3 Comment
components on those system elements is required per the Standard. See FAQ III-2-A (page 20).		
Ohio Valley Electric Corp.	No	The documentation requirements for the inspection activities with three month intervals are oppressive and should not be a part of the protection system maintenance standard.
Response: The SDT thanks you for your comments. The SDT disagrees; it is left to the entity to adopt effective methods to document these activities.		
CPS Energy	No	1. The first problem that I have is the 3 Months for the Protection system communications equipment and channels component. My main concern with this interval is that it is so extremely short and I am concerned that there may not be any rational behind it. What studies, surveys, or statistical data were used to determine that 3 months is necessary to protect the reliability of the BES? It doesn't make sense that a communications signal needs to be checked every 3 months but the protective relay that utilizes that scheme needs to be checked at most only every 6 years. 2. What concerns me the most with the 3 month interval for my company is with on-off power line carrier DCB schemes? We only have these schemes on tie lines, and it can be difficult to implement a checkback system with another utility who might utilize different carrier equipment. This type of scheme is also intended to be inherently insecure and is frequently more or less tested with faults in the system. The SPCTF should do surveys to determine what is presently done with these type of systems or provide some other rationale for the communication requirements. It is not totally clear from the documents, but it appears that the only way to avoid the 3 month check for an on-off power-line carried DCB scheme is to have an automated check back scheme. Is this correct? Or is alarming from the carrier equipment adequate? 3. My second problem is with the 6 year maximum maintenance interval for the breaker trip coil in tables 1b and 1c. By having to verify that each breaker trip coil is electrically operated, you might as well perform a functional test to test the protection system control circuitry. Electrically operating the trip coil tests the breaker as much as it test the actual trip coil. Also, if you have a primary and secondary trip coil, is it really necessary to test this often? What studies or statistical data were used to determine that testing the breaker trip coils every 6 years is necessary to protect the reliability of the BES? 4. My third problem is with the intervals requirements for the UVLS/UFLS systems. Other than testing and calibration of electromechanical UVLS/UFLS, most other tests probably should require at most 10 years for these types of systems. These systems don't require the performance level of most other systems as stated in the supplementary reference. The testing and calibration of electromechanical UFLS should possibly be even shorter than the 6 year requirement due to problems with drift with these type of relays. What studies, surveys, or statistical data were used to determine the intervals in related to UFLS/UVLS.?
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 3 Comment
1. The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays. **2. The automated check back systems are common ways to verify the integrity of the relay communication channel. It would only be moved to Level 2 if the check back test is monitored remotely and the tests are run daily. Without check back equipment, it will be necessary to have personnel at both ends and manually initiate a signal and verify that the remote equipment operates.** **3. In the experience of the SDT and the NERC SPCTF, the 6-year interval is appropriate. The SPCTF also conducted an informal survey of entities representing approximately 2/3 of the NERC net-energy-for-load and a review of IEEE surveys to validate these intervals. See the Supplementary Reference Document, Section 8 (page 9).** **4. In the experience of the SDT and the NERC SPCTF, the 6-year interval is appropriate. The SPCTF also conducted an informal survey of entities representing approximately 2/3 of the NERC net-energy-for-load and a review of IEEE surveys to validate these intervals. See the Supplementary Reference Document, Section 8 (page 9). The maintenance of the other Protection System components associated with UFLS/UVLS is specifically stated to correspond with the intervals for the relays themselves.**		
Consumers Energy Company	No	1. The interval for Protection System Control Circuitry (breakers trip coil) should be set at 12 years since this is a scheme test. This test requires testing of the circuit and not just the coil. 2. The interval for Protection System Control Circuitry (trip circuit) should be set at 12 years since this is a scheme test. The Protection System Control Circuitry (trip circuit) test would require tripping off customers on radial distribution circuits which is not acceptable. 3. The interval for a station battery service test (lead acid) should be set at 5 years based on NFPA 70B.
Response: The SDT thanks you for your comments. **1. The SDT believes that the intervals indicated in the standard are appropriate. The standard allows the use of Performance-Based maintenance if your experience supports it.** **2. The SDT believes that the intervals indicated in the standard are appropriate. The standard allows the use of Performance-Based maintenance if your experience supports it. The standard applies only to Protection Systems on BES components as established by your regional BES definition.** **3. NFPA 70B is a recommended practice which is voluntary, and is not a standard that establishes any requirements that must be measurable. NERC standard PRC-005 requirements are loosely aligned with some of the NFPA standards. However, the Maximum Maintenance Intervals required in PRC-005-2 were established to be measurable and enforceable. If an owner chooses to perform the Maintenance Activities outlined in Table 1 of the standard at a lesser interval the owner is free to do so.**		
RRI Energy	No	1. The intervals need to be defined on a calendar quarters or calendar years, especially for intervals listed as 3 months. The demonstration of maintenance on rolling three-month intervals will be an onerous record

Organization	Yes or No	Question 3 Comment
		keeping task, particularly when relying upon planning and tracking software that scheduled recurring tasks on the same day of an interval. 2. Given the magnitude of the number of trip circuits, the requirements set an un-acceptable trap of non-compliance from a record keeping perspective. The resources required to keep and maintain flawless records are too much to justify the intervals. A non-compliance is the result if the breakers that happen to be in an open state when the officially "documented" inspection is recorded and is missed by accidental oversight on follow-up. If the requirement remains, it should be waived for any breaker that is operated during the defined interval.
Response: The SDT thanks you for your comments. **1. The SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" or "four times per year" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.** **2. The dc control circuit maintenance to which you refer has been removed from the standards. The SDT disagrees that the record keeping is excessively burdensome; it is left to the entity to adopt effective methods to document these activities.**		
Progress Energy	No	The rational for microprocessor-based relay intervals is examined, but all others are strictly based on industry weighted average of survey results. We believe the team should use a more empirical, documented approach to determining these intervals, as many companies have longer intervals that they currently have documented for their basis. If these have been accepted as satisfactory in previous audits, why should they be required to change just to meet an arbitrary number?
Response: The SDT thanks you for your comments. The standard permits entities to use Performance-based maintenance if they have documented experience which supports doing so.		
Northeast Power Coordinating Council	No	1. We question whether any maintenance activity should be as long as 12 years. Considering the rate of change in personnel and technology, the working group should reduce the time period by redefining the requirement if necessary, or eliminate the standard requirement. 2. In addition, the DC components have too many tests at confusing intervals. Confusion will make it difficult to implement or follow the exact method used.
Response: The SDT thanks you for your comments. **1. In the experience of the SDT and the NERC SPCTF, the intervals within the standard are appropriate. The SPCTF also conducted an informal survey of entities representing approximately 2/3 of the NERC net-energy-for-load and a review of IEEE surveys to validate these intervals. (See**		

Organization	Yes or No	Question 3 Comment
Supplementary Reference Document, Section 8.4, page 13) **2. The SDT has modified the standard in consideration of your comments and simplified the maintenance activities associated with dc supplies.**		
Detroit Edison	No	What is the basis for the three month interval for verifying breaker trip coil continuity? Will the investment required to facilitate this really result in the presumed expected increased reliability?
Response: The SDT thanks you for your comments and has removed the requirement.		
Manitoba Hydro	No	1. When we have redundant digital relay system that would fall under Level 1c category with a 12 year maintenance cycle, but the Protection System Control Circuitry is non-monitored so it falls under Level 1a, with a 6 year maintenance cycle. We will have to complete relay maintenance and trip testing every 12 years and trip testing only every 6 years, therefore we must complete trip testing twice as often as we are doing the maintenance. We feel that relay maintenance and trip testing should be completed at the same frequency. 2. The Protection System Control Circuitry (Breaker Trip Coil) checks every three months is too excessive. These circuits are checked during trip testing of the Protection scheme, at the 6 or 12 year interval. 3. If we have a redundant digital relay system, using a IEC61850 communication from the relay to a common breaker aux trip relay, what level does this system fall under?
Response: The SDT thanks you for your comments. **1. Whether relay systems are redundant are immaterial in determining appropriate maintenance intervals. The SDT believes that the intervals established in the standard are appropriate. The Tables have been revised extensively; the SDT invites you to review the revised Tables to determine how they affect your system.** **2. The requirement to which you refer has been removed from the Table.** **3. Whether relay systems are redundant are immaterial in determining appropriate maintenance intervals. You will need to evaluate all components to determine applicable maintenance activities; the digital relays MAY fall under Table 1c, but other components may fall under any of the Tables.**		
Xcel Energy	No	Within the tables, several components related to UFLS/UVLS systems have an interval of “when the associated UVLS or UFLS system is maintained.” Yet, there is no maximum interval established for a UVLS or UFLS system. We feel this item should be clarified. If the intent of the SDT is to tie the testing to when the UFLS/UVLS relays are maintained, so that all components are tested at the same time, then this should be made clear. One possible resolution would be to change the interval to read: “when the associated UVLS/UFLS relays are maintained”.

Organization	Yes or No	Question 3 Comment
Response: The SDT thanks you for your comments. The interval for the UVLS or UFLS system relays is established within Table 1a, Table 1b, and Table 1c. The intent of the SDT is to facilitate concurrent maintenance of all components associated with these systems at a common location.		
AECI	No	1. Comments: Table 1a 3 months for protection system coil check out seems extreme. Should be at least 1 year. 2. Same as comment 4 for the communication checkout on page 9.
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard to remove the requirement to which you refer.** **2. See response to your question 4 comment on communication checkout.**		
Puget Sound Energy	Yes	PSE appreciates the explanation of calendar provided in the supplementary reference on page 14. Further clarity would be gained by an example that is not at the end of a calendar year. For example if a relay was maintained June 15, 2008, would it be due for maintenance again no later than June 30, 2014 or December 31, 2014.
Response: The SDT thanks you for your comments. For your example, the maintenance would have to be completed within 2014.		
Bonneville Power Administration	Yes

Operations and Maintenance	Yes	

Organization	Yes or No	Question 3 Comment
Otter Tail Power	Yes	
Saskatchewan Power Corporation	Yes	
TVA	Yes	
Western Area Power Administration	Yes	

4. Within Tables 1b and 1c, the draft standard establishes parameters for condition-based maintenance, where the condition of the devices is known by means of monitoring within the substation or plant and the condition is reported. Do you agree with this approach? If not, please explain in the comment area.

Summary Consideration: Most respondents agreed with the general approach regarding condition-based maintenance, many of them with questions and/or comments. Many of the comments requested clarification of any of a variety of specific provisions within Tables 1b and 1c, and revisions were made to the Tables to present the information more clearly. The activities for control circuits and for dc supply were considerably re-worked.

Organization	Yes or No	Question 4 Comment
Green Country Energy LLC		No Preference at this time.
Exelon Generation Company, LLC	No	1. Please provide more clarification on what constitutes "partially monitoring." For example, is a computer auxiliary contact alarm count as partial monitoring? Would a common alarm between relays meet the definition of partial monitoring? 2. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs. 3. Table 1b Station dc supply (that has as a component valve regulated lead-acid batteries) should provide an additional optional activity for "Total replacement of battery at an interval of four (4) years. 4. There seems to be a disconnect between the monitoring attribute and maintenance activity. For example, the monitoring attribute "Monitoring and alarming of the station dc supply voltage/detection and alarming of dc grounds" has the maintenance activity "verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire batter bank. (3 calendar years) or " Verify that the station battery can perform as designed by evaluating the measure cell/unit internal ohmic values to station battery baseline (3 months)." The maintenance activity does not support the monitoring attribute. 5. If an entity has implemented Table 1b and/ or Table 1c, is there an acceptable length of time that the monitoring equipment can be out of service without falling back to Table 1a requirements?
Response: The SDT thanks you for your comments.		

Organization	Yes or No	Question 4 Comment
1. A common alarm would meet the definition of partially monitored. See FAQ V-3-A (page 38). 2. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue. 3. The SDT believes that total replacement of a VRLA battery set at an interval of four (4) years in lieu of not conducting a capacity test at the maximum maintenance interval of 3 calendar years, or evaluating the measured cell/unit internal ohmic values to the station battery's baseline at the maximum maintenance interval of 3 months would put the owner of the battery set out of compliance with the standard. The SDT believes the three calendar year Maximum Maintenance Interval for conducting a capacity test (listed in Table 1) cannot be exceeded. If an owner does a total replacement of the battery within a three calendar year interval from initial installation of a VRLA battery set, the owner will be compliant with the standard. Extending the time that a VRLA goes beyond the Maximum Maintenance Interval in Table 1 without verification that it can perform as designed is not adequate to insure that the station battery will perform reliably. 4. The monitoring attributes describe "what you know of the component via the monitoring", while the activities describe what must be done relative to the "things you don't know". Therefore, it's expected that the attributes and activities will be dissimilar. 5. The equipment used to monitor the alarms must be returned to service within the shortest Table 1a interval of the monitored components. For example, if monitoring is used to defer the 3-month Table 1a maintenance activity related to Protection System Control Circuitry, the monitoring function must be returned to service within 3 months. This has been added to Table 1b and Table 1c as a requirement.		
American Transmission Company	No	1. ATC does not believe that there is a relay, on the market today, that has the ability to fully monitor itself as described in Table 1c. We believe that Table 1c should be deleted. (Table 1b could cover any device that has the ability to fully monitor if such a device is developed in the future.) ATC does not believe that NERC Reliability Standards should be used as an enticement for manufacturers to develop specific devices. 2. Under the "General Description" in Table 1c, there is a reporting requirement identifying a 1 hour window. ("must be reported within 1 hour or less of the maintenance-correctable issue occurring, to the location where action can be taken.") ATC believes that the team needs to define if this action is a phone call or physically verify the maintenance correctable issue which is occurring.
Response: The SDT thanks you for your comments. 1. Your observation may be accurate at the present time and is not limited to protective relays. The standard was developed with future improvements		

Organization	Yes or No	Question 4 Comment
in technology and practices in mind. **2. This reporting requirement is intended to be by whatever means is available, to a location where resolution of the maintenance-correctable issue can be initiated.**		
Duke Energy	No	For utilities like us with large numbers of relays it's too complicated, which drives us back to Table 1a.
Response: The SDT thanks you for your comments. The standard was written with enough flexibility to allow entities to make the best business decision for their situation. Some entities may decide that Table 1a is the best fit for their situation.		
AEP	No	How would the failure of a SCADA system affect the ability to take advantage of monitoring?
Response: The SDT thanks you for your comments. **It doesn't, as long as the SCADA system is returned to service within the shortest Table 1a interval of the monitored components. For example, if monitoring is used to defer the 3 month Table 1a maintenance activity related to Protection System Control Circuitry, the monitoring function must be returned to service within 3 months. This has been added to Table 1b and Table 1c as a required attribute for the associated type of protection system component.**		
Illinois Municipal Electric Agency	No	IMEA supports comments submitted by Florida Municipal Power Agency regarding use of the word "every" in Table 1c.
Response: The SDT thanks you for your comments. See response to FMPA.		
Pepco Holdings Inc.	No	Monitoring and alarming of the station dc supply and detection and alarming of dc grounds are required to qualify for Level 2 monitoring of battery / dc systems. While the presence of dc ground may affect protection and control operations, they do not affect any of the systems for which dc ground alarming is listed as a monitoring criteria. Recommend removing this criterion from the battery & dc system monitoring criteria and adding it as a maintenance activity, with frequency of testing based on presence of detection / alarming.
Response: The SDT thanks you for your comments. The dc ground alarm may identify a maintenance correctable issue, which must be resolved according to Requirement R4. The SDT believes that dc ground detection is usually a part of battery maintenance; this is sometimes even included in the battery charger.		
Electric Market Policy	No	Recommend that all Level 2 three-month maintenance intervals be changed to a quarterly based system where only 4 inspections are required per year. Given a 3 month maximum interval, activities would need to be scheduled every 2 months, which would result in six inspections per year. Our experience of four

Organization	Yes or No	Question 4 Comment
		inspections per year has proven to be successful.
Response: Thank you for your comments .SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" or "four times per year" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		
SERC (PCS)	No	Recommend that all Level 2 three-month maintenance intervals be changed from 3 months to quarterly. Given a 3 month maximum interval an entity would need to schedule these tasks every 2 months. This would result in six inspections per year. In the experience of many of our utilities, four inspections per year have proven to be successful.
Response: The SDT thanks you for your comments. SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" or "four times per year" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		
Wolverine Power Supply Cooperative, Inc.	No	See question 2 response
Response: The SDT thanks you for your comments. See Question 2 response.		
SCE&G	No	Several maximum maintenance intervals are 3 months. Since this is an absolute maximum period, entities would need to schedule on a 2 month basis to assure the 3 month maximum is met, i.e., 6 times per year. We recommend that 3 month periods be increased to 4 months which allows scheduling every 3 months. An alternate method of achieving the same result is to state periodic requirements of quarterly or 4 times per year.
Response: The SDT thanks you for your comments. SDT believes that the "3 Calendar Month" interval is necessary to maintain the periodicity of the maintenance activities. "Once per calendar quarter" or "four times per year" would allow up to a 6-month practical interval, which would not maintain this periodicity. This DOES permit entities to use four inspections per year provided that they carefully manage their maintenance activities.		
Detroit Edison	No	Table 1b indicates that this (level 2) includes all elements of level 1 monitoring. However, level 1 is constantly referred to as unmonitored in other places.
Response: The SDT thanks you for your comments and modified Table 1b to address your comment by removing this reference from the header of the table.		

Organization	Yes or No	Question 4 Comment
Southern Company	No	1. Table 1b should allow self-monitored circuits that are not alarmed but are monitored and logged by personnel daily or more often. Many plants and substations have personnel that do in person checks of unmanned control rooms. This is the equivalent of "Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures." For example, dc system ground potential lights and dc system volt meters exist on most control room bench boards or exist in the digital control systems at generating stations. These devices are monitored by operators in manned control rooms. 2. On Table 1b, Protection System Control Circuitry (Trip Coils and Auxiliary Relays), the monitoring component calls for "Monitoring and alarming of continuity of trip coil(s)." Clarify that "trip coil(s)" excludes Breaker Failure Initiate relay coil(s). 3. On Table 1b, Protection System Control Circuitry (Trip Coils and Auxiliary Relays) Experience has shown that electrically operating fully monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend eliminating this maintenance requirement from Table 1b. 4. On Table 1c, Protection System Control Circuitry (Trip Coils and Auxiliary Relays) Experience has shown that electrically operating fully monitored breaker trip coils, auxiliary relays, and lockout relays every 6 years is not warranted. This testing introduces risk from a human error perspective as well as from additional switching and clearances required. We recommend changing this maximum maintenance interval to 12 years. 5. Component monitoring attributes need to be defined for all components in table 1b and 1c. For example, the attributes for voltage and current sensing devices could be that "Voltage and current input circuits are monitored and alarmed". 6. Based on past performance, the requirement to electrically operate trip coils, auxiliary relays, and lockout relays every 6 years in Table 1b is not warranted. We recommend complete functional testing including electrical operation of breaker trip coils, auxiliary trip relays, and lockout relays every 12 years in tables 1b and 1c.

Response: Thank you for your response.

1. The SDT modified the Table 1b header to address your comment by adding "condition or" to the General Description. See FAQ V-1-D (page 30).

2. The SDT has modified the standard to clarify that this monitoring addresses monitoring of the trip circuit(s), rather than the trip coil(s).

3. The SDT believes that it is important that these mechanical devices be periodically (physically) exercised to assure that they will operate properly.

Organization	Yes or No	Question 4 Comment
4. The SDT believes that the intervals in the table are appropriate. The standard allows entities to utilize Performance-Based maintenance if they have appropriate documented experience. **5. The tables have been modified to address this issue, except where no relevant monitoring attributes exist.** **6. The SDT believes that the intervals in the table are appropriate. The standard allows entities to utilize Performance-Based maintenance if they have appropriate documented experience.**		
US Bureau of Reclamation	No	The condition based monitoring only provides for a very narrow process and excludes sound judgment in determining maintenance intervals. As long as the registered entity establishes parameters by which variation in the prescribed maintenance intervals are determined, justified variation should be allowed.
Response: The SDT thanks you for your comments. The SDT, in accordance with FERC Order 693, has prescribed maximum allowable maintenance intervals for unmonitored Protection System components (Table 1a), partially-monitored Protection System components (Table 1b), and fully-monitored Protection System components (Table 1c). For further discussion pertaining to intervals see Supplementary Reference Document, Section 8 (page 9). To allow an entity to use their discretion to extend these intervals, absent adoption of the criteria established for performance-based maintenance, would be contrary to the direction established by FERC. For further discussion pertaining to performance based maintenance see Supplementary Reference Section 9.

MRO NERC Standards Review Subcommittee	Yes	A. The MRO NSRS agrees with this approach; however, I think most entities will not see the advantage of condition-based maintenance until they can resolve any gaps in data retention. If an entity was retaining a set of maintenance records but failed to include all the needed information as specified in this standard so they would need to adjust their maintenance procedure to collect all information and then they would need to wait for the entire retention period until they could start using the extended maintenance interval. If an entity had a collateral set of records which verified the information that lacked in the original maintenance record then could the entity start using the extended maintenance interval? For example, an entity has records showing that they have maintained a voltage or current transformer within the prescribed maintenance interval listed in level 1 monitoring (which is a maximum 12 year maintenance interval). Could this same entity go to level 3 monitoring (which is a continuous maintenance interval) immediately if it can query their SCADA and produce detailed records indicating the accuracy of the PT or CT for the maintenance records already retained? B. For lockout relays, if commissioning tests are done diligently, the trip DC availability is continuously monitored and the trip coil itself is continuously monitored, is it necessary to operate these relays for functional testing? For breaker failure lockout relays, re-verifying the operation of the coil and all the contacts could mean taking multiple breakers and line terminals out of service at the same time. Functional trip tests could cause unintentional tripping of equipment, cause equipment damage and interruption of service to customers. It's hard to see how the reliability of the BES is significantly improved by doing this test. The MRO NSRS feels the risk of adverse impact could be greatly reduced by a longer interval such as 12 years. C. In table 1c, the word “continuous or continuously monitored” is used. Please clarify the “within 1 hour” time frame takes into account that there may be a communication outage (failover) that will prevent an entity to “continuously” monitor a device.

Response: The SDT thanks you for your comments.

A. It appears to the SDT that this comment actually is addressing performance-based maintenance, rather than condition-based maintenance. If the entity has all the necessary records to support immediate moving to a specific level of maintenance, or to performance-based maintenance, there should be no barrier to such an action.

B. The SDT is not aware of any monitoring system that can verify that these mechanical devices can indeed physically operate properly; thus the

Organization	Yes or No	Question 4 Comment
interval is established at 6 years. (See Supplementary Reference Document Section 15.4, page 23.) **C. "Continuous monitoring" is an attribute of the Protection System component to produce an indication of state or status; the 1-hour constraint refers to the communication method used to monitor the indications. The equipment used to monitor the alarms must be returned to service within the shortest Table 1a interval of the monitored components. For example, if monitoring is used to defer the 3 month Table 1a maintenance activity related to Protection System Control Circuitry, the monitoring function must be returned to service within 3 months. This has been added to Table 1b and Table 1c as a required attribute for the associated type of protection system component.**		
City Utilities of Springfield, MO	Yes	CU agrees with the approach, but, may not agree with the exact wording in the tables. For instance, the use of the word "every" in table 1c in "Protection System components in which every function required for correct operation of that component is continuously monitored and verified" may be overstating the level of monitoring that would realistically enable a Protection System to use table 1c.
Response: The SDT thanks you for your comments. Table 1c establishes that, with the monitoring attributes specified, periodic maintenance may not be necessary at all. In order to facilitate this, the constraint, "every function required for correct operation of that component is continuously monitored and verified" must be met. If a component cannot meet this constraint, it must be addressed within either Table 1b or Table 1a, as appropriate.		
Florida Municipal Power Agency, and its Member Cities	Yes	FMPA agrees with the approach, but, may not agree with the exact wording in the tables. For instance, the use of the word "every" in table 1c in "Protection System components in which every function required for correct operation of that component is continuously monitored and verified" may be overstating the level of monitoring that would realistically enable a Protection System to use table 1c.
Response: The SDT thanks you for your comments. Table 1c establishes that, with the monitoring attributes specified, periodic maintenance may not be necessary at all. In order to facilitate this, the constraint, "every function required for correct operation of that component is continuously monitored and verified" must be met. If a component cannot meet this constraint, it must be addressed within either Table 1b or Table 1a, as appropriate.		
JEA	Yes	Is it possible that for coil monitored equipment, such as LOR coils, that they were left out, of this Table allowing for a longer maintenance interval. Certainly LOR continuous coil monitoring with alarming to a 24 hour 7 day a week manned location, with emergency dispatch, would allow for a longer maintenance interval for continuously monitored LORs. Suggestion here might be alignment with continuously self-tested, monitored and alarmed microprocessor relays at 12 years.
Response: The SDT thanks you for your comments. Monitoring of the coil of these devices does not assure that the device will mechanically operate properly; thus the interval for verification of proper physical operation is established at 6 years similarly to Table 1a and Table 1b. (See Supplementary		

Organization	Yes or No	Question 4 Comment
Reference Document, Section 15.4, page 23.)		
ITC Holdings	Yes	We agree with the approach. We have several issues with the details of Maintenance Issues, Interval and Monitoring Attributes. See previous comments for Questions 2 and 3.
Response: The SDT thanks you for your comments. See response to your comments in Questions 2 and 3.		
Ameren	Yes	We agree with the condition-based approach. Our comments in 3 above apply to Tables 1b and 1c as well. We note that Table 1b Station dc supply intervals are the same as Table 1a. Why doesn't the monitoring cause 1b intervals to be longer than 1a?
Response: The SDT thanks you for your comments. The standard (specifically Table 1b) has been modified in consideration of your comment.		
Lower Colorado River Authority	Yes	We commend the drafting team for recognizing the advantages of using monitored systems and a condition-based approach. This approach recognizes the benefits of using newer technologies and will give utilities added incentive to update their relay systems.
Response: The SDT thanks you for your support.		
Puget Sound Energy	Yes	

5. Within PRC-005 Attachment A, the draft standard establishes parameters for performance-based maintenance, where the historical performance of the devices is known and analyzed to support adjustment of the maximum intervals. Do you agree with this approach? If not, please explain in the comment area.

Summary Consideration: Many of the respondents agreed with this approach, but comments indicated concern about perceived administrative difficulties in establishing performance-based maintenance programs. The SDT responded to these concerns by noting that associated administrative program development is one of the considerations that an entity must address when contemplating use of such a program.

Organization	Yes or No	Question 5 Comment
Green Country Energy LLC		N/A does not apply
MRO NERC Standards Review Subcommittee	No	A. The MRO NSRS is concerned that this approach could lead to non-compliance if the company follows this process and a Compliance Auditor disagrees with the method that was used. An applicable entity should be protected if they follow the standard appropriately. There should be some assurance of a grace period for mitigation if this selected approach was not accepted. B. Please provide the basis for having at least 60, then taking 30 (50%) for testing/maintenance. This may give an unfair advantage to larger companies rather than being fair across the board. This places an undue burden on smaller companies by having to team up with other asset owners.
Response: The SDT thanks you for your comments. **A. See Attachment A of standard. The entity has three years to get performance to an acceptable level (under 4% countable events) or get on the appropriate time-based interval.** **B. The requirement for having 60 and testing 30 is based on having a statistically significant number of devices. Please see Section 9.1 (page 16) of the Supplementary Reference Document for a discussion of the statistical basis. The standard allows smaller entities to share data in order to support their ability to utilize performance-based maintenance.**		
CenterPoint Energy	No	a. CenterPoint Energy lauds the SDT for recognizing that strict imposition of the maximum interval approach creates problems which the SDT attempts to correct by allowing performance-based adjustments. CenterPoint Energy believes the majority of industry commenters will agree with CenterPoint Energy's assessment that the maximum interval approach is problematic and should be dropped from the proposal. However, if the majority of industry commenters agree with the SDT's approach, then a performance-based option to correct the problems introduced by the maximum interval requirements should remain.

Organization	Yes or No	Question 5 Comment
		b. CenterPoint Energy answered "No" to question 5 because CenterPoint Energy believes the arduous path of creating a new set of problems with a rigid approach (maximum interval requirements) and then introducing a complex set of auditable requirements to provide an option (performance-based maintenance) to mitigate the harm of the rigid approach is ill-advised and fraught with pitfalls. Stated otherwise, using performance-based adjustments to correct inappropriate maximum intervals would not be necessary if the inappropriate maximum intervals were not imposed. CenterPoint Energy believes a better approach is to avoid introducing the new set of problems that then have to be mitigated by not imposing problematic maximum intervals. c. Followed to its logical conclusion, using performance-based adjustments to correct inappropriate maximum intervals is a contorted way of arriving at the philosophy embodied in the current set of standards in which entities determine the maximum intervals appropriate for their circumstances and performance. CenterPoint Energy's concern is that the contortions needed to arrive at the same point, in addition to being unnecessary, will be difficult for most entities to navigate. An entity making a good faith effort to comply with the performance-based adjustments will have to navigate through the complexities and nuances of the approach, as illustrated by the extensive set of documents the SDT has provided in an attempt to explain all the requirements and nuances. As an entity attempts to manage this hurdle, the entity will likely have to deal with the reality that the granularity of performance metrics do not exist in most cases to justify to an auditor the rationale for the adjustments to the inappropriate maximum intervals. For example, CenterPoint Energy has asserted that it has had good battery performance using existing practices. However, the assertion is anecdotal. CenterPoint Energy cannot recall any instances where it had a relay misoperation due to battery failure in over twenty five years. CenterPoint Energy does not attempt to keep performance metrics on events that historically occur less than four times a century and CenterPoint Energy believes most entities will be in the same situation. d. If an entity is somehow able to overcome these hurdles, the entity will almost certainly encounter skepticism for what will be viewed as an exception to the default requirement embodied in the standard. Even if an entity can overcome likely skepticism in an audit, the entity will be in a severely disadvantaged situation if a protection system component for which the maintenance interval has been adjusted, based on the entity's good faith effort and reasoned judgment, nevertheless is a contributing factor in a major reliability event investigation, regardless of whether the maintenance interval adjustment contributed to the failure. No matter what maintenance intervals are used, protection system components could fail. If the maintenance interval has been adjusted and if failure occurs, it will likely be unknown whether the interval adjustment was in fact a contributing factor or whether the failure would have occurred anyway. e. Faced with this dilemma, in addition to all the other hurdles to overcome in attempting to adjust an inappropriate maximum interval, the reality is that most entities will accept the inappropriate maximum interval and over-maintain their protection system components, and introduce a new set of reliability risks from such over-maintenance. For these reasons, CenterPoint Energy advises against creating a new set of problem by imposing rigid maximum intervals and then attempting to correct the problems through a performance-based

Organization	Yes or No	Question 5 Comment
		mechanism that in actual practice would likely be illusory.
Response: The SDT thanks you for your comments. **a. FERC order 693 requires that NERC establish maximum time intervals. The criteria for performance-based maintenance are established for entities that wish to establish other intervals based on concise stated criteria.** **b. FERC order 693 requires that NERC establish maximum time intervals. The SDT believes that the established intervals are appropriate. The criteria for performance-based maintenance are established for entities that wish to establish other intervals based on concise stated criteria.** **c. Entities are not required to use PBM, but instead may elect to simply use the intervals established in Table 1a, Table 1b, and/or Table 1c. However, if an entity keeps the necessary metrics to conform to Attachment 1, it may find opportunities within PBM; however, the SDT has established that maintenance of station batteries must be performed within a time-based maintenance program.** **d. The standard established maximum intervals, minimum maintenance activities, and, for PBM, minimum requirements (and performance). If an entity is concerned about whether these intervals will yield acceptable performance, it may perform more maintenance, more frequently, than established within the standard.** **e. FERC order 693 requires that NERC establish maximum time intervals. The criteria for performance-based maintenance are established for entities that wish to establish other intervals based on concise stated criteria, but entities are not required to use PBM.**		
ITC Holdings	No	Appendix A fixes a 4% level of "countable events". Is this number the industry average for countable events? Has the industry average actually been determined? The basis for the 4% requirement noted in Paragraph 5 of Appendix A should be included in the reference document. Also a sample calculation for adjusting the interval is needed to clarify the requirement.
Response: The SDT thanks you for your comments. We used failure and calibration data from some of the utilities on the drafting team to determine the 4% level; this value is also determined such that a single countable event on the 30 unit minimum test sample established via the statistical analysis described in Section 9 of the Supplementary Reference Document (page 15) does not exceed the threshold. See FAQ IV-3-D thru IV-3-F (pages 25-26) which discusses types of Misoperations and correcting segment performance.		
American Transmission Company	No	ATC agrees with this approach but is concerned that Attachment A does not contain enough language to support an entity that implements this practice. This attachment needs to clearly state that following your performance-based maintenance practices satisfies an entity's compliance obligations. Entities should not be subject to non-compliance over disagreements with their performance-based maintenance methodology.
Response: The SDT thanks you for your comments. The SDT believes Attachment A does contain enough language to support PBM, and this language is further supported by technical guidance from Section 9 of the Supplementary Reference Document (page 15). Additionally, R3 of the standard specifically provides that an entity that follows the requirements detailed in Attachment A is indeed in compliance. The SDT will consider any		

Organization	Yes or No	Question 5 Comment
suggested improvements.		
E.ON U.S.	No	E.ON U.S. recommends keeping with time-based intervals (and the improvement thereof) and staying clear of condition-based performance for the generating stations. But that is not meant to preclude other companies from doing condition-based, if they so prefer.
Response: The SDT thanks you for your comments.		
Indianapolis Power & Light Co.	No	Establishing historical performance and keeping the documentation up to date makes this almost useless
Response: The SDT thanks you for your comments. Entities are not required to use PBM.		
Florida Municipal Power Agency, and its Member Cities	No	FMPA believes that the documented process outlined in Attachment A; "Criteria for Performance Based Protection System Maintenance Program" is biased towards larger entities. The requirement that the minimum population of 60 individual components of a particular segment is required to make a component applicable to this program automatically eliminates most of the small or medium sized entities. Further the need to first test a minimum of 30 individual components in any segment reinforces the same size limitation. FMPA suggests that the Performance-Based Protection System Maintenance Program allow for regional shared databases applicable towards meeting the establishment and testing criteria of similar individual components. This practice will allow for the inclusion of entities of all sizes. This will also provide a greater format for the discussion of lessons learned and improvements to the testing database on a regional basis.
Response: The SDT thanks you for your comments. The requirement for having 60 and testing 30 is based on having a statistically significant number of devices. Please see Section 9.1 of the Supplementary Reference Document (page 16) for a discussion of the statistical basis. The standard allows smaller entities to share data in order to support their ability to utilize performance-based maintenance. See footnote 4 of Attachment A.		
Duke Energy	No	For utilities like us with large numbers of relays it's too complicated, which drives us back to Table 1a.
Response: The SDT thanks you for your comments. Entities are not required to use PBM.		
Illinois Municipal Electric Agency	No	IMEA supports comments submitted by Florida Municipal Power Agency that the process outlined in Attachment A is biased towards larger utilities.
Response: The SDT thanks you for your comments. The requirement for having 60 and testing 30 is based on having a statistically significant number of devices. Please see Section 9.1 of the Supplementary Reference Document (page 16) for a discussion of the statistical basis. The standard allows smaller entities to share data in order to support their ability to utilize performance-based maintenance. See footnote 4 of Attachment A.		

Organization	Yes or No	Question 5 Comment
City Utilities of Springfield, MO	No	It appears that Attachment A was written for large utilities. Some allocation needs to be made for utilities with smaller numbers of components.
Response: The SDT thanks you for your comments. The requirement for having 60 and testing 30 is based on having a statistically significant number of devices. Please see Section 9.1 of the Supplementary Reference Document (page 16) for a discussion of the statistical basis. The standard allows smaller entities to share data in order to support their ability to utilize performance-based maintenance. See footnote 4 of Attachment A.		
Saskatchewan Power Corporation	No	Saskatchewan agrees with the approach, but requires clarification in the definition of segment. The definition uses a population of 60 or more individual components but in the establishment of a PSMP, it only asks for a population of 30 or more. Which number will be used to define the segment?
Response: The SDT thanks you for your comments. The requirement is that a minimum population of 60 units be present, and that at least 30 units be tested on time-based maintenance (Table 1a) prior to moving to PBM. A minimum of 30 units tested is also used for ongoing analysis of the PBM performance, as specified in Attachment A. Please see Section 9.1 of the Supplementary Reference Document (page 16) for a discussion of the statistical basis.		
Austin Energy	No	See item # 10 Comments
Response: See item #10 response.		
Wolverine Power Supply Cooperative, Inc.	No	See question 2 response
Response: See question 2 response.		
Northeast Power Coordinating Council	No	The concept is acceptable, but the requirements to follow in Appendix A seem to be a deterrent from attempting to use this process. Is the term “common factors” meant to take into account variables at locations that can affect the components” performance (lightning, water damage, humidity, heat, cold)”
Response: The SDT thanks you for your comments. The SDT has attempted to make Attachment A as straight forward as possible. The term “common factors” does mean common variables that are expected to affect performance of the component such as lightning, water damage, humidity, heat and cold. The term also means common variables such as design, manufacture, performance history, etc that are expected to affect performance of the component.		
US Bureau of Reclamation	No	The parameters established can only be implemented with documentation that defined in the document but is

Organization	Yes or No	Question 5 Comment
		not readily available.
Response: Before utilizing a PBM for their Protection Systems, an entity must develop the supporting documentation via application of a time-based program (using the Table 1a intervals) in accordance with Attachment A.

Western Area Power Administration	Yes	
Wisconsin Electric	Yes	
Xcel Energy	Yes	
FirstEnergy	Yes	Although we agree with the parameters of the proposed PBM, we have the following comments: 1. We question the inclusion of Misoperations in countable events as described in footnote 4. Since standard PRC-004 already requires analysis and mitigation of Protection System Misoperations through a Corrective Action Plan, entities should not be required to repeat this analysis and mitigation in PRC-005. We ask that the SDT clarify the requirements to allow a tie between PRC-005 and PRC-004 so as to assure work is not duplicated. 2. We are not receptive to using this methodology to develop intervals due to the detailed tracking and analysis that will be required to establish maximum intervals. The approach may suit other utilities and thus, we are not opposed to the methodology being contained within the standard.

Organization	Yes or No	Question 5 Comment
Response: The SDT thanks you for your comments. **1. PRC-004 should be used to handle reporting of the Misoperation and its corrective action. However, the misoperation should be included as a countable event required for PBM analysis. The documentation of correction of problems per PRC-004 should also suffice to address resolution of the corresponding maintenance-correctable issue for PRC-005.** **2. Entities are not required to use PBM.**		
JEA	Yes	Approach appears to be well explained. Only one are of concern and that would be delaying the advancement of replacement of EM relay systems with microprocessor, if the PBM population were to decrease below the 60, resulting in not meeting the sample minimum population criteria. Falling below this 60 population sample minimum, might result in an immediate compliance violation.
Response: The SDT thanks you for your comments. The standard is not meant to delay replacement of relays. An entity should do an annual analysis of it segment size and countable events. As the segment population approaches 60, the entity should transition back to a time-based program per Table 1a, Table 1b, or 1c, as appropriate, and assure that the remaining components are maintained accordingly.		
Exelon Generation Company, LLC	Yes	None
TVA	Yes	Should allow inclusion of dc systems as well.
Response: The SDT thanks you for your comments. A Station DC supply that does not include batteries may be fit into a PBM. See Section 15 of the Supplementary Reference Document (page 21) (and FAQ IV-3-G, page 26) for a discussion of why station batteries cannot be included in a PBM.		
Ameren	Yes	While we agree with the approach, batteries should be allowed, not excluded.
Response: The SDT thanks you for your comments. See Section 15 of the Supplementary Reference Document (page 21) (and FAQ IV-3-G, page 26) for a discussion of why station batteries cannot be included in a PBM.		
Puget Sound Energy	Yes	

6. The SDT has provided a "Supplementary Reference Document" to provide supporting discussion for the Requirements within the standard. Do you have any comments on the Supplementary Reference Document? Please explain in the comment area.

Summary Consideration: In general, respondents expressed appreciation for the additional technical discussion included within this document. The SDT responded to many comments by explaining the relationship between the Standard and the Reference Document. Several respondents suggested that elements of the extensive discussion be contained within the standard itself, which is contrary to the guidance within the paradigm for NERC Standards.

Organization	Yes or No	Question 6 Comment
Bonneville Power Administration		Will this document be a part of the standard? Are its explanations the official interpretation of the standard?
Response: The FAQ and the Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.

Western Area Power Administration	No	
Wolverine Power Supply Cooperative, Inc.	No	
US Bureau of Reclamation	No	The document will require revisions. 1. Performance based maintenance is establishing a strategy to achieve a desired performance. The document limits strategy to statistical analysis of failure rates. 2. The document assumes a modern protection system with a high level of monitoring. Facilities which barely qualify would not have high end monitoring installed. 3. The document also refers to "exercising a circuit breaker through t relay tripping circuits using remote control capabilities via data communication." This repeated several times throughout the document as a means of increasing the TBM. This function, if indeed used, would require maintenance. This function is very dangerous and could introduce a cyber vulnerability.
Response: The SDT thanks you for your comments. **1. As you say, PBM is an option to achieve a desired performance. The result should be a documented acceptable level of performance, and statistical analysis of failure rates is required as a minimum method to achieve this level of performance.** **2. The standard addresses all generations of equipment with varying levels of monitoring capability, and establishes requirements which address the equipment with no monitoring capability, as well as facilitating effective use of monitoring capabilities of the equipment that DOES have those capabilities.** **3. Exercising a circuit breaker through the relay tripping circuits via a remote communication method is an available option to those entities that wish to use it to satisfy maintenance intervals established in the standard, not to increase them; this is presented as an example of how entities may be able to use remotely performed activities to minimize maintenance requiring station visits. If an entity is concerned about risks presented from remote maintenance activities, they are not required to use such methods. Issues relating to cyber security are outside the scope of this Standard.**		
Ontario Power Generation	No	A well prepared and useful document.
Response: The SDT thanks you for your support.		
MRO NERC Standards Review	No	N/A

Organization	Yes or No	Question 6 Comment
Subcommittee		
Exelon Generation Company, LLC	No	None
Entergy Services, Inc	No	1. Regarding Section 2.3, Applicability of New Protection System Maintenance Standards, there needs to be clarification and examples of applicable relaying associated with the language: and that are applied on, or are designed to provide protection for the BES. For example, is the application of reverse power schemes and directional overcurrent schemes considered applicable when considering the impact to the protection of the BES? 2. We agree with the application of the term “calendar” in the PRC-005-2 Protection System Maintenance Supplementary Reference document. There should be enough flexibility in interval assignments to allow for annual maintenance planning, scheduling and implementation.
Response: The SDT thanks you for your comments. **1. Please refer to Clause 4 (Applicability) of the standard itself, and to the FAQ document (FAQ III – 2 – A, page 20), for further information on this. It appears that this comment is focused on generation plants; Clause 4.2.5.1 of the draft standard states, “Protection system components that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.” This Applicability clause would have to be applied to the specific instance of concern.** **2. The SDT thanks you for your comments.**		
PacifiCorp	No	Very helpful.
Response: The SDT thanks you for your comments.		
Austin Energy	Yes	
Ameren	Yes	1) We disagree with the page 22 statement that batteries cannot be a unique population segment of a PBM. 2) What role does the Supplement play in Compliance Monitoring and Enforcement?
Response: The SDT thanks you for your comments. **1. Thank you for your comment concerning your disagreement with the standard Drafting Team that batteries cannot be a unique population segment of a PBM. In FAQ IV-3-G (page 26) and the Supplementary Reference Document (See Section 15.4, page 23), the Drafting team states why batteries are excluded from PBM. The Drafting Team still believes, that for the reasons stated in the FAQ, that batteries cannot be a unique population segment of a**		

Organization	Yes or No	Question 6 Comment
PBM. There was much debate on this topic in the standard drafting process. It is well known that like batteries will behave differently for even slight variations of outside influences such as temperature, station load, battery charger action, number of duty cycles and even time spent on inventory shelf before first charge. The manufacturers' literature all state that you must control outside influences to attain a level of satisfactory performance. To prove this level of satisfactory performance (and possibly to help detect poor performance from outside influences) you must conduct certain routine tests. Routine tests are included within the Standard's tables of maintenance activities. **2. The FAQ and the Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.**		
FirstEnergy	Yes	1. Sec. 2.3 (pg. 4) This section appears to be discussing the purpose of the standard and not the applicability. We suggest changing the title of Sec. 2.3 to "Purpose of New Protection System Maintenance Standard." Also, in Sec. 2.3 it states: "The applicability language has been changed from the original PRC-005: '... affecting the reliability of the Bulk Electric System (BES) ...' To the present language: '... and that are applied on, or are designed to provide protection for the BES.' However, the posted Draft 1 of PRC-005-2 still has the original Purpose statement. Is the SDT planning to revise the Purpose statement as discussed in Sec. 2.3 of the Ref. document? It appears that this statement is included in the applicability section 4.2.1 but believe it is more appropriate as a general purpose statement applying to the whole standard. 2. Sec. 2.4 (pg. 4) Remove the extra word "that" from the second sentence of this section. 3. In the Supplementary reference, section 15.4 Batteries and DC Supplies, third paragraph, the SDT indicates these tests are recommended in IEEE 450-2002 to ensure that there are no open circuits in the battery string. This is essentially a continuity check of the battery string. In the fourth paragraph, the SDT states that "..."continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards." 4. The SDT in Table 1a, the Maintenance Activity "Verify continuity and cell integrity of the entire battery", and in Table 1b, the Maintenance Activity "Verify electrical continuity of the entire battery". Based on the information in the Supplementary reference, the owner has to choose a method to verify continuity and the measurement of specific gravity and cell temperatures could be the selected method, however it should not be a required maintenance activity as shown in Tables 1a and 1b.

Organization	Yes or No	Question 6 Comment
Response: The SDT thanks you for your comments. **1. This clause of the document DOES specifically discuss the Applicability clause of the Standard; PRC-005-2 Section 4.2.1 states "Protection Systems that are applied on, or are designed to provide protection for the BES."** **2. The Supplementary Reference Document has been changed in consideration of your comment – the extra "that" has been removed.** **3. The standard and FAQ (See FAQ II-5-D, page 13) have been modified in consideration of your comments concerning checking continuity using specific gravity.** **4. Table 1a and Table 1b of the draft standard have been modified to remove requirements relating to measurement of cell temperature and specific gravity.**		
CPS Energy	Yes	Adds to the confusion with the standard, FAQ, and Supplemental. The three documents at times describe things a little differently.
Response: The SDT thanks you for your comments and is aligning the associated documents with changes to the standard.		
AEP	Yes	Although helpful in understanding and clarifying intent, the requirements of a standard should be clearly written so that multiple, lengthy supporting documents are not needed. These supporting documents do not get recorded into the registry as part of the standard and may or may not be used by auditors during compliance audits which could lead to different interpretations.
Response: The SDT thanks you for your comments. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.		
CenterPoint Energy	Yes	CenterPoint Energy believes the need for an extensive "Supplementary Reference Document", in addition to 13 pages of tables and an attachment in the standard itself, illustrates that the proposal is too prescriptive and complex for most entities to practically implement. CenterPoint Energy would prefer the SDT leave the existing requirements substantially intact or, if most industry commenters prefer the SDT's approach, that the SDT

Organization	Yes or No	Question 6 Comment
		attempt to simplify it.
Response: The SDT thanks you for your comments. The NERC Standard Development Procedure establishes that the standard prescribe requirements, but avoid "how to" or "why" discussions. The SDT, in accordance with FERC Order 693, has prescribed maximum allowable maintenance intervals for various Protection System Components, has provided opportunities for entities to use advanced technologies to perform physical maintenance less frequently, and to use analytical techniques to customize their intervals. At its simplest, an entity could implement a pure time-based program utilizing Table 1a, and much of the additional explanation in the Supplementary Reference Document would not be needed by that entity.		
Public Service Enterprise Group Companies	Yes	Figure 2 "typical generation system" shows a typical auxiliary medium voltage bus, suggest that a line of distinction (dotted line) be added to the figure that defines the element connected to the BES (station Aux Transformer - SAT) and equipment not associated with protection of the SAT be shown as not part of the BES-PSMP.
Response: The SDT thanks you for your comments. The figures are provided to help describe the components of the Protection System, and are not intended to fully describe the boundaries of the BES, the definition of which may vary by Region.		
Wisconsin Electric	Yes	How much authority or weight will this document have with Compliance staff? If potential violations of the standard requirements are alleged by Compliance staff, can this document be cited by an entity when the document provides clarifying information on the requirements?
Response: The SDT thanks you for your comments. This document is not part of the standard, but is intended to provide the rationale of the SDT, as well as guidance about how the various requirements might be met. The explanations are not an "official" interpretation of the standard, but may be useful to determine how to implement various facets of the standard.		
Green Country Energy LLC	Yes	Huge help to us!
Response: Thank you for your support.		
Platte River Power Authority Maintenance Group	Yes	1. It isn't clear in the Supplementary Reference Document why lock-out relays (86) are included as a component of Protection Systems that require a 6 year maximum interval. Historically we haven't experienced any failures with lock-out relays and feel the risk of causing a system reliability issue by removing it from service and restoring it far outweighs the benefits of testing it. What, if any evidence, i.e. equipment failure, does the standard drafting team use to mandate routine testing of 86 devices? Are we fixing something that isn't broke here? 2. The FERC order directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system be carried out within a maximum allowable interval that is

Organization	Yes or No	Question 6 Comment
		appropriate to the type of the protection system and its impact on the reliability of the BPS. It would seem more appropriate to allow each entity to set their own maximum allowable interval based on studies and historical data of their specific protection system and impact on the reliability of the BPS opposed to a blanket approach that covers all systems regardless of their size or system configuration.
Response: The SDT thanks you for your comments. **1. There are events in the industry that point to a failure of an electro-mechanical 86 device failing, and these devices are essential to proper functioning of the Protection System. PBM principles can be utilized to extend maintenance intervals. (See Supplementary Reference Document, Section 9, page 15.)** **2. FERC Order 693 directed that NERC establish maximum maintenance intervals, which does not provide the latitude to continue to allow entities to set their own intervals. The SDT has, however, added the ability of an entity to follow PBM principles, as you describe, thus adjusting the time intervals between required hands-on maintenance activity to reflect an entity's experience.**		
Progress Energy	Yes	Progress Energy is concerned that separating this document from the standard may lead to issues down the road. If the desire is to consolidate and clarify existing standards, then the two documents should be merged. Otherwise the reference document may get lost from the standard, or might get changed without due process, or might not even be recognized by FERC.
Response: The SDT thanks you for your comments. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.		
Southern Company	Yes	1.Section 15.3 DC Control Circuitry: Although we agree with the premise that auxiliary trip relays and lock-out relays are similar in nature to EM relays and breakers, we believe that based on past performance, a complete functional test trip every 6 years is not warranted. This complete functional test introduces additional risk to our maintenance program not only from a human error perspective but also from the additional frequency of switching and outages required. Our experience has shown that 12 years is an appropriate maximum time interval (rather than 6 years.) 2. The Protection System Maintenance Supplementary Reference (Draft 1), section 8.4, states that the intervals using the term "calendar" are allowed to be completed by the end of the applicable period, not necessarily

Organization	Yes or No	Question 6 Comment
		exactly at the interval specified. The only intervals specified in the PRC-005-2 tables are “calendar years” and “months”. We believe that the “calendar” description should be extended to the “months” designator also to also provide some maintenance flexibility (i.e. if an inspection were performed March 1st and was on a three month interval, it would not be required until the end of June). This section should remove the term “calendar” and use “months” and “years” with an appropriate explanation of the intent of the durations.
Response: The SDT thanks you for your comments. **1. The SDT believes that the intervals within the standard are appropriate. The standard permits the use of Performance-Based maintenance if an entity has documented experience that supports longer intervals.** **2. The standard was modified to append “Calendar” in front of “Months” in the Tables in consideration of your comment.**		
Dynegy	Yes	Suggest including operational verification (i.e. analysis of protection system operation after a system event) as an acceptable method of verification.
Response: The SDT thanks you for your comments. Verification through analysis of events is an acceptable method of verification. Section 11 of the Supplementary Reference Document (page 18) speaks to this topic.		
Oncor Electric Delivery	Yes	The “Supplementary Reference Document” provides good technical justification for the various approaches to a maintenance program (Time Based, Performance Based, and Condition Based) or combinations of these programs that an owner of a Protection System can follow.
Response: The SDT thanks you for your support.		
Xcel Energy	Yes	The information in the supplementary reference document is very helpful and valuable. Yet, it is not clear how the document would be managed/revised, nor what role it plays in compliance monitoring. There needs to be a clear understanding if everything in the document is required for compliance, e.g. criteria for monitored systems, etc. Additionally, we feel that evidence should be addressed within the supplementary reference document.
Response: The SDT thanks you for your support. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo		

Organization	Yes or No	Question 6 Comment
industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance. **The Supplementary Reference Document and FAQ have been updated to include a discussion pertaining to evidence for compliance.**		
Saskatchewan Power Corporation	Yes	The supplementary reference document is useful information if properly explained and justified. Are the suggestions in the reference document to become part of the standard, or simply recommendations of best practice from industry and serve as a document to reduce the number of interpretations requested?
Response: The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.		
Lower Colorado River Authority	Yes	The Supplementary Reference is well written and helpful in explaining the drafting teams thought process.
Response: The SDT thanks you for your support.		
Duke Energy	Yes	We strongly believe that this document should be made a part of the standard, either as an Attachment or worked into the requirements and tables. This will bring clarity to PRC-005 that is needed to get away from all the past problems that were due to a lack of clarity with the previous PRC-005 standards. Also, all the explanations and guidance lose force if they are not part of the standard. Auditors will only be bound by the standard.
Response: The SDT thanks you for your comments. The NERC Standard Development Procedure establishes that the standard prescribe requirements, but avoid “how to” or “why” discussions. The SDT, in accordance with FERC Order 693, has prescribed maximum allowable maintenance intervals for various Protection System Components, has provided opportunities for entities to use advanced technologies to perform physical maintenance less frequently, and to use analytical techniques to customize their intervals. At its simplest, an entity could implement a pure time-based program utilizing Table 1a, and much of the additional explanation in the Supplementary Reference Document would not be needed by that entity.		

Organization	Yes or No	Question 6 Comment
ITC Holdings	Yes	1. Will clarifications in the Reference Document be enforceable with the standard? 2. For example page 11 of the reference document notes “Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by comparison of known values of other sources on live circuits or by using test currents and voltages on equipment out of service for maintenance.” Can a maintenance program be confidently established using this or other testing methods included in the reference document? 3. A condensed definition of “Condition Based Maintenance” as described in Section 6 of the Reference document should be included in the standard document itself.
Response: The SDT thanks you for your comments. **1. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.** **2. The NERC Standard Development Procedure establishes that the standard prescribe requirements, but avoid “how to” or “why” discussions.** **3. Condition Based Maintenance is not intended to be a defined term; however, a discussion of the attributes of condition-based maintenance is captured within the header of Table 1b and Table 1c of the Standard.**		
E.ON U.S.	Yes	1. With reference to Section 8.1., under additional notes is the following bullet:5. Aggregated small entities will naturally distribute the testing of the population of UFLS/UVLS systems and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. This implies that incorrect performance of a “relatively small quantity” of UFLS relays is acceptable but with the understanding that it is not optimal. E.ON U.S. agrees with this statement in principle, in that the UFLS program is spread out across the system, and there is not a one to one performance expectation as there is with a transmission line or generation protection system. This calls into question the required intervals for testing of these types of relays, and the performance expectations in a PBM program. Given the number of relays spread out across the distribution system, the testing requirements of UFLS relays require longer testing intervals than other bulk transmission system

Organization	Yes or No	Question 6 Comment
		components. 2. 8.2 Is this requirement expected to be retroactive? That is, if the previous retention policy was followed to the letter, an entity could be fully in compliance based on the previous standard, but not be in compliance if PRC-005-2 were retroactive. 3. 8.3 And 8.4 This discussion explains how time based maintenance intervals were determined. The conclusion is based upon surveys of SPCTF members and their existing practices, and seemed to arrive at a maintenance interval based upon a simple average weighed by the size of the reporting utility. No consideration appears to have been given to utilities who have successfully operated with longer test and calibration intervals. In section 5 of the Supplementary Reference it is stated that “excessive maintenance can actually decrease the reliability of the component or system.” With that in mind, some of the intervals defined in the table seem too aggressive. 4. With the proposed PRC-005-2, the Drafting Team has effectively shortened the recommendation for UFLS relays from 10 years to 6 years, with reference to the recommendations of the Protection System Maintenance Technical Reference. E.ON U.S. believes that this is inconsistent with previous comments in Section 8.1, bullet 5 of the notes. 5. Consistent with the comments above and based on E ON U.S.’s internal testing, calibration and verification experience, E.ON U.S. recommends maintenance on UFLS relays that comprise a protection scheme distributed over the power system to be no less than 10 years for Level 1 monitoring and no less than 15 years for Level 2 monitoring. For a PBM program, require the number of countable events within a segment to be no more than 10%, not 4% as proposed.
Response: The SDT thanks you for your comments. **1. The SDT believes that the intervals specified in the standard are appropriate.** **2. The new standard will be effective according to the dates established within the standard. The Implementation Plan posted with the standard establishes a path for entities to migrate from their current practices and schedules to those imposed in this standard when approved.** **3. Entities that have successful experience with equipment at intervals beyond the Standard’s tables can utilize the Standard’s PBM option.** **4. The SDT believes that the intervals specified in the standard are appropriate, and disagrees that the intervals are inconsistent with the cited clause of the Supplementary Reference Document.** **5. Allowing the countable events to be increased to 10% would clearly allow an entity to increase its time interval between testing if there was a failure of less than 10% of the testing segment. However, SDT contends that would be an unacceptably high rate of mal-performing Protection System components, and would be detrimental to system reliability. The acceptable failure rate needs to balance between a goal of ultimate reliability and what could be reasonably expected of a well-performing component population.**		

Organization	Yes or No	Question 6 Comment
AECI	No	
Puget Sound Energy	Yes	PSE appreciates this document as it provides a lot of further clarity. However, we wonder how this document might be used during an audit. What is the formal process for the supplementation reference document to be changed? How will entities be notified?
Response: The SDT thanks you for your support. This document is not part of the standard, but is intended to provide the rationale of the SDT, as well as guidance about how the various requirements might be met. The explanations are not an "official" interpretation of the standard, but may be useful to determine how to implement various facets of the standard. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.		

7. The SDT has provided a "Frequently-asked Questions" document to address anticipated questions relative to the standard. Do you have any comments on the FAQ? Please explain in the comment area.

Summary Consideration: In general, respondents expressed appreciation for the additional technical discussion included within this document. The SDT responded to many comments by explaining the relationship between the standard and the FAQ. Several respondents suggested that elements of the extensive discussion be contained within the standard itself, which is contrary to the guidance within the paradigm for NERC Standards. Additionally, many of the comments in Questions 1-5 were addressed by developing additional FAQ content and referring the respondents to the revised FAQ.

Organization	Yes or No	Question 7 Comment
SCE&G		1. The FAQ should be expanded to address the issues raised above with verification of trip circuits as to what is an acceptable method meeting the intent of the standard. 2. We also suggest changing "prove" to "verify" on FAQ 3a to be consistent with the wording of the requirement. 3. Also, for a single bus with one set of bus potential transformers, how does one verify proper functioning of the potentials? Is a reasonableness criterion adequate?
Response: The SDT thanks you for your comments. 1. **The SDT agrees. The FAQ has been modified to address your concerns. (See FAQ II-4-E, page 11.)** 2. **The SDT agrees. The FAQ has been modified to address your concerns. (See FAQ II-3-A, page 8.)** 3. **The entity must verify that the protective devices are receiving the expected potential from the potential transformers or equivalent. If the potentials, both magnitude and phase angle, can be determined to be reasonable, that would suffice. (See FAQ II-3-A, page 8.)**		
Bonneville Power Administration		Will this document be a part of the standard? Are its explanations the official interpretation of the standard?
Response: The SDT thanks you for your comments. **The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document.**

E.ON U.S.	No	E.ON U.S. disagrees with commissioning tests not being considered as a baseline for subsequent maintenance activities. Commissioning tests should be counted as the initial testing in the scheme of a maintenance program
Response: The SDT thanks you for your comments. **As long as the requirements of the standard are met by the commissioning tests, they can "start the clock" for future maintenance testing. The FAQ has been reworded to clarify this point. (The revised FAQ is IV-2-B, page 23.)**		
Ontario Power Generation	No	It was a good idea to prepare such a document.
Response: The SDT thanks you for your support.		
Pepco Holdings Inc.	No	Item 3.B. (Page 6) claims that a small measurable quantity in 3I0 and 3V0 inputs to relays -may- be evidence that the circuit is performing properly. This statement is weak at best, and incorrect at worst. A balanced transmission system may exhibit 3I0 and 3V0 quantities that are not measurable, and those that are measurable cannot be compared to other readings, since CT/PT error often exceeds system imbalance. Since these inputs are verified at commissioning, recommend that maintenance verification require ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.
Response: The SDT thanks you for your comments. **The SDT agrees; See FAQ II-3-B, page 9.**		
Exelon Generation Company, LLC	No	None
MRO NERC Standards Review Subcommittee	No	Overall, the FAQ's are helpful toward understand what the SDT was thinking. Explanations for questions dealing with the maintenance activities (e.g., battery testing) indicate an attempt to line up the requirement with IEEE standards. While it is commendable to attempt alignment reliability standards with other industry standards, it also begs the question of why requirements that are already covered by other standards should be repeated in reliability standards. In addition, if the other standards are changed, then they could become inconsistent with or contradictory to the reliability standard.
Response: The SDT thanks you for your support. The IEEE standards are voluntary standards, and do not establish any requirements, and also are not measurable. PRC-005 standard requirements are loosely aligned with the IEEE standards and any future minor changes to those IEEE standards would not significantly alter the correlation between PRC-005 standard requirements for batteries and the IEEE recommendations.		

Organization	Yes or No	Question 7 Comment
American Transmission Company	No	Overall, the FAQ's are helpful. Explanations for questions dealing with the maintenance activities (e.g., battery testing) indicate an attempt to line up the requirement with IEEE standards. While commendable to attempt alignment with the industry, it is further justification that maintenance activities should not be included in the standard. Over the long term, technology or IEEE standards could change making the compliance standard inconsistent.
Response: The SDT thanks you for your support. The IEEE standards are voluntary standards, and do not establish any requirements, and also are not measurable. PRC-005 standard requirements are loosely aligned with the IEEE standards and any future minor changes to those IEEE standards would not significantly alter the correlation between PRC-005 standard requirements for batteries and the IEEE recommendations.		
PacifiCorp	No	Very helpful.
Response: Thank you for your support.		
Austin Energy	Yes	
Entergy Services, Inc	Yes	
Manitoba Hydro	Yes	
Public Service Enterprise Group Companies	Yes	1) R1 - PRC-005-1 required the protection owner to supply a "basis" for the chosen maintenance intervals. Is it intended that the new standard will no longer require the protection owners to provide a basis for their intervals as long as they meet (or better) the published required intervals? 2) Compliance 1.4 Data Retention Needs more clarity. Some items require 12 years maximum maintenance interval. However, we may perform the same maintenance in 6 years. The requirement for data retention is 2 maintenance intervals. In this example, does this mean 12 years or 24 years? Are we required to maintain records for the maximum maintenance intervals allowed by the standard or only for the two shorter maintenance intervals that we actually use? 3) Compliance will need some guidance on to what is required for "proper documentation". Generally, the relay technicians will scribe the actual test values for a given tests requiring the application of AC voltage and current. However, as an example, when performing DC checks (DC aux relay), the technician may simply state that the aux relay is "OK" without stating the DC coil pickup value in volts. Is this acceptable? Another example may be when performing battery inspections (i.e., verify proper voltage of station battery, verify that no DC grounds exist, etc), the inspector may simply indicate/document that the battery is "Ok". This would indicate that appropriate 3 month inspections (as per table 1a) were completed and found to be within tolerances. Is this acceptable? If

Organization	Yes or No	Question 7 Comment
		specific details are required to be stored on test media (paper test sheets, computer based data storage, etc), then please make some comments as such. 4) Table 1a DC supply. The 3 month inspection requires “verify that no dc supply grounds are present”. This needs further clarification. What is the defined “limit” to determine whether we have a DC ground? The detection methods for determining the presence of a DC ground will vary from indicating light balance to actual DC ammeters or voltmeters. It is assumed that the intent of this requirement is to ensure that there are no full DC grounds (dead shorts) in the DC terminals. Please clarify. 5) In the group by type of BES facility descriptions on pages 15 and 16 there is discussion about generation station auxiliary transformers and associated protection devices. It also cites examples of relays which need not be included even though they could result in tripping of the generating station. The line of demarcation is not well defined in the FAQs or in the standard itself. Suggest that verbiage be added that clearly defines the element (transformer) directly connected to the BES and its associated protection is what is included in the PSMP requirements, items connected at lower voltage (down stream) are not within the PSMP requirement. 6) On page 15, the sample list of what is included in the standard, suggest that the list be expanded to show what is not included (a relay that monitors parameters and is used for control/ alarm but not protection); generator excitation controls that trip an auxiliary exciter. The list of items not included in the PSMP but that could trip the unit should be further defined and expanded.

Response: The SDT thanks you for your comments.

1. The SDT agrees that no basis is required for level 1 monitoring as detailed in Table 1a. Monitoring attributes will be required to meet Table 1b and Table 1c requirements. A performance based program will require further documentation; see Attachment A of the standard.

2. The SDT has modified the Data Retention area of the standard to clarify this.

3. The SDT will consider acceptable forms of evidence when developing the Measures. See the FAQ IV-1-B, page 21. Also, see Section 15.6 (page 24) of the Supplementary Reference Document for a discussion of “evidence”.

4. Table 1a has been modified to address this, and an FAQ (FAQ II-5-I, page 15) has been added to clarify this. The revised language in the standard reads:

Check for unintentional grounds.

5. The SDT agrees; the FAQ has been modified to address your concerns see FAQ III-2-A, page 20.

6. The definition of Protection System states that “Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.” Controls and alarms are excluded per the definition.

Organization	Yes or No	Question 7 Comment
Ameren	Yes	1) We don't think an Executive Summary is needed. 2) Please include the Supplement's explanation of A/D verification method from Supplement page 9. 3) What role does the FAQ play in Compliance Monitoring and Enforcement? 4) Refer to question 2 and add our items # 2, 3, 4, 5, 7, and 11 to FAQ. 5) Please add FAQ that provides the NERC Compliance Registry Criteria for Generating Facilities, to clarify applicability to >20MVA direct BES connection, aggregate >75MVA etc. 6) FAQ 2A p17 states that commissioning is construction, not maintenance. It seems like you're ignoring the significant verification, testing, inspection, and calibration activities that occur in commissioning. Should the in-service date be assigned to these components for determining their next maintenance? 7) Refer to question 3 and add our items # 4 to FAQ.
Response: The SDT thanks you for your comments. **1. The SDT thanks you for your input.** **2. The SDT agrees; this information was already present in FAQ V-3-B (page 38).** **3. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document.** **4. The SDT agrees; see our response to your comment on Question 2.** **5. The NERC Compliance Registry Criteria and Regional BES definitions are themselves requirements upon entities, and need not be explained within the PRC-005 FAQ.** **6. As long as the requirements of the standard are met by the commissioning tests, they can "start the clock" for future maintenance testing. See FAQ IV-2-B (page 23).** **7. The SDT agrees; see our response to your comment on Question 3.**		
NextEra Energy Resources	Yes	a. NextEra Energy believes the need for an extensive "Supplementary Reference Document", in addition to 13 pages of tables and an attachment in the standard itself, illustrates that the proposal is too prescriptive and complex for most entities to practically implement. NextEra Energy would prefer the SDT leave the existing

Organization	Yes or No	Question 7 Comment
		requirements substantially intact or, if most industry commenters prefer the SDT's approach, that the SDT attempt to simplify it.7. The SDT has provided a "Frequently-asked Questions" document to address anticipated questions relative to the standard. Do you have any comments on the FAQ? Please explain in the comment area. 1 Yes 0 No Comments: a. An alternative to measuring battery specific gravity is to measure float voltage and float current as described in Annex A4 of IEEE Std 450-2002. b. FAQ Page 17 (#1B): It is outside the jurisdiction of the standards development team to determine acceptable forms of evidence. This should be decided by the Regional Entities. c. FAQ Page 15 (#1A): This question should not have been included since it is addressing the definition of BES, which is currently being addressed by another NERC Group. d. FAQ Page 15 (#2): Although the FAQ is not enforceable, the answer provided may be interpreted as enforceable. This should be included in the standard and not in the FAQ.
Response: The SDT thanks you for your comments. **The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities and maximum intervals necessary to implement an effective PSMP.** **a. The SDT has modified the standard in consideration of your comment by removing the maintenance activity of measuring specific gravity.** **b. Other commenters have requested assistance in determining applicable evidence. The SDT has provided guidance that agrees with entities' experience regarding effective evidence during actual audits. See FAQ IV-1-B, page 21 and Supplementary Reference Document, Section 15.6, page 24.** **c. Including the definition of the BES in the FAQ is helpful to some entities, and addresses common questions from other commenters; the FAQ states that the RRO's may have additional criteria.** **d. The FAQ is intended to present examples of applicable devices, and is not intended to be all-inclusive. The requirements are established by the standard definition of Protection System and the section 4 ("Applicability").**		
CPS Energy	Yes	Adds to the confusion with the standard, FAQ, and Supplemental. The three documents at times describe things a little differently.
Response: The SDT thanks you for your comments, however in the future please be more specific and identify the actual discrepancies so we can		

Organization	Yes or No	Question 7 Comment
improve the documents.		
AEP	Yes	Although helpful in understanding and clarifying intent, the requirements of a standard should be clearly written so that multiple, lengthy supporting documents are not needed. These supporting documents do not get recorded into the registry as part of the standard and may or may not be used by auditors during compliance audits which could lead to different interpretations.
Response: The SDT thanks you for your comments. The SDT believes that providing additional references helps clarify the requirements in the standard. The SDT must address the directives of FERC orders 672 and 693 without being too prescriptive within the standard itself. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.		
Transmission Owner	Yes	An alternative to measuring battery specific gravity is to measure float voltage and float current as described in Annex A4 of IEEE Std 450-2002.
Response: The SDT has modified the standard in consideration of your comment by removing the maintenance activity of measuring specific gravity.		
SERC (PCS)	Yes	Change “prove” to “verify” on FAQ 3a (under Voltage and Current Sensing Devise Inputs to Protective Relays) to be consistent with the wording of the requirement.
Response: The SDT thanks you for your comments. See FAQ II-3-A (page 8) – the word, “prove” was replaced with “verify” as proposed.		
Detroit Edison	Yes	Example #1 on page 21 states “A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)”. However, Table 1b indicates that detection and alarming of dc grounds is also required for level 2.
Response: The SDT thanks you for your comments. The cited example is intended to show a mixture of Level 1 and Level 2 monitored components. Those components not equipped with Level 2 monitoring must be maintained in accordance with Table 1a. Also, see the Decision Tree at the end of the FAQ, addressing DC Supply monitoring levels.		
ITC Holdings	Yes	1. FAQ page 6 question 3C should be clarified in the standard document itself. What is the technical justification for omitting insulation testing of the wiring for DC control, potential and current circuits between the station-yard equipment and the relay schemes? We feel this wiring is susceptible to transients which, over time, may compromise the insulation, and therefore should be tested. 2. FAQ page 17 question 2A the standard should define when the first maintenance activity is to be performed. We include our maintenance activities during commissioning, and set the next maintenance due date based on the testing interval.

Organization	Yes or No	Question 7 Comment
		3. Will clarifications in the FAQs be enforceable with the standard? Can a maintenance program be confidently established using this or other answers included in the FAQ's?
Response: The SDT thanks you for your comments. **1. The SDT does not believe that insulation testing needs to be included within the minimum required maintenance activities; the SDT is not aware of a body of evidence that suggests that these tests should be included as a requirement. The proposed standard does not prevent an entity from including such tests in its program if their experience has indicated that such testing is needed. Furthermore, requirements for checking for proper current and voltage at the relays and checking for DC grounds, provides some assurance of cable insulation integrity.** **2. As long as the requirements of the standard are met by the commissioning tests, they can "start the clock" for future maintenance testing. See FAQ IV-2-B, page 23.** **3. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority.**		
Nebraska Public Power District	Yes	On page 17, the answers to questions 2B and 2C indicate that there is no allowance or provision to exceed the Maximum Maintenance Interval under any circumstances, except that natural disasters or other events of force majeure will receive special consideration when determining sanctions. The rigidity of this performance requirement could conceivably require equipment to be tested even though it is out of service in order to remain compliant, adding unnecessary cost and waste to the PSMP of the regulated entities. We believe that a prescriptive process for deferring testing and maintenance beyond the stated interval would be beneficial to allow the necessary flexibility to manage the PSMP effectively.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue. **Should maintenance be due on equipment that is out-of service for a protracted period, the required maintenance should only be necessary before the equipment is returned to service. However, you may encounter compliance challenges if you did not complete the maintenance during the scheduled period, and should be prepared to document the out-of-service period and the subsequent maintenance.**		
Southern Company	Yes	Part of the responses could be more correctly stated: Page 11E, "why is specific gravity testing required" The specific gravity measurements do not reflect accurate state of charge for lead-calcium batteries. (Float current is

Organization	Yes or No	Question 7 Comment
		a better parameter for this indication)
Response: The SDT thanks you for your comments concerning specific gravity being required. The SDT has modified the standard by removing the requirement for specific gravity testing.		
FirstEnergy	Yes	Pg. 17 (What forms of evidence are acceptable) Although Measures are not yet developed and posted with the standard, we wanted to point out that the SDT should consider adding these acceptable forms of evidence in the measures of the standard.
Response: The SDT thanks you for your comments. The SDT will consider identifying acceptable forms of evidence when developing the Measures.		
Progress Energy	Yes	Progress Energy is unclear how a new/revised standard can have a 30 page FAQ document associated with it. If questions need to be addressed, the answers should be incorporated into the existing standard. During this stage of the draft, all questions should be addressed, not left to the side in an “interpretation” paper.
Response: The SDT thanks you for your comments. The SDT believes that providing additional references helps clarify the requirements in the standard. The SDT must address the directives of FERC orders 672 and 693 without being too prescriptive within the standard itself. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.		
RRI Energy	Yes	Reverse power relays do not belong in the list of devices within the scope of this standard; reverse power is not used for generator protection or protection of a BES element. Aside from the protection of reverse power for other non-BES equipment, a generator can operate continuously as a generator, synchronous condenser, or a synchronous motor. Reverse power relays (or reverse power elements in multi-function relays) is commonly used as a control function for automatic shut-down purposes, which is not a protective function. Other reverse power protection, with longer time delays, is provided for turbine protection, which is not within the scope of the NERC Standards.
Response: The SDT thanks you for your comments. For some power plants, the reverse power relays trip the generation output breaker(s) and thus are in scope per section 4.2.5.1 of the standard. The list of devices provides examples which may or may not be in scope of the standard depending upon how they applied.		
CenterPoint Energy	Yes	See CenterPoint Energy’s response to question 6. The need for an FAQ document in addition to an extensive “Supplementary Reference Document” further illustrates the complexity and impracticality of the proposed standard revisions.
Response: The SDT thanks you for your comments. See the response to your comments on Question 6.		

Organization	Yes or No	Question 7 Comment
The SDT believes that providing additional references helps clarify the requirements in the standard. The SDT must address the directives of FERC orders 672 and 693 without being too prescriptive within the standard itself. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate document.		
Oncor Electric Delivery	Yes	The FAQ document is an excellent resource document for Protection System Owners to understand why the maintenance activities listed in the proposed standard were chosen.
Response: The SDT thanks you for your support.		
JEA	Yes	The FAQ is a well written document and the team should take pride in its clarity and informative content. One area that would be good to have further clarification, is if the SDT could provide a current industry product or example of the "software latches or control algorithms, including trip logic processing implemented as programming components, such as a microprocessor relay that takes the place of (conventional) discrete component auxiliary relays or lockout relays that do not have to be routinely tested." Is this a microprocessor lockout relay (that does not require trip testing?)
Response: The SDT thanks you for your support. The description indeed does reflect a microprocessor relay with imbedded lockout relay functions that does not require trip testing for the lockout function. However, the breaker trip coil would still need to be tested as otherwise required in the standard. Because of the NERC Antitrust Policy, the SDT is unable to provide commercial examples.		
Northeast Power Coordinating Council	Yes	The FAQ is helpful in answering many of the obvious questions.
Response: The SDT thanks you for your support.		
Saskatchewan Power Corporation	Yes	The FAQ section is beneficial, but would suggest reviewing it to determine if it can be integrated within the reference document.
Response: The SDT thanks you for your support. The SDT will, to the degree possible, integrate material from the FAQ into the Supplementary Reference Document. The SDT additionally believes that there is value in the FAQ that presents the material as questions and answers.		
Lower Colorado River Authority	Yes	The Frequently-asked Questions document is very well written and very helpful. The decision trees are a good addition.
Response: The SDT thanks you for your support.		

Organization	Yes or No	Question 7 Comment
Xcel Energy	Yes	1. The Frequently-asked Questions seem to act as interpretations to the standard. What roll will they play in determining compliance? 2. On table 1b (page 11) the UFLS and UVLS maintenance activities indicate that tripping of the interrupting device is not required, but it uses the term “functional trip test”. The FAQ indicates that a “functional trip test” does require tripping the interrupting device. This conflicts with what is in the table and should be corrected in the FAQ to reflect that no trip is required.
Response: The SDT thanks you for your comments. **1. The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document.** **2. The SDT agrees with your comment. See FAQ II-4-E, page 11.**		
Illinois Municipal Electric Agency	Yes	Under “Group by Type of BES Facility”, 1. (page 15) “The radial exemption in the BES definition should be clarified to include transmission subsystems within a single municipality, where the transmission facilities serving only subsystem load with one transmission source - essentially operate radially. A more practical application of the radial exemption would address smaller TOs whose system has minimal potential to impact the BES as a whole.
Response: The SDT thanks you for your comments. The BES is a NERC and Regional defined term, and is outside the scope of this drafting team. Requests for clarification regarding the BES definition should be referred to your Regional Entity. It isn't clear to the SDT whether the example you request is appropriate or accurate.		
Duke Energy	Yes	We strongly believe that this document should be made a part of the standard, either as an Attachment or worked into the requirements and tables. This will bring clarity to PRC-005 that is needed to get away from all the past problems that were due to a lack of clarity with the previous PRC-005 standards. Also, all the explanations and guidance lose force if they are not part of the standard. Auditors will only be bound by the standard.
Response: The SDT thanks you for your comments. The SDT must address the directives of FERC orders 672 and 693 without being too prescriptive within the standard itself. The SDT feels that providing additional references helps clarify the requirements in the standard and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. According to the NERC Standard Development Procedure, a standard is to contain only the prescriptive requirements; supporting discussion is to be in a separate		

Organization	Yes or No	Question 7 Comment
document.		
AECI	Yes	**Group by Type of Maintenance Program:** **2. Time-Based Protection System Maintenance (TBM) Programs** **A. What does this Maintenance standard say about commissioning?** Commissioning tests are regarded as a construction activity, not a maintenance activity. **COMMENT 1:** If we understand the question and answer correctly, we disagree. We believe that the standard should accept commissioning as the first date for the maintenance testing if the commissioning tests correspond to the Standard's TBM testing procedures. Otherwise, maintenance tests on a new substation will be required to be completed (again) based on the Implementation Plan guidelines for PRC-005-02. **Group by Type of Maintenance Program:** **2. Time-Based Protection System Maintenance (TBM) Programs** **C. If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc.), how will this affect my compliance with this standard.** The NERC Sanction Guidelines provide that the Compliance Monitor will consider extenuating circumstances when considering any sanctions. **COMMENT 2:** We feel that guidelines should be provided for "extenuating circumstances", specifically addressing natural disasters.
Response: The SDT thanks you for your comments. **The FAQ will be reworded to clarify that commission tests can be used to establish initial performance of maintenance as long as the requirements Tables 1a, 1b, & 1c are fulfilled. See FAQ IV-2-B, page 23.** **The SDT believes that "extenuating circumstances" are addressed by the NERC Sanction Guidelines, and are therefore a discretionary issue between the entity and the Compliance Enforcement Authority. Because of the variability in natural disasters and their potential impact on Protection System maintenance programs, it does not seem practical to develop measurable requirements addressing this issue in the context of this standard. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 (page 9) of the Supplementary Reference Document for a discussion on this issue.**		
Puget Sound Energy	Yes	PSE appreciates this document as it provides a lot of further clarity. PSE hopes this document will be updated through by comments and questions provided during the development process. We wonder how this document might be used in an audit as well. What is the formal process for the supplementation reference document to be

Organization	Yes or No	Question 7 Comment
		changed? How will entities be notified?

Response: Thank you for your support.

The FAQ and Supplementary Reference Document are provided as references to present detailed discussions about determination of maintenance intervals and other useful information regarding establishment of a maintenance program, and do not have statutory effect. The SDT believes that these documents provide potentially useful information to the entity in developing and sustaining an effective PRC-005 program, and hopes that these documents will be useful to the entity in establishing support of their program when it is reviewed by the Compliance Enforcement Authority. It is the drafting team's intent that these documents be posted with the standard when approved similarly to the CIP FAQ and the PRC-023 reference document. In order that these documents are initially posted with PRC-005-2 when approved, they must undergo industry comment and review, and the Standards Committee must be convinced through that process that the documents align with the standard and are relevant to the standard. With future revisions to PRC-005, the FAQ and Supplemental Reference Document will have to undergo SDT review and industry comment to remain posted with the standard, and the Standards Committee will have to remain convinced of their accuracy and relevance.

8. If you are aware of any conflicts between the proposed standard and any regulatory function, rule, order, tariff, rate schedule, legislative requirement, or agreement please identify the conflict here.

Summary Consideration: Most respondents were unaware of any conflicts. Some felt that conflicts existed with existing business or Regional practices, or with other organizations such as the Nuclear Regulatory Commission. The SDT provided clarifying explanations to illustrate that conflicts are not actually present.

Organization	Question 8 Comment
ITC Holdings	Comments: We are not aware of any conflicts.
Response: The SDT thanks you for your comments.	
MRO NERC Standards Review Subcommittee	Conflict: Order 672 says that standards should be clear and unambiguous.
Response: The SDT thanks you for your comments. The SDT must address the directives of FERC orders 672 and 693 without being too prescriptive within the standard itself. The SDT believes that providing additional references helps clarify the requirements in the standard. Also, the SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general.	
Lower Colorado River Authority	Conflict: Potential conflict with PRC-023 as to which PRS systems are applicable per this standard. Comments: PRC-005-2 requires compliance for this standard for all non-radial systems over 100 kV; while, PRC-023-1 prescribes it as below: 1. Title: Transmission Relay Loadability2. Number: PRC-023-13. Purpose: Protective relay settings shall not limit transmission loadability; not interfere with system operators' ability to take remedial action to protect system reliability and; be set to reliably detect all fault conditions and protect the electrical network from these faults.4. Applicability: 4.1. Transmission Owners with load-responsive phase protection systems as described in Attachment A, applied to facilities defined below:4.1.1 Transmission lines operated at 200 kV and above.4.1.2 Transmission lines operated at 100 kV to 200 kV as designated by the Planning Coordinator as critical to the reliability of the Bulk Electric System.4.1.3 Transformers with low voltage terminals connected at 200 kV and above.4.1.4 Transformers with low voltage terminals connected at 100 kV to 200 kV as designated by the Planning Coordinator as critical to the reliability of the Bulk Electric System.4.2. Generator Owners with load-responsive phase protection systems as described in Attachment A, applied to facilities defined in 4.1.1 through 4.1.4.4.3. Distribution Providers with load-responsive phase protection systems as described in Attachment A, applied according to facilities defined in 4.1.1 through 4.1.4., provided that those facilities have bi-directional flow capabilities.4.4. Planning Coordinators. We believe Bulk Electric System (BES) owners resources would be better utilized by focusing on relay systems as defined in

Organization	Question 8 Comment
	the above PRC-023-1 and this would still provide high level of reliability for the BES, since not all facilities operating between 100 200KV are critical to the BES. This would not preclude any utilities from applying this standard to other facilities operating at the lower voltage range. Why did the drafting team not use the application language sited in the “Protection System Maintenance - A NERC Technical Reference” which is similar to what is described above from PRC-023-1?
Response: The SDT thanks you for your comments. The Energy Policy Act of 2005, as well as various FERC orders and the NERC Standards Development Process requires that reliability standards should be applicable to the BES (or, in the case of the Energy Policy Act, the BPS, which is almost synonymous). In the case of PRC-023-1, cited in the comment, that SDT as well as the NERC Staff was required to carefully explain why this standard was not specifically applicable to the BES, but instead to a subset of the BES. The 2007-17 SDT has determined that a similar rationale cannot be effectively determined for PRC-005-2, and thus specified that it should be applicable to the BES. It is noted that this applicability is similar to the applicability for PRC-005-1.	
Exelon Generation Company, LLC	Conflict 1. Nuclear generators are licensed to operate and regulated by the Nuclear Regulatory Commission (NRC). Each licensee operates in accordance with plant specific Technical Specifications (TSs) issued by the NRC. TS allow for a 25% grace period may be applied to TS Surveillance Requirements (SRs). Referencing NRC issued NUREGs for Standard Issued Technical Specifications (NUREG-143 through NUREG-1434) Section 3.0, "Surveillance Requirement (SR) Applicability, SR 3.02 states the following:" The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." 2. Battery Charger Testing 2a. All conditions (grounds, voltages etc) should be compared to "acceptable limits" as specified in nuclear station design basis documents, industry standards or vendor data. 2b. IEEE 450 does not use the word "proper" as utilized in Table 1a (e.g., "record voltage of each cell v/s verify proper voltage of each individual cell.") 3. The NRC Maintenance Rule (10 CFR 50.65) requires monitoring the effectiveness of maintenance to ensure reliable operation of equipment within the scope of the Rule. Adjustments are made to the PM (preventative maintenance) program based on equipment performance. The Maintenance Rule program should provide an acceptable level of reliability and availability for equipment within its scope. Comments: 4. All maintenance activities should include a "grace" period to allow for changes to a nuclear generator's refueling schedule and emergent conditions that would prevent the safe isolation of equipment and/or testing of function. "Grace" periods align with currently implemented nuclear generator's maintenance and testing programs.

Organization	Question 8 Comment
	5. The 3-month maximum interval should be extended to include a grace period to ensure that a 25% grace period is included to align with current nuclear templates that implement NRC TS SRs are documented in the response to Question 8.

Response: The SDT thanks you for your comments.

1. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.

2a. The SDT agrees that each entity establishes its own "acceptable limits". In this case, "acceptable limits" would seem to be determined in the materials cited, and would apply for PRC-005-2.

2b. The SDT agrees. The SDT modified the standard to address your concerns. The revised maintenance activity now reads: Inspect cell condition of individual battery cells where cells are visible, or measure battery cell/unit internal ohmic values where cells are not visible.

3. The entity must satisfy all applicable requirements (in this case, NERC PRC-005-2 and the NRC 10 CFR 50.65) as they apply to common equipment. Since the NRC requires monitoring of the effectiveness of the program, you must do so even if this isn't in the NERC standard.

4. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.

5. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. Ontario Power Generation	Not aware of any
Georgia System Operations	Not aware of any.

Organization	Question 8 Comment
Corporation	
American Transmission Company	Order 672 says that standards should be clear and unambiguous. This proposed standard is very complex. While the standard allows entities to select the appropriate maintenance strategy (time based, performance based or conditioned based) for their system the amount of data and tracking required to demonstrate compliance will be overwhelming.
Response: The SDT thanks you for your comments. At its simplest, using time-based maintenance and Table 1a, the documentation requirements should not be vastly different than those to prove compliance to PRC-005-1 for a strong compliance program. If more advanced strategies are used, documentation requirements to demonstrate compliance may very well increase. **The SDT believes that it has clearly and unambiguously defined the minimum activities and maximum intervals necessary to implement an effective PSMP, and presented advanced strategies for those entities who wish to utilize them.**	
Indianapolis Power & Light Co.	Performing some of the maintenance activities may cause conflict with regional ISOs and their safe operation of the BES
Response: The SDT thanks you for your comments. To minimize system impact of such maintenance, the maintenance necessarily should be scheduled at a time that minimizes the risks.	
Northeast Power Coordinating Council	Yes--NPCC Directory #3, NPCC Key Facility Maintenance Tables. All areas must implement changes at the same time.
Response: The SDT thanks you for your comments. PRC-005-2 is a NERC standard and as such it will have its own implementation plan. PRC-005-2 when implemented will be an ERO-wide standard which establishes minimum requirements; to the degree that these requirements are more stringent than those currently imposed by any individual Regional Entity, the NERC requirements will govern. Any individual Regional Entity can establish MORE stringent requirements.	
Puget Sound Energy	PRC-STD-005 PRC-005-2 requires a Protection System Maintenance Program (PSMP) while PRC-STD-005 requires a Transmission Maintenance and Inspection Plan (TMIP). Historically the requirements of PRC-005-1 and PRC-STD-005 folded nicely into one consistent plan. Could the maximum intervals identified in PRC-005-2 be expected or audited against under PRC-STD-005 where it does not indicated that much specificity? PRC-STD-005 requires maintenance of lines and breakers over and above what PRC-005-2 the expectations relative to breakers should align.
Response: The SDT thanks you for your comments. An entity can be audited to both NERC Reliability Standards and to Regional Standards, provided that both are mandatory and enforceable. Where applicable, Regional Standards will have more stringent requirements. As for intervals, where different intervals apply to the same piece of equipment, the more stringent intervals apply. Also, the NERC intervals would apply only to the equipment	

Organization	Question 8 Comment
associated with those intervals within the NERC Standard. If the Regional requirements address equipment not addressed within the NERC Standard, only the Regional requirements are relevant.	

9. If you are aware of the need for a regional variance or business practice that we should consider with this project, please identify it here.

Summary Consideration: A number of respondents suggested that the standard should allow "grace periods" to defer maintenance because of a variety of expected difficulties in completing the required activities within the established intervals. The SDT consistently responded that a "grace period" would be contrary to a measurable standard, and that entities should manage their programs to assure that the required activities are completed on schedule.

Organization	Regional Variance or Business Practice	Question 9 Comment
TVA	Business Practice	Allow for deferrals to coordinate with generator outages.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.		
Exelon Generation Company, LLC	Business Practice	Business Practice: Nuclear Electric Insurance Limited (NEIL) variance allowance.
Response: The SDT thanks you for your comments. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. ITC Holdings		Comment: We are not aware of any regional variance or business practice that should be considered

Organization	Regional Variance or Business Practice	Question 9 Comment
		with this project.
Response: The SDT thanks you for your comment.		
Green Country Energy LLC	Business Practice	Contractual commitments existing prior to NERC stds make it difficult to comply with some of the maintenance activities.
Response: The SDT thanks you for your comment. Existing contracts may need to be adjusted to accommodate compliance to NERC standards.		
City Utilities of Springfield, MO		CU is not aware of a need for a regional variance.
Response: The SDT thanks you for your comment.		
Florida Municipal Power Agency, and its Member Cities		FMPA is not aware of a need for a regional variance
Response: The SDT thanks you for your comment.		
Electric Market Policy	Regional Variance	1. It is our understanding that once Project 2009-17: "Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State" is approved, that the definition of a "Transmission Protection System" would be included within PRC-005-2 or included within the NERC Glossary of Terms. However, the specific protection that would be considered part of the "Transmission Protection System" would also depend on the regional definition of the BES. 2. We suggest that the regions develop a supplement that provides further clarification on what constitutes a "Transmission Protection System" given the regional definition of the BES.
Response: The SDT thanks you for your comments. **1. The 2009-17 interpretation addresses PRC-005-1. The SDT will monitor this interpretation to determine if any changes need to be made to PRC-005-2 in response to this interpretation. In general, a definition cannot be established via the Interpretation process, but only through the comprehensive Standards Development process.** **2. You should present this concern to your region.**		
SERC (PCS)	Regional Variance	1, It is our understanding that once Project 2009-17: "Interpretation of PRC-004-1 and PRC-005-1 for

Organization	Regional Variance or Business Practice	Question 9 Comment
		Y-W Electric and Tri-State" is approved, that the definition of a "Transmission Protection System" would be included within PRC-005-2 or included within the NERC Glossary of Terms. However, the specific protection that would be considered part of the "Transmission Protection System" would also depend on the regional definition of the BES. 2. We suggest that the regions develop a supplement that provides further clarification on what constitutes a "Transmission Protection System" given the regional definition of the BES.
Response: The SDT thanks you for your comments. **1. The 2009-17 interpretation addresses PRC-005-1. The SDT will monitor this interpretation to determine if any changes need to be made to PRC-005-2 in response to this interpretation. In general, a definition cannot be established via the Interpretation process, but only through the comprehensive Standards Development process.** **2. You should present this concern to your region.**		
American Transmission Company	Business Practice	Jointly-owned facilities should be a component of this standard. Comments: ATC shares services at Substations; consider dividing the services, i.e. batteries and PTs.
Response: The SDT thanks you for your comments. This is a registration issue and it's not within the scope of the SDT. If a company owns a facility that meets the applicability section as described in this standard then it is responsible for the maintenance activities as described in this standard.		
Ontario Power Generation	Regional Variance	Maintenance activities, and especially intervals, prescribed in NPCC Directory 3 (Maintenance Criteria for BPS Protection) often differ from those in PRC 005 - 02. We recommend that NPCC aligns Directory #3 with PRC 005 - 02 as much as possible. Technical justification should be provided for any variance.
Response: The SDT thanks you for your comments. Any Regional Entity may develop its own requirements, as long as they are not less stringent than the NERC requirements. **The SDT suggests that the commenter communicate with the NPCC regional staff regarding this concern.**		
AEP		No none regional or business practice variances known.
Nebraska Public Power District		None
PacifiCorp		None known.

Organization	Regional Variance or Business Practice	Question 9 Comment
Georgia System Operations Corporation		None.
Operations and Maintenance		None.
Northeast Power Coordinating Council		Not aware of any regional variance or business practice.
Response: The SDT thanks you for your comment.		
JEA	Regional Variance	Regional variances in the Bulk Electric System definition as applied across regions allows for PSMP to vary possibly even for the same region crossing tie lines. Also, accepted maintenance practices by one region vary from accepted maintenance practices from another region. In the case of lower kV non-redundant bus lockout protection systems, one region may allow for the protection system to be taken out of service to perform maintenance, while another region may specifically prohibit this practice (don't leave energized equipment protected by delayed clearing, etc.)
Response: The SDT thanks you for your comment.		
Duke Energy	Regional Variance	Regions with ISO's and RTO's - Where the independent system operator (ISO) is not the same company as the entity doing testing and maintenance, the independent system operator could prevent the entity from performing scheduled maintenance and testing due to outage request constraints. There should be no violation in such a situation, and the maintenance and testing just rescheduled.
Response: The SDT thanks you for your comments. **The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 (page 9) of the Supplementary Reference Document for a discussion on this issue.**		
Wisconsin Electric	Regional Variance	See above Question 2, Item 7: There needs to be some recognition that Protection System's applied on distribution-voltage systems may be included in a regional definition of a BES Protection System. These systems are not designed or operated in the same way as Transmission or Generation

Organization	Regional Variance or Business Practice	Question 9 Comment
		Protection Systems. Therefore, it is reasonable that these systems be subject to less rigorous requirements.
Response: The SDT thanks you for your comments. See our response above to Question #2, item 7.		

10. If you have any other comments on this standard that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: This question generated numerous comments and many respondents repeated comments offered earlier in the document. Several of the respondents objected to the establishment of maximum allowable intervals at all, and suggested that it should be left to the entities to establish their own intervals; the SDT explained that this would be directly contrary to FERC directives related to the four current standards which are being addressed within this project. Additional technical comments covered the full spectrum of the material in the standard and associated reference documents, and resulted in extensive changes to the standard and in changes to both the Supplementary Reference (mostly to correct inconsistencies) and to the FAQ (including addition of many additional topics). There was also concern about the documentation necessary to demonstrate compliance.

Organization	Question 10 Comment
Ameren	1) Documentation could be a monumental task. Although FAQ 1B allows a comprehensive set of forms of documentation, a very large number of people are involved across this set at most utilities. Producing a particular needle in the haystack may take longer than an auditor would expect. Inspection forms can be structured to capture abnormal conditions, and thus normal conditions are not recorded. Some items, like the red light monitoring a trip coil, may only be reported by exception (i.e., “red light out, replaced bulb” but if the red light is on an operator may not report that). 2) We presume that the SDT would expect transmission facilities to be switched out of service if maintenance would result in those facilities being unprotected. We think this should be stated or clarified, as there may be entities that still use differential cutoff switches or other means of disabling protection for testing and have not considered the consequences of a concurrent fault.
Response: The SDT thanks you for your comments. **1. Much of your concern can be addressed within your program by careful design of your maintenance tracking forms and systems. In your example of a red light, your maintenance can include documentation forms that require completion of either of multiple choices (e.g., OK, Not OK with resolution, etc).** **2. This consideration relates to general planning, design, and operational issues, and is outside the scope of this standard. Various other NERC standards apply.**	
Public Service Enterprise Group Companies	1) R4 requires all maintenance correctable issues identified as part of a time based maintenance plan to be resolved in that same maintenance period. This places a burden on some items (for example, 3 month battery inspections) to achieve adequate resolution for problems that are not an immediate threat. For example, if a battery with a somewhat out of allowable range specific gravity is found near the end of the maintenance period, scheduling and performing the work to replace the battery could reasonably extend somewhat beyond the end of maintenance period. PSE&G requests that the drafting team revisit this

Organization	Question 10 Comment
	requirement and allow flexibility for corrections to be made within a specified reasonable timeframe when correctible issues are identified that for practical reasons require extension for work completion beyond the end of the current maintenance interval. 2) Section 4.2.5.5 of the standard should define provide an example that just the transformer connected to the BES is included and specifically exclude connected equipment beyond the LV terminals. 3) Draft implementation plan for requirements R2, R3 & R4 discusses table 1a as basis, should also address tables 1b and 1c.
Response: The SDT thanks you for your comments. **1. Requirement R4, Part4.3 has been added to the standard in consideration of your comments. It reads as follows:** R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctable issues[2] as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]* 4.3 Assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues[3]. **2. The SDT disagrees with your comment. For example, current transformers on low-voltage transformer bushings or low-voltage breakers, which are associated with differential relays, must be considered within application of PRC-005-2. See Figure 2 in the Supplemental Reference Document (page 28) for an illustration.** **3. The SDT believes that the implementation period for PRC-005-2 must be kept as brief as possible; until PRC-005-2 is fully implemented, entities will have to be compliant with PRC-005-2 for those components for which implementation has been completed, and with PRC-005-1 for all other components. However, entities may need considerable time to become compliant with the more specific requirements of PRC-005-2. An implementation period based on Table 1a seems to be the best compromise period to achieve this. Additionally, the Implementation Plan does not require that entities adopt the Table 1a activities and intervals, but instead just refers to the Table 1a components and their intervals for establishment of a phased implementation.**	
Wisconsin Electric	1. In the definition of a Protection System Maintenance Program, the statement is made that "A maintenance program CAN include..." with a list of seven attributes following. Is it the intent that the PSMP "SHALL include one or more of the following"? What is to prevent Compliance staff from concluding that all seven of these attributes MUST be included in the PSMP? 2. The standard should more clearly describe what is meant by "verify..." when used in a Maintenance Activity description. Does

[2] A maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action

[3] A maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity and that requires follow-up corrective action.

Organization	Question 10 Comment
	this require actual paper or electronic documentation? If so, then this should be explicitly stated in the Maintenance Activity description. We maintain above that the recurring and routine maintenance activities having a 3 month interval should be revised to use alternate words such as "Check" or "Observe". For example, "Check the continuity of the breaker trip circuit...", or "Observe the voltage of the station battery". This activity should not be required to have paper or electronic documentation or evidence. It should be sufficient to have these activities included in the PSMP. 3. It is stated in the Supplementary Reference that actual event data from fault records may be used to satisfy certain Maintenance Activities, yet the standard itself does not appear to allow for this. Will such evidence be accepted by Compliance staff?
Response: The SDT thanks you for your comments. **1. Yes, a PSMP should include one or more of the listed activities for any specific component. The definition is intended to identify the possible attributes of a PSMP. Only those attributes relevant to a specific program and component need be included in the PSMP for that component. The proposed definition includes the following phrase, making it clear that the PSMP does not have to include all listed items,** "A maintenance program for a specific component includes one or more of the following activities:" **2. The SDT thanks you for your comments and has modified the standard in consideration of your comments.** **3. It is difficult to predict what will be accepted by Compliance staff; the SDT believes that you will need to establish a method to capture the evidentiary data from fault records (such as what is empirically verified, when, and how) within your maintenance records. See FAQ IV-1-B (page 21), FAQ II-3-B (page 9) and Section 11 (page 18) of the Supplemental Reference Document.**	
Bonneville Power Administration	1. Tables 1a, 1b, and 1c were cumbersome to use because we found ourselves flipping back and forth to compare the requirements for the different levels of monitoring. Also, in some cases, the types of components were slightly different between the tables, which created confusion. We believe that it would be much easier to decipher a single table that listed each type of component only once and showed the requirements and maintenance intervals for the different levels of monitoring on a single page. Even if it took an entire page for each component, it would be very useful to see all of the options for that component without having to flip back and forth between tables. 2. Please clarify the requirements for trip coils. Table 1a has as a component type "breaker trip coil only", with a maximum maintenance interval of 3 months, while Table 1b has as a component type "trip coils and auxiliary relays". Table 1b say that there are no monitoring attributes for this component and to use the level 1 intervals, but then gives a maximum maintenance interval of 6 years, which doesn't agree with the 3 month interval given in Table 1a. 3. The terminology used to describe the secondary currents and voltages provided to the relay is confusing. Under the modified definition of a protection system, it includes the term "voltage and current sensing inputs to protective relays", and in the tables it uses the term "current and voltage circuit inputs". These terms, especially the use of the word input, give the impression that the actual input circuitry of the protective relay is what is being described, but we believe that these terms are really meant to describe the secondary currents and voltages from the instrument transformers (or other devices). BPA suggests revising the terminology

Organization	Question 10 Comment
	to describe the secondary currents and voltages. For example, in the maintenance activities section of the tables, you could say, "Verify that the secondary current and voltages provided to the relay are correct". 4. There is no mention to what the thresholds are when performing these maintenance activities or what corrective actions must take place and by when they need to be carried out. Is this something we should expect to see soon? 5. The need to measure the cell/unit internal ohmic value every 18 months can be argued. BPA's Substation Maintenance crew performs these measurements once every 24 months and with the Operators monthly inspections, we have been able to effectively catch any problems before a severe event/failure. 6. Communications: It is not clear specifically what equipment is included in "communications". The test interval of 12 years in table 1b is too long to verify continued proper operation of transfer trip tone equipment. Monitoring the presence of the channel does not provide any indication of whether the equipment can initiate a trip. Consequently, a required minimum interval of 12 calendar years is too long and does not do anything to verify proper communications support of the relay scheme. A shorter interval of 6 years, such as that in table 1a makes more sense from a functionality standpoint.
Response: The SDT thanks you for your comments. **1. The SDT has experimented with various arrangements of the Tables with some input from external parties, and feels that the presentation shown in the standard is the best way to present this complex information. To the degree possible, the SDT has attempted to make the arrangement of the three tables as similar as possible to address your concern.** **2. The cited sections of Table 1a, Table 1b, and Table 1c have been extensively revised.** **3. The SDT modified the standard to address your comments by revising the description of these components within the tables and by modifying the Protection System definition.** **4. Note 1 to Table 1a, Table 1b, and Table 1c specify, "adjustment is required to bring measurement accuracy within parameters established by the asset owner based on the specific application of the component." Clause R4.3 has been added to the standard to require that the entity "initiate any necessary activities to correct unresolved maintenance correctible issue." Because corrective actions will vary widely in type and scope, it is difficult to specify when it must take place; simple corrective actions may occur rapidly, but highly involved actions may take an extended period to complete.** **5. Thank you for your comments concerning the evaluation of cell/unit internal ohmic values to the station base line at the Maximum Maintenance Interval in Table 1. Because trending is an important element of ohmic measurement evaluation, the SDT believes that extending the Maximum Maintenance Interval listed in Table 1 for evaluating internal ohmic values would not provide the necessary information for proper evaluation of the ability of the station battery to perform as designed.** **6. The SDT has defined the minimum activities and the maximum intervals necessary to implement an effective PSMP. Some entities may feel that they need to maintain Protective System components more frequently.**	
Exelon Generation Company,	1. Battery testing should be added to Table 1c for Station dc supply (that uses a battery and charger)

Organization	Question 10 Comment
LLC	2. Table 1c Condition based maintenance. Consider adding Battery Capacity Test on a 6-year interval regardless of other condition based maintenance performed. 3. Evaluating the measured cell/unit internal ohmic values to station battery baseline does not provide an evaluation of battery capacity please explain rational for maintenance activity. 4. If the Table 1a maintenance interval is reached and the entity is unable to perform the maintenance task, is it acceptable to install temporary external monitoring or other measures to defer the maintenance to Table 1b or Table 1c interval? Is it acceptable in Table 1b to substitute additional or augmented maintenance activities or operator rounds to extend intervals? 5. Table 1c for equipment with "continuous monitoring" states the maximum maintenance interval of "continuous" this does not seem correct wording consider revising to state "not required." 6. The NERC standard should be revised to include a specific allowance for a deferral or variances of a maintenance activity based on a formal technical evaluation. Nuclear generating units allow for deferrals and/or variances on certain equipment based on emergent conditions that would prevent safe isolation and/or testing of function. It should be noted that any deferrals and/or variances if justified are to be based on a formal evaluation and not based on work management or resource issues. 7. The maintenance intervals and maintenance activities should be referenced directly to a basis document to ensure guidelines have a specific technical basis (e.g., IEEE-450).

Response: The SDT thanks you for your comments.

1. The SDT has modified the standard in consideration of your comments concerning Table 1c. Within Draft 2 of the standard, testing of the battery is not required if all performance attributes of the battery are monitored.

2. The SDT has modified the standard in consideration of your comments concerning Table 1c and the need for testing to verify that the battery can perform as designed.

3. The SDT believes that this Maintenance Activity is a viable alternative that a Vented Lead-Acid or Valve-Regulated Lead Acid battery owner can perform at the Maximum Maintenance Interval of Table 1 in place of conducting a capacity test. See FAQ II-5-F (page 14) and FAQ II-5-G (page 14).

4. R2 of the standard establishes that the entity “ensure the components to which the condition-based criteria are applied (as specified in Tables 1b or 1c), possess the necessary monitoring attributes.” It appears irrelevant as to when the monitoring system is installed within the Table 1a monitoring interval, as long as the monitoring satisfies the attributes established in Table 1b or Table 1c as appropriate. If operator rounds, etc, are performed to the intervals established within the Table 1b general requirements, address the monitoring attributes specified within the Table, and are appropriately documented, they meet the requirements. However, it seems to the SDT that any temporary monitoring, etc, will have to be in place BEFORE you are overdue on maintenance and therefore out of compliance.

5. The Maintenance Activities describe that maintenance is actually being performed continuously via the monitoring system. Stating “continuous” for the interval provides a valuable link to FERC Order 693, which directs NERC to establish maximum maintenance intervals.

Organization	Question 10 Comment
6. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue. **7. IEEE Standards are voluntary unless they are adopted by an "authority having jurisdiction', thus the IEEE Standards could be adopted here in their entirety. However, they would require consistent and continual review by NERC to assure that they are, and continue to be, relevant. The SDT elected instead to use them as a source of material, and to include the relevant required tests within the NERC Standard.**	
FirstEnergy	1. BES reclosing schemes were recently questioned in a PRC-005-1 interpretation but there is no mention of reclosing schemes in the draft standard. This interpretation should be integrated into the requirements of PRC-005-2. 2. Lack of Exception Process - The standard as written does not reflect the fact that any one group, such as a TO performing maintenance on a BES, does not have full control over when an outage can be taken to perform maintenance activities. Especially regarding functional testing, where the equipment needs to be exercised resulting in some BES components being de-energized, it can be very difficult in certain parts of the T&D system to obtain the necessary outage to complete these tasks. Even with proper planning, changes in system conditions and unforeseen equipment problems in other areas can impact the ability to schedule an equipment outage appropriately. Accordingly, a TO can be penalized for not completing prescribed maintenance within prescribed limits due to factors outside of their control. This type of scenario has already been experienced where maintenance activities are scheduled upwards of a year in advance, and then inclement weather or system conditions outside of a TO's service territory (e.g. unanticipated generating unit shutdown) prevent the work from taking place. 3. The standard should provide some specific guidance to allow relief for such situations, or that properly incents or even requires independent system operators (ISOs) and other outside groups to also ensure maintenance is completed within prescribed intervals. If a TO properly considers factors such as weather (not scheduling critical outage during middle of summer), resource commitment, schedule (the requested outage window is at least one year before maximum interval is met), time of day (performing work during afterhours period when load is down) etc. then if outages are still denied, that the TO is not penalized for being out of compliance as maximum intervals are exceeded. This suggested "exception process" should provide requirements for all parties involved, both those performing the maintenance as well as those controlling and overseeing the system. There should be required documentation to prove that the parties on both sides made proper efforts to complete the required maintenance, as well as discuss conflict resolution. 4. With regard to the phrase "including identification of the resolution of all maintenance correctible issues" in Req. R4, we feel that this requirement should be a subset of R4 since it is part of the implementation of the PSMP. We suggest removing the phrase from the main requirement of R4 and creating a new 4.3 as follows:"4.3. For all maintenance programs, identify resolutions for all encountered maintenance correctible issues and take corrective action within a time period suitable for maintaining reliability

Organization	Question 10 Comment
	of the affected protection system." 5. With regard to the proposed modification of "Protection System", we suggest adding the word "devices" after "voltage and current sensing". This would also match what appears to be the SDT's intended wording as shown in the Supplementary Reference Document sec. 2.2. Also, we suggest modifications to the proposed definition to add clarity to the types of communications system protection and the voltage and current sensing devices. The following is our suggestion for wording of the definition:"Protective relays, communication systems used in communications aided (or pilot) protection, voltage and current sensing devices and their secondary circuits to protective relays, station DC supply, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices." 6. Protection System Communication Equipment and Channels - Some power line carrier equipment has automatic testing and remote alarming and some that does not. For other relay communication schemes (e.g., tone transfer trip ckts), if the circuit travels over our private communications network (fiber or microwave radio), the communication equipment is remotely monitored/alarmed. In other cases it is not remote monitored. We ask for clarification as follows: As part of our maintenance program, we check that signal level, reflected power, and data error rate are all within tolerance at the interface between the end equipment and the communication link. Our question is: Does this meet the intent of the proposed requirements in PRC-005-2 for maintenance activities for Protection System Communication Equipment and Channels? Or do the requirements ask for something beyond this? 7. We suggest combining 4.2.2, 4.2.3 and 4.2.4 to read as a new 4.2.2 "Protection System components which are installed as an underfrequency load shedding, under voltage load shedding or Special Protection System for BES reliability."

Response: The SDT thanks you for your comments.

1. The SDT is required to include/adopt material from approved interpretations within the standard. In the case of reclosing relays, the referenced interpretation stated that reclosing relays are NOT included, and the draft standard excludes them.

2. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.

3. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 (page 9) of the Supplementary Reference Document for a discussion on this issue

4. The SDT has modified the standard in consideration of your comment. Requirement R4, Part 4.3 was added and now reads: Assure either that the

Organization	Question 10 Comment
components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues[4]. **5. The SDT believes that your suggestions regarding the Protection System definition may address predominant current technology relatively accurately, but may be constraining with regards to emerging technologies.** **6. If there is remote monitoring of the Channel, then Level 2 requirements indicate a 12 calendar year interval for the tests you describe. If the system is unmonitored a manual check back or a check of the automated check back is required at a 3 month interval. Unmonitored systems would also have the signal level, reflected power and data error rate check done on a 6 year interval.** **7. The SDT elected to list these components within separate subrequirements in order to maintain linkage to the legacy PRC-008, PRC-011, and PRC-017 standards. Your suggestion may be better adopted in a future revision of this standard (following approval of PRC-005-2).**	
Dynegy	1. The proposed definition of Protection System needs further clarification. Suggest changing wording around DC supply to read as follows: "...and DC control circuitry associated with protective devices from the station DC supply". 2. Suggest revising Section 4.2 to separate time based program as its own item under R4.3. 3. Change title on Table 1a to clarify level 1 monitoring as time based.
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard in consideration of your comment. The following phrase was added to the definition:** and associated circuitry from the voltage and current sensing devices **2. R4.1 currently addresses implementation of maintenance programs per Table 1a, Table 1b, and Table 1c as different “flavors” of a time-based program, depending on the degree of monitoring present for the various components. The SDT feels that this is the correct approach. R4.2 specifically addresses performance-based maintenance, and does not seem relevant to the text of your comment.** **3. The SDT has modified the standard in consideration of your comment and added “Time-based” to the title of Table 1a.**	
MRO NERC Standards Review Subcommittee	A. In the applicability section 4.2.5.5, change the statement to say, “Protection systems for BES connected station-service transformers for generators that are part of the BES.” B. In the applicability section 4.2.5, change the statement to replace “are part of” with “directly connected to”. The “are part of” will be left to interpretation. Please indicate the added reliability benefit by collecting this in Table 1a Page 9 protection system

[4] A maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity and that requires follow-up corrective action.

Organization	Question 10 Comment
	communication equipment and channels. C. If a breaker failure relay is also being used for sync-check, is it required to verify the voltage inputs since they are used for a closing function and not a tripping function? It is understood that the current inputs would have to be verified since these are used for breaker failure tripping. D. Please clarify requirement R1-1.1, does one have to individually list out each Protection System and its associated maintenance activities or can the PSMP be a generalized procedure that covers each of the components in all of a utility's Protection Systems? E. All references to breakers should be eliminated; thus, eliminate breaker trip coils. Breakers are primarily mechanical in nature and should be excluded similar to mechanical relay systems such as sudden pressure relays. F. Clarify that trip coils checks or tests can be verified through alternate means other than physically tripping the coil or potentially requiring system outages to physically trip a coil. Alternate tests could consist of checking self monitoring relays, continuity lights, etc. Trip coil tests could require transmission line outages which can be denied by regulatory authorities due to system conditions beyond an entity's control. Significant delays of months or longer could occur to obtain a transmission line outage. Further, potentially requiring transmission line outages for trip coil test could harm BES reliability by increase the number of force transmission line outages due to testing. System reliability could be significantly negatively impacted anytime testing on trip circuits is performed due to human errors causing outages or regional disturbances. G. One item R1.3 (inclusion of batteries) was questioned as why this was specifically called out. It should be part of the definition. H. Define the term "condition-based". I. The format of the tables is poor with 17 line items addressed in each. It is difficult to relate one table to another because they are not consistent with regard to the type of components. For example table 1a references of components a "breaker trip coil (only)" and the 1b references "trip coils and auxiliary relays". J. R1.1 please add "as they apply to the applicable entity". As stated now, all three tables must be accomplished. K. Please add the words "time based maintenance methods" to table 1a for clarity in the heading. L. Table 1b under general description, last sentence the word "elements" should be replaced with "maintenance activities" which will provide exactly what is intended. M. Table 1b, if maintenance activities for level 2 monitoring include level 1 maintenance activities, then redundant activities in table 2 that are contained in table 1 should be removed (the same for table 3 to table 2 to table 1). N. If an entity maintenances a protective relay such that it is included in level 2 monitoring (a Condition Based Maintenance program) and this relay is considered to have a maximum interval of 12 years, does the entity need to also perform the maintenance activities for level 1 monitoring since the table 1b header indicates, "General Description: Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for

Organization	Question 10 Comment
	alarmed failures. Monitoring includes all elements of level 1 monitoring with additional monitoring attributes as listed below for the individual type of component"?

Response: The SDT thanks you for your comments.

A. The station-service transformer impacts proper operation of the BES generator, whether the station service transformer is connected to the BES (for example, at 138 kV) or not (for example, connected at 46 kV). (See FAQ III-2-A, page 20)

B. This suggestion may actually bring a small, non-BES, generator facility that is connected to the BES into scope. For example, if a Region specifies that any generator greater than 20 MVA connected at 100 kV or above is BES, your suggestion would bring a 10 MVA generator (similarly connected) into scope. Clause 4.2.5 currently limits applicability to BES generators.

C. No. The maintenance activities for this component have been modified to clarify.

D. The entity may use whatever method it wishes, but the documentation of the program and the implementation of the program needs to be adequate to satisfy the Compliance Enforcement Authority that the program meets the requirements of the standard. Please be advised that all requirements of the standard must be met, including that the relevant activities in the Tables are performed.

E. The SDT believes that the breaker trip coils are a vital electrically-operated component of the DC control circuit, and they therefore must be included. For testing the breaker trip coil, the breaker must be observed to trip; however, such additional testing such as travel recorder, breaker timing, etc need not be performed to satisfy PRC-005.

F. The SDT considers that the electro-mechanical devices (trip coils, aux relay coils, etc) need to be periodically exercised to assure that they operate properly. Much of the rest of the control circuit can be verified by monitoring, including continuity of the coils, but this doesn't assure operating integrity of these devices. An entity is necessarily obligated to manage its maintenance program to complete the necessary activities on time, and various other NERC standards address the management of risk related to planned outages.

G. In the Protection System Maintenance – Frequently Asked Questions (FAQ) document (FAQ IV-3-G, page 26.) and Supplementary Reference Document Section 15.4 (page 23), the Drafting Team explains why batteries are excluded from PBM and the standard should include all batteries associated with a Protection System in a time-based program.

H. The SDT declines to introduce a defined term for this. Table 1b and Table 1c identify condition-based maintenance to include consideration of the known condition of the component within condition-based maintenance. The Supplemental Reference Document (Section 6, page 8) and the FAQ (V-3, page 38 and V-4, page 39) also describe condition-based maintenance considerations.

I. The SDT has modified to Tables to make them more consistent with each other.

J. The SDT has modified the standard in consideration of your comment. The original Pwas replaced with a new Part 1.1 and a new Part 1.3 was added as shown below,

1.1. Identify all Protection System components.

1.3 For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used

Organization	Question 10 Comment
per Requirement 1, Part 1.2.	
K. The SDT has modified the standard in consideration of your comment - and added "Time-based" to the title of Table 1a.	
L. The SDT has modified the standard in consideration of your comment. The revised language does not use the word, "elements" – it reads:	
M. The SDT disagrees. Repeating the activities in Table 1b or Table 1c allows the entity to not refer back to the previous table.	
N. If an entity decides to implement Table 1b for qualified components, the activities in Table 1b supersede the comparable activities in Table 1a. Requirement R1 has been modified to clarify.	
CenterPoint Energy	a. CenterPoint Energy believes the existing maintenance standards are preferable to the approach embodied in this proposal. However, if most entities agree with the SDT's approach, CenterPoint Energy recommends deleting Under-Frequency Load Shedding (UFLS) and Under-Voltage Load Shedding (UVLS) system equipment from the scope of this proposal because the performance requirements for UVLS and UFLS are substantially different from transmission and generation protection schemes. Few would argue that protection schemes that clear faults on the Bulk Electric System must be very reliable, much more reliable than schemes that shed distribution load for under-voltage or under-frequency situations. If an entity plans to shed a contemplated level of load for a contemplated set of circumstances based upon planning simulations, that plan would translate into a certain number of distribution feeders that are reasonably predicted to shed a load amount that is reasonably close, but not exactly equal (unless by chance) to the contemplated amount of load shed. For example, if a certain number of distribution circuits equals 10% of the entity's load during one time (such as system peak), that same amount of distribution circuits will almost certainly equal a different percentage of the entity's load at other times. So, if hypothetically 100 distribution circuits are armed with UVLS or UFLS relays set a given trip point, the actual percentage of load that will be shed will vary under different system conditions. Therefore, if 95 of the distribution circuits actually trip on one occasion and 98 trip on another occasion, the difference in system performance is immaterial because the exercise is not that precise, especially when planning simulation uncertainties are also introduced into the picture. For these reasons, CenterPoint Energy believes it is unreasonable to impose a high level of rigidity into load shedding schemes when the designs of the schemes inherently do not depend on such rigidity. If the SDT agrees, then the revised standard would not be applicable to Distribution Providers, and 4.1.3 can be deleted. b. CenterPoint Energy also disagrees with the proposed expansion of the Protection System definition. The present definition does not include trip coils; and correctly so, as trip coils are part of the circuit breaker. A protection system has correctly performed its function if it provides tripping voltage up to the breaker's trip coils. From that point, the breaker can fail to timely interrupt fault current due to several factors such as a binding mechanism that affects breaker clearing time, a broken pull rod, a bad insulating medium, or bad trip coils. Local breaker failure protection is installed to address the various possible causes of circuit breaker failure. Planning standard TPL-001 tables 1C and 1D specifically support the present definition, as Delayed Clearing is noted as due to "stuck breaker or protection system failure".
Response: The SDT thanks you for your comments.	

Organization	Question 10 Comment
a. The four legacy standards are combined here in response to several suggestions, including from FERC (in Order 693) because of substantial equipment similarities. For the reasons that you note, the activities specified for UFLS and UVLS protection are somewhat less comprehensive than those for fault protection. **b. The SDT contends that the trip coil itself is an integral and essential component of the station control circuitry, and it must be assured that the trip coil operates. The SDT has also been diligent in excluding any facets of the breaker mechanism from consideration, thereby excluding consideration of many of the failure types listed. Many breaker failure schemes are designed with the presumption that the trip coil is properly initiated, and are more focused on mechanism failures.**	
NextEra Energy Resources	a. The level of effort that will be required to be in compliance in accordance to PRC-005-2 is substantial. Also, it will be difficult to create one maintenance program for all NextEra Energy sites that establishes maintenance intervals based the implementation of a combination of the three allowable types of maintenance programs (time-based, condition based, and/or performance based maintenance). As a result, a high risk exists that something will be missed or carried out incorrectly. b. What is the implementation period? How will the standard be implemented in relation to the entity's maintenance scheduled in accordance with existing intervals specified in the current Protection System Maintenance and Testing Procedure that meets the requirements of PRC-005-1 but will exceed PRC-005-2's established maximum intervals? Once PRC-005-2 becomes mandatory, entities should not be required to re-do testing in accordance with the new intervals. Instead, entities should be allowed to implement the newly established intervals after the last known cycle. c. Protection System Maintenance Program (PSMP): (c1) The PSMP definition would be better defined if the first sentence was changed to "An ongoing program by which Protection System components are kept in working order and where malfunctioning components are restored to working order." (c2) Please clarify what is meant by "relevant" under the definition of Upkeep. Should "relevant" be changed to "necessary"? (c3) The definition of Restoration would also be more explicit if changed to:The actions to return malfunctioning components back to working order by calibration, repair or replacement. (c4) Please clarify the definition of Restoration. For example, if a direct transfer trip system has dual channels for extra security even though only one channel is required to protect the reliability of the BES and one channel fails, must both be restored to be compliant? d. Protection System (modification): (d1) Voltage and current sensing inputs to protective relays" should be changed to "voltage and current sensors for protective relays." Voltage and current sensors are components that produce voltage and current inputs to protective relays. (d2) "Auxiliary relays" should be changed to "auxiliary tripping relays" throughout PRC-005-2, FAQ and the Draft Supplementary Reference.

Organization	Question 10 Comment
	(d3) The word "proper" should be removed from the standard. It is ambiguous and should be replaced with a word or words that are clear and concise. e. Additionally, NextEra Energy concurs with the following comments made by other entities: (e1) PRC-005 Sect B (R2): More clarity needs to be provided. Does this requirement require the utility to document the capabilities of its various protection components to determine fully and partially monitored protection systems? If so the requirement for such documentation should be clearly spelled out. Usually each requirement has a measurement (of compliance) and I'm not clear how this will be done. (e2) PRC-005 Sect B (R4.1): A "grace period" similar to the NPCC Criteria should be considered in case it is not possible to obtain necessary outages.

Response: The SDT thanks you for your comments.

a. We agree that the effort may be substantial. However, the effort and compliance risk can be minimized by simply implementing Table 1a, together with R1 and R4.

b. A proposed Implementation Plan was posted with this draft of the standard, and will continue to be posted with future drafts (including ballot drafts when the standard reaches that stage). Please review the posted Implementation Plan.

c1. The SDT does not believe that the suggested change is substantive, and sees no reason to make it.

c2. Some updates may not affect the operation of the device as applied, and therefore are not relevant. "Necessary" would imply an additional level of review to determine whether the device would operate properly without the updates, while "relevant" simply implies that the update applies to the function.

c3. The SDT does not believe that the suggested change is substantive, and sees no reason to make it.

c4. The standard establishes that all components need to be fully maintained, and that they will function as designed. The SDT appreciates that some "restoration" activities may take an extended time to complete, but also contends that restoration to the designed condition is a vital element of maintenance.

d1. The SDT has modified the standard in consideration of your comments.

d2. "Auxiliary tripping relays" may exclude essential other internal Protection System functions. Therefore, the SDT declines to adopt this suggestion.

d3. "Proper", "working condition", "correct", etc, are all somewhat subjective terms that address the application-specific requirements related to the specific use. For example, one entity's design standards may require that an electromechanical relay be within a 2% tolerance of the ideal operating characteristics, while another may only require that it be within 5%. Each of these is proper, correct, etc, for the application.

e1. The requirement establishes that an entity be able to prove that the specified monitoring attributes are met. There may be many methods of documenting this – see Section 15.6 of the Supplemental Reference Document (page 24) which was posted with this standard. Measures, etc, will be included with the next posted draft of the standard.

Organization	Question 10 Comment
e2. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document for a discussion on this issue.	
City Utilities of Springfield, MO	As proposed, this standard is very long and complex. Additionally, in requirement R1, bullet 1.1 ought to state "For each component used in each Protection System, include all "applicable" maintenance activities specified in Tables 1a, 1b and 1c". For instance, if every component has continuous monitoring, why should the program include 1a and 1b?
Response: The SDT thanks you for your comments. The SDT has modified the standard in consideration of your comments. The original Part 1.1 was replaced with a new Part 1.1 and a new Part 1.3 was added as shown below, 1.1. Identify all Protection System components. 1.3 For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2.	
Austin Energy	Austin Energy is meticulous in adhering to the current maintenance standard and is convinced that its current maintenance and documentation program is adequate to maintain its reliable electric power system. 1. Austin Energy appreciates the good intentions of the SDT but believes that the approach taken increases complexities to the maintenance process, introduces unwarranted workload in excessive documentation, is inflexible towards system configuration and experience, and is over prescriptive in nature. The approach also fails to distinguish the harmful effects of over-maintenance, increasing reliability risk due to human error and ultimately affecting the overall performance and reliability of the system. 2. Another concerning issue is the addition of the breaker trip coil to the protection system definition. Our position is that the trip coil should be part of the breaker. The protection system would be considered operating correctly if it provided the output signal for the trip coil when expected. Hence the trip coil should be excluded from the new protection system definition. 3. Performance based maintenance as specified in the attachment is extremely difficult and cumbersome to navigate. The intricate requirements are difficult to comprehend and will entrap entities making a good faith effort to comply. We believe this approach may become burdened with undesirable consequences. 4. Last but not least, Austin Energy believes that under-frequency load shedding (UFLS) and under-voltage load shedding (UVLS) systems should not be included in the scope of this new proposal. UFLS and UVLS are a wholly different entity as compared to the Bulk Electric System (BES). Rigidity imposed onto distribution system equipment, operating schemes and performance is uncalled for and overreaching.
Response: The SDT thanks you for your comments. **1. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address**	

Organization	Question 10 Comment
observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP. To minimize system impact of such maintenance and possible errors, the maintenance necessarily should be scheduled at a time that minimizes the risks. **2. The SDT contends that the trip coil itself is an integral and essential component of the station control circuitry and it must be assured that the trip coil operates. The SDT has also been diligent in excluding any facets of the breaker mechanism from consideration.** **3. If an entity considers that a PBM would be difficult to implement, they may choose to implement simple time-based maintenance (Table 1a) and/or condition-based maintenance (Tables 1b and Table 1c). This option is provided for those who elect to take advantage of the opportunities presented.** **4. The four legacy standards are combined here in response to several suggestions, including from FERC Order 693 because of substantial equipment similarities. The SDT disagrees that the requirements for UFLS and UVLS are "uncalled for and overreaching", and has specified less stringent requirements for these devices.**	
Progress Energy	Comments: 1- Requirement R4 "Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctible issues as follows: " Based on the definition provided (A maintenance correctable issue is a failure of a device to operate within design parameters that can be restored to functional order by calibration, repair or replacement.) Pr ogress Energy believes that this will become a potential tracking issue. To maintain all of the data required to meet this definition can be onerous. 2- The biggest concern with the proposed PRC is that for many entities, the proposed maintenance and intervals will greatly increase the entities workloads. There are not enough relay technicians available to handle this increased workload across the country. 3- The Implementation Plan for R2, R3, and R4 identified in the Draft Implementation Plan for PRC-005-02, dated July 21, 2009, is very reasonable. This plan recognizes that it is unrealistic to expect entities that are presently using intervals that exceed the maximum allowable intervals to immediately be in compliance with the new intervals. It allows implementation to be implemented across the maximum allowable interval. This is a reasonable approach for the following reasons: a. Sufficient resources are not available to perform the additional maintenance proposed on an accelerated basis. b. It allows the staggering of the PMs so that resource loading can be balanced. Without the ability to stagger the PMs, there would be an initial "bow-wave" of PMs and future "bow-waves" each time the interval is up. 4- The Implementation Plan for R1 identified in the Draft Implementation Plan for PRC-005-02, dated July 21, 2009, is not reasonable. The implementation plan requires entities to be 100% compliant three months following approval of the PRC. This is not a reasonable timeframe given the program changes required, including: a. A massive effort to review circuit schematics to determine whether equipment meets the definition of partial-monitored or

Organization	Question 10 Comment
	unmonitored. b. Many procedures, basis documents, and job plans will need to be revised or created. c. The work management tool will have to be modified to reflect the new intervals. 5- PRC-008-1 placed only the relays associated with UFLS in the compliance program. Contrary to PRC-008-1, the draft PRC-005-02 places all components (relays, instrument transformers, dc supply, breaker trip paths) in the compliance program. This forces much of the distribution-level components to be placed in the compliance program. 6- The response to Item 2A of the FAQ Document, page 17, seems to indicate that commissioning test results do not have to be captured as the initial test record, only the in-service date. Is this a correct interpretation of the response? 7- Table 1a (Unmonitored Protection Systems) seems to indicate that a complete functional trip test must be performed for the UFLS/UVLS protection system control circuitry. This wording is identical with the wording for the protection system control circuitry (except UFLS/UVLS) table entry. This implies that UFLS/UVLS functional testing should include tripping of the feeder breakers for these unmonitored systems. Table 1b (Partially-Monitored Protection Systems) indicates that actual tripping of circuit breakers is not required under the UFLS/UVLS control circuit functional testing. Is this because trip coil continuity is being monitored and alarmed under Level 2 Monitoring? Must feeder breakers be tripped during the functional testing if the trip coil continuity is not monitored and alarmed (unmonitored protection system)? 8- All standards to be retired should be specifically listed in the Implementation Plan.

Response: The SDT thanks you for your comments.

1. **Requirement R4.3 has been added to the standard to address some of these concerns. It reads as follows:**

   R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctable issues as follows:

   4.3. Assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues.

2. The SDT understands that workloads may increase. However, with increasing sensitivity to degraded system performance, the increased attention to Protection System maintenance is critical to BES reliability. NERC's analysis of major system events reveals that Protection System maintenance is a contributing factor to many major system problems.

3. The SDT appreciates that you recognize these issues which were central in developing the Implementation Plan.

4. Table 1a provides activities and intervals for components for which Level 2 or Level 3 maintenance cannot be fully justified. Additionally, considerable time can transpire between successful balloting and regulatory approvals and major elements of the standard will be largely established even well before balloting. Entities are encouraged to proactively begin making the necessary program adjustments.

Organization	Question 10 Comment
5. PRC-008 currently addresses "UFLS equipment" which is a bit vague. Arguably, the identified components within PRC-005-2 may be regarded as various portions of "UFLS equipment". The SDT contends that the indicated activities are necessary, and notes that some of the activities are less stringent than for other Protection System components. **6. FAQ IV-2-A, page 22) now indicates that commissioning records are one option to establish the start date of maintenance intervals, and to establish the baseline.** **7. The Tables have modified to clarify that actual tripping of the breakers is not required for Protection System control circuitry for UFLS/UVLS only.** **8. The SDT agrees. The Implementation Plan will be modified to indicate retirement of the four legacy standards upon the completion of the Implementation Plan.**	
Nebraska Public Power District	Definition of Terms: 1. Footnote 2 for R4 defines a "maintenance correctable issue". This should be added to the Definition of Terms section. 2. Sections 4.2.5.4 and 4.2.5.5 inappropriately extend Generator Protection Systems to Station Service Transformers. These are components necessary for plant operation however they are not part of the generator protection scheme. This conclusion is supported by the explanations on page 16 of the FAQ. 3. The FAQ states the operation of the listed station auxiliary transforms protective relays would result in the trip of the generating unit and, as such, would be included in the program. The FAQ goes on to state that relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of those loads could result in a trip of the generating unit. The FAQ appears to be inconsistent. Station auxiliary transformers are included because they would result in the trip of the generating unit while other loads such as pumps, fans, etc., are excluded even if their trip could result in a trip of the generating unit. In my opinion, the station service transformers like pumps, fans, etc. are components necessary for plant operation but not necessary for generator protection and should therefore be excluded from PRC-005-2 by removing Sections 4.2.5.4 and 4.2.5.5 from the standard and modifying the FAQ accordingly. 4. R1 (1.1) First sentence: "For each component used in each Protection System..." is ambiguous. The sentence should be revised to say..."For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, and 1c." This limits the components to only those identified by the definition of a Protection System. 5. R2 End of sentence: "possess the necessary monitoring attributes." is ambiguous. The sentence should be revised to say..."possess the monitoring attributes identified in Tables 1b or 1c." This specifically defines which attributes are necessary. 6. R4 I am concerned with including the phrase "including identification of the resolution of all maintenance correctible issues". Providing evidence of implementation of the PSMP will require the collection and submittal of all work documents that restored a device to functional order by calibration, repair, or replacement. It is reasonable to assume that appropriate corrective actions were taken for each specific situation. Identification of the resolution will add a significant documentation burden without adding to the reliability of the BES. Implementation of the PSMP may be evidenced without including identification of the resolution of all

Organization	Question 10 Comment
	maintenance correctible issues. It is interesting to note that nowhere in PRC-005-2 does it state that you have to take corrective actions to return a component to normal operating conditions. "No action taken" can be the resolution taken by the utility of a maintenance correctible issue.

Response: The SDT thanks you for your comments.

1. Establishing this term within the "Definition of Terms" would add this to the NERC Glossary. Instead, the SDT believes that this term is relevant only to this Standard, and that establishing it in the Glossary of Terms rather than simply as a term within this standard would expose entities to potential compliance exposure by having to refer to the Glossary to implement the standard.

2. Station service transformers are system components and the Protection Systems on those system components must be maintained as indicated in this standard. (See FAQ III-2-A, page 20)

3. Many of the components (pumps, fans, etc) are redundant, and a plant may be able to withstand loss of one of these. However, the loss of the station service transformer will result in simultaneous loss of many such elements, and will result in immediate plant shutdown. Also, the station service transformers may be necessary to achieve an orderly plant shutdown, and the loss of a station service transformer may result in a more abrupt plant shutdown. Improper Protection System performance due to maintenance issues must not be the cause of such an event. (See FAQ III-2-A, page 20)

4. The SDT has modified the standard in consideration of your comment. The original Part 1.1 was replaced with a new Part 1.1 and a new Part 1.3 was added as shown below,

1.1. Identify all Protection System components.

1.3 For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2.

4. The SDT has modified the standard in consideration of your comment. The requirement was modified to read as follows:

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses condition-based maintenance intervals in its PSMP for partially or fully monitored Protection Systems shall ensure the components to which the condition-based criteria are applied, possess the monitoring attributes identified in Tables 1b or 1c.

6. A fundamental tenet of compliance is that "if it's not documented, it's not done." Therefore, the documentation you describe will likely be necessary to demonstrate compliance. The PSMP definition, the new R4.3, and the General Requirements of each Table all establish that maintenance-correctable issues need to be resolved. If there is a maintenance-correctable issue, "no action taken" does not seem to be an acceptable response.

Organization	Question 10 Comment
Florida Municipal Power Agency, and its Member Cities	1. Facilities applicability 4.2.2, due to the changes in applicability of the draft PRC-006, ought to refer say something like UFLS which are installed per requirements of PRC-006 rather than per ERO requirements. 2. In requirement R1, bullet 1.1 ought to state "For each component used in each Protection System, include all "applicable" maintenance activities specified in Tables 1a, 1b and 1c". For instance, if every component has continuous monitoring, why

Organization	Question 10 Comment
	should the program include 1a and 1b?
Response: The SDT thanks you for your comments. **1. The existing PRC-006 establishes that entities install UFLS in accordance with Regional requirements (which, by extension, are ERO requirements). In accordance with FERC Order 693, PRC-006 is currently undergoing revision to be a continent-wide standard, in which case it will itself be an ERO requirement. Clause 4.2.2 applies equally to either situation.** **2. Requirement R1has been modified in consideration of your comment. The original Part 1.1 was replaced with a new Part 1.1 and a new Part 1.3 was added as shown below,** 1.1. Identify all Protection System components. 1.3 For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2.	
American Transmission Company	1. General Comment: The requirements section of the standard seems acceptable. 2. NOTE: Why does R1.3 identify the inclusion of batteries? We believe that this should be part of the definition. 3. We believe that the team needs to define the term “condition-based”. 4. Does the Protection System definition in PRC-005-2 or interpretation of the standard and the tables line up with other NERC Standards? 5. The table formats (1a through 1b) are confusing and should be reconsidered. We found is difficult to relate one table to another. (No consistency in the Type of components)
Response: The SDT thanks you for your comments. **1. The SDT thanks you for your support.** **2. R1.3 specifies that batteries can be tested ONLY via TBM. That is the intent of the requirement. In the Protection System Maintenance – Frequently Asked Questions (FAQ) document (FAQ IV-3-G, page 26.) which accompanied the standard and in the Supplementary Reference Document, Section 15.4 (page 23), the SDT explains why batteries are excluded from PBM and the standard should include all batteries associated with a Protection System in a time-based program.** **3. The SDT declines to introduce a defined term for this. Table 1b and Table 1c identify condition-based maintenance to include consideration of the known condition of the component within condition-based maintenance. The Supplemental Reference Document, Section 6 (page 8) and the FAQ (V-3, page 38 and V-4, page 39) also describe condition-based maintenance considerations.** **4. The SDT was required to investigate all uses of this defined term with NERC standards and assure that these changes are consistent with the other**	

Organization	Question 10 Comment
applications. **5. The SDT has modified to Tables to make them more consistent with each other.**	
CPS Energy	Have several comments and questions: 1. I think that the way that the tables are done is confusing. My biggest complaint is that the "breakdown" of the Type of Component varies between the tables. For example, in tables 1a and 1B, you have Protective Relays, but in table 1c, you have Protective Relays and Protective Relays with trip contacts. This is a little confusing at times. 2. I also find the UFLS/UVLS requirements confusing as well. It can be confusing to figure out when the UFLS/UVLS has a separate requirement. Would prefer to see the UVLS/UFLS in separate tables; e.g. 2a, 2b, 2c. 3. SPCTF should provide the basis for how the intervals in table 1 were derived. While the supplemental describes that a survey of its members with a weighted average was used to determine the maintenance intervals. However, what is not clear is what exactly was surveyed in terms of components. Was it just relay calibration testing? Functional testing? What about communications, voltage and current sensing devices, trip coils, etc? Was UVLS and UFLS looked at separately from transmission? Was generation also considered as well? Why did values change from the SPCTF technical reference "Relay Maintenance Technical Reference" dated September 13, 2007? For example, UVLS/UFLS testing and calibration went from 10 years to 6 years for un-monitored, communications went from 6 months to 3 months for un-monitored, and instrument transformer testing went from 7 years to 12 years for un-monitored systems. What is the basis for the intervals? 4. The committee should reconsider the use of the term "A/D converters". The point of the requirement is to assure that the analog signal from the instrument transformer is correct to the processor. Two problems with just saying "A/D converters". One, it ignores the digital relay input transformers of microprocessor relays. The SEL-4000 test set can bypass these transformers. Would using this test set be adequate to test the "A/D converters"? Two, some relays, such as the SEL-311L, perform an A/D self-test. I do not think that the A/D self-test performs the testing that is being sought by the document. 5. Could a better example of "Calendar Year" be provided? Is it simply the years difference, or should the days be included as well? In your example in the reference document, you show that December 15, 2008 and December 31, 2014 as meeting the requirement of 6 calendar years. Would like to see a more exaggerated example. Would an unmonitored protective relay is calibrated on January 1, 2008 and then again on December 31, 2014 meet the "Maximum Maintenance Interval" of "6 Calendar Years"? 6. Does the standard address breakers and other switching devices that do not have "trip coils". Magnetic actuated circuit breakers, reclosers, and possibly other devices do not have trip coils to monitor or test. Do the trip coil testing and requirements fully take this account? If a breaker does not have a trip coil, is some other type of test required? Does not having a trip coil prevent extending the Protection System Control Circuitry interval to 12 years? 7. The requirement for testing Voltage and Current Sensing devices should be better thought out as to what is trying to be accomplished. On page 11 of the reference document, item 6 under "Additional Notes for Table" it states that "phase value and

Organization	Question 10 Comment
	phase relationships are both equally important to prove". In both the FAQ document (page 6, 3A) and the reference document (page 21, 15.2), several methods to verify the voltage and current sensing inputs to the protective relays and satisfy the requirement are given. However, these methods do not all seem to verify the same thing. Totalizing watts and vars on the bus verifies that the current transformers are correctly and providing correct signals to the relays, but do not necessarily verify that the voltage sensing device is necessarily correct if the same PT is used for all relays on the bus. Performing a saturation test on a CT and a ratio test on the PT does not verify the phase angle relationships, which is stated as important on page 11 of the reference document. What exactly needs to be accomplished by the Voltage and Current Sensing devices testing? That an analog signal is getting from the instrument transformer to the device? That the signal is an accurate representation of the measured quantity? What about frequency for UFLS relays, where voltage magnitude may not be that important? Do CT's need to be verified for multiple CT grounds? Do the any examples described necessarily find multiple ct grounds? 8. This standard should also address the ramifications of RRO's not allowing for equipment to be removed from service for testing. Either RRO's should be required to allow outages in some time frame or leeway should be given to entities that cannot get equipment out for maintenance because RRO's will not grant reasonable outage times for testing and maintenance. 9. Page 13 of the reference document states that the 3-month inspection should include checking that "equipment is free of alarms, check any metered signal levels, and that power is still applied." What is meant by "metered signal levels"? What does the term "metered" mean, specifically in terms of an on-off power line carrier scheme? 10. It appears that if a company on a TBM plan has shorter intervals than the maximum allowable of this proposed standard, the company would not be in violation if they did not meet their own plan but still met the intervals required by this proposed standard. Is this true? Could this actually reduce reliability of the BES if companies are now allowed to extend intervals to those listed in this document without any justification?

Response: The SDT thanks you for your comments.

1. The SDT has modified to Tables to make them more consistent with each other.

2. Many of the components of UFLS and UVLS are very similar to other generic Protection System components, with similar maintenance activities. The SDT has modified the Tables to clarify activities which apply specifically to UFLS and/or UVLS.

3. The SPCTF, in an earlier technical paper, provided descriptions of the derivation of the intervals, but this technical paper was not charged with developing a measurable standard. The SDT has used this information, as well as consideration of system and generation plant operating constraints, EPRI reports, IEEE surveys, and experience of SDT members and others, to develop the intervals in the tables. These intervals were also adjusted to address the SPCTF's recommendations about grace periods without providing grace periods. The SDT also considered intervals that supported establishment of systemic maintenance programs.

4. The SDT modified the standard in consideration of your comment. A/D converters are now discussed only in the Monitoring Attributes within Table 1c; otherwise, the relay must be confirmed to operate properly. However, the SDT did NOT define methodology.

5. Disregard the complete date and just look at the year portion. For a 6 calendar-year interval, if the test date was IN 2004, the next test date must be IN or

Organization	Question 10 Comment
before 2010. 6. Where relevant to the requirements of the standard, any of these devices apply similarly. Many of the alternate technologies mentioned do not seem relevant to BES Protection Systems, but instead to UFLS and/or UVLS systems. The required maintenance activities for these components do not require actual test tripping. 7. No single method of verification may be relevant for every imaginable situation. The activities relevant to Voltage and Current Sensing Devices have been revised in consideration of your comment. 8. Some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Allowing a "grace period" would create a standard that is not measurable. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue. Outages must be planned in accordance the Reliability Coordinators (RRO's, or RE's, have no role in this) to support reliable system operation. 9. "Metered signal levels" refer to the communication signal levels which are part of proper communications system function for certain equipment, such as power-line carrier systems. The SDT is continuing to align the three documents (Standard, Supplemental Reference, and FAQ) to assure consistency. 10. You will be held to compliance with your plan, whatever it is, under R4, but your plan must also adhere to the intervals established by NERC. As long as you still have elements subject to PRC-005-1, you need to comply with the program established for PRC-005-1. When you have fully implemented PRC-005-2, the requirements of PRC-005-1 no longer apply. However, the SDT hopes that entities that feel that a shorter interval is appropriate will continue to use that interval.	
JEA	1. Implementation Plan - Strongly encourage keeping the implementation plan and allow for an extension of the implementation plan for the time required to fund, design, procure, install and commission redundant protection systems for current non-redundant lockout systems at the lower kV levels of the BES. 2. Our present and past performance of LOR and auxiliary relays will support a PBM/CBM program that allows for a much longer time than the six years proposed for EM LOR trip testing. To use a TBM for LORs of six years, may in fact, lower the reliability of the BES due to the complete outages required, along with the detailed procedures that must be created and rigorously followed to perform these tests without subsequent load loss on the BES.
Response: The SDT thanks you for your comments. 1. If an entity expects to encounter difficulty in performing the maintenance specified in the standard, the SDT encourages them to begin implementation of the necessary features to support maintenance while the standard is still in a development or approval stage. 2. The SDT encourages you to begin assembling the documentation necessary to support a PBM for these components such that you may implement that PBM when the standard becomes effective.	
Consumers Energy Company	1. In Table 1a for Station dc supply it requires verification that no dc supply grounds are present. DC grounds are common

Organization	Question 10 Comment
	occurrences and the activity should be to document if dc grounds are present. 2. Please specify how cell to cell connection resistance is measured. 3. For station dc supply (battery is not used) change “Verify the continuity of all circuit connections that can be affected by wear and corrosion” to “Inspect all circuit connections that can be affected by wear and corrosion.” 4. Is “metered and monitored” equivalent to “alarming”? 5. If a component failure causes the unit to trip, what is the purpose of testing it? It will always test positive until the point of failure and that point is identified when the unit trips. 6. In the Facilities Section 4.2.5.4 “station service transformer” should be changed to “unit connected auxiliary transformer” to be consistent with Figure 2 of the Supplement Reference Document. 7. Facilities Section 4.2.5.5 should also include “System connected auxiliary transformers are excluded when only used for unit start-up.” 8. There should be an allow variance period (grace period) for the testing intervals. 9. The maximum allowable time periods should be in calendar years, defined as “occurring anytime during the calendar year.” 10. The following statement should be added to Requirement 1.2: “Identification at a program level is permissible if all components use the same maintenance method.”

Response: The SDT thanks you for your comments.

1. The SDT has modified the standard in consideration of your comments concerning dc grounds – the maintenance activity was revised to read, ‘Check for unintentional grounds.”

2. The IEEE Standards 1188 and 450 have very detailed descriptions of how to measure cell to cell connection resistance using a Micro-Ohm Meter.

3. Upon consideration of your comment, the SDT determined that it is important to both “check the continuity” and to verify the physical condition. Therefore, the standard has been modified to include both.

4. Not necessarily. “Metered and monitored” are more detailed than “alarming”. Alarms simply report an abnormal condition, while “metered and monitored” will probably actually report values.

5. In this case, testing of the component should assure that the component functions properly and thus does NOT result in an unintended trip of its system component, and that it WILL trip when called upon to do so.

6. The SDT contends that “station service transformer” is a more universal description for this component. The Supplemental Reference Document has been modified for consistency.

7. The SDT contends that “startup transformer” Protection Systems also need to be maintained per PRC-005-2. During startup, these components are

Organization	Question 10 Comment
critical for reliability. On the other hand, maintenance of the Protection Systems on these system elements should be somewhat easier to schedule. **8. The SDT considered this issue when developing the intervals, and realizes that some entities may need to perform certain maintenance activities more frequently to assure that the activities are performed within the required intervals. Specifically, for generation facilities, there would seem to be numerous opportunities within the 6-year or longer intervals to perform the required maintenance during a scheduled plant outage, and maintenance with shorter intervals can be characterized as non-intrusive maintenance, more of an inspection than anything else; the SDT believes that this maintenance can be done on-line. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive. Please refer to Section 8 of the Supplementary Reference Document (page 9) for a discussion on this issue.** **9. All multi-year periods ARE in calendar years. There are other essential shorter intervals, and the SDT does not agree that these can be extended to a minimum of one calendar year – most of these activities are "inspection" type activities. The SDT does not believe that it is necessary to define this term; "Calendar year" seems to be a very precise term in itself.** **10. To the degree that you can concisely describe your program this way, and demonstrate implementation of your program, it does not seem to the SDT that this modification to the requirement is necessary.**	
ITC Holdings	1. In the Definitions of Terms, the Protection System (modification) should include control circuits up to and including the trip coil of ground switches used in protection schemes. 2. Footnote 2 (Maintenance correctable issue) should be included in the Definition of Terms in the body of the standard.
Response: The SDT thanks you for your comments. **1. To the degree that the ground switch (or, more properly, the Protection System that operates the ground switch) is protecting a BES element, the SDT classifies the ground switch as an interrupting device.** **2. Establishing this term within the "Definition of Terms" would add this to the NERC Glossary. Instead, the SDT believes that this term is relevant only to this standard, and that establishing it in the Glossary of Terms rather than simply as a term within this standard would expose entities to potential compliance exposure by having to refer to the Glossary to implement the standard.**	
Entergy Services, Inc	1. It would be beneficial to also include an explanation or definition of the term "calendar year" in the standard. It is not readily apparent in the draft standard, especially in light of the new maximum interval requirements, that a task can be performed anytime between 1/1 and 12/31. 2. Although addressed in the FAQ and Supplement, the terms "Upkeep" and "Restoration" are referenced in the definitions section of the standard but are not used anywhere else in the document, or with regard to routine activities. They should be eliminated from the standard unless there are upkeep or restoration requirements.
Response: The SDT thanks you for your comments.	

Organization	Question 10 Comment
1. Disregard the complete date and just look at the year portion. For a 6-calendar-year interval, if the test date was IN 2004, the next test date must be IN 2010. **2. While "upkeep" is not used in the standard, the SDT has identified the term as a component of maintenance. "Restoration" is used in R4.3 and within the header of each Table.**	
AEP	1. Monitoring and tracking the activities prescribed in the standard seem too complex to manage at a level needed for auditable compliance. The activities prescribed seem to lean toward conventional protection systems and do not take into account newer special technology devices (High Voltage DC, Static Var Compensator and Phase Shifting transformer controls) and how there are to included. 2. R1 1.2 Does the draft standard require a basis for an entities" defined time based maintenance intervals or can an entity just move directly to the intervals prescribed and use the standard as its basis" 3. R4. This requirement seems to refer to failed equipment and its reporting. This corrective maintenance activity is outside of the interpreted preventative maintenance theme of the standard and adds another layer of complexity in compliance data retention. It also implies that a failed piece of equipment or segment could remain failed for the entire maintenance interval. 4a.Tables 1a & 1b. Station dc supply (that has as a component any type of battery) Interval: 18 months - This requirement incorporates specific gravity testing (where applicable). Although (where applicable) is not defined, it seems it refers to all non-sealed batteries. 4b. For sealed batteries, a more frequent internal ohmic test is prescribed. The same 18 month requirement incorporates ohmic testing which is essentially equivalent to specific gravity. Specific gravity and measure of internal temperature are invasive tests which subject personnel to handling acid and subject the battery to damage. If the logic for sealed batteries is to do more frequent ohmic testing why not allow more frequent ohmic testing as a substitute for specific gravity? We would suggest ohmic testing every 6 months with any questionable results rechecked using specific gravity. This eliminates excessive intervention into all cells and gives a validity check on the ohmic testing. 4c.For Ni-Cad the performance service test has no option (6 year intervals). Typically, the Ni-Cad can yield a low voltage indication; however testing the cells in pairs allows testing and finding bad cells. Why not offer a more frequent ohmic test for the Ni-Cads? 5. Facilities 4.2.1 and R1. "applied on, or are designed to provide protection for the BES." This may be in conflict with Regional Entity (RE) BES definitions. There needs to a clear understanding of what is included and what is not without regional differences. There should be no responsibilities or requirements of the RE. BES also takes on different meanings depending upon which of the many standards it is applied. Data Retention 1.4 Data retention for two intervals could mean that records would need to be kept for 24 years. This seems impractical. Could audit evidence be used in lieu of actual data for long intervals? 6. Tables: Where the interval is in months, the term "calendar" months should be used for clarification.

Organization	Question 10 Comment
	7. Table 1a:“verify the continuity of the breaker trip coil”. The SDT assumed that Trip Coil Monitoring (TCM) could be accomplished by verifying/inspecting red lights. This may be true in most cases, but there are designs that do not incorporate this type of TCM and the breaker would have to be exercised every 3 months if not operated by natural events unless the scheme gets replaced. This seems counterproductive to the reliability of the BES. The implementation plan does not take the time required for upgraded systems into consideration. 8. Table 1a DC Supply, 3 month interval “Verify no dc supply grounds are present.” Does this mean that you are non-compliant if you have a DC ground? This also needs to be clarified as to the amount of acceptable ground that could be present. Table 1a PS communications equipment channels 3 month interval: Do the activities imply that only alarms be verified and that no channel “playback” be performed? 9. If SPR relay or similar auxiliary relay is excluded as a protective relay, then do we not have to verify its tripping contact as part of the DC system? 10. Table 1a The exclusion of UVLS/UFLS from certain activities is confusing. Does trip coil monitoring not have to be performed on these systems? Tables: 11. Since PT and CT devices themselves are not included in the PS definition, then the word “devices” should be removed from the type of component column describing inputs to the relay. 12. Table 1a. Even though an entity may be on time-based intervals, would a natural occurring fault event reset the maintenance clock for the protection segment involved? 13. Assessment of Impact of Proposed Modification to the Definition of Protection System: Reclosing and certain auxiliary relays have been excluded from protection system definition. This new definition would have an impact on other PRC standards that use this term in its requirements, specifically the Misoperations investigation and reporting standards. These other standards, as written today, are not clearly written as to the application and assumptions as to what is included in a protection system. 14. Trip coil Monitoring: If the trip coil is actually part of the DC circuitry, then why is there a differing (shorter) interval for this series connected element?

Response: The SDT thanks you for your comments.

1. The SDT invites additional participation to address such devices.

2. There is no additional basis required for an entity to adopt the maximum allowable intervals established within the standard.

3. The SDT has modified the standard to require that an entity also initiate correction of maintenance-correctable issues. There is no time-period specified for actually correcting maintenance-correctable issues in recognition of the wide variety of activities that may be represented.

4a. The SDT has modified the standard in consideration of your comments concerning specific gravity not being applicable to non-sealed batteries. The

Organization	Question 10 Comment
maintenance activities no longer include any reference to specific gravity. **4b. The SDT has modified the standard in consideration of your comments concerning specific gravity and internal temperature. The maintenance activity associated with specific gravity and internal temperature was removed from the revised standard.** **4c. Presently there are no other options that are available today to verify that a Ni-Cad battery can perform as designed.** **5. NERC standards establish minimum requirements, which can be expanded on by Regional Entities. This standard does NOT place any requirements upon the Regional Entity. BES is a defined NERC and Regional Entity term which applies uniformly to the various standards. The Records Retention section has been modified to read as follows:** The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer. **6. The SDT has modified the standard in consideration of your comment and the word, "Calendar" was added to clarify that the term "months" means "calendar months"** **7. The SDT has removed the cited requirement.** **8. The SDT has modified the standard in consideration of your comments concerning dc grounds (changed to "Check for unintentional grounds" and compliance FAQ II-5-I, (page 15) explains that the entity is responsible to determine if corrective actions are needed upon detection of unintentional dc grounds.** **9. Yes.** **10. The Tables have been modified to better delineate the specific activities related to components associated with UFLS/UVLS relays.** **11. The definition has been further modified to add these devices.** **12. Only to the degree that the Protection System operation for the natural fault verified the functions and "performed" the activities within the Table. See FAQ II-4-C, page 10 and Supplementary Reference Document, Section 15.3, page 22.** **13. The SDT, in accordance with the NERC Standard Development Procedure, analyzed all other uses of the defined term, "Protection System" within the NERC standards, and, in a document which was posted with the standard and other associated documents during the comment period, listed all other uses and concluded that there is no impact on the other uses. Reclosing relays are still not listed in the definition, but auxiliary relays, which previously were not listed and now are, were implicit in the previous "dc control circuits".** **14. The Tables have been modified to remove this shorter-interval specific activity.**	
Green Country Energy LLC	None
Georgia System Operations Corporation	None.

Organization	Question 10 Comment
Operations and Maintenance	None.
ENOSERV	On Table 1A, the maximum time lengths are too long, especially for electro relays. A prime example is when testing a KD relay on a yearly basis and most of the time needs to be adjusted because of how far off it comes out. Allowing entities to take their time up to six calendar years may be too long.
Response: The SDT thanks you for your comments. See the Supplementary Reference Document, Section 5.1, page 7.	
Xcel Energy	Please clarify if the following are subject to PRC-005-2 requirements: 1) a battery that is in a station where the only BES element is a UFLS scheme 2) batteries used only to support communication elements (microwave houses)
Response: The SDT thanks you for your comments. **1) The SDT has modified the standard to clarify that the only DC Supply maintenance activity relevant to UFLS is to verify the DC supply voltage.** **2) The proper functioning of such batteries (communication system) will be addressed by the verification and monitoring of the communications system, and by addressing maintenance correctable issues related to the communications system. See FAQ II-5-K, page 15.**	
BGE	1. PRC-005-2R1 1.2 Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods and identify the associated maintenance interval. Comment: The existing standard PRC-005-1 requirement R1.1 says a maintenance program must include the maintenance and testing intervals and their basis. PRC-005-2 does not have a similar requirement, and the associated FAQ indicates the standard “establishes the time-basis for a Protection System Maintenance Program to a level of detail not previously required”. Does PRC-005-2 require evidence to support the basis for a defined maintenance interval, or is the basis now purely defined by PRC-005-2? 2. R2 Each transmission owner ....shall ensure the components to which condition-based criteria are applied....possess the necessary monitoring attributes? Comment: Depending on the evidence requirements that are enforced this could be a very large undertaking offsetting the benefit of extending intervals with CBM. It would be helpful to understand what the drafting team or other stakeholders would envision as appropriate evidence supporting this requirement. 3. R4 Each transmission owner ....shall implement its PSMP, including the identification of the resolution of all maintenance correctable issues as follows :4.1 ....within the maximum allowable intervals not to exceed those established in table 1a, 1b, 1c Comment: It’s inferred that this requirement applies to maintenance correctable issues that are discovered as a consequence of scheduled maintenance and not as a consequence of monitoring or misoperations. If that inference is incorrect the requirement

Organization	Question 10 Comment
	imposes an unequal playing field for the resolution of known correctable issues depending on the monitoring being employed, not to mention an unreasonably long allowance for the correction of some serious problems. On the other hand, the requirement imposes an unreasonably short period of time for the resolution of some issues that may be associated with short interval maintenance/inspection intervals, such as battery grounds. 4. Section D1.4 Data Retention? The Transmission Owner shall...retain documentation for two maintenance intervals.... Comment: Recognizing that in order to achieve compliance PS owners will execute scheduled maintenance on shorter intervals than the maximum requirement it's uncertain what this means. Example: Max interval for instrument transformers is 12 years, we maintain every six. Is the requirement for 24 years of data or 12? It seems like there ought to be an upper limit. 24 years is a very long time. Table 1a Protection System Control Circuitry (Breaker trip coil only); 3 month maximum interval; verify the continuity....of the trip circuit.....except for breakers that remain open for the entire maintenance interval. Comments: What's the failure-probability justification for this requirement when other similar dc control components have a maximum interval of 6 years? It seems like the SDT made an assumption that all trip coils are monitored by red lights and could be verified by inspection and said somewhat arbitrarily, "do it because you can". "Remaining open for the entire maintenance interval" is a poorly reasoned effort to arrive at a necessary exception. Even if the red-light-through-the-trip-coil assumption is accurate for a normally open breaker, it's unreasonable to demand that an inspection take place if it's closed at anytime during the interval. The actual time that its closed might be seconds or a few minutes, but that time would make the exception moot and put the owner out of compliance. On the subject of three month maximum intervals in general: One can agree that three months is about the right time for some of these inspections, batteries in particular. However as written, three months and a day is "out of compliance". More flexibility would avoid a lot of meaningless "technical fouls". How about four times a year not more than four months between each...or something like that. 5. Table 1aStation DC supply (that has as a component any type of battery); verify that no dc supply grounds are present? Comment: All grounds are not created equal. No guidance for acceptance criteria is given, nor is evaluation/acceptance criteria explicitly made the responsibility of the battery owner (as it is for relay calibration). Without any guidance the requirement of "no" grounds is open to unreasonable interpretation (there is always a ground if one considers a high enough resistance) and high impedance grounds that do not present a risk to the PS will consume effort and attention unnecessarily. 6. Station DC supply (that has as a component any type of battery); Measure to verify that the specific gravity and temperature of each cell is within tolerance? Comment: It is not clear that a specific gravity test provides any better data concerning battery health than an impedance test, but specific gravity testing is a requirement. Can the impedance test be performed as routine maintenance in lieu of a specific gravity test? 7. General Comment: It is not clear whether Communications batteries should be held to the same testing/maintenance requirements as the station battery. Communications batteries are in place to supply relatively low power electronic equipment and do not have to provide energy to trip a breaker. Simple monitoring of the channel may be sufficient to assure battery

Organization	Question 10 Comment
	availability, and a less rigorous maintenance plan may be appropriate based on the continuous monitoring and low duty of the battery. 8. FAQ Group by Monitoring Level A level 2 (partially) monitored Protection System or an individual component of a level 2 monitored Protection System has monitoring and Alarm circuits on the Protection System components. The alarm circuits must alert a 24-hour staffed operations center. Comment: The standard Table 1b, General Description for Level 2 monitoring is simply described as Protection System components whose alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed features. This appears to be a conflict between the FAQ and the standard. The more stringent requirement of the FAQ, for the reporting facility to be manned 24 hours per day, could be read to imply a requirement for a specific time to respond to an alarm. Is there such a requirement? Is there an implied requirement to document the alarm condition and the response time?
Response: The SDT thanks you for your comments. **1. If a time-based or condition-based program is used according to Tables 1a, 1b, and 1c, no additional basis is needed. If the entity elects to use Performance-based maintenance, the activities in Attachment A must be used to establish the related basis.** **2. See FAQ V-1-D, page 22 for a discussion relevant to your comment.** **3. The SDT has modified the standard in consideration of your concern concerning the interval of checking for unintentional dc grounds and the ability to remove the unintentional ground from the dc system. R4 of The SDT has modified the standard to require initiation of the resolution of maintenance-correctable issues, rather than to identify their resolution. See FAQ II-5-I, page 15.** **4. The data retention section has been modified to read as follows:** The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer. **5. Both the standard and FAQ document have been modified in consideration of your comments concerning dc grounds to specify that it is up to the owner to determine if corrective actions are needed for unintentional dc grounds. See FAQ II-5-I, page 15.** **6. The standard has been revised to remove maintenance activities related to specific gravity.** **7. Communication system batteries are not included in the requirements for "Station Batteries". The entity must ensure proper operation of the relay communications circuit which would include adequate maintenance of the equipment including the communication system batteries The proper functioning of such batteries (communication system) will be addressed by the verification and monitoring of the communications system, and by addressing maintenance correctable issues related to the communications system. (See FAQ II-5-K, page 15.)** **8. The FAQ has been modified to remove this apparent additional requirement.**	
Transmission Owner	Protection System Maintenance Program (PSMP)

Organization	Question 10 Comment
	a. The PSMP definition would be better defined if the first sentence was changed to "An ongoing program by which Protection System components are kept in working order and where malfunctioning components are restored to working order." b. Please clarify what is meant by "relevant" under the definition of Upkeep. Should "relevant" be changed to "necessary"? c. The definition of Restoration would also be more explicit if changed to "The actions to return malfunctioning components back to working order by calibration, repair or replacement. d. Please clarify the definition of Restoration. For example, if a direct transfer trip system has dual channels for extra security even though only one channel is required to protect the reliability of the BES and one channel fails, must both be restored to be compliant? e. Protection System (modification) "Voltage and current sensing inputs to protective relays" should be changed to "voltage and current sensors for protective relays." Voltage and current sensors are components that produce voltage and current inputs to protective relays. f. "Auxiliary relays" should be changed to "auxiliary tripping relays" throughout PRC-005-2, FAQ and the Draft Supplementary Reference. g. The word "proper" should be removed from the standard. It is ambiguous and should be replaced with a word or words that are clear and concise.

Response: The SDT thanks you for your comments.

a. The SDT does not believe that the suggested change is substantive, and sees no reason to make it.

b. Some updates may not affect the operation of the device as applied, and therefore are not relevant. "Necessary" would imply an additional level of review to determine whether the device would operate properly without the updates, while "relevant" simply implies that the update applies to the function.

c. The SDT does not believe that the suggested change is substantive, and sees no reason to make it.

d. The standard establishes that all components need to be fully maintained, and that they will function as designed. The SDT appreciates that some "restoration" activities may take an extended time to complete, but also contends that restoration to the designed condition is a vital element of maintenance.

e. The critical task is to verify that the proper representation of the primary current and voltage signals will get to the protective relays. The "Type of Protection System Component" has been modified in an effort to clarify.

f. "Auxiliary tripping relays" may exclude essential other internal Protection System functions. Therefore, the SDT declines to adopt this suggestion.

g. "Proper", "working condition", "correct", etc, are all somewhat subjective terms that address the application-specific requirements related to the specific use. For example, one entity's design standards may require that an electromechanical relay be within a 2% tolerance of the ideal operating characteristics, while another may only require that it be within 5%. Each of these is proper, correct, etc, for the application.

Organization	Question 10 Comment
Ohio Valley Electric Corp.	1. R1.2 seems to require owners to establish there own intervals and basis. Compliance with these requirements should be based on the intervals that are in tables 1a, 1b and 1c. 2. R4 implies that all maintenance correctible issues must be resolved within the Maintenance Activity Intervals. A diligent effort to restore proper function of a system should not be penalized if it does not fall within the prescribed maintenance interval.
Response: The SDT thanks you for your comments. **The SDT has modified the standard in consideration of your comment. The Parts of Requirement R1 were modified to read as follows:** 1.1. Identify all Protection System components. 1.2 Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods and identify the associated maintenance interval. 1.3 For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2. 1.4 Include all batteries associated with a Protection System in a time-based program. **2. The SDT has modified the standard to require INITIATION of resolution, not the actual resolution. The revised footnote reads as follows:** A maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action.	
E.ON U.S.	1. Recently, NERC made an interpretation on PRC-005-1 which stated that battery chargers were not to be included as part of the standard. This version of the standard seems to be in direct conflict with that interpretation, and for the reasons stated above E.ON U.S. recommends that battery chargers not be included in the standard. E.ON U.S. believes that capacity or AC impedance only needs to be done to determine service life, and therefore a periodic testing of station DC supply does not seem necessary or prudent. 2. Regarding the “Retention of Records”, retaining records of the latest test seems adequate. E.ON U.S. does not understand the point of retaining records for the past two test results. This is particularly true for equipment for which there are relatively long testing intervals, for example, 12 years. Retaining result documents from 24 years ago seems unnecessary and impractical. 3. With regard to NERC’s PRC-005-2 Supplementary Reference Section 2.4 on Applicable Relays, E.ON U.S. offers the following comments: 3.1. This section extends the applicable relay coverage to IEEE type # 86 and IEEE type # 94. Some utilities define their turbine trip relay as an IEEE type #94. E.ON U.S. interprets that the NERC scope of applicable relays is that the turbine trip relays would be excluded; however, it would further clarify this exclusion if it were mentioned as an example in the last sentence. 3.2. The Tables in proposed standard PRC-005-2 require additional clarity. E.ON U.S. suggests renaming tables to 1, 2 and 3 to

Organization	Question 10 Comment
	match Level 1, 2 and 3 monitoring. The wording and format of text is not consistent between tables. 3.3. The fields in the tables are incoherent. E.ON U.S. interpretation is that intervals and activities for UFLS and UVLS are different than other relay systems and components, but this is unclear. E.ON U.S. believes a separate table or sections for UFLS and UVLS would provide more clarity. 4. In section 7 of the Supplementary Reference the SDT refers to the Bulk Power System instead of the Bulk Electric System. These are not interchangeable and the SDT needs to explain the need to use the term in this case. The phrase “support from protection equipment manufacturers” is used several times in the technical reference (Section 8 and Section 13) yet there is no manufacturer represented on the SDT. Rather than developing one size fits all requirements applicable to all equipment, E.ON U.S. suggests that the SDT pursue comments from manufacturers to obtain recommendations on what they believe is required to maintain and test their equipment.
Response: The SDT thanks you for your comments. **1. Although this SDT team (as an Interpretation Drafting Team) drafted the recent NERC interpretation of Protection System as it is applied to PRC-005-1, the SDT believes that the charger is an integral portion of the Station DC supply; thus it has been added to the definition of Protection System by replacing “station batteries” in the current definition of Protection System to “station dc supply” in the definition for the proposed standard (PRC-005-2). The SDT disagrees with your contention that testing of the station dc supply is necessary; the station dc supply is a critical component of the Protection System, and it must be verified that it can perform its required function.** **2. A single record is not adequate to demonstrate that the equipment has been maintained according to the intervals.** **3.1. The SDT revised the Supplementary Reference to remove references to IEEE function numbers except where they are critical to the discussion.** **3.2. The SDT believes that it is actually a single table with multiple sections and has retained the table numbering. The SDT has worked to improve the consistency between the table sections.** **3.3. The tables have been revised to clarify this area.** **4. The Supplementary Reference Document has been modified to use the NERC-defined term of “Bulk Electric System” or its defined abbreviation BES, rather than “Bulk Power System” or BPS. As for manufacturer input, the SDT is concerned that it would be a violation of NERC Anti-Trust rules to seek input from manufacturers.**	
Duke Energy	Regarding the Implementation Plan, 1. R1 compliance should be the first day of the first calendar quarter 18 months following applicable regulatory approvals. Entities will need this time to change monitoring equipment and develop extensive new work practices and procedures to assure time frames and documentation of practices comply with the wording of the revised standard. 2. The time frames for R2, R3 and R4 are adequate except in cases where upgrades have to be developed and implemented in

Organization	Question 10 Comment
	order to be able to meet the intervals (such as breaker trip coil verification every three months). 3. FAQ 2C “If I am unable to complete the maintenance as required due to a major natural disaster, how will this effect my compliance with the standard.” Response is the Compliance monitor will consider extenuating circumstances? We would like to see this statement clarified as to the time frame extensions that result in non compliance or fines. 4. R4 States “each transmission owner” shall implement its PSPM, including identification of the resolution of all maintenance correctable issues. If the intent is to document resolution to misoperations this is a reasonable request. If the intent is to document that a relay was found out of calibration on a routine test, which was corrected by recalibration we need some clarity on expectations of how that would be recorded and tracked. As written this statement is vague and somewhat confusing since % of allowable error may vary utility to utility. R4 doesn’t appear to allow any time beyond the stated intervals for repairs or replacements that may take additional time. PRC-005-2 is maintenance and testing standard, and R4 inappropriately requires a replacement strategy and an obsolescence strategy. Is R4 intended to apply to all equipment in Table 1?
Response: The SDT thanks you for your comments. **1. The SDT believes that time provided for R1 is sufficient. Additionally, entities can use the time required for NERC Board of Trustees and regulatory approvals to work on implementation.** **2. The SDT believes that the times provided for R2, R3, and R4 are adequate.** **3. The specific issues of how the Compliance Enforcement Authority would address this issue is outside the scope of the SDT. The response in the FAQ (FAQ IV-2-D, page 23) is extracted directly from the NERC Sanction Guidelines (effective January 15, 2008)** **4. The SDT has modified the standard to require initiation of the resolution of maintenance-correctable issues that cannot be resolved during the on-site maintenance; this is focused on assuring that the Protection System is capable of performing its desired function. R4 is intended to apply to ALL equipment in the PSMP.**	
Northeast Power Coordinating Council	1. Requirements 4.2.5.4 and 4.2.5.5 require clarification. It is recommended that the drafting team provide a schematic diagram to provide clarity as to which generator and system connected transformers are included in this facility identification. 2. When Measures are added to the Standard, the SDT must consider how the owner will be required to assess and document the decision of which table will apply to each protection. While this is a compliance element, the standard should provide clarity on this matter. As written, the requirement does not seem to be measurable. 3. Requirement R4 requires clarification on what is meant by “including identification of the resolution of all maintenance correctible issues as follows:” Correctible issues should not be combined in the same sentence with the layout of the tables. 4. Table 1b: In the section for “Protection system communication equipment and channels”, there needs to be clarification on “verify that the performance of the channel and the quality of the channel meets the performance criteria, such as via measurement of signal level, reflected power, or data error rate.” This may be done as a pass fail test during trip checks. If the

Organization	Question 10 Comment
	communication line successfully sends proper signals for the trip checks, then the communication line is acceptable and no additional measurement are taken. 5. Table 1c: There is some confusion on what is expected on items that have a Maximum Maintenance Interval reported as “Continuous”. For example, a component in the “Protection System telecommunication equipment and channels” how would one provide documentation or proof of the continuous verification of the two items listed in the maintenance activities” In other words how does one prove “Continuous verification of the communication equipment alarm system is provided” and “Continuous verification that the performance and the quality of the channel meet the performance criteria is provided”. These activities appear to be “monitoring attributes” more so than they are maintenance activities. 6. Additionally, the Continuous “Maximum Maintenance Interval” needs clarification because • the interval is a monitoring interval and not a maintenance interval • a strict interpretation of “Continuous” could require redundant monitoring systems be installed or locations staffed by personnel to monitor equipment in the event remote monitoring capabilities are unavailable • It is unclear how to provide proof to an auditor that continuous monitoring has occurred over a given interval? 7. Table 1a, 1b, and 1c: The maintenance activity for battery chargers are to perform testing of the charger at full rated current and verify current-limit performance. The drafting team should provide an industry standard as how to perform this check, or specify an industry equivalent test. 8. The Table 1b Level 2 Monitoring Attributes for Component “Monitoring and alarming of continuity of trip coil(s)” should be changed to read “Monitoring and alarming of continuity of all DC circuits including the trip coil(s)”. The present wording is confusing and can be interpreted to mean that the DC control circuitry needs to be checked every 12 years, as opposed to what we perceive to be the intended 6 years. 9. The Maintenance Activities in Table 1c are not consistent with the Level 3 Monitoring Attributes for Component “Protection system telecommunications equipment and channels.” 10. “Continuous verification of interface to protective relays” should be added as a third activity should be added under the Maintenance Activities column.” 11. In Section A. Introduction, 4.2.4 should be made to read “Protection System components which are installed as a Special Protection System for BES reliability. 12. For Requirement 4.1, a “grace period” similar to the NPCC criteria should be considered in case it is not possible to obtain any necessary outages to get the prescribed maintenance done. 13. Requirement R1 should be modified to read “Each Transmission Owner, Generator Owner, and Distribution Provider shall develop, document, and implement a Protection System Maintenance Program (PSMP) for its Protection Systems that use” This

Organization	Question 10 Comment
	revision reinforces what is necessary to ensure proper compliance with the program. 14. "The standard has multiple component tests required at different and conflicting intervals, some interdependent. Preference is to have the component listed with a common maintenance and testing interval assigned (list the testing required at 2, 4 and 6 years). This same interval should apply to all areas in the table." 15. Life span of PC's, software and software license's are much less than 12 years or asset life. This presents a problem during an audit where proof is required. The components in modern relays have not been proven over these extended time periods, users are dependent on proper functions of the alarm output of IED's. Prefer more frequent maintenance cycles over having to continuously document proof of a robust CBM or PBM program. 16. The burden placed to provide proof of compliance with a CBM or PBM maintenance program seems to outweigh any benefit in maintenance costs or reliability.

Response: The SDT thanks you for your comments.

1. Figure 2 in the Supplementary Reference Document (page 28) illustrates generator-connected and system-connected station service transformers. Additionally, 4.2.5.4 and 4.2.5.5 (in the Applicability section) further state, "for generators that are part of the BES", which must be taken in the context of the Regional Entity BES definition.

2. It is beyond the scope of a standard to require specific documentation; the entity must determine what documentation is necessary to clearly demonstrate that they are meeting the requirements. FAQ V-1-D, page 30 provides a discussion to assist in this determination.

3. The footnote for R4 has been modified to read as follows: A maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action.

4. A functional test only proves that the communication equipment is working. Table 1b requires that the performance criteria, such as signal levels, reflected power, etc are verified against the original performance criteria established when the channel was commissioned. See FAQ II-6-D, page 17.

5. For items with a maximum maintenance interval of "continuous", no activities are required, and the specified activities acknowledge that the monitoring of the component IS addressing the maintenance of the component.

6. The general information within the Table describes the attributes needed to achieve the Level 3 monitoring, and R2 requires that the entity establish a basis for the components to be addressed within Table 1c. Supplementary Reference Document, Sections 13 and 14 (page 20) provide discussion on this, and the Decision Trees in the FAQ and FAQ IV-1-A, page 21 also discuss this.

7. The SDT has modified the standard to remove this requirement in consideration of your comments.

8. The SDT has modified the standard to remove this requirement in consideration of your comments.

9. Table 1c has been modified to improve the consistency.

10. The SDT is not clear as to what you are suggesting.

Organization	Question 10 Comment
11. The SDT has modified the standard in consideration of your comment. As revised, 4.2.4 reads as follows: Protection System components installed as a Special Protection System for BES reliability. **12. The SDT is concerned that a "grace period", if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a "grace period" would not conform to this directive.** **13. Documentation is a matter of demonstrating compliance, not of meeting the technical requirements of the Standard. R4 specifies the implementation of the PSMP.** **14. The testing specified for many components is different for the varying intervals; therefore, a separate table entry is present for each distinct interval. For the most part, the intervals are multiples of each other, (3-months, 18-months, 3-years, 6-years, and 12-years).** **15. Entities are certainly free to perform maintenance more frequently than specified in the standards.** **16. Entities do not have to adopt CBM or PBM; the entity must decide if the benefits of such programs justify the additional administrative effort.**	
Saskatchewan Power Corporation	1. Saskatchewan recommends that the PC's and RC's designate what equipment is applied to protect the BES and should be included in the protection maintenance program. It is questionable whether the facility owners or Distribution Providers will know. 2. What are the impacts on the BES from the protection systems identified in Facilities 4.2.5 and the FAQ? For example there is an impact on the BES from generator under-frequency protection not being properly coordinated, but assuming it is and if it is not maintained isn't the impact to the unit itself? Inadvertent energization protection also seems to be an impact to the unit itself not the BES? The standard should be concerned with protection systems that impact the BES not equipment protection that has localized impacts however important they may be. 3. Change Facilities 4.2.2 to "Protection System components used for under-frequency load-shedding systems which are installed to prevent system under-frequency collapse for BES reliability." The reference to ERO is unnecessary and inappropriate.
Response: The SDT thanks you for your comments. **1. The SDT disagrees. This standard applies to Protection Systems applied on, or that are designed to provide protection for the BES as defined by the Regional Entities.** **2. Fundamentally, if a system component is part of the BES, the protection on that component indeed affects the BES.** **3. The SDT believes that this Applicability is correctly stated in the standard. This directly reflects the current PRC-008-1 standard.**	
Detroit Edison	1. Suggest that the term "alarmed failures" in the table headings be changed to "alarmed abnormalities" to better indicate that the monitored parameter may be in an abnormal state or out of range but not necessarily failed. 2. Does "system-connected" station service transformers refer to transformers connected to the BES or transformers connected to

Organization	Question 10 Comment
	a system at any voltage level? 3. Is the intent of R1.1.2 that each Protection System component (specific relay at specific location) be listed individually with its associated maintenance method and interval or can the general component category be listed as such? 4. Regarding R4, further clarification would be helpful in understanding the intent of the term “resolution of all maintenance correctible issues” as it applies to R4.1 and R4.2. Is it intended that “maintenance correctible issues” be completed within the interval? 5. It is recommended that each line in the tables be given a number or letter designation to make reference to that row easier.
Response: The SDT thanks you for your comments. **1. The SDT understands your comment, and has elected to leave the terminology in the standard unchanged. While “failure” is not a defined term within the standard, the 11th Edition of Merriam Webster’s Collegiate Dictionary includes, within the definition of failure, several relevant applications of this term, including “an omission of occurrence or performance”, “a failing to perform a duty or expected action”, “a state of inability to perform a normal function”, and “an abrupt cessation or normal functioning”.** **2. This phrase refers to generation plant station-service transformers connected at any voltage level, provided that the generator is part of the BES.** **3. This depends on the description of your program. You will need to describe your program in a way that will satisfy the requirements of the Standard.** **4. The SDT has modified the standard to require initiation of the resolution of maintenance-correctible issues, with no specific time-frame on completing the resolution.** **5. The SDT thanks you for your suggestion. This has been considered several times during the development of the tables, and several different arrangements attempted, and the SDT believes that the current presentation is the most effective way to present this complex material. The SDT will, however, continue to consider suggestions to improve this.**	
SERC (PCS)	The “zero tolerance” structure proposed combined with the large volume and complexity of Protection System components forces an entity to shorten their intervals well below maximum. We instead propose a calendar increment carryover period in which a small percentage of carryover components would be tracked and addressed. For example, up to 1% of an entity’s communication channel 6 year verifications could carryover into the next year. These carryover components would be addressed with high priority in that next calendar increment. There are many barriers to 100% completion or zero tolerance. Some utilities have over ten thousand components.
Response: The SDT thanks you for your comments. The SDT is concerned that a “grace period”, if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a “grace period” would not conform to this directive.	

Organization	Question 10 Comment
Electric Market Policy	1. The “zero tolerance” structure proposed within this standard combined with the large volume and complexity of Protection System components requires a utilities processes and built-in grace periods to perform to perfection. Although this is a worthy goal for our industry, this can result in a large number of non-compliances for minor documentation issues or slightly missed maintenance schedules on an insignificant percentage of relays. The processing of these non-compliances can be costly in terms of resources that could be better utilized to address other transmission reliability matters. To provide a better approach, we suggest an incremental carryover system be permitted that would allow up to 0.5 percent of the PRC-005 maintenance task to be carried over to the next period, provided they are random events (not repetitive). As an example, a small percentage of our Protective System Control Trip tests on a 6-year interval could be carried over into the next calendar year when a generator outage is rescheduled. With this provision, these few tests could be handled without risk of a generator trip and without a compliance consequence. These carryover tasks could be addressed through an action plan with a defined completion date, and could be documented through a regional web portal. There are many barriers to 100% completion at a zero tolerance level with this volume of tasks.
Response: The SDT thanks you for your comments. The SDT is concerned that a “grace period”, if permitted, would be used to establish a de-facto longer interval, and that the established intervals would thus not be measurable. Additionally, FERC Order 693 directed that NERC establish maximum maintenance intervals, and allowing for a “grace period” would not conform to this directive.	
Oncor Electric Delivery	1. The drafting team is to be commended for taking the Technical Paper and Draft Standard that was prepared by the NERC System Protection and Control Taskforce (SPCTF) and the recommendations of the SAR drafting team to create PRC-005-2. This draft standard allows the owners of Protection Systems several options in establishing a maintenance program tailored to their equipment and the topography of their system.
Response: The SDT thanks you for your support.	
US Bureau of Reclamation	The significance of this issue is not reflected in the period of time needed to review the documents. The supplement has many good ideas; however, the concept is going further than needed for establishing consistent maintenance intervals.
Response: The SDT thanks you for your comments. The NERC Standard Development Process normally allows for only 30-day or 45-day comment postings. The SDT intends to continue to use only the 45-day posting period of these in recognition of the extensive material to review.	
RRI Energy	1. The standard was written to implement generally accepted practices, but has developed requirements that are overly prescriptive relative to what will be required to demonstration compliance. The standard should not assume the need to write all aspects of a maintenance program into the standard or that maintenance programs will only consist of the standard requirements. Protection systems of the BES have and will continue to perform very reliably with the basic elements of a maintenance program without the need to divert resources for the development of excessive documentation to demonstrate compliance. PRC-005-1 is the most violated standard in the industry; not because of the lack of maintenance to protection systems, but because the

Organization	Question 10 Comment
	documentation requirements of the standard, given the large magnitude of components that fall within the scope of the standard. This standard significantly increases the administrative burden for additional documentation, without corresponding improvements to the reliability of the BES. 2. Recommend rewording A.4.2.5.1 as follows: "Generator Protection system components that trip the generator circuit breakers to separate and isolate the generator from the BES either directly in the breaker trip coil circuit or through interposing lockout or auxiliary tripping relays." This document should not expand the compliance scope beyond the definition of the BES. The generator protection systems that "trip the generator" also perform additional control functions that extend beyond the electrical isolation of the generating unit from the BES. These additional circuits do not protect the BES and do not belong in the scope of this document. 3. Recommend rewording A.4.2.5.4 as follows: "Protection systems for generator-connected station service transformers that trip the generator circuit breakers to separate and isolate the generator from the BES." This document should not expand the compliance scope beyond the definition of the BES. Related protection circuits of the transformer not involved with the electrical isolation of the generating unit from the BES does not belong in the scope of this document. 4. Recommend rewording A.4.2.5.5 as follows: "Protection systems for BES elements connecting to the station service transformers of generating stations." This document should not expand the compliance scope beyond the definition of the BES. The requirement incorporates radial feeds (with dedicated breakers) into the scope of the standard that are not necessarily a part of the BES as defined by some RRO's. Station service transformers are not necessarily required for generating unit operation. In some cases there are redundant sources for startup or back-up power. Protection of these transformers does not belong in the scope of the standard if they are not a part of the BES. 5. The suggested rewording of R1.2 is as follows: "Identify whether each Protection System component is addressed through time-based, condition-based, performance-based, or a combination of these maintenance methods." The requirement for the registered entity to list the interval of maintenance does not belong in the standard, especially since the maximum intervals are listed in the standard tables. The registered entity may have internal documents that intentionally target a shorter duration than the maximum interval of Table 1a. The failure to meeting those internally established targets can be a violation of the standard by the wording of this requirement. Allow R4 of the standard to identify the maximum allowable intervals. 6. In R4, the requirement for "identification of the resolution of all maintenance correctible issues" should be separated from the maintenance intervals; which define the maximum intervals of maintenance activities. The requirement should be eliminated to remove the overly prescriptive requirements of auditable documentation. If retained, a rewording of the requirement is as follows: "Each Transmission Owner, Generator Owner, and Distribution Provider shall identify the resolution of all issues identified and not corrected at the time the maintenance is initiated and the protected element is returned to service." The documented resolution of maintenance correctible issues (if retained) should apply only to activities that are unresolved and incomplete during the normal maintenance process. The standard should not micromanage the documentation process by creating requirements for excessive auditable records needed to demonstrate compliance of routine maintenance activities. 7. In R4, the requirements for Generator Owners which establish the durations of maximum allowable intervals should be

Organization	Question 10 Comment
	separated from the Transmission Owners, even if the intervals are the same. The reason is to allow for the assignment of different Violation Risk Factors. The Violation Risk Factor for the application of a 20 MVA generating unit with an operating capacity factor of less than 5%, and connected to a 138 kV system, should not be the same as those applied to a 500kV transmission line. The violation risks factors for these two applications are significantly different, and the ability to recognize this is not permitted by the standard presently. 8. Similarly, the criteria used for the sizing of station batteries for a large generating station is very different than those used for transmission facilities. Very little of the generating station battery sizing is related to BES protection, and nearly all generator protection system operations occur without reliance upon the battery. Without NERC standard requirements, Generator Owners have their own natural incentives to maintain batteries for the protection of the turbine generator bearings on the loss of AC power. With the most basic requirements of an inspection and maintenance program, there is an extremely high degree of reliability given the typical design of DC systems within a generating station, even without documented compliance to a rigid set of standards. With very basic, elementary maintenance (documented or not), the statistical probability for the random and simultaneous failure of multiple battery cells to disable the protection system of a generating station for the milliseconds of time required to separate a generating unit from the BES is insignificant (well in excess of 1 billion to 1 across an entire calendar quarter). 9. Violation risk factors and the resulting penalties for non-compliance need to be realistic.

Response: The SDT thanks you for your comments.

1. The SDT believes that the level of prescription within the standard is necessary to satisfy the guidance in FERC Order 693, and also to address observations from the Compliance Monitoring entities (the Regional Entities and NERC) that PRC-005-1 is excessively general. FERC Order 672 also specifies that NERC Reliability Standards should be clear and unambiguous. The SDT has therefore defined the minimum activities necessary to implement an effective PSMP.

2. The SDT believes that the standard is correct as drafted. Not only does the generator need to be disconnected, but this BES component must also be protected. Please refer to FAQ III-2-A, page 20 for a discussion of relevant Protection System components.

3. A loss of a generator-connected station auxiliary transformer will result in a loss of the generating plant if the plant is being provided with auxiliary power from that source.

4. A loss of a system-connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source, and this auxiliary transformer may directly affect the ability to start up the plant and to connect the plant to the system.

5. Inclusion of the intervals is necessary for PBM, and entities may elect to commit to more demanding intervals because of their experience.

6. The SDT has modified the standard to require initiation of the resolution of maintenance-correctible issues, but establishes no time line for the actual resolution, in recognition of the wide variation in the type of problems and the scale of the resolution.

7. The SDT disagrees. It the protection on the cited 20 MVA generating unit fails to properly isolate the unit from the system for fault conditions, it could have serious effects on reliability.

Organization	Question 10 Comment
8. The SDT believes that the station dc supply is such an integral part of the Protection System of a generating station that, it falls under NERC Reliability Standard purview and at a minimum must be maintained using the Maintenance Activities and Maximum Maintenance Intervals of Table 1. **9. The SDT will consider this with developing VRFs and VSLs.**	
Lower Colorado River Authority	We commend the work done by the SDTSDT. In particular, the merging of previous standards PRC-005-0, PRC-008-0, PRC-011-0, and PRC-017-0 which will help with the efficient management of these standards.
Response: The SDT thanks you for your support.	
Ontario Power Generation	We note that Verification of Voltage and Current Sensing Device Inputs to Protective Relays is a somewhat ambiguous activity. NERC's audit observation team came up with a similar finding. The supporting documents provide some clarity but in our opinion it would be helpful if the SDT could elaborate this activity in more detail in the Table itself.
Response: The SDT thanks you for your comments. The Tables have been modified to clarify this issue.	
Southern Company	1. We presently utilize a UFLS system distributed across many transmission and distribution substations. Are the station batteries located in stations with no network transmission protection schemes (other than UFLS) subject to the requirements of PRC-005-2? This was not addressed in previous revisions. 2. We presently utilize a UVLS system distributed across many transmission and distribution substations. Are the station batteries located in stations with no network transmission protection schemes (other than UVLS) subject to the requirements of PRC-005-2? 3. In the applicability section, there is no exception for smaller units and those with very low capacity factors. Rather, those that "are part of the BES" are in the scope. We recommend that smaller units and low capacity factor units be exempt from the requirements of this standard or have extended maintenance intervals. Refer to the current SERC supplement for PRC-005-1. Section II.A. of the May 29, 2008: SERC Supplement Maintenance & Testing Protection Systems (Transmission, Generation, UFLS, UVLS, & SPS) NERC Reliability Standards PRC-005-1, PRC-008, PRC-011, & PRC-017.The applicability section paragraph 4.2.4 should read "are installed" rather than "is installed". 4. Note 2 at the bottom of the table (1c) implies that one has to apply voltage and inject current into the microprocessor relay to perform trip checks. Is this the intent of the statement? If so, Note 2 should be revised to make clear the intention. We don't think this is necessary with microprocessor relays since they monitor inputs 5. Why is the Violation Severity Level Matrix not a part of this standard revision? 6. In cases where a common dc system exists between a generator owner and transmission owner, who is the responsible entity? 7. We appreciate the work that went into the implementation plan. We agree with the concept of phasing in mandatory compliance

Organization	Question 10 Comment
	and the timing of the implementation. 8. Consider defining the Monitoring Levels once and reformatting the information contained within Tables 1a, 1b, and 1c to regroup the information by component type rather than by Monitor Level. When considering the various monitoring levels for the protection system components, each entity will consider each component type apart from the others when determining the Monitor Level to apply, so this reorganization will assist the end user to understand and apply the levels. See samples attached as a separate document:
Response: The SDT thanks you for your comments. **1. The SDT has modified the standard to clarify that the only DC Supply requirement relevant to UVLS and UFLS is to verify the DC supply voltage, and that this may be performed in conjunction with the UFLS/UVLS maintenance itself.** **2. The SDT has modified the standard to clarify that the only DC Supply requirement relevant to UVLS and UFLS is to verify the DC supply voltage, and that this may be performed in conjunction with the UFLS/UVLS maintenance itself.** **3. This is properly a NERC registration issue and one of the regional BES definitions. We appreciate that you may disagree with these, but you should seek resolution via other means. The SDT has modified the standard in consideration of your editorial concern. It the protection on a small generating unit fails to properly isolate the unit from the system for fault conditions, it could have serious effects on reliability.** **4. Note 2 has been removed from the Table.** **5. Even though the SDT worked on a VSL matrix during development of this draft, the SDT elected to constrain this posting only to the requirements and supporting developments. The SDT believes that this was such an extensive body of material that it would be distracting to include compliance elements. The SDT also recognized that extensive changes were likely to occur to the standard in response to this posting, and considered this in their decision to not include compliance elements. They will be included in the next posting.** **6. The SDT believes that the owner of the battery is responsible. This can be worked out by agreements between the entities.** **7. The SDT thanks you for your support.** **8. The SDT has experimented with various arrangements of the Tables with some input from external parties, and believes that the presentation shown in the standard is the best way to present this complex information. The SDT has attempted to make the arrangement of the three tables as similar as possible to address your concern.**	
PacifiCorp	What is the definition of "Calendar Year"? Does the term "Six calendar years" include any date in 2004 to any date in 2010?
Response: The SDT thanks you for your comments. Disregard the complete date and just look at the year portion. For a 6 calendar-year interval, if the test date was IN 2004, the next test must be completed by the end of 2010.	

Organization	Question 10 Comment
AECI	
Puget Sound Energy	Great improvement in the standards and clarity of expectations. We appreciate the combining of the multiple PRC standards. PSE would appreciate the comments and clarification needed regarding the interpretation for PRC-005 under Project 2009-17 to be included in PRC-005-2. It appears that the interpretation allowed regions to define variances due to the variance in the Regional Entity definitions of the BES. But how the BES is defined and documented as such creates ongoing confusion for the registered entities.
Response: The SDT thanks you for your comments. The NERC definition for BES specifically includes, "As specified by the regions". As long as this definition persists, the issue noted in your comments will also persist. It is outside the scope of this standard to address these issues.	

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010

Description of Current Draft:
This is the second draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined pre-ballot review and comment.	June 11–July 16, 2010
2. Conduct initial ballot.	July 8–July 17, 2010
3. Drafting Team Responds to Comments.	July 19–July 22, 2010
4. Post response to comments and modified standard.	July 23, 2010
5. Conduct 10-day recirculation ballot.	July 23–August 2, 2010
6. Present to BOT for action.	August 5, 2010

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

- Verification — A means of determining that the component is functioning correctly.
- Monitoring — Observation of the routine in-service operation of the component.
- Testing — Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- Inspection — To detect visible signs of component failure, reduced performance and degradation.
- Calibration — Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Upkeep — Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.
- Restoration — The actions to restore proper operation of malfunctioning components.

Protection System (modification) — Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

A. Introduction

1. Title: **Protection System Maintenance**

2. Number: PRC-005-2

3. Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. Applicability:

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems applied on, or designed to provide protection for the BES.

4.2.2 Protection System components used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection System components used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection System components installed as a Special Protection System for BES reliability.

4.2.5 Protection Systems for generator Facilities that are part of the BES, including:

4.2.5.1 Protection System components that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

4.2.5.2 Protection Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection Systems for generator-connected station service transformers for generators that are part of the BES.

4.2.5.5 Protection Systems for system-connected station service transformers for generators that are part of the BES.

5. (Proposed) Effective Date: See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES[1] and that are applied on, or are designed to provide protection for the BES. The PSMP shall meet the following criteria: *[Violation Risk Factor: High] [Time Horizon: Long Term Planning]*

1.1. Identify all Protection System components.

1.2. Identify whether each Protection System component is addressed through time-based (per Table 1a), condition-based (per Table 1b or 1c), performance-based (per Attachment A), or a combination of these maintenance methods and identify the associated maintenance interval.

1.3. For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2.

1.4. Include all batteries associated with the station dc supply component of a Protection System in a time-based program.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses condition-based maintenance intervals in its PSMP for partially or fully monitored Protection Systems shall ensure the components to which the condition-based criteria are applied, possess the monitoring attributes identified in Tables 1b or 1c. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance correctable issues[2] as follows: *[Violation Risk Factor: Medium] [Time Horizon: Long Term Planning]*

4.1. For time-based or condition-based maintenance programs, perform, the maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System components according to the PSMP established per Requirement R1within maximum allowable intervals not to exceed those established in Tables 1a, 1b, and 1c.

4.2. For performance-based maintenance programs, perform, the maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System components in accordance within the maximum allowable intervals established per Requirement R3.

4.3. Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues[3].

---

[1] Devices that sense non-electrical conditions, such as thermal or transformer sudden pressure relays are not included within the scope of this standard**.**

[2] A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action

[3] A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration while performing the initial on-site maintenance activity and that requires follow-up corrective action.

C. Measures

M1. Each Transmission Owner, Generator Owner and Distribution Provider will have a documented Protection System Maintenance program that addresses protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices, as required by Requirement R1. For each protection system component, the documentation shall include the type of maintenance program applied, maintenance activities, and maintenance intervals as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner and Generator Owner that uses a condition-based maintenance program should have evidence such as engineering drawings or manufacturer's information showing that the components possess the monitoring attributes identified in Tables 1b or 1c, as required by Requirement R2.

M3. Each Transmission Owner, Generator Owner, or Distribution Provider that uses a performance-based maintenance program should have evidence such as equipment lists, maintenance records, and analysis records and results that its performance-based maintenance program is in accordance with Requirement R3.

M4. Each Transmission Owner, Generator Owner, or Distribution Provider shall have evidence such as maintenance records or maintenance summaries (including dates that the components were maintained) that it has implemented the Protection System Maintenance Program in accordance with Requirement R4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

1.2. Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer.

The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

1.4. Additional Compliance Information

None.

2. Violation Severity Levels

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for no more than 5% of the components, failed to either • Identify the component, • Specify whether the component is being addressed by time-based, condition-based, or performance-based maintenance, or • Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.	The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for greater than 5%, but no more than 10% of the components, failed to either • Identify the component, • Specify whether the component is being addressed by time-based, condition-based, or performance-based maintenance, or • Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.	The entity's PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for greater than 10%, but no more than 15%, of the components, failed to either • Identify the component, • Specify whether the component is being addressed by time-based, condition-based, or performance-based maintenance, or • Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.	The entity's PSMP failed to address one or more of the types of components included in the definition of 'Protection System' OR Entity has not established a PSMP. OR The entity's' PSMP included all of the 'types' of components included in the definition of 'Protection System', but, for more than 15% of the components, failed to either • Identify the component, • Specify whether the component is being addressed by time-based, condition-based, or performance-based maintenance, or • Include all maintenance activities specified in Table 1a, Table 1b, or Table 1c, as applicable.
R2	Entity has Protection System components in a condition-based PSMP, but documentation to support Partially-Monitored Protection System classification or Fully-Monitored Protection System classification is incomplete on no more than 5% of the Protection System components maintained according to Tables 1b and 1c.	Entity has Protection System elements in a condition-based PSMP, but documentation to support Partially-Monitored Protection System classification or Fully-Monitored Protection System classification is incomplete on more than 5%, but 10% or less, of the Protection System components maintained according to Tables 1b	Entity has Protection System elements in a condition-based PSMP, but documentation to support Partially-Monitored Protection System classification or Fully-Monitored Protection System classification is incomplete on more than 10%, but 15% or less, of the Protection System components maintained according to Tables 1b	Entity has Protection System elements in a condition-based PSMP, but documentation to support Partially-Monitored Protection System classification or Fully-Monitored Protection System classification is incomplete on more than 15% of the Protection System components maintained according to Tables 1b and 1c.

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
		and 1c.	and 1c.	
R3	Entity has Protection System elements in a performance-based PSMP but has: 1) Failed to reduce countable events to less than 4% within three years. OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for 5% or less of components in any individual segment OR 3) Maintained a segment with 54-59 components or containing different manufacturers.	NA	Entity has Protection System elements in a performance-based PSMP but has failed to reduce countable events to less than 4% within four years.	Entity has Protection System components in a performance-based PSMP but has: 1) Failed to reduce countable events to less than 4% within five years. OR 2) Failed to annually document program activities, results, maintenance dates, or countable events for over 5% of components in any individual segment. OR 3) Maintained a segment with less than 54 components. OR 4) Failed to annually update the list of components, • Perform maintenance on the greater of 5% of the segment population or 3 components, or • Annually analyze the program activities and results for each segment.
R4	Entity has failed to complete scheduled program on 5% or less of total Protection System components.	Entity has failed to complete scheduled program on greater than 5%, but no more than 10% of total Protection System components.	Entity has failed to complete scheduled program on greater than 10%, but no more than 15% of total Protection System components.	Entity has failed to complete scheduled program on greater than 15% of total Protection System components. OR Entity has failed to initiate resolution of maintenance-correctable issues

E. Regional Variances

None

F. Supplemental Reference Documents

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. PRC-005-2 Protection System Maintenance Supplementary Reference — July 2009.
2. NERC Protection System Maintenance Standard PRC-005-2 FREQUENTLY ASKED QUESTIONS — Practical Compliance and Implementation DRAFT 1.0 — June 2009

Version History

Version	Date	Action	Change Tracking
2	TBD	Complete revision, absorbing maintenance requirements from PRC-005-1, PRC-008-0, PRC-011-0, PRC-017	Complete revision

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Protective Relays	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify that settings are as specified. For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System. For microprocessor relays, verify acceptable measurement of power system input values.
Voltage and Current Sensing Inputs to Protective Relays and associated circuitry	12 Calendar Years	Verify proper functioning of the current and voltage **signals** necessary for Protection System operation from the voltage and current sensing devices to the protective relays.
Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)	6 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System.
Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (except for UFLS or UVLS)	12 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System.
Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only)	6 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except .that verification does not require actual tripping of circuit breakers or interrupting devices.
Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only)	12 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuit, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System, except that verification does not require actual tripping of circuit breakers or interrupting devices.

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (used only for UVLS or UFLS)	(when the associated UVLS or UFLS system is maintained)	Verify proper voltage of the dc supply.
Station dc supply	18 Calendar Months	Verify: • State of charge of the individual battery cell/units • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery cell-to-cell connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • The condition of non-battery-based dc supply
Station dc supply (that has as a component any type of battery)	3 Calendar Months	Check: • Electrolyte level (excluding valve-regulated lead acid batteries) • Station dc supply voltage • For unintentional grounds
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	3 Calendar Years - or - 3 Calendar Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Vented Lead-Acid Batteries)	6 Calendar Years - or - 18 Calendar Months	Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc supply (battery is not used)	6 Calendar Years	Verify that the dc supply can perform as designed when the ac power from the grid is not present.
Station dc Supply (battery is not used)	18 Calendar Months	Verify proper voltage of the station dc supply. Verify that no unintentional dc supply grounds are present. Perform a visual inspection, of all components of the station dc supply to verify that the physical condition of the station dc supply is as desired and any visual inspection if required by the manufacturer on the condition of the dc supply that is the source of dc power when ac power is unavailable. Verify where applicable the proper voltage level of each component of the station dc supply. Verify the correct operation of ac powered dc power supplies. Verify the continuity of all circuit connections that can be affected by wear or corrosion. Inspect all circuit connections that can be affected by wear and corrosion.
Associated communications systems	3 Calendar Months	Verify that the Protection System communications system is functional.
Associated communications systems	6 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s).

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify proper functioning of the relay trip outputs. For microprocessor relays verify the proper functioning of the A/D converters. Verify that settings are as specified.
Relay sensing for Centralized UFLS or UVLS systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Protective Relays	Includes • Internal self diagnosis and alarm capability • Alarm must assert for power supply failures • Input voltage or current waveform sampling three or more times per power cycle • Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming	12 Calendar Years	Verify the status of relays is normal with no alarms indicated. Verify acceptable measurement of power system input values. For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System. Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken. Verify correct operation of output actions that are used for tripping.
Voltage and Current Sensing Inputs to Protective Relays and associated circuitry	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	12 Calendar Years	Verify the proper functioning of current and voltage circuit signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays.
Control Circuitry (Trip Coils and Auxiliary Relays)	Monitoring and alarming of continuity of trip circuits(s)	6 Calendar Years	Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Control Circuitry (Trip Circuits) (except for UFLS/UVLS)	Monitoring of Protection System component inputs, outputs, and connections with reporting of monitoring alarms to a location where action can be taken Connection paths using electronic signals or data messages are monitored by periodic signal changes or messages that verify ability to convey Protection System operating values	12 Calendar Years	Verify that the alarms will be received at the location where action can be taken.
Control and trip circuitry	Monitoring of the continuity of breaker trip circuits along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil(s), including any auxiliary contacts essential to proper Protection System operation. If a trip circuit comprises multiple paths, each of the paths must be monitored, including monitoring of the operating coil circuit(s) and the tripping circuits of auxiliary tripping relays and lockout relays. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken.	12 Calendar Years	Verify that the alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring			
Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components			
General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply	Monitor and alarm for: • Station dc supply voltage • Unintentional dc grounds • Electrolyte level of all cells in a station battery • Individual battery cell/unit state of charge • Battery continuity of station battery • Cell-to-cell and battery terminal resistance	6 Calendar Years	Verify that the monitoring devices are calibrated (where necessary) and alarms will be received at the location where action can be taken.
Station dc supply	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	18 Calendar Months	Inspect: • Cell condition of individual battery cells where cells are visible, or measure battery cell/unit internal ohmic values where cells are not visible • Physical condition of battery rack • The condition of non-battery based dc supply
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	3 Calendar Years - or - 3 Calendar Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)

Table 1b — Condition-Based Maintenance - Level 2 Monitoring			
Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components			
General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Vented Lead-Acid batteries)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	6 Calendar Years - or - 18 Calendar Months	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc Supply (battery is not used)	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	6 Calendar Years	Verify that the dc supply can perform as designed **when ac power** from the grid is not present.
Associated communications system	Monitoring and alarming of protection communications system by mechanisms that check for presence of the communications channel.	12 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s). Verify proper functioning of alarm notification.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	Includes internal self diagnosis and alarm capability, which must assert for power supply failures. Includes input voltage or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.	12 Calendar Years	Verify the status of relays as in service with no alarms. Verify acceptable measurement of power system input values the proper function of the A/D converters (if included in relay). Verify proper functioning of the relay trip outputs. Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken.
Relay sensing for centralized UFLS or UVLS systems	See the attributes of Level 2 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the UFLS/UVLS	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See the attributes of Level 2 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the SPS	Perform all of the Maintenance activities listed above as established for components of the SPS, at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1c — Condition-based Maintenance — Level 3 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components

General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Level 3 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Protective Relays	Relay A/D converters are continuously monitored and alarmed	Continuous	Continuous verification of the status of the relays Alarm on change of settings
Protective Relays with trip contacts	All Level attributes, except relay possesses mechanical output contacts	12 Calendar Years	Verify proper functioning of the relay trip contacts.
Voltage and Current Sensing Inputs to Protective Relays and associated circuitry	Verification of the analog values (magnitude and phase angle) measured by the microprocessor relay or comparable device, by comparing against other measurements using other voltage and current sensing devices	Continuous	Continuous verification and comparison of the current and voltage signals from the voltage and current sensing devices of the Protection System
Protection System control and trip circuitry	Monitoring and alarming of the alarm path itself	Continuous	Continuous verification of the status of the monitored control circuits
Station dc supply	No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	18 Calendar Months	Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • The condition of non-battery-based dc supply

Table 1c — Condition-based Maintenance — Level 3 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components

General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Level 3 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	3 Calendar Years - or - 3 Calendar Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)
Station dc supply (that has as a component Vented Lead-Acid Batteries)	No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	6 Calendar Years - or - 18 Calendar Months	Verify that the station battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc Supply (any battery technology)	Monitoring and alarming for station dc supply voltage, unintentional dc grounds, electrolyte level of all cells of a station battery, individual battery cell/unit state of charge, battery continuity of station battery and cell-to-cell and battery terminal resistance	Continuous	Continuous monitoring of station dc supply voltage, unintentional dc grounds, electrolyte level of all cells of a station battery, individual battery cell/unit state of charge, battery continuity of station battery and cell-to-cell and battery terminal resistance are provided with alarming to remote location upon any failure of the monitoring device or when sensors for the devises are out of calibration.

Table 1c — Condition-based Maintenance — Level 3 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components

General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Level 3 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Station dc Supply which do not use a station battery	No Level 3 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals	6 Calendar Years	Verify that the dc supply can perform as designed when the ac power from the grid is not present.
Associated communications systems	Evaluating the performance of the channel and its interface to protective relays to determine the quality of the channel and alarming if the channel does not meet performance criteria	Continuous	Continuous verification that the performance and quality of the channel meets performance criteria is provided. Continuous verification of the communications equipment alarm system is provided.
UVLS and UFLS relays that comprise a protection scheme distributed over the power system.	The relay A/D converters are continuously monitored and alarmed.	Continuous	Continuous verification of the status of the relays Alarm on change of settings Verification does not require actual tripping of circuit breakers or interrupting devices
Relay sensing for centralized UFLS or UVLS systems.	See the attributes of Level 3 Monitoring for the individual components of the UFLS/UVLS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.

Table 1c — Condition-based Maintenance — Level 3 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection System Components **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
SPS	See the attributes of Level 3 Monitoring for the individual components of the SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Notes for Table 1a, Table 1b, and Table 1c

1. For some Protection System components, adjustment is required to bring measurement accuracy within parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

Segment: In this procedure, the term, "segment" is a grouping of Protection Systems or components from a single manufacturer, with common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components.[4]

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Table 1 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events[5] for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and

---

[4] Entities with smaller populations of component devices may aggregate their populations to define a segment and shall share all attributes of a single performance-based program for that segment.

[5] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.

implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. Standards Committee approves SAR for posting on June 5, 2007.
2. The SAR was posted for comment from June 11, 2007–July 10, 2007.
3. The SC approves development of the standard on August 13, 2007.
4. First posting of revised standard on July 24, 2009.
5. Second posting of revised standard on June 11, 2010

Description of Current Draft:
This is the second draft of the Standard. This standard merges previous standards PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0. It also addresses FERC comments from Order 693, and addresses observations from the NERC System Protection and Control Task Force, as presented in *NERC SPCTF Assessment of Standards: PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing, PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs, PRC-011-0 — UVLS System Maintenance and Testing, PRC-017-0 — Special Protection System Maintenance and Testing.*

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Post for combined pre-ballot review and comment.	June 11–July 16, 2010
2. Conduct initial ballot.	July 8–July 17, 2010
3. Drafting Team Responds to Comments.	July 19–July 22, 2010
4. Post response to comments and modified standard.	July 23, 2010
5. Conduct 10-day recirculation ballot.	July 23–August 2, 2010
6. Present to BOT for action.	August 5, 2010

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program ~~can include:~~for a specific component includes one or more of the following activities:

- Verification — A means of determining that the component is functioning correctly.
- Monitoring — Observation of the routine in-service operation of the component.
- Testing — Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- ~~Physical i~~Inspection — To detect visible signs of component failure, reduced performance and degradation.
- Calibration — Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- Upkeep — Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.
- Restoration — The actions to restore proper operation of malfunctioning components.

Protection System (modification) — Protective relays, communication systems necessary for correct operation of protective ~~devices~~functions, voltage and current sensing inputs to protective relays~~,~~ and associated circuitry from the voltage and current sensing devices, station ~~DC~~ dc supply, and ~~DC~~ control circuitry associated with protective functions from the station ~~DC~~ dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

A. Introduction

1. **Title:** **Protection System Maintenance**

2. **Number:** PRC-005-2

3. **Purpose:** To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained.

4. **Applicability:**

4.1. Functional Entities:

4.1.1 Transmission Owners

4.1.2 Generator Owners

4.1.3 Distribution Providers

4.2. Facilities:

4.2.1 Protection Systems ~~that are~~ applied on, or ~~are~~ designed to provide protection for the BES.

4.2.2 Protection System components used for underfrequency load-shedding systems ~~which are~~ installed per ERO underfrequency load-shedding requirements.

4.2.3 Protection System components used for undervoltage load-shedding systems ~~which are~~ installed to prevent system voltage collapse or voltage instability for BES reliability.

4.2.4 Protection System components ~~which is~~ installed as a Special Protection System for BES reliability.

4.2.5 Protection Systems for ~~Generator~~generator Facilities that are part of the BES, including:

4.2.5.1 Protection ~~system~~System components that act to trip the generator either directly or via generator lockout or auxiliary tripping relays.

4.2.5.2 Protection ~~systems~~Systems for generator step-up transformers for generators that are part of the BES.

4.2.5.3 Protection ~~systems~~Systems for transformers connecting aggregated generation, where the aggregated generation is part of the BES (e.g., transformers connecting facilities such as wind-farms to the BES).

4.2.5.4 Protection ~~systems~~Systems for generator-connected station service transformers for generators that are part of the BES.

4.2.5.5 Protection ~~systems~~Systems for system-connected station service transformers for generators that are part of the BES.

~~5.~~

5. **(Proposed) Effective Date:** ~~**TBD**~~ ~~To Be Determined~~See Implementation Plan

B. Requirements

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES[1] and that are applied on, or are designed to provide protection for the BES. The PSMP shall meet the following criteria: *[Violation Risk Factor: ~~TBD~~High] [Time Horizon: Long Term Planning]*

~~**1.1.** For each component used in each Protection System, include all maintenance activities specified in Tables 1a, 1b, and 1c.~~

1.1. Identify all Protection System components.

1.2. Identify whether each Protection System component is addressed through time-based (per Table 1a), condition-based (per Table 1b or 1c), performance-based (per Attachment A), or a combination of these maintenance methods and identify the associated maintenance interval.

1.3. For each Protection System component, include all maintenance activities specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, Part 1.2.

~~**1.3.**~~**1.4.** Include all batteries associated with the station dc supply component of a Protection System in a time-based program.

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses condition-based maintenance intervals in its PSMP for partially or fully monitored Protection Systems shall ensure the components to which the condition-based criteria are applied, ~~(as specified in Tables 1b or 1c),~~ possess the ~~necessary~~ monitoring attributes identified in Tables 1b or 1c. *[Violation Risk Factor: ~~TBD~~Medium] [Time Horizon: Long Term Planning]*

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: ~~TBD~~Medium] [Time Horizon: Long Term Planning]*

R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, including identification of the resolution of all maintenance ~~correctible~~correctable issues[2] as follows: *[Violation Risk Factor: ~~TBD~~Medium] [Time Horizon: Long Term Planning]*

4.1. For time-based or condition-based maintenance programs, perform, the ~~Maintenance~~ maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System components ~~within~~according to ~~your~~the PSMP established per Requirement R1within maximum allowable intervals not to exceed those established in Tables 1a, 1b, and 1c.

4.2. For performance-based maintenance programs, perform, the maintenance activities detailed in Table 1 (for the appropriate monitoring level(s)) for all Protection System

[1] Devices that sense non-electrical conditions, such as thermal or transformer sudden pressure relays are not included within the scope of this standard.

[2] A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration~~, repair or replacement.~~ while performing the initial on-site maintenance activity, and that requires follow-up corrective action

components in accordance within the maximum allowable intervals established per Requirement R3.

4.3. Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues[3].

C. Measures~~(TBD)~~

M1. Each Transmission Owner, Generator Owner and Distribution Provider will have a documented Protection System Maintenance program that addresses protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices, as required by Requirement R1. For each protection system component, the documentation shall include the type of maintenance program applied, maintenance activities, and maintenance intervals as specified in Requirement R1, Parts 1.1 through 1.4.

M2. Each Transmission Owner and Generator Owner that uses a condition-based maintenance program should have evidence such as engineering drawings or manufacturer's information showing that the components possess the monitoring attributes identified in Tables 1b or 1c, as required by Requirement R2.

M3. Each Transmission Owner, Generator Owner, or Distribution Provider that uses a performance-based maintenance program should have evidence such as equipment lists, maintenance records, and analysis records and results that its performance-based maintenance program is in accordance with Requirement R3.

M4. Each Transmission Owner, Generator Owner, or Distribution Provider shall have evidence such as maintenance records or maintenance summaries (including dates that the components were maintained) that it has implemented the Protection System Maintenance Program in accordance with Requirement R4.

~~C.~~D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

Regional Entity

~~**1.2. Compliance Monitoring Period and Reset Time Frame**~~

~~1.3.~~1.2. ~~Not Applicable~~**Compliance Monitoring and Enforcement Processes:**

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

[3] A maintenance correctable issue is a failure of a device to operate within design parameters that cannot be restored to functional order by repair or calibration while performing the initial on-site maintenance activity and that requires follow-up corrective action.

~~1.4.~~1.3. Data Retention

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation ~~for~~ of the two most recent performances of each distinct maintenance ~~intervals~~activity for the Protection System components, or to the previous on-site audit date, whichever is longer.

~~or for the time period specified above, whichever is longer~~The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.

~~1.5.~~1.4. Additional Compliance Information

None.

~~2.~~

2. Violation Severity Levels ~~– TBD~~

Table 1a — Time-Based Maintenance — Level 1 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection ~~Systems~~System Components

General Description: Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Maximum Maintenance Interval	Maintenance Activities
Protective Relays	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify ~~proper functioning of the relay trip outputs~~that settings are as specified. For microprocessor relays ~~verify~~ , check the relay inputs and outputs that are essential to proper functioning of the ~~A/D converters (Note 2)~~Protection System. ~~**Verify that settings are as specified.**~~ For microprocessor relays, verify acceptable measurement of power system input values.
Voltage and Current Sensing ~~Devices~~ ~~-~~Inputs to Protective Relays and associated circuitry	12 Calendar Years	Verify proper functioning of the current and voltage ~~**circuit inputs**~~ signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays.
~~Protection System~~ Control ~~Circuitry (Breaker Trip Coil Only)~~and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)	6 Calendar Years~~3 Months~~	~~Verify the continuity of the breaker trip circuit including trip coil (except for protection system control circuitry associated with breakers that remain open for the entire "maintenance interval" period).~~ Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System.
~~Protection System~~ Control ~~Circuitry (Trip Circuits)~~and trip circuits with unmonitored solid-state trip or auxiliary contacts (except for UFLS or UVLS)	~~6~~12 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip ~~circuit~~circuits, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System.
Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only)	6 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuits, including all electromechanical trip and auxiliary contacts essential to proper functioning of the Protection System, except .that verification does not require actual tripping of circuit breakers or interrupting devices.

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection ~~Systems~~System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
~~Protection System~~ Control ~~Circuitry (Trip Circuits)~~and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only)	~~(when the associated UVLS or UFLS system is maintained)~~12 Calendar Years	Perform a complete functional trip test that includes all sections of the Protection System control and trip circuit, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System~~.~~, except that verification does not require actual tripping of circuit breakers or interrupting devices.
Station dc Supply (used only for UVLS or UFLS)	(when the associated UVLS or UFLS system is maintained)	Verify proper voltage of the dc supply.
Station dc supply ~~Station dc supply (that has as a component any type of battery)~~	18 Calendar Months~~3 Months~~	Verify: • State of charge of the individual battery cell/units • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery cell-to-cell connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack • The condition of non-battery-based dc supply ~~Verify proper electrolyte level (excluding valve-regulated lead acid batteries).~~ ~~Verify proper voltage of the station battery.~~ ~~Verify that no dc supply grounds are present.~~

Table 1a — Time-Based Maintenance — Level 1 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection ~~Systems~~System Components

General Description: Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Maximum Maintenance Interval	Maintenance Activities
Station dc supply (that has as a component any type of battery)	3 Calendar Months	Check: • Electrolyte level (excluding valve-regulated lead acid batteries) • Station dc supply voltage For unintentional grounds~~Verify proper electrolyte level (excluding valve-regulated lead acid batteries).~~ ~~Verify proper voltage of the station battery.~~ • ~~Verify that no dc supply grounds are present.~~
~~Station dc supply (that has as a component any type of battery)~~	~~18 Months~~	~~Verify proper voltage of each individual cell or unit in the station battery.~~ ~~Verify that station battery charger provides the correct float and equalize voltages.~~ ~~Verify continuity and cell integrity of entire battery.~~ ~~Perform a visual cell inspection of all cells for "cell condition" (where cells are visible) or measurement of cell/unit internal ohmic values (where cells are not visible).~~ ~~Measure that specific gravity and temperature of each cell is within tolerance(where applicable)~~ ~~Verify cell to cell and terminal connection resistance is within tolerance~~ ~~Inspect the structural integrity of the battery rack.~~
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	3 Calendar Years - or - 3 Calendar Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)

Table 1a — Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection ~~Systems~~System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Vented Lead-Acid Batteries)	6 Calendar Years ~~Or~~ - or - 18 Calendar Months	Verify that the station battery can perform as designed by conducting a performance, service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
Station dc supply (battery is not used)~~(that uses~~~~which do not use a~~ station battery ~~and charger)~~	6 Calendar Years	Verify that the ~~battery charger~~dc supply can perform as designed ~~by testing that~~when the ~~charger will provide full rated current and will properly current-limit.~~ac power from the grid is not present.
Station dc Supply (battery is not used)	18 Calendar Months	Verify proper voltage of the station dc supply. Verify that no unintentional dc supply grounds are present. Perform a visual inspection, of all components of the station dc supply to verify that the physical condition of the station dc supply is as desired and any visual inspection if required by the manufacturer on the condition of the dc supply that is the source of dc power when ac power is unavailable. Verify where applicable the proper voltage level of each component of the station dc supply. Verify the correct operation of ac powered dc power supplies. Verify the continuity of all circuit connections that can be affected by wear or corrosion. Inspect all circuit connections that can be affected by wear and corrosion.
~~Station dc Supply (used only for UVLS or UFLS)~~	~~(when the associated UVLS or UFLS system is maintained)~~	~~Verify proper voltage of the dc supply.~~

Table 1a ~~—~~ Time-Based Maintenance — Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection ~~Systems~~System Components **General Description:** Protection System components which do not have self-monitoring alarms, or if self-monitoring alarms are available, the alarms are not transmitted to a location where action can be taken for alarmed failures. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.		
Type of Protection System Component	**Maximum Maintenance Interval**	**Maintenance Activities**
~~Protection system~~Associated communications ~~equipment and channels.~~systems	3 Calendar Months	Verify that the Protection System communications ~~monitoring and alarms reflect the intended communications~~ system ~~condition by means of a substation inspection.~~is functional.
~~Protection system~~Associated communications ~~equipment and channels.~~systems	6 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment ~~outputs.~~ inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s).
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	6 Calendar Years	Test and calibrate the relays (other than microprocessor relays) with simulated electrical inputs. (Note 1) Verify proper functioning of the relay trip outputs. For microprocessor relays verify the proper functioning of the A/D converters ~~(Note 2)~~ . Verify that settings are as specified.
Relay sensing for Centralized UFLS or UVLS ~~systems~~systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Protective Relays	Includes ~~internal~~ • Internal self diagnosis and alarm capability~~, which~~ • Alarm must assert for power supply failures~~. Includes input~~ • Input voltage or current waveform sampling three or more times per power cycle~~, and conversion~~ • Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming	12 Calendar Years	Verify the status of relays is normal with no alarms indicated. Verify ~~the~~acceptable measurement of power system input values. For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the ~~A/D converters within the relay by testing or comparing values against other devices~~Protection System. ~~Verify proper functioning of the relay trip outputs.~~ Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken. ~~See Note 2.~~Verify correct operation of output actions that are used for tripping.
Voltage and Current Sensing ~~Devices~~ Inputs to Protective Relays and associated circuitry	No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	12 Calendar Years	Verify the proper functioning of current and voltage circuit ~~inputs~~signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays.
~~Protection System~~ Control Circuitry (Trip Coils and Auxiliary Relays)	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals~~Monitoring and alarming of continuity of trip circuits(s)	6 Calendar Years	Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components			
General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
~~Protection System~~ Control Circuitry (Trip Circuits) (except for UFLS/UVLS)	~~Monitoring and alarming of continuity of trip coil(s)~~ Monitoring of Protection System component inputs, outputs, and connections with reporting of monitoring alarms to a location where action can be taken Connection paths using electronic signals or data messages are monitored by periodic signal changes or messages that verify ability to convey Protection System operating values	12 Calendar Years	~~Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System.~~ Verify that the ~~relay~~ alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
~~**Protection System Control Circuitry (Trip Circuits) (UFLS/UVLS Systems Only)**~~Control and trip circuitry	~~Monitoring and alarming of continuity of trip coil(s)~~ Monitoring of the continuity of breaker trip circuits along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil(s), including any auxiliary contacts essential to proper Protection System operation. If a trip circuit comprises multiple paths, each of the paths must be monitored, including monitoring of the operating coil circuit(s) and the tripping circuits of auxiliary tripping relays and lockout relays. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken.	~~(when the associated UVLS or UFLS system is maintained)~~12 Calendar Years	~~Perform a complete functional trip test that includes all sections of the Protection System trip circuit, including all auxiliary contacts essential to proper functioning of the Protection System. (Verification does not require actual tripping of circuit breakers or interrupting devices.)~~ Verify that the ~~relay~~ alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components

General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Level 2 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Station dc supply ~~(that has as a component any type of battery)~~	~~Monitoring~~Monitor and ~~alarming of the station~~ alarm for: • Station dc supply voltage • ~~Detection and alarming of~~ Unintentional dc grounds~~.~~ • Electrolyte level of all cells in a station battery • Individual battery cell/unit state of charge • Battery continuity of station battery • Cell-to-cell and battery terminal resistance	~~3 Months~~ 6 Calendar ~~y~~Years	~~Verify proper electrolyte level (excluding Valve-Regulated Lead Acid batteries).~~ Verify that the monitoring devices are calibrated (where necessary) and alarms will be received at the location where action can be taken.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring

Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components

General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component.

General Maintenance Requirements: Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	Level 2 Monitoring Attributes for Component	Maximum Maintenance Interval	Maintenance Activities
Station dc supply~~(that has as a component any type of battery)~~	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~ No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	18 Calendar Months	~~Verify proper voltage~~Inspect: Cell condition of ~~each~~ individual ~~cell or unit in the station~~ battery~~.~~ ~~Verify that station battery charger provides the correct float and equalize voltages.~~ ~~Verify electrical continuity of the entire battery.~~ • ~~Perform a visual cell inspection of all~~ cells ~~for "cell condition" (~~where cells are visible~~)~~, or ~~measurement of~~ measure battery cell/unit internal ohmic values~~. (~~ where cells are not visible~~)~~ ~~Measure that specific gravity and temperature of each cell is within tolerance. (where applicable)~~ ~~Verify cell to cell and terminal connection resistance is within tolerance.~~ • ~~**Inspect the structural integrity of the**~~ Physical condition of battery rack • ~~Verify that the~~ The condition of non-battery ~~voltage and~~based dc supply~~ground alarms will be received at the location where action can be taken.~~
Station dc supply (that has as a component Valve Regulated Lead-Acid batteries)	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~ No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	3 Calendar Years - or - 3 Calendar Months	Verify that the station battery can perform as designed by conducting a performance or service capacity test of the entire battery bank. (3 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (3 months)

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc supply (that has as a component Vented Lead-Acid batteries)	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	6 Calendar Years - or - 18 Calendar Months	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank. (6 calendar years) - or - Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. (18 Months)
Station dc supply (that has as a component Nickel-Cadmium batteries)	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	6 Calendar Years	Verify that the substation battery can perform as designed by conducting a performance service, or modified performance capacity test of the entire battery bank.
~~Station dc supply (that uses a battery and charger)~~	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~	~~6 Calendar Years~~	~~Verify that the battery charger can perform as designed by testing that the charger will provide full rated current and will properly current-limit.~~

Table 1b — Condition-Based Maintenance - Level 2 Monitoring			
Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components			
General Description: Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (battery is not used)	~~Monitoring and alarming of the station dc supply voltage.~~ ~~Detection and alarming of dc grounds.~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities	~~18 Months~~ 6 Calendar Years	Verify ~~proper voltage of~~ that the ~~station~~ dc supply~~, and where applicable, of each component of the station dc supply.~~ ~~Verify the proper operation of ac powered dc power supplies.~~ ~~Verify the continuity of all circuit connections that~~ can ~~be affected by wear or corrosion.~~ ~~Perform a visual inspection, of all components of the station dc supply to verify that the physical condition of the station dc supply is~~ **perform as** ~~desired and any visual inspection if required by the manufacturer on the condition of the dc supply that is the source of dc power~~**designed** when ac power ~~is unavailable.~~ ~~Verify that the station dc supply voltage and dc supply ground alarms will be received at a location where action can be taken.~~from the grid is not present.
~~Station dc Supply (used only for UVLS or UFLS)~~	~~No Level 2 monitoring attributes are defined – use Level 1 Maintenance Activities and intervals~~	~~(when the associated UVLS or UFLS system is maintained)~~	~~Verify proper voltage of the dc supply~~
~~Protection system~~Associated communications ~~equipment and channels.~~system	Monitoring and alarming of protection communications system by mechanisms that check for presence of the communications channel.	12 Calendar Years	Verify that the performance of the channel and the quality of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s). Verify proper functioning of alarm notification.

Table 1b — Condition-Based Maintenance - Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities for Partially Monitored Protection System Components **General Description:** Protection System components whose conditions or alarms are automatically provided daily (or more frequently) to a location where action can be taken for alarmed failures. ~~Monitoring includes all elements~~Detected maintenance-correctable issues for Level 2 Monitored Protection Systems must be reported within 1 day or less of ~~level 1~~ the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 2 monitoring ~~with additional~~ includes all monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 2 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	Includes internal self diagnosis and alarm capability, which must assert for power supply failures. Includes input voltage or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.	12 Calendar Years	Verify the status of relays as in service with no alarms. ~~Verify the~~Verify acceptable measurement of power system input values the proper function of the A/D converters (if included in relay). Verify proper functioning of the relay trip outputs. Verify that settings are as specified. Verify that the relay alarms will be received at the location where action can be taken.
Relay sensing for centralized UFLS or UVLS systems	See the attributes of Level ~~1~~2 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the UFLS/UVLS	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See the attributes of Level ~~1~~ 2 Monitoring for the individual components of the SPS	See Maintenance Intervals for the individual components of the SPS	Perform all of the Maintenance activities listed above as established for components of the SPS, at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Table 1c — Condition-based Maintenance — Level 3 Monitoring **Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection ~~Systems~~System Components** **General Description:** Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all ~~elements~~attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.

Type of Protection System Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
Station dc Supply (any battery ~~is not used)~~technology)	Monitoring and alarming ~~the~~for station dc supply ~~status, including output~~ voltage, unintentional dc grounds, electrolyte level of ~~the dc supply.~~ ~~Monitoring~~all cells of a station battery, individual battery cell/unit state of charge, battery continuity of station battery and ~~alarming if the performance capability of the dc supply is degraded.~~ ~~Detection~~cell-to-cell and ~~alarming of dc grounds.~~battery terminal resistance	Continuous	~~Continuous verification of the status of the station dc supply and its ability to deliver dc power when required, is provided.~~Continuous monitoring of station dc supply voltage, unintentional dc grounds, electrolyte level of all cells of a station battery, individual battery cell/unit state of charge, battery continuity of station battery and cell-to-cell and battery terminal resistance are provided with alarming to remote location upon any failure of the monitoring device or when sensors for the devises are out of calibration.
Station dc Supply ~~(used only for UVLS or UFLS)~~which do not use a station battery	No Level 3 monitoring attributes are defined – use Level ~~2~~1 Maintenance Activities and intervals	~~(when the associated UVLS or UFLS system is maintained)~~6 Calendar Years	Verify ~~proper voltage of~~that the dc supply can perform as designed when the ac power from the grid is not present.
~~Protection system telecommunications equipment and channels.~~Associated communications systems	Evaluating the performance of the channel and its interface to protective relays to determine the quality of the channel and alarming if the channel does not meet performance criteria	Continuous	Continuous verification that the performance and quality of the channel meets performance criteria is provided. Continuous verification of the communications equipment alarm system is provided.

Table 1c — Condition-based Maintenance — Level 3 Monitoring			
Maximum Allowable Testing Intervals and Maintenance Activities for Fully Monitored Protection ~~Systems~~System Components			
General Description: Protection System components in which every function required for correct operation of that component is continuously monitored and verified, and detected maintenance-correctable issues reported. Level 3 Monitored Protection Systems also includes verification of the means by which alarms and monitored values are transmitted to a location where action can be taken. Detected maintenance-correctable issues for Level 3 Monitored Protection Systems must be reported within 1 hour or less of the maintenance-correctable issue occurring, to a location where action can be taken to initiate resolution of the maintenance-correctable issue. Level 3 Monitoring includes all ~~elements~~attributes of Level 2 Monitoring, with additional monitoring attributes as listed below for the individual type of component. **General Maintenance Requirements:** Perform maintenance activities listed and initiate necessary corrective actions in accordance with Requirement R4.			
Type of Protection System Component	**Level 3 Monitoring Attributes for Component**	**Maximum Maintenance Interval**	**Maintenance Activities**
UVLS and UFLS relays that comprise a protection scheme distributed over the power system.	The relay A/D converters are continuously monitored and alarmed.	Continuous	Continuous verification of the status of the relays~~. (Note 2)~~ Alarm on change of settings Verification does not require actual tripping of circuit breakers or interrupting devices
Relay sensing for centralized UFLS or UVLS systems.	See the attributes of Level 3 Monitoring for the individual components of the UFLS/UVLS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified.
SPS	See the attributes of Level 3 Monitoring for the individual components of the SPS	See Maintenance Activities	Perform all of the Maintenance activities listed above as established for components of the SPS at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS components whose operation leads to that control action must each be verified.

Notes for Table 1a, Table 1b, and Table 1c

1. For some Protection System components, adjustment is required to bring measurement accuracy within parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.
2. ~~Microprocessor relays typically are specified by manufacturers as not requiring calibration, but power system input values must be verified as correct within the Table intervals. The integrity of the digital inputs and outputs will be verified with the Protection System Control Circuitry.~~

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

Segment: In this procedure, the term, "segment" is a grouping of Protection Systems or ~~component devices~~components from a single manufacturer, with common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components.[4]

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of components included in each designated segment of the Protection System component population.
2. Maintain the components in each segment according to the time-based maximum allowable intervals established in Table 1 until results of maintenance activities for the segment are available for a minimum of 30 individual components of the segment.
3. Document the maintenance program activities and results for each segment, including maintenance dates and countable events[5] for each included component.
4. Analyze the maintenance program activities and results for each segment to determine the overall performance of the segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Protection System components and segments and/or description if any changes occur within the segment.
2. Perform maintenance on the greater of 5% of the components (addressed in the performance based PSMP) in each segment or 3 individual components within the segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each segment to determine the overall performance of the segment.
4. If the components in a Protection System segment maintained through a performance-based PSMP experience 4% or more countable events, develop, document, and

---

[~~4~~4] Entities with smaller populations of component devices may aggregate their populations to define a segment and shall share all attributes of a single performance-based program for that segment.

[5] Countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure.

implement an action plan to reduce the countable events to less than 4% of the segment population within 3 years.

5. Using the prior year's data, determine the maximum allowable maintenance interval for each segment such that the segment experiences countable events on no more than 4% of the components within the segment, for the greater of either the last 30 components maintained or all components maintained in the previous year.

Draft Implementation Plan for PRC-005-02

Background:
In developing the implementation plan, the Standard Drafting Team considered the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

General Considerations:
Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the protection system components identified in PRC-005-2 Table 1a) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same protection system component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components
- For each component, whether maintenance of that component is still being addressed under PRC-005-1 or has been moved under PRC-005-2
- Evidence that each component has been maintained under the relevant requirements

Implementation plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter six months following Board of Trustees adoption.

Implementation plan for Requirements R2, R3, and R4:

1. For Protection System Components with maximum allowable intervals of less than 1 year, as established in Table 1a,
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 12 months following applicable regulatory approval, or in those jurisdictions where no

regulatory approval is required, on the first day of the first calendar quarter 12 months following Board of Trustees adoption.

2. For Protection System Components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Table 1a,
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

3. For Protection System Components with maximum allowable intervals of 6 years, as established in Table 1a,
   a. The entity shall be 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.
   b. The entity shall be 60% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 6 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 6 calendar years following Board of Trustees adoption.

4. For Protection System Components with maximum allowable intervals of 12 years, as established in Table 1a,
   a. The entity shall be 30% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   b. The entity shall be 60% compliant on the first day of the first calendar quarter following 8 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 8 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 12 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Draft Implementation Plan for PRC-005-02

Background:
In developing the implementation plan, the Standard Drafting Team considered the following:

1. The requirements set forth in the proposed standard establish maximum allowable maintenance intervals for the first time. The established maximum allowable intervals may be shorter than those currently in use by some entities.
2. For entities using longer intervals than the maximum allowable intervals established in the proposed standard, it is unrealistic for those entities to be immediately in compliance with the new intervals. Further, entities should be allowed to become compliant in such a way as to facilitate a continuing maintenance program.
3. ~~Until an entity is 100% compliant with PRC-005-2, the entity must be in compliance with PRC-005-1 for those components for which the implementation schedule for PRC-005-2 is not yet applicable.~~

~~4.~~3. Entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.

General Considerations:
Each Transmission Owner, Generator Owner, and Distribution Provider shall follow the protection system maintenance and testing program it used to perform maintenance and testing to comply with PRC-005-1, PRC-008-0, PRC-011-0, and PRC-017-0 (for the protection system components identified in PRC-005-2 Table 1a) until that Transmission Owner, Generator Owner or Distribution Provider meets initial compliance for maintenance of the same protection system component, in accordance with the phasing specified below.

For audits that are conducted during the time period when entities are modifying their existing protection system maintenance and testing programs to become compliant with the maintenance activities and intervals specified in PRC-005-2, each responsible entity must be prepared to identify:

- All of its applicable protection system components
- For each component, whether maintenance of that component is still being addressed under PRC-005-1 or has been moved under PRC-005-2
- Evidence that each component has been maintained under the relevant requirements

Implementation plan for Requirement R1:

- Entities shall be 100% compliant on the first day of the first calendar quarter three months following applicable regulatory approvals, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ~~three~~six months following Board of Trustees adoption.

Implementation plan for Requirements R2, R3, and R4:

1. For Protection System Components with maximum allowable intervals of less than 1 year, as established in Table 1a,
    a. The entity shall be 100% compliant on the first day of the first calendar quarter 12 months following applicable regulatory approval, or in those jurisdictions where no

regulatory approval is required, on the first day of the first calendar quarter 12 months following Board of Trustees adoption.

2. For Protection System Components with maximum allowable intervals 1 year or more, but 2 years or less, as established in Table 1a,
   a. The entity shall be 100% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.

3. For Protection System Components with maximum allowable intervals of 6 years, as established in Table 1a,
   a. The entity shall be 30% compliant on the first day of the first calendar quarter 2 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 2 calendar years following Board of Trustees adoption.
   b. The entity shall be 60% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 6 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 6 calendar years following Board of Trustees adoption.

4. For Protection System Components with maximum allowable intervals of 12 years, as established in Table 1a,
   a. The entity shall be 30% compliant on the first day of the first calendar quarter 4 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 4 calendar years following Board of Trustees adoption.
   b. The entity shall be 60% compliant on the first day of the first calendar quarter following 8 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 8 calendar years following Board of Trustees adoption.
   c. The entity shall be 100% compliant on the first day of the first calendar quarter 12 calendar years following applicable regulatory approval, or in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter 12 calendar years following Board of Trustees adoption.

Applicability:
This standard applies to the following functional entities:

- Transmission Owners
- Generator Owners
- Distribution Providers

Implementation Plan for the Revised Definition of Protection System

Prerequisite Approvals or Activities:

The implementation of the revised definition is not dependent upon any other activity.

Recommended Modifications to Already Approved Standards

The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 – Nuclear Plant Interface Coordination
- PER-005-1 – System Personnel Training
- PRC-001-1 – System Protection Coordination

The term, "protection system" shall be capitalized where used in these standards when the definition of "Protection System" is approved by applicable regulatory authorities.

Proposed Effective Date:

Each responsible entity (Distribution Provider that owns a transmission Protection System, Transmission Owner, and Generator Owner) shall modify its protection system maintenance and testing program description and basis document(s) (required in Requirement R1 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) as necessary to reflect the modified definition of 'Protection System' by the end of the first calendar quarter six months following regulatory approvals and implement any additional maintenance and testing (required in Requirement R2 of PRC-005-1 – Transmission and Generation Protection System Maintenance and Testing) by the end of the first complete maintenance and testing cycle described in the entity's program description and basis document(s) following establishment of the program changes resulting from the revised definition.

The original definition of "Protection System" shall be retired at the same time the revised definition becomes effective.

Unofficial Comment Form for Proposed Definition of Protection System for Project 2007-17

Please **DO NOT** use this form. Please use the electric comment form at the link below to submit comments on the draft definition of "Protection System." Comments must be submitted by **July 16, 2010**. If you have questions please contact Al McMeekin at Al.McMeekin@nerc.net or by telephone at 803.530.1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:
The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) posted a proposed revision to the definition of the term, "Protection System" and proposed revisions to PRC-005-2 — Protection System Maintenance for a 45-day public comment period from July 24, 2009 through September 8, 2009. There were 55 sets of comments, including comments from more than 130 different people from over 75 companies representing all of the 10 Industry Segments, however less than 10 of these sets of comments included any comments on the proposed modification to the term, "Protection System."

The drafting team posted a table that showed all the existing uses of the term, "Protection System" in already approved standards, and concluded that the new definition of Protection System (which clarifies that the dc Supply is part of a Protection System) remains consistent with the existing uses. The non-capitalized version of the term, "protection system" is used in the following approved standards:

- NUC-001-2 — Nuclear Plant Interface Coordination
- PER-005-1 — System Personnel Training
- PRC-001-1 — System Protection Coordination

The proposed modifications address ambiguities the PSMT SDT identified within the existing approved definition, and are important for the detailed use of the definition within the draft PRC-005-2 standard.

When the Board of Trustees was asked to approve an interpretation of PRC-005-1 that was written by the PSMT SDT, the board acknowledged the reliability gap identified by the drafting team and directed that work to close this reliability gap should be given "priority." In support of this direction, the PSMT SDT has separated its work in refining PRC-005-2 from its work in revising the definition of "Protection System."

The drafting team initially proposed changes to the definition as shown below:

> Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays ~~devices~~, station DC supply ~~batteries~~, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

Based on stakeholder comments, the drafting team made minor changes to the proposed definition as shown below.

> Protective relays, ~~associated~~ communication systems necessary for correct operation of protective ~~devices~~functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and ~~DC~~ control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

The proposed definition of Protection System now reads as follows:

> Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

1. Do you believe the proposed definition of Protection System is ready for ballot? If not, please explain why.

   ☐ Yes

   ☐ No

   Comments:

2. Do you agree with the implementation plan for the revised definition of Protection System? The implementation plan has two phases – the first phase gives entities at least six months to update their protection system maintenance and testing program; the second phase starts when the protection system maintenance and testing program has been updated and requires implementation of any additional maintenance and testing associated with the program changes by the end of the first complete maintenance and testing cycle described in the entity's revised program. If you disagree with this implementation plan, please explain why.

   ☐ Yes

   ☐ No

Unofficial Comment Form for 2nd Draft of the Standard for Protection System Maintenance and Testing Project 2007-17

Please **DO NOT** use this form. Please use the electronic comment form at the link below to submit comments on the 2nd draft of the PRC-005-2 standard for Protection System Maintenance and Testing. Comments must be submitted by **July 16, 2010.** If you have questions please contact Al McMeekin at al.mcmeekin@nerc.net or by telephone at 803-530-1963.

http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Background Information:
The Protection System Maintenance and Testing Standard Drafting Team (PSMT SDT) has made substantial changes to the second posting of PRC-005-2 base on comments received from the industry. The changes included:

- Re-naming the standard from "Protection System Maintenance and Testing" to "Protection System Maintenance"
- Revisions to the standard and tables regarding the maintenance activities and associated maintenance intervals
- Revisions to the tables regarding condition-based and performance based maintenance programs
- Revisions to the Supplemental Reference and the FAQ documents

In addition, Violation Risk Factors (VRFs), Time Horizons, Measures, and Compliance elements including Violation Security Levels (VSLs) have been supplied with this version of the draft standard. The rationale for the team's assignments pertaining to the VRFs and VSLs are posted in a separate document.

The PSMT SDT would like to receive industry comments on this standard.

1. The SDT has made significant changes to the minimum maintenance activities and maximum allowable intervals within Tables 1a, 1b, and 1c, particularly related to station dc supply and dc control circuits. Do you agree with these changes? If not, please provide specific suggestions for improvement.

   ☐ Yes
   ☐ No
   Comments:

2. The SDT has included VRFs and Time Horizons with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement.

   ☐ Yes
   ☐ No
   Comments:

3. The SDT has included Measures and Data Retention with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for improvement.

☐ Yes

☐ No

Comments:

4. The SDT has included VSLs with this posting. Do you agree with the assignments that have been made? If not, please provide specific suggestions for change.

   ☐ Yes

   ☐ No

   Comments:

5. The SDT has revised the "Supplementary Reference" document which is supplied to provide supporting discussion for the Requirements within the standard. Do you agree with the changes? If not, please provide specific suggestions for change.

   ☐ Yes

   ☐ No

   Comments:

6. The SDT has revised the "Frequently-Asked Questions" (FAQ) document which is supplied to address anticipated questions relative to the standard. Do you agree with these changes? If not, please provide specific suggestions for change.

   ☐ Yes

   ☐ No

   Comments:

7. If you have any other comments on this Standard that you have not already provided in response to the prior questions, please provide them here.

NERC Protection System Maintenance Standard PRC-005-2

FREQUENTLY ASKED QUESTIONS - Practical Compliance and Implementation

April 16, 2010

Informative Annex to Standard PRC-005-2

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

Table of Contents

Introduction

The following is a draft collection of questions and answers that the PSMT SDT believes could be helpful to those implementing NERC Standard PRC-005-2 Protection System Maintenance. As the draft standard proceeds through development, this FAQ document will be revised, including responses to key or frequent comments from the posting process. The FAQ will be organized at a later time during the development of the draft Standard.

This FAQ document will support both the Standard and the associated Technical Reference document.

Executive Summary

- Write later if needed

Terms Used in PRC-005-2

Maintenance Correctable Issue – As indicated in footnote 2 of the draft standard, a maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration while performing the initial on-site maintenance activity, and that requires follow-up corrective action.

Segment – As indicated in *PRC-005-2 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*, a segment is a "A grouping of Protection Systems or components of a particular model or type from a single manufacturer, with other common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components."

Component – This equipment is first mentioned in Requirement 1.1 of this standard. A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. Types of components are listed in Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems"). For components such as dc circuits, the designation of what constitutes a dc control circuit component is somewhat arbitrary and is very dependent upon how an entity performs and tracks the testing of the dc circuitry. Some entities test their dc circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of "dc control circuit components." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – As indicated in footnote 4 of *PRC-005-2 Attachment A, Criteria for a Performance-based Protection System Maintenance Program*, countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.

Frequently Asked Questions

I General FAQs:

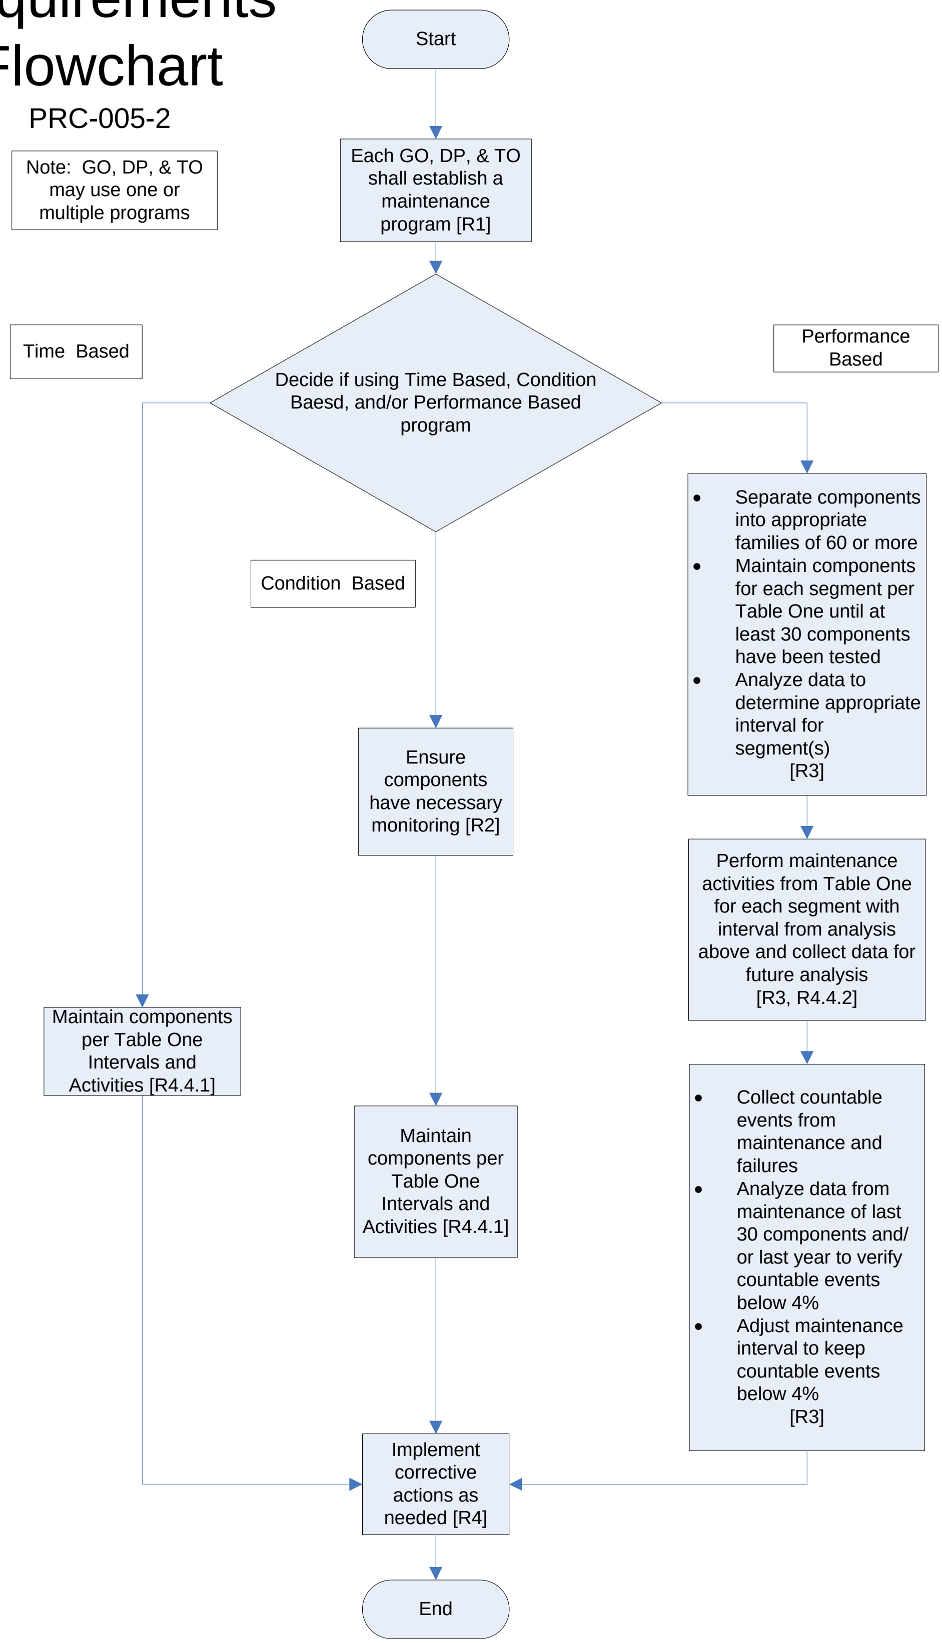
1. The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R2) and performance-based Maintenance (R3) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to follow R1 and R4 and perform ONLY time-based maintenance according to Table 1a, eliminating R2 and R3 from consideration altogether. If an entity then wishes to take advantage of monitoring on its Protection System components, R2 comes into play, along with Tables 1b and 1c. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, R3 applies.

Please see the following diagram, which provides a “flow chart” of the standard.

Requirements Flowchart

PRC-005-2



II Group by Type of Protection System Component:

1. All Protection System Components

A. Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this standard?

No. As stated in R1, this standard covers protective relays that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

B. Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented Maintenance program, and is focused on establishing Requirements rather than prescribing methodology to meet those Requirements. Between the activities identified in Tables 1a, 1b, and 1c, and the various components of the definition established for a "Protection System Maintenance Program", PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

2. Protective Relays

A. How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The component "Upkeep" in the definition of a Protection System Maintenance Program, addresses "Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device." The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to Upkeep for Protective Relays. However, the entity should assure that the relay continues to function properly after implementation of firmware changes.

B. Please clarify what is meant by restoration in the definition of maintenance.

The component "Restoration" in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to

Restoration; R4.3 of the standard does require that the entity “initiate any necessary activities to correct unresolved maintenance correctable issues”. Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electro-mechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work

C. If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance cycles is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

D. What is meant by “Verify that settings are as specified” maintenance activity in tables 1a and 1b?

Verification of settings is an activity directed mostly towards microprocessor based relays.

For relay maintenance departments that choose to test microprocessor based relays in the same manner as electro-mechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states “…settings are as specified.”

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that this was done is sufficient.

The drafting team was careful not to require “…that the relay settings be correct…” because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is simply to check that the settings in the relay match the settings specified to those placed into the relay.

E. Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in tables 1a and 1b?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

F. I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

G. I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are applied on, or are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

H. We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system uprates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection system component performs a Protection system function then it must be maintained. If the component no longer performs Protection System functions than it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

I. While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2

requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R4.3 states (the entity must):
The entity must assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues.

J. If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R4.3) (in essence) state that the entity assure the components are within the owner's acceptable operating parameters, if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements. Documentation is always a necessity ("*If it is not documented then it wasn't done!*")
Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

K. What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

3. Voltage and Current Sensing Device Inputs to Protective Relays

A. What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.

- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds

- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.

- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different CT's.

- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

  The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

B. The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities may be also verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

C. Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

D. My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

4. Protection System Control Circuitry

A. Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

B. The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a dc battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

C. How do I test each dc Control Circuit path, as established for level 2 (partially monitored protection systems) monitoring of a "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1b specifies that each breaker trip coil, auxiliary relay, and lockout relay must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

D. What does this standard require for testing an Auxiliary Tripping Relay?

Table 1 requires that the trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) operate(s) electrically and that their trip output(s) perform as expected. Auxiliary outputs not in a trip path (i.e. alarming or DME input) are not required to be checked.

E. What does a functional trip test include?

An operational trip test must be performed on each portion of a trip circuit. Each control circuit path that produces a trip signal must be verified; this includes trip coils, auxiliary tripping relays, lockout relays, and communications-assisted-trip schemes.

A trip test may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip path, provided that testing of the various portions of the trip scheme verifies all of the portions, including parallel paths, and overlaps those portions.

A circuit breaker or other interrupting device needs to be trip tested at least once per trip coil..

Discrete-component auxiliary relays and lock-out relays must be verified by trip test. The trip test must verify that the auxiliary or lock-out relay operates electrically and that the relay's trip output(s) change(s) state. Software latches or control algorithms, including trip logic processing implemented as programming component such as a microprocessor relay that take the place of (conventional) discrete component auxiliary relays or lock-out relays do not have to be routinely trip tested.

Normally-closed auxiliary contacts from other devices (for example, switchyard-voltage-level disconnect switches, interlock switches, or pressure switches) which are in the breaker trip path do not need to be tested.

F. Is a Sudden Pressure Relay an Auxiliary Tripping Relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63, and is excluded from the Standard by footnote 1.

G. The standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?

An auxiliary relay, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

H. What is a Lock-out Relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

I. My mechanical device does not operate electrically and does not have calibration settings; what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

5. Station dc Supply

A. What constitutes the station dc supply as mentioned in the definition of Protective System?

The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

B. In the Maintenance Activities for station dc supply in Table 1, what do you mean by “continuity”?

Because the Standard pertains to maintenance not only of the station battery, but also the whole station dc supply, continuity checks of the station dc supply are required. “Continuity” as used in Table 1 refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal, otherwise there is no way of determining that a station battery is available to supply dc current to the station.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service.

C. Why is it necessary to verify the continuity of the dc supply?

In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.

If the battery charger is not sized to handle the maximum dc current required to operate the protective systems, it is sized only to handle the constant dc load of the station and the charging current required to bring the battery back to full charge following a discharge. At those stations, the battery charger would not be able to trip breakers and switches if the battery experiences loss of continuity.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- ◊ Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- ◊ Loss of electrical continuity of the station battery will cause, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

D. How do you verify continuity of the dc supply?

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the substation dc circuitry.

Although the Standard prescribes what must be done during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery.

- ◊ One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- ◊ A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- ◊ Manufacturers of microprocessor based battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1 to insure that the station dc supply will provide the required current to the Protection System at all times.

E. When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium), the maintenance activity chosen, and the type of time based monitoring level selected.

For example, if you have a Valve Regulated Lead-Acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every three months.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

F. Why in Table 1 are there two Maintenance Activities with different Maximum Maintenance Intervals listed to verify that the station battery can perform as designed?

The two acceptable methods for proving that a station battery can perform as designed are based on two different philosophies. The first activity requires a capacity discharge test of the entire battery set to verify that degradation of one or several components (cells) in the set has not deteriorated to a point where the total capacity of the battery system falls below its designed rating. The second maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the battery set to determine that each component can perform as designed and therefore the entire battery set can be verified to perform as designed.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a battery set may degrade to an unacceptable level without causing the total battery set to fall below its designed rating under capacity testing. However, since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

G. What is the justification for having two different Maintenance Activities listed in Table 1 to verify that the station battery can perform as designed?

IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid (VRLA), and nickel-cadmium batteries, respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed.

The first maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries.

The second maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement (taken at the time of the battery set's acceptance capacity test), low-capacity cells can be identified and eliminated to keep the battery set capable of performing as designed. This maintenance activity is applicable only for vented lead-acid and VRLA batteries.

H. Why in Table 1 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA, vented lead-acid, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity. Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

I. What is required to comply with the "Unintentional Grounds" requirement?

In most cases, the first ground that appears on a battery pole is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised to demonstrate that a check is routinely done for Unintentional DC Grounds.

J. Where the standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example to I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient??

A single check-off per battery bank is sufficient.

K. Does this standard refer to Station batteries or all batteries, for example Communication Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communication sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System.

6. Protection System Communications Equipment

A. What are some examples of mechanisms to check communications equipment functioning?

For Level 1 unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are:

◊ On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier checkback test from one terminal.
◊ Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing a loss-of-guard indication or alarm. For frequency-shift power line power-line carrier systems, the guard signal level meter can also be checked.
◊ Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
◊ Digital communications systems have some sort of data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For Level 2 partially monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are:

◊ On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier checkback tests, with remote alarming of failures.
◊ Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
◊ Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
◊ Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.

For Level 3 fully monitored Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

◊ In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
◊ Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

B. What is needed for the 3-month inspection of communication-assisted trip scheme equipment?

The 3-month inspection applies to Level 1 (Unmonitored) equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (ie FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard.

C. Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communication system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communication equipment.

D. In Table 1b, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For Level 1 systems this alarm will probably be on the panel. For Level 2 and Level 3 systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of protective system communications channel performance criteria:

◊ For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
◊ An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use checkback testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
◊ Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
◊ Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase

information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

7. UVLS and UFLS Relays that Comprise a Protection System Distributed Over the Power System

A. We have an Under Voltage Load Shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage for a transmission system that was intact except for the line that was out of service.

This Standard is not applicable to this UVLS.

B. We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

C. What does “distributed over the power system” mean?

This refers to the common practice of applying UFLS on the distribution system, with each UFLS individually tripping a relatively low value of load. Therefore, the program is implemented via a large number of individual UFLS components performing independently, and the failure of any individual component to perform properly will have a minimal impact on the effectiveness of the overall UFLS program. Some UVLS systems are applied similarly.

8. SPS or Relay Sensing for Centralized UFLS or UVLS

A. Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test.

B. What about SPS interfaces between different entities or owners?

All SPS owners should have maintenance agreements that state which owner will perform specific tasks. SPS segments can be tested individually, but must overlap.

C. What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

D. How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?

Components of the SPS, UFLS, or UVLS should be maintained like similar components used for other Protection System functions.

The output action verification may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS, UFLS, or UVLS components whose operation leads to that control action must each be verified.

E. What does “centralized” mean?

This refers to the practice of applying sensing units at many locations over the system, with all these components providing intelligence to an analytical system which then directs action to address a detected condition. In some cases, this action may not take place at the same location as the sensing units. This approach is often applied for complex SPS, and may be used for UVLS where necessary to address the conditions of concern.

III Group by Type of BES Facility:

1. All BES Facilities

A. What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms Used in Reliability Standards, and is not being modified within this draft Standard.

NERC's approved definition of Bulk Electric System is:

> As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a *June 16, 2007 Informational Filing*.

2. Generation

A. Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

A loss of a system-connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source, and this auxiliary transformer may directly affect the ability to start up the plant and to connect the plant to the system. Thus, operation of any of the following relays associated with system-connected station auxiliary transformers would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit.

3. Transmission

A. Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

IV Group by Type of Maintenance Program:

1. All Protection System Maintenance Programs

A. I can't figure out how to demonstrate compliance with the requirements for level 3 (fully monitored) Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for level 3 (fully monitored) Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be comprehensive.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c. However, even if there is no equipment available today that can meet this level of monitoring, the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

B. What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database screen shots that demonstrate compliance information
- Diagrams, engineering prints, schematics, maintenance and testing records, etc.
- Logs (operator, substation, and other types of log)
- Inspection forms
- U.S. or Canadian mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Database lists and records

- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known and accounted for.

C. If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

The replacement component must be tested to a degree that assures that it will perform as intended. If it is desired to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

D. Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: “Company A” has a maintenance plan that requires its electro-mechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within “Company A’s” stated maximum time interval of 4.5 years.

The intent is not to have three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

2. Time-Based Protection System Maintenance (TBM) Programs

A. What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified on Table 1a of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

An entity would be wise to retain commissioning records to show a maintenance start date. (See next FAQ).

B. How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a facility and its associated Protection System were placed in service. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the maintenance program should clearly identify when maintenance is first due.

C. The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals.

D. If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this standard.

The NERC Sanction Guidelines provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.[1]

E. What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?

Any entity can choose to test some or all of their Protection System more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently.

F. We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In

1 Sanction Guidelines of the North American Electric Reliability Corporation. Effective January 15, 2008.

lieu of station visits many activities can be accomplished with automated monitoring and alarming.

G. Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables. Therefore you should design your maintenance plan such that it is not in conflict with the Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan.

3. Performance-Based Protection System Maintenance (PBM) Programs

A. I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

B. Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they can not prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

C. When establishing a performance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

D. What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

Human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation.

Certain types of Protection System component errors that cause Misoperations are not considered countable events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

E. What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

F. If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed count as a maintenance activity, and "reset the clock" on everything you've done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group.

G. Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a performance-based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition-based maintenance program using Level 3 monitoring of the battery used in a station dc supply can not do so. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, Level 3 monitoring of a battery can eliminate the requirement for periodic testing and some inspections (see Level 3 Monitoring Attributes for Component of table 1c).

H. Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

- For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

- This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

- This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.
- After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.
- This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

- After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

- After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

- After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

V Group by Monitoring Level:

1. All Monitoring Levels

A. Please provide an example of the level 1 monitored (unmonitored) versus other levels of monitoring available?

A level 1 (Unmonitored) Protection System has no monitoring and alarm circuits on the Protection System components.

A level 2 (Partially) monitored Protection System or an individual component of a level 2 (Partially) monitored Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert a 24-hr staffed operations center.

There can be a combination of monitored and unmonitored Protection Systems within any given substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of level 2 (Partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
◊ Instrumentation transformers, with no monitoring, connected as inputs to that relay. (level 1)
◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
◊ A circuit breaker with a trip coil, with no monitor circuit. (level 1)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components have maximum test intervals of:

◊ The microprocessor relay is verified every 12 calendar years.
◊ The instrumentation transformers are verified every 12 calendar years.
◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #2: A combination of level 2 (partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with integral alarm that is not connected to SCADA. (level 1)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (level 1)
◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
◊ A circuit breaker with a trip coil, with no circuits monitored. (level 1)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components have maximum test intervals of:

◊ The microprocessor relay is verified every 6 calendar years.
◊ The instrumentation transformers are verified every 12 calendar years.
◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #3: A combination of level 2 (partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
◊ Instrument transformers, with no monitoring, connected as inputs to that relay (level 1)
◊ Battery without any alarms connected to SCADA (level 1)
◊ Circuit breaker with a trip coil, with no circuits monitored (level 1)

Given the particular components, conditions, and using the Table 1 (“Maximum Allowable Testing Intervals and Maintenance Activities”), the particular components shall have maximum test intervals of:
◊ The microprocessor relay is verified every 12 calendar years.
◊ The instrument transformers are verified every 12 calendar years.
◊ The battery is verified every 3 months, every 18 months, plus, depending upon the type of battery used it may be verified at other maximum test intervals, as well.
◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

B. What is the intent behind the different levels of monitoring?

The intent behind different levels of monitoring is to allow less frequent manual intervention when more information is known about the condition of Protection System components.

C. Do all monitoring levels apply to all components in a protection system?

No. For some components in a protection system, certain levels of monitoring will not be relevant. See table below:

D. My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant monitors the alarms and other indications and reports them within the given time limits that are stated in the criteria of the Table 1b or Table 1c.

Monitoring Level Applicability Table

(See related definition and decision tree for various level requirements)

Protection Component	Level 1 (Unmonitored)	Level 2 (Partially Monitored)	Level 3 (Fully Monitored)
Protective relays	Y	Y	Y
Instrument transformer Inputs to Protective Relays	Y	N	Y
Protection System control circuitry (Other than aux-relays & lock-out relays)	Y	Y	Y
Aux-relays & lock-out relays	Y	N	N
DC supply (other than station batteries)	Y	Y	Y
Station batteries	Y	N	N
Protection system communications equipment and channels	Y	Y	Y
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	Y	Y	Y
SPS, including verification of end-to-end performance, or relay sensing for centralized UFLS or UVLS systems	Y	Y	Y

Y = Monitoring Level Applies
N = Monitoring Level Not Applicable

E. When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R2 of the standard, is it necessary to provide this documentation via a device by device listing of components and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc systems are Level 2 - Partially Monitored by stating the following within the program description:

> "All substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc systems of Substation X, Substation Y, and Substation Z are considered Level 1 - Unmonitored and subject to Table 1a requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided via a device by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

F. How do I know what monitoring level I am under? – Include Decision Trees

Decision Trees are provided below for each of the following categories of equipment to assist in the determination of the level of monitoring.

- ◊ Protective Relays
- ◊ Current and Voltage Sensing Devices
- ◊ Protection System Control Circuitry
- ◊ Station dc Supply
- ◊ Protection System Communication Systems

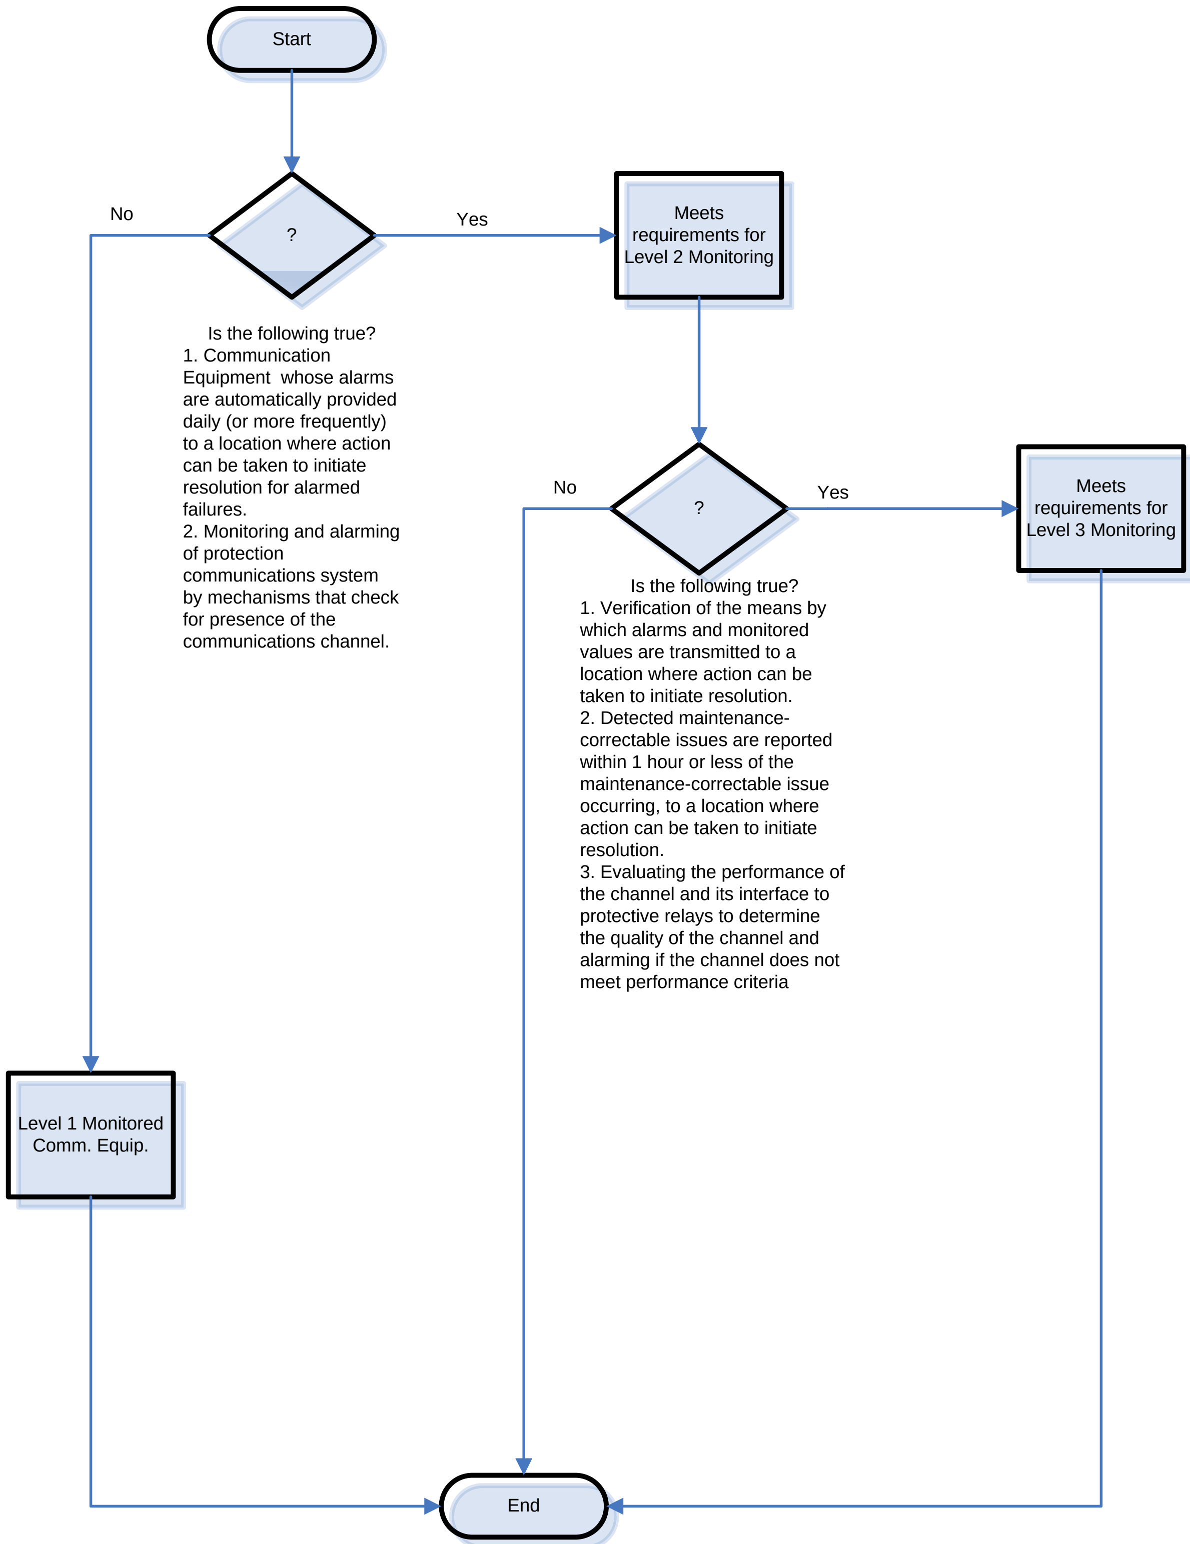
COMMUNICATION SYSTEM
MONITOR LEVEL
DECISION TREE



2. **Level 1 Monitored Protection Systems (Unmonitored Protection Systems)**

   A. **We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?**

   This system is made up of components that are level 1 (unmonitored). Assuming a time-based protection system maintenance program schedule, each component must be maintained per Table 1a – Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities.

3. **Level 2 Monitored Protection Systems (Partially Monitored Protection Systems)**

   A. **We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Is this an unmonitored or a partially-monitored system? How often must I perform maintenance?**

   The protective relay is a level 2 (partially) monitored component of your protection system and can be maintained every 12 years or when a maintenance correctable issue arises. Assuming a time-based protection system maintenance program schedule, this component must be maintained per Table 1b – Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities

   The rest of your protection system contains components that are level 1 (unmonitored) and must be maintained within at least the maximum verification intervals of Table 1a.

   B. **How do I verify the A/D converters of microprocessor-based relays?**

   There are a variety of ways to do this. Examples include using values gathered via data communications and automatically comparing these values with values from other sources, and using groupings of other measurements (such as vector summation of bus feeder currents) for comparison if calibration requirements assure acceptable measurement of power system input values. Other methods are possible.

   C. **For a level 2 monitored Protection System (Partially Monitored Protection System) pertaining to Protection System communications equipment and channels, how is the performance criteria involved in the maintenance program?**

   The entity determines the performance criteria for each installation, depending on the technology implemented. If the communication channel performance of a Protection System varies from the pre-determined performance criteria for that system, these results should be investigated and resolved.

D. My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1b requirements for inclusion as Level 2?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

4. Level 3 Monitored Protection Systems (Fully Monitored Protection Systems)

A. Why are there activities defined for a level-3 monitored Protection System? The technology does not seem to exist at this time to implement this monitoring level.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c. However, even if there is no equipment available today that can meet this level of monitoring; the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

Table of Contents

Introduction

The following is a draft collection of questions and answers that the PSMT SDT believes could be helpful to those implementing NERC Standard PRC-005-2 Protection System Maintenance. As the draft standard proceeds through development, this FAQ document will be revised, including responses to key or frequent comments from the posting process. The FAQ will be organized at a later time during the development of the draft Standard.

This FAQ document will support both the Standard and the associated Technical Reference document.

Executive Summary

- ~~To be added~~Write later if needed~~.~~

Terms Used in PRC-005-2

Maintenance Correctable Issue – As indicated in footnote 2 of the draft standard, a maintenance correctable issue is a failure of a device to operate within design parameters that can not be restored to functional order by repair or calibration~~, repair or replacement~~ while performing the initial on-site maintenance activity, and that requires follow-up corrective action.

Segment – As indicated in *PRC-005-2 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*, a segment is a "A grouping of Protection Systems or ~~component devices~~components of a particular model or type from a single manufacturer, with other common factors such that consistent performance is expected across the entire population of the segment, and shall only be defined for a population of 60 or more individual components."

Component – This equipment is first mentioned in Requirement 1~~, Part 1~~.1 of this standard. A component is any individual discrete piece of equipment included in a Protection System, such as a protective relay or current sensing device. Types of components are listed in Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities for Unmonitored Protection Systems"). For components such as dc circuits, the designation of what constitutes a dc control circuit ~~element~~component is somewhat arbitrary and is very dependent upon how an entity performs and tracks the testing of the dc circuitry. Some entities test their dc circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of "dc control circuit ~~elements~~components." Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices~~;~~, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

Countable Event – As indicated in footnote 4 of *PRC-005-2 Attachment A, Criteria for a Performance-based Protection System Maintenance Program*, countable events include any failure of a component requiring repair or replacement, any condition discovered during the verification activities in Table 1a through Table 1c which requires corrective action, or a Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System component configuration errors, or Protection System application errors are *not* included in Countable Events.

Frequently Asked Questions

I General FAQs:

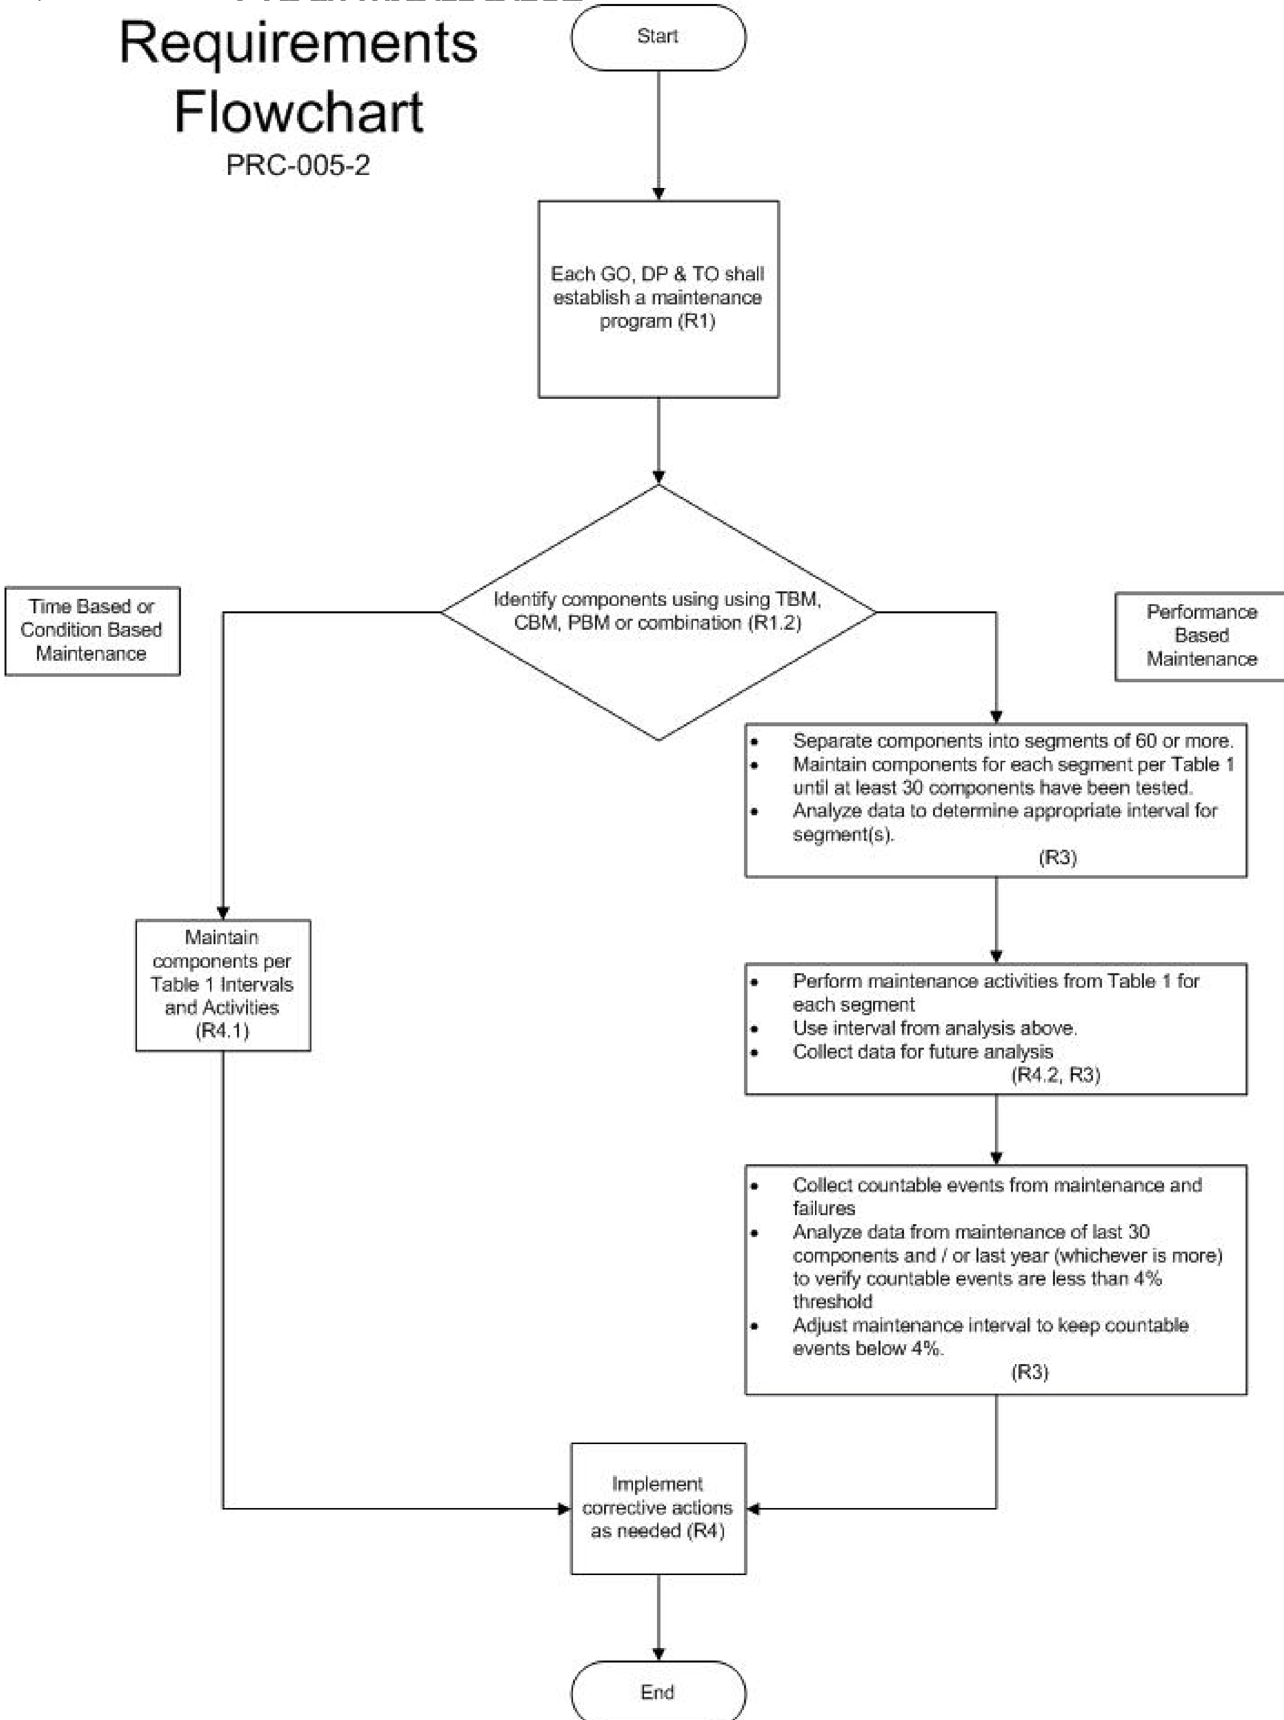
1. **The standard seems very complicated, and is difficult to understand. Can it be simplified?**

   Because the standard is establishing parameters for condition-based Maintenance (R2) and performance-based Maintenance (R3) in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to follow R1 and R4 and perform ONLY time-based maintenance according to Table 1a~~;~~, eliminating R2 and R3 from consideration altogether. If an entity then wishes to take advantage of monitoring on its Protection System components, R2 comes into play, along with Tables 1b and 1c. If an entity wishes to use historical performance of its Protection System components to perform performance-based Maintenance, R3 applies.

   Please see the following diagram, which provides a "flow chart" of the standard.

Requirements Flowchart

PRC-005-2



II Group by Type of Protection System Component:

1. All Protection System Components

A. Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this standard?

No. As stated in R1, this standard covers protective relays that use measurements of voltage, current and/or phase angle to determine anomalies and to trip a portion of the BES. Reclosers, reclosing relays, closing circuits and auto-restoration schemes are used to cause devices to close as opposed to electrical-measurement relays and their associated circuits that cause circuit interruption from the BES; such closing devices and schemes are more appropriately covered under other NERC Standards. There is one notable exception: if a Special Protection System incorporates automatic closing of breakers, the related closing devices are part of the SPS and must be tested accordingly.

B. Why does PRC-005-2 not specifically require maintenance and testing procedures as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-2 requires a documented Maintenance program, and is focused on establishing Requirements rather than prescribing methodology to meet those Requirements. Between the activities identified in Tables 1a, 1b, and 1c, and the various components of the definition established for a “Protection System Maintenance Program”, PRC-005-2 establishes the activities and time-basis for a Protection System Maintenance Program to a level of detail not previously required.

2. Protective Relays

A. How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The component “Upkeep” in the definition of a Protection System Maintenance Program, addresses “Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer’s hardware and software service advisories which are relevant to the application of the device.” The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to Upkeep for Protective Relays. However, the entity should assure that the relay continues to function properly after implementation of firmware changes.

B. Please clarify what is meant by restoration in the definition of maintenance.

The component “Restoration” in the definition of a Protection System Maintenance Program, addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in Table 1a, Table 1b, and Table 1c do not present any requirements related to

Restoration; R4.3 of the standard does require that the entity “initiate any necessary activities to correct unresolved maintenance correctable issues”. Some examples of restoration (or correction of maintenance-correctable issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electro-mechanical or solid-state protective relays to micro-processor based relays following the discovery of failed components. Restoration, as used in this context is not to be confused with Restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices and keeps them in working order. If an equipment item is repaired or replaced then the entity can restart the maintenance-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements; in other words do not discard maintenance data that goes to verify your work

C. If I upgrade my old relays then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced then the entity can restart the maintenance-activity-time-interval-clock if desired, however the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance cycles is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

D. What is meant by “Verify that settings are as specified” maintenance activity in tables 1a and 1b?

Verification of settings is an activity directed mostly towards microprocessor based relays.

For relay maintenance departments that choose to test microprocessor based relays in the same manner as electro-mechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously disabled but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the Standard states “…settings are as specified.”

Many of the microprocessor based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement a simple recorded acknowledgement that this was done is sufficient.

The drafting team was careful not to require “…that the relay settings be correct…” because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is simply to check that the settings in the relay match the settings specified to those placed into the relay.

E. Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in tables 1a and 1b?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection, and thus the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

~~B.~~F. I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses only devices "that are applied on, or are designed to provide protection for the BES." Protective relays, providing only the functions mentioned in the question, are not included.

~~C.~~G. I use my protective relays for fault and disturbance recording, collecting oscillographic records and event records via communications for fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as disturbance monitoring equipment, the NERC standard PRC-018-1 R3 & R6 states the maintenance requirements, and is being addressed by a Standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are applied on, or are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

H. We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system uprates, upgrades and overall changes meet any and all other requirements and standards then the requirements of PRC-005-2 are simple – if the Protection system component performs a Protection system function then it must be maintained. If the component no longer performs Protection System functions than it does not require maintenance activities under the Tables of PRC-005-2. While many entities might physically remove a component that is no longer needed there is no requirement in PRC-005-2 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-2 for Protection System components not used.

I. While performing relay testing of a protective device on our Bulk Electric System it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-2 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-2

requirement although the protective device may be unable to be returned to service under normal calibration adjustments. R4.3 states (the entity must):
The entity must assure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate any necessary activities to correct unresolved maintenance correctable issues.

J. If I show the protective device out of service while it is being repaired then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R4.3) (in essence) state that the entity assure the components are within the owner's acceptable operating parameters, if not then actions must be initiated to correct the deviance. The type of corrective activity is not stated; however it could include repairs or replacements. Documentation is always a necessity ("*If it is not documented then it wasn't done!*")
Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

K. What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

3. Voltage and Current Sensing Device Inputs to Protective Relays

A. What is meant by "…verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays~~…"~~ …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must ~~prove~~verify that the protective relay is receiving the expected values from the voltage and current sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. ~~Some examples follow:~~While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.

- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds

- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.

- Compare the values, as determined by the questioned relay~~,~~ (such as, but not limited to, a query to the microprocessor relay), to another protective relay monitoring the same line, with currents supplied by different ~~CTs.~~CT's.

- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc) and verified by calculations and known ratios to be the values expected. For example a single PT on a 100KV bus will have a specific secondary value that when multiplied by the PT ratio arrives at the expected bus value of 100KV.

- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.

- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that, an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring systems.

B. The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

~~These values will be zero, or very small, for any reasonably balanced system. To verify these values by comparison, you will need to rely on the normal condition that your system is not perfectly balanced, and there will usually be a small zero-sequence current or voltage, and these values can be measured with instruments having a sufficiently low resolution range. A reading of precisely zero will probably suggest that there is an opening (or some other problem) in the measuring circuit. A finite value of a few percent of the phase quantities, however, may suggest that the measuring circuit is indeed performing properly.~~

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities may be also verified by use of oscillographic records for connected microprocessor relays as recorded during system disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known fault locations.

C. Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not ~~required by the Maintenance Standard~~specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

D. My plant generator and transformer relays are electromechanical and do not have metering functions as do microprocessor based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment like voltmeters and clamp on ammeters to measure the input signals to the relays. This practice seems very risky and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

4. Protection System Control Circuitry

A. Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual components' maximum allowable testing intervals.

B. The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-2 are intended to verify the integrity of tripping circuits~~,~~, including the breaker trip coil~~,~~, as well as the presence of auxiliary supply (usually a dc battery~~)~~) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-2 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

C. How do I test each dc Control Circuit path, as established for level 2 (partially monitored protection systems) monitoring of a "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1b specifies that each breaker trip coil~~,~~, auxiliary relay~~,~~, and lockout relay must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as fault clearing.

D. What does this standard require for testing an Auxiliary Tripping Relay?

Table 1 requires that the trip test must verify that the auxiliary tripping relay ~~(94)~~ (s) and/or lockout relay ~~(86) operates~~(s) operate(s) electrically and that their trip output(s) perform as expected. Auxiliary outputs not in a trip path (i.e. alarming or DME input) are not required to be checked.

E. What does a functional trip test include?

An operational trip test must be performed on each portion of a trip circuit. Each control circuit path that produces a trip signal must be verified; this includes trip coils, auxiliary tripping relays ~~(94),~~, lockout relays ~~(86)~~, and communications~~-~~-assisted-trip schemes.

A trip test may be an overall test that verifies the operation of the entire trip scheme at once, or it may be several tests of the various portions that make up the entire trip ~~scheme~~path, provided that testing of the various portions of the trip scheme verifies all of the portions, including parallel paths, and overlaps those portions.

A circuit breaker or other interrupting device needs to be trip tested at least once per trip coil~~. Breaker auxiliary contacts that are essential for the proper operation of the protective relay trip-circuit (or trip-logic) must be verified as providing the correct breaker open/close status information to the Protection System.~~.

Discrete-component auxiliary relays ~~(94)~~ and lock-out relays ~~(86)~~ must be ~~proven~~verified by trip test~~.~~. The trip test must verify that the auxiliary or lock-out relay operates electrically and that the relay's trip output(s) change(s) state. Software latches or control algorithms, including trip logic processing implemented as programming component such as a microprocessor relay that take the place of (conventional) discrete component auxiliary relays or lock-out relays do not have to be routinely trip tested.

Normally-closed auxiliary contacts from other devices (for example, switchyard-voltage-level disconnect switches, interlock switches, or pressure switches) which are in the breaker trip path do not need to be tested.

F. Is a Sudden Pressure Relay an Auxiliary Tripping Relay?

No. IEEE C37.2-2008 assigns the device number 94 to auxiliary tripping relays. Sudden pressure relays are assigned device number 63, and is excluded from the Standard by footnote 1.

G. The standard specifically mentions Auxiliary and Lock-out relays; what is an Auxiliary Tripping Relay?

An auxiliary relay~~,~~, IEEE Device Number 94, is described in IEEE Standard C37.2-2008 as "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

H. What is a Lock-out Relay?

A lock-out relay, IEEE Device Number 86, is described in IEEE Standard C37.2 as "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

I. My mechanical device does not operate electrically and does not have calibration settings~~;~~, what maintenance activities apply?

You must conduct a test(s) to verify the integrity of the trip circuit. This standard does not cover circuit breaker maintenance or transformer maintenance. The standard also does not cover testing of devices such as sudden pressure relays (63), temperature relays (49), and other relays which respond to mechanical parameters rather than electrical parameters.

5. Station dc Supply

A. What constitutes the station dc supply as mentioned in the definition of Protective System?

The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies beside the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new the maintenance activities for these station dc supplies may change over time.

B. In the Maintenance Activities for station dc supply in Table 1, what do you mean by "continuity~~"?~~?"

Because the Standard pertains to maintenance not only of the station battery~~,~~, but also the whole station dc supply, continuity checks of the station dc supply are required. "Continuity" as used in Table 1 refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal, otherwise there is no way of determining that a station battery is available to supply dc current to the station.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path the battery set will not be available for service.

C. Why is it necessary to verify the continuity of the dc supply?

In the event of the loss of the ac source or battery charger~~,~~, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity~~,~~, the battery cannot perform this function.

If the battery charger is not sized to handle the maximum dc current required to operate the protective systems, it is sized only to handle the constant dc load of the station and the charging current required to bring the battery back to full charge following a discharge. At those stations, the battery charger would not be able to trip breakers and switches if the battery experiences loss of continuity~~.~~.

At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- ◊ Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- ◊ Loss of electrical continuity of the station battery will cause, regardless of the battery ~~charger's~~charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional 1 to 2 second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed which could violate system performance standards.

D. How do you verify continuity of the dc supply?

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery unless the battery charger is taken out of service. At that time a break in the continuity of the station battery current path will be revealed because there will be no voltage on the substation dc circuitry.

Although the Standard prescribes what must be done during the maintenance activity it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery~~.~~.

- ◊ One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.

◊ A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.

◊ Manufacturers of microprocessor based battery chargers have developed methods for their equipment to periodically (or continuously) ~~tested~~test for battery continuity~~.~~. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.

No matter how the electrical continuity of a battery set is verified it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1 to insure that the station dc supply will provide the required current to the Protection System at all times.

~~**E.Why is specific gravity testing required?**~~

~~Specific gravity testing measures the state of the charge for each individual cell, and is performed to determine the condition of the charging system as well as the condition of the individual cell.~~

~~Specific gravity measurements can also be used as an indication of loss of continuity over a period of time. Specific gravity measurement is a method of determining the state of charge of a battery. Loss of continuity in the battery circuit will not allow charging current to flow through the battery and the battery cells will eventually self discharge causing the specific gravity to approach the specific gravity value of water which is 1.0.~~

~~If the specific gravity measurements taken during an inspection are determined to be low, this indicates that the battery is in a state of discharge. If no recent high discharges of the battery have occurred and the float voltage is normal, then the continuity of the battery circuit can be suspected and other tests such as measuring battery current should be made to determine if the specific gravity readings are an indication of loss of battery continuity.~~

~~F.~~E. When should I check the station batteries to see if they have sufficient energy to perform as designed?

The answer to this question depends on the type of battery (valve regulated lead-acid, vented lead acid, or nickel-cadmium~~),~~), the maintenance activity chosen, and the type of time based monitoring level selected.

For example, if you have a Valve Regulated Lead-Acid (VRLA~~)~~) station battery~~,~~, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than every three months.

If, for a VRLA station battery~~,~~, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every 3 calendar years.

~~G.~~F. Why in Table 1 are there two Maintenance Activities with different Maximum Maintenance Intervals listed to verify that the station battery can perform as designed?

The two acceptable methods for proving that a station battery can perform as designed are based on two different philosophies. The first activity requires a ~~capacitive~~capacity discharge test of the entire battery set to ~~prove~~verify that degradation of one or several components (cells) in the set has not deteriorated to a point where the total capacity of the battery system falls below its designed rating. The second maintenance activity requires tests and evaluation of the internal ohmic measurements on each of the individual cells/units of the battery set to determine that each component can perform as designed and therefore the entire battery set can be ~~proven~~verified to perform as designed.

The maximum maintenance interval for discharge capacity testing is longer than the interval for testing and evaluation of internal ohmic cell measurements. An individual component of a battery set may degrade to an unacceptable level without causing the total battery set to fall below its designed rating under capacity testing. However, since the philosophy behind internal ohmic measurement evaluation is based on the fact that each battery component must be ~~proven~~verified to be able to perform as designed, the interval for verification by this maintenance activity must be shorter to catch individual cell/unit degradation.

~~H.~~G. What is the justification for having two different Maintenance Activities listed in Table 1 to verify that the station battery can perform as designed?

IEEE Standards 450, 1188, and 1106 for vented lead-acid~~,~~, valve-regulated lead-acid (VRLA~~),~~), and nickel-cadmium batteries~~,~~, respectively (which together are the most commonly used substation batteries on the BES) go into great detail about capacity testing of the entire battery set to determine that a battery can perform as designed.

The first maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for capacity testing that were designed to align with the IEEE battery standards. This maintenance activity is applicable for vented lead-acid~~,~~, valve-regulated lead-acid~~,~~, and nickel-cadmium batteries~~.~~.

The second maintenance activity listed in Table 1 for verifying that a station battery can perform as designed uses maximum maintenance intervals for evaluating internal ohmic measurements in relation to their baseline measurements that are based on industry experience, EPRI technical reports and application guides, and the IEEE battery standards. By evaluating the internal ohmic measurements for each cell and comparing that measurement to the cell's baseline ohmic measurement (taken at the time of the battery set's acceptance capacity test), low-capacity cells can be identified and eliminated to keep the battery set capable of performing as designed. This maintenance activity is applicable only for vented lead-acid and VRLA batteries~~.~~.

~~I.~~H. Why in Table 1 of PRC-005-2 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The three IEEE standards (1188, 450, and 1106) for VRLA~~,~~, vented lead-acid~~,~~, and nickel-cadmium batteries all recommend that as part of any battery inspection the battery rack should be inspected. The purpose of this inspection is to ~~prove~~verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity. Because the battery rack is specifically designed for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

I. What is required to comply with the "Unintentional Grounds" requirement?

In most cases, the first ground that appears on a battery pole is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional DC ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on unintentional DC grounds. The standard merely requires that a check be made for the existence of Unintentional DC Grounds. Obviously a "check-off" of some sort will have to be devised to demonstrate that a check is routinely done for Unintentional DC Grounds.

J. Where the standard refers to "all cells" is it sufficient to have a documentation method that refers to "all cells" or do we need to have separate documentation for every cell? For example to I need 60 individual documented check-offs for good electrolyte level or would a single check-off per bank be sufficient??

A single check-off per battery bank is sufficient.

K. Does this standard refer to Station batteries or all batteries, for example Communication Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communication sites. The batteries covered under PRC-005-2 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System.

6. Protection System Communications Equipment

A. What are some examples of mechanisms to check communications equipment functioning?

For Level 1 unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every three months during a substation visit. Some examples are:

- ◊ On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier checkback test from one terminal.
- ◊ Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing a loss-of-guard indication or alarm~~.~~. For frequency-shift power line power-line carrier systems, the guard signal level meter can also be checked.
- ◊ Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- ◊ Digital communications systems have some sort of data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For Level 2 partially monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel~~,~~, and activating alarms that can be monitored remotely. Some examples are:

- ◊ On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier checkback tests, with remote alarming of failures.

- ◊ Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- ◊ Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- ◊ Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.

For Level 3 fully monitored Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays~~.~~.

- ◊ In many communications systems signal quality measurements including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- ◊ Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

B. What is needed for the 3-month inspection of communication-assisted trip scheme equipment?

The 3-month inspection applies to Level 1 (Unmonitored) equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms, check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (ie FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard.

C. Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communication system?

This equipment is presently classified as being part of the Protection System Control Circuitry and tested per the portions of Table 1 applicable to Protection System Control Circuitry rather than those portions of the table applicable to communication equipment.

D. In Table 1b~~,~~, the Maintenance Activities section of the Protective System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria". What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally an alarm will be indicated. For Level 1 systems this alarm will probably be on the panel. For Level 2 and Level 3 systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each protective system communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm~~.~~. Following are some examples of protective system communications channel performance criteria:

- ◊ For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm~~.~~.
- ◊ An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use checkback testing to determine channel performance~~.~~. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- ◊ Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- ◊ Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm~~.~~.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be - it just requires that the entity establish nominal criteria so protective system channel monitoring can be performed.

7. UVLS and UFLS Relays that Comprise a Protection System Distributed Over the Power System

A. We have an Under Voltage Load Shedding (UVLS~~)~~) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation as stated indicates that the tripping action was intended to prevent low distribution voltage for a transmission system that was intact except for the line that was out of service.

This Standard is not applicable to this UVLS~~.~~.

~~UVLS installed to prevent system voltage collapse or voltage instability for BES reliability is covered by this standard.~~

B. We have a UFLS scheme that sheds the necessary load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant as opposed to a single failure to trip of, for example, a Transmission Protection System Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

C. What does "distributed over the power system" mean?

This refers to the common practice of applying UFLS on the distribution system, with each UFLS individually tripping a relatively low value of load. Therefore, the program is implemented via a large number of individual UFLS components performing independently, and the failure of any individual component to perform properly will have a minimal impact on the effectiveness of the overall UFLS program. Some UVLS systems are applied similarly.

8. SPS or Relay Sensing for Centralized UFLS or UVLS

A. Do I have to perform a full end-to-end test of a Special Protection System?

No. All portions of the SPS need to be maintained, and the portions must overlap, but the overall SPS does not need to have a single end-to-end test.

B. What about SPS interfaces between different entities or owners?

All SPS owners should have maintenance agreements that state which owner will perform specific tasks. SPS segments can be tested individually, but must overlap.

C. What do I have to do if I am using a phasor measurement unit (PMU~~)~~) as part of a Protection System or Special Protection System?

Any Phasor Measurement Unit (PMU~~)~~) function whose output is used in a protection system or Special Protection System (as opposed to a monitoring task) must be verified as a component in a Protection System.

D. How do I maintain a Special Protection System or Relay Sensing for Centralized UFLS or UVLS Systems?

Components of the SPS~~,~~, UFLS~~,~~, or UVLS should be maintained like similar components used for other Protection System functions.

The output action verification may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the SPS~~,~~, UFLS~~,~~, or UVLS components whose operation leads to that control action must each be verified.

E. What does "centralized" mean?

This refers to the practice of applying sensing units at many locations over the system, with all these components providing intelligence to an analytical system which then directs action to address a detected condition. In some cases, this action may not take place at the same location as the sensing units. This approach is often applied for complex SPS, and may be used for UVLS where necessary to address the conditions of concern.

III Group by Type of BES Facility:

1. All BES Facilities

A. What, exactly, is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms Used in Reliability Standards, and is not being modified within this draft Standard.

NERC's approved definition of Bulk Electric System is:

> As defined by the Regional Reliability Organization, the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher. Radial transmission facilities serving only load with one transmission source are generally not included in this definition.

Each Regional Entity implements a definition of the Bulk Electric System that is based on this NERC definition, in some cases, supplemented by additional criteria. These regional definitions have been documented and provided to FERC as part of a ~~*June 16, 2007 Informational Filing*~~*June 16, 2007 Informational Filing*.

2. Generation

A. Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, and generator connected station auxiliary transformer to meet the requirements of this Maintenance Standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay may include but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays

- Stator-ground relays
- Communications-based protection systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays
- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step up or generator-connected station auxiliary transformers, operation of any the following associated protective relays frequently would result in a trip of the generating unit and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

A loss of a system-connected station auxiliary transformer could result in a loss of the generating plant if the plant was being provided with auxiliary power from that source~~.~~, and this auxiliary transformer may directly affect the ability to start up the plant and to connect the plant to the system. Thus, operation of any of the following relays associated with system-connected station auxiliary transformers would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program even if the loss of the those loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program even if a trip of these devices might eventually result in a trip of the generating unit.

3. Transmission

A. Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-2 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

IV Group by Type of Maintenance Program:

1. All Protection System Maintenance Programs

A. I can't figure out how to demonstrate compliance with the requirements for level 3 (fully monitored~~)~~) Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for level 3 (fully monitored~~)~~) Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This Standard does not presume to specify what documentation must be developed; only that it must be comprehensive.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c~~.~~. However, even if there is no equipment available today that can meet this level of monitoring, the Standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

B. What forms of evidence are acceptable?

Acceptable forms of evidence~~,~~, as relevant for the Requirement being documented, include but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database screen shots that demonstrate compliance information
- Diagrams, engineering prints, schematics, maintenance and testing records, etc.
- Logs (operator, substation, and other types of log)
- Inspection forms
- U.S. or Canadian mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Database lists and records
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known and accounted for.

C. If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

The replacement component must be tested to a degree that assures that it will perform as intended. If it is desired to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

D. Please use a specific example to demonstrate the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld. For example: "Company A" has a maintenance plan that requires its electro-mechanical protective relays be tested, for routine scheduled tests, every 3 calendar years with a maximum allowed grace period of an additional 18 months. This entity would be required to maintain its records of maintenance of its last two routine scheduled tests. Thus its test records would have a latest routine test as well as its previous routine test. The interval between tests is therefore provable to an auditor as being within "Company A's" stated maximum time interval of 4.5 years.

The intent is not to have three test results proving two time intervals, but rather have two test results proving the last interval. The drafting team contends that this minimizes storage requirements while still having minimum data available to demonstrate compliance with time intervals.

If an entity prefers to utilize Performance Based Maintenance then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

2. Time-Based Protection System Maintenance (TBM~~)~~) Programs

A. What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

~~Commissioning tests are regarded as a construction activity, not a maintenance activity.~~

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the maintenance activities specified on Table 1a of PRC-005-2, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-2 assumes that thorough commission testing was performed prior to a protection system being placed in service. PRC-005-2 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content and therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

An entity would be wise to retain commissioning records to show a maintenance start date. (See next FAQ).

B. How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a facility and its associated Protection System were placed in service. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the maintenance program should clearly identify when maintenance is first due.

~~B.~~C. **The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?**

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals.

~~C.~~D. **If I am unable to complete the maintenance as required due to a major natural disaster (hurricane, earthquake, etc), how will this affect my compliance with this standard.**

The NERC Sanction Guidelines provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.[1]

~~D.~~E. **What if my observed testing results show a high incidence of out-of-tolerance relays, or, even worse, I am experiencing numerous relay misoperations due to the relays being out-of-tolerance?**

Any entity can choose to test some or all of their Protection System more frequently (or, to express it differently, exceed the minimum requirements of the Standard). Particularly, if you find that the maximum intervals in the Standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently.

F. **We believe that the 3-month interval between inspections is unneccessary, why can we not perform these inspections twice per year?**

The standard drafting team believes that routine monthly inspections are the norm. To align routine station inspections with other important inspections the 3-month interval was chosen. In lieu of station visits many activities can be accomplished with automated monitoring and alarming.

G. **Our maintenance plan calls for us to perform routine protective relay tests every 3 years; if we are unable to achieve this schedule but we are able to complete the procedures in less than the Maximum Time Interval then are we in or out of compliance?**

You are out of compliance. You must maintain your equipment to your stated intervals within your maintenance plan. The protective relays (and any Protection System component) cannot be tested at intervals that are longer than the maximum allowable interval stated in the Tables. Therefore you should design your maintenance plan such that it is not in conflict with the

1 Sanction Guidelines of the North American Electric Reliability Corporation. Effective January 15, 2008.

Minimum Activities and the Maximum Intervals. You then must maintain your equipment according to your maintenance plan.

3. Performance-Based Protection System Maintenance (PBM)) Programs

A. I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for performance-based maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

B. Can an owner go straight to a performance-based maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a performance-based maintenance program immediately. The owner will need to comply with the requirements of a performance-based maintenance program as listed in the standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they can not prove that they have collected the data as required for a performance-based maintenance program then they will need to wait until they can prove compliance.

C. When establishing a ~~perfomance~~performance-based maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my performance-based intervals?

No. You must use actual in-service test data for the components in the segment.

D. What types of misoperations or events are not considered countable events in the performance-based Protection System Maintenance (PBM)) Program?

Countable events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned.

Human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered countable events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation.

Certain types of Protection System component errors that cause Misoperations are not considered countable events~~.~~. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

E. What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a performance-based maintenance system. Some examples are listed below.

- The maximum allowable interval~~,~~, as established by the performance-based maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment~~.~~.
- Identifiable sub-groups of components within the established segment~~,~~, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a performance-based maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- Components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

F. If I find (and correct) a maintenance-correctable issue as a result of a misoperation investigation (Re: PRC-004), how does this affect my performance-based maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required misoperation investigation/corrective action), the actions performed count as a maintenance activity, and "reset the clock" on everything you've done. In a performance-based maintenance program, you also need to record the maintenance-correctable issue with the relevant component group and use it in the analysis to determine your correct performance-based maintenance interval for that component group.

G. Why are batteries excluded from PBM~~?~~? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery~~.~~, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a ~~Performance~~performance-based Protection System Maintenance (PBM~~)~~) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria.

Similarly Functional Entities that want to establish a condition-based maintenance program using Level 3 monitoring of the battery used in a station dc supply can not do so. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries~~.~~. However, Level 3 monitoring of a battery can eliminate the requirement for periodic testing and some inspections (see Level 3 Monitoring Attributes for Component of table 1c).

H. Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60.

They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30.

- For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested.

After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate.

- This entity is now allowed to extend the maintenance interval if they choose.

The entity chooses to extend the maintenance interval of this population segment out to 10 years.

- This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year.
- After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures.
- This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

- After a year they again find 6 failures out of the 125 units tested. 6/125= 5% failures.

In response to the 5% failure rate, the entity decreases the testing interval to 7 years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected.

- After a year they again find 6 failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried 5 years and they were under the 4% limit and they tried 7 years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to 5 years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to 6 years. This means that they will now test 167 units per year (1000/6).

- After a year they again find 6 failures out of the 167 units tested. 6/167= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 6 years or less. Entity chose 6 year interval and effectively extended their TBM (5 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; this is there to prevent an entity from "gaming the system". An entity might arbitrarily extend time intervals from 6 years to 20 years. In the event that an entity finds a failure rate greater than 4% then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

V Group by Monitoring Level:

1. All Monitoring Levels

A. Please provide an example of the level 1 monitored (unmonitored) versus other levels of monitoring available?

A level 1 (Unmonitored) Protection System has no monitoring and alarm circuits on the Protection System components.

A level 2 (Partially) monitored Protection System or an individual component of a level 2 (Partially) monitored Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert a 24-hr staffed operations center.

There can be a combination of monitored and unmonitored Protection Systems within any given substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of level 2 (Partially) monitored and level 1 (unmonitored) components within a given Protection System is:

◊ A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
◊ Instrumentation transformers, with no monitoring, connected as inputs to that relay. (level 1)
◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
◊ A circuit breaker with a trip coil, with no monitor circuit. (level 1)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum test intervals of:

- ◊ The microprocessor relay is verified every 12 calendar years.
- ◊ The instrumentation transformers are verified every 12 calendar years.
- ◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
- ◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #2: A combination of level 2 (partially) monitored and level 1 (unmonitored~~)~~) components within a given Protection System is:

- ◊ A microprocessor relay with integral alarm that is not connected to SCADA. (level 1)
- ◊ Instrument transformers, with no monitoring, connected as inputs to that relay. (level 1)
- ◊ A vented lead-acid battery with low voltage alarm connected to SCADA. (level 2)
- ◊ A circuit breaker with a trip coil~~,~~, with no circuits monitored. (level 1)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components have maximum test intervals of:

- ◊ The microprocessor relay is verified every 6 calendar years.
- ◊ The instrumentation transformers are verified every 12 calendar years.
- ◊ The battery is verified every 6 calendar years by performing a performance capacity test of the entire battery bank or by evaluating the measured cell/unit internal ohmic values to station battery baseline every 18 months.
- ◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

Example #3: A combination of level 2 (partially) monitored and level 1 (unmonitored~~)~~) components within a given Protection System is:

- ◊ A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center. (level 2)
- ◊ Instrument transformers, with no monitoring, connected as inputs to that relay (level 1)
- ◊ Battery without any alarms connected to SCADA (level 1)
- ◊ Circuit breaker with a trip coil~~,~~, with no circuits monitored (level 1)

Given the particular components, conditions, and using the Table 1 ("Maximum Allowable Testing Intervals and Maintenance Activities"), the particular components shall have maximum test intervals of:

- ◊ The microprocessor relay is verified every 12 calendar years.
- ◊ The instrument transformers are verified every 12 calendar years.
- ◊ The battery is verified every 3 months, every 18 months, plus, depending upon the type of battery used it may be verified at other maximum test intervals, as well.
- ◊ The circuit breaker trip circuits and auxiliary relays are tested every 6 calendar years.

B. What is the intent behind the different levels of monitoring?

The intent behind different levels of monitoring is to allow less frequent manual intervention when more information is known about the condition of Protection System components.

C. Do all monitoring levels apply to all components in a protection system?

No. For some components in a protection system, certain levels of monitoring will not be relevant. See table below:

D. My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based system?

Yes, provided the station attendant monitors the alarms and other indications and reports them within the given time limits that are stated in the criteria of the Table 1b or Table 1c.

Monitoring Level Applicability Table

(See related definition and decision tree for various level requirements)

Protection Component	Level 1 (Unmonitored)	Level 2 (Partially Monitored)	Level 3 (Fully Monitored)
Protective relays	Y	Y	Y
Instrument transformer Inputs to Protective Relays	Y	N	Y
Protection System control circuitry (Other than aux-relays & lock-out relays)	Y	Y	Y
Aux-relays & lock-out relays	Y	N	N
DC supply (other than station batteries~~)~~)	Y	Y	Y
Station batteries	Y	N	N
Protection system communications equipment and channels	Y	Y	Y
UVLS and UFLS relays that comprise a protection scheme distributed over the power system	Y	Y	Y
SPS~~,~~, including verification of end-to-end performance, or relay sensing for centralized UFLS or UVLS systems	Y	Y	Y

Y = Monitoring Level Applies
N = Monitoring Level Not Applicable

~~D.~~E. **When documenting the basis for inclusion of components into the appropriate levels of monitoring as per Requirement R2 of the standard, is it necessary to provide this documentation via a device by device listing of components and the specific monitoring attributes of each device?**

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc systems are Level 2 - Partially Monitored by stating the following within the program description:

> "All substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device level list of exclusions. Example:

> "Except as noted below, all substation dc systems are considered Level 2 - Partially Monitored and subject to Table 1b requirements as all substation dc systems are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc systems of Substation X, Substation Y, and Substation Z are considered Level 1 - Unmonitored and subject to Table 1a requirements as they are not equipped with ground detection capability."

Regardless whether this documentation is provided via a device by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure but should be retrievable if requested by an auditor.

~~E.~~F. How do I know what monitoring level I am under? – Include Decision Trees

Decision Trees are provided below for each of the following categories of equipment to assist in the determination of the level of monitoring.

- ◊ Protective Relays
- ◊ Current and Voltage Sensing Devices
- ◊ Protection System Control Circuitry
- ◊ Station dc Supply
- ◊ Protection System ~~Communications Equipment and Channels~~Communication Systems

2. **Level 1 Monitored Protection Systems (Unmonitored Protection Systems)**

   A. **We have an electromechanical (unmonitored~~)~~) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?**

   This system is made up of components that are level 1 (unmonitored~~).~~). Assuming a time-based protection system maintenance program schedule, each component must be maintained per Table 1a – Level 1 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities.

3. **Level 2 Monitored Protection Systems (Partially Monitored Protection Systems)**

   A. **We have a 30 year old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil~~.~~. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Is this an unmonitored or a partially-monitored system? How often must I perform maintenance?**

   The protective relay is a level 2 (partially) monitored component of your protection system and can be maintained every 12 years or when a maintenance correctable issue arises. Assuming a time-based protection system maintenance program schedule, this component must be maintained per Table 1b – Level 2 Monitoring Maximum Allowable Testing Intervals and Maintenance Activities

   The rest of your protection system contains components that are level 1 (unmonitored~~)~~) and must be maintained within at least the maximum verification intervals of Table 1a~~.~~.

   B. **How do I verify the A/D converters of microprocessor~~-~~-based relays?**

   There are a variety of ways to do this. Examples include using values gathered via data communications and automatically comparing these values with values from other sources, and using groupings of other measurements (such as vector summation of bus feeder currents) for comparison if calibration requirements assure acceptable measurement of power system input values. Other methods are possible.

   C. **For a level 2 monitored Protection System (Partially Monitored Protection System) pertaining to Protection System communications equipment and channels, how is the performance criteria involved in the maintenance program?**

   The entity determines the performance criteria for each installation, depending on the technology implemented. If the communication channel performance of a Protection System varies from the pre-determined performance criteria for that system, these results should be investigated and resolved.

D. My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1b requirements for inclusion as Level 2?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the maintenance-correctable issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

4. Level 3 Monitored Protection Systems (Fully Monitored Protection Systems)

A. Why are there activities defined for a level-3 monitored Protection System? The technology does not seem to exist at this time to implement this monitoring level.

There may actually be some equipment available that is capable of meeting level-3 monitoring criteria, in which case it may be maintained according to Table 1c~~.~~

. However, even if there is no equipment available today that can meet this level of monitoring~~,~~; the Standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the Standard technology-neutral. The standard drafting team wants to avoid the need to revise the Standard in a few years to accommodate technology advances that are certainly coming to the industry.

PRC-005-2

Protection System Maintenance

Draft Supplementary Reference

May 27, 2010

Prepared by the

Protection System Maintenance and Testing Standard Drafting Team

PRC-005-2

Project 2007-17

Table of Contents

This supplementary reference to PRC-005-2 borrows heavily from the technical reference by the System Protection and Control Task Force (SPCTF) (Protection System Maintenance Technical Reference paper approved by the Planning Committee in September 2007). Additionally, the Protection System Maintenance and Testing Standard Drafting Team (PSMTSDT) for PRC-005-2 (Project 2007-17) utilized maintenance program data from various generation and transmission utilities across the NERC boundaries; as well as data from IEEE and EPRI.

1. Introduction and Summary

NERC currently has four reliability standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of Protection and Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. This revision of PRC-005-1 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults or system problems, the protection systems may not operate for extended periods. A Misoperation - a false operation of a protection system or a failure of the protection system to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. A maintenance or testing program is used to determine the performance and availability of protection systems.

Typically, utilities have tested protection systems at fixed time intervals, unless they had some incidental evidence that a particular protection system was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring relays, and correctness of settings. Typically, a protection system must be visited at its installation site and removed from service for this testing.

Fundamentally, a reliability standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005-1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

Definition of *Protection System* (excerpted from the NERC Standards Glossary of Terms):

Protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Proposed Modification to NERC Glossary Definition

The Protection Systems Maintenance and Testing Standard Drafting Team (PSM SDT), proposes changes to the NERC glossary definition of *Protection Systems* as follows:

Protection System (modification) - Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing devices inputs to protective relays and associated circuitry from the voltage and current sensing devices, station DC supply, and control circuitry, associated with protective functions from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:
"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:
"*… and that are applied on, or are designed to provide protection for the BES.*"

The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional definitions of the BES.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those relays that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

3. Relay Product Generations

The likelihood of failure and the ability to observe the operational state of a critical protection system, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the protection system must be monitored, or else verified periodically.
- Ability to capture fault records showing how the protection system responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of protection system monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the protection system outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior protection system generations.

4. Definitions

Protection System Maintenance Program (PSMP) – An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program for a specific component includes one or more of the following activities:

An ongoing program by which Protection System components are kept in working order and where malfunction components are restored to working order

Verification – A means of determining that the component is functioning correctly.

- **Monitoring** – Observation of the routine in-service operation of the component.
- **Testing** – Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- **Inspection** – To detect visible signs of component failure, reduced performance and degradation.
- **Calibration** – Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.
- **Upkeep** – Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer’s hardware and software service advisories which are relevant to the application of the device.

- **Restoration** – The actions to restore proper operation of malfunctioning components.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which protection systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on protection system components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire protection system tripping chain is able to operate the breaker.

Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the protection system has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components.

- PBM – performance-based maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

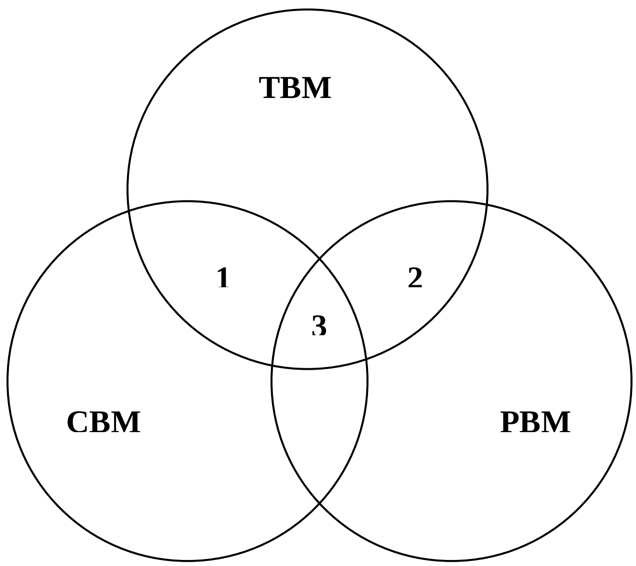
- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics.

  Microprocessor based protective relays that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include the ac signal inputs, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals. For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM. This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

5.1 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the protection system, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relay self monitoring, for example), the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor protection system elements. These relays and IEDs generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in relay logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillograph records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the relay front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the protection system.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some relays will show health problems by incorrect relaying before being caught in the next test round. The frequent or continuous

nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

7. Time-Based versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained device is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification (as specified in the header and the “Monitoring Attributes” column of Tables 1b and 1c of PRC-005-2), meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system elements as contained in Table 1a.

The result is that:

This NERC standards permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within maximum time intervals specified in Tables 1a, 1b and 1c of PRC-005-2.

8. Maximum Allowable Verification Intervals

The Maximum Allowable Testing Intervals and Maintenance Activities requirements show how CBM with newer relay types can reduce the need for many of the tests and site visits that older protection systems require. As explained below, there are some sections of the protection system that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total protection system functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1 Table of Maximum Allowable Verification Intervals

Table 1, in the standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows a typical Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures.

While it is easy to associate protective relays to the three levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables (Tables 1a, 1b and 1c collectively *Tables*) from PRC-005-2:

- First check the table header description to verify that your equipment meets the monitoring requirements. If your equipment does not meet the monitoring requirements of Table 1c then check Table 1b. If your equipment does not meet the requirements of Table 1b then use Table 1a.
- If you find a piece of equipment that meets the monitoring requirements of Table 1b or 1c then you can take advantage of the extended time intervals allowed by Table 1b and 1c. Your maintenance plan must document that this component can be maintained by the requirements of Table 1b or 1c because it has the necessary attributes required within that Table.
- Once you determine which table applies to your equipment's monitoring requirements then check the Maintenance Activity that is required for that particular component. This Maintenance Activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more then you must document more.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must document those activities more often.
- Any given set of Protection System equipment can be maintained with any combination of Tables 1a, 1b and 1c. An entity does not have to stick to Table 1a just because some of its equipment is un-monitored.
- An entity does not have to utilize the extended time intervals in Tables 1b or 1c. An easy choice to make is to simply utilize Table 1a. While the maintenance activities resulting from choosing to use only Table 1a would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for unmonitored, partially monitored and fully monitored protection systems:

Table 1 Maximum Allowable Testing Intervals and Maintenance Activities

Level 1 Monitoring (Unmonitored) Table 1a

This table applies to electromechanical, analog solid state and other un-monitored Protection Systems components. This table represents the starting point for all required maintenance activities. The object of this group of requirements is to have specific activities accomplished at maximum set time intervals. From this group of activities it follows that CBM or PBM can increase the time intervals between the hands-on maintenance actions.

Level 2 Monitoring (Partially Monitored) Table 1b

This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location (at least daily) where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process – the monitoring and alarming functions must be shown to work.

Level 3 Monitoring (Fully Monitored) Table 1c

This table applies to microprocessor relays and other associated Protection System components in which every element or function required for correct operation of the Protection System component is monitored continuously and verified, including verification of the means by which failure alarms or indicators are transmitted to a location within 1 hour or less of the maintenance-correctable issue occurring. This is the highest level of monitoring and if it is available then this gives an entity the ability to have continuous testing of their (Level 3 Monitored) Protection System Component and thus does not have to manually intervene to accomplish routine testing chores. Level 3 Fully Monitored yields continuous monitoring advantages but has substantial technical hurdles that must be overcome; namely that monitoring also verifies the failure of the monitoring and alarming equipment. Without this important ingredient a device that is thought to be continuously monitored could be in an alarm state without the asset owner being aware of this alarm state.

Additional Notes for Table 1a, Table 1b, and Table 1c

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.
2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs must be verified within the Table intervals.
3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.
4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System elements physical inspection of station batteries for

signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program.

6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to verify).

7. Verify the protection system tripping function by performing an operational trip test on all components contained in the trip circuit. This includes circuit breaker or circuit switcher trip coils, auxiliary tripping relays (94), lock-out relays (86), and communications-assisted trip scheme elements. Each control circuit path that carries trip signal must be verified, although each path must be checked only once. A maintenance program may include performing an overall test for the entire system at one time, or several split system tests with overlapping trip verification. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test.

8. "End-to-end test" as used in this supplementary reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

9. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

10. Notes 1-9 attempt to describe the testing activities they do not represent the only methods to achieve these activities but rather some possible methods.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system will typically be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits.

8.3 Basis for Table 1 Intervals

SPCTF authors collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the header of Table 1b. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for partial monitoring as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

PSMT SDT further notes that the SPCTF also allowed 25% extensions to the “maximum time intervals”. With a 5 year time interval established between manual maintenance activities and a 25% time extension then this equates to a 6.25 year maximum time interval. It is the belief of the PSMT SDT that the SPCTF understood that 6.25 years was thereby an adequate maximum time interval between manual maintenance activities. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. A 10 year interval with a 25% allowed extension equates to a maximum allowed interval of 12.5 years between manual maintenance activities. The Standard does not allow extensions on any component of the protection system; thus the maximum allowed interval for these devices has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table’s use of the term “Calendar” in the column for “Maximum Maintenance Interval”. The PSMT SDT deemed it necessary to include the term “Calendar” to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term “Calendar” to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Section 9 describes a performance-based maintenance process which can be used to justify maintenance intervals other than those described in Table 1.

Section 10 describes sections of the protection system, and overlapping considerations for full verification of the protection system by segments. Segments refer to pieces of the protection system, which can range from a single device to a panel to an entire substation.

Section 11 describes how relay operating records can serve as a basis for verification, reducing the frequency of manual testing.

Section 13 describes how a cooperative effort of relay manufacturers and protection system users can improve the coverage of self-monitoring functions, leading to full monitoring of the bulk of the protection system, and eventual elimination of manual verification or testing.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of like devices from the same manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment.

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)
z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended:

Minimum Population Size to use Performance-based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for Level 1 monitoring, (Table 1a). Time intervals can be lengthened provided the last year's worth of devices tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a mis-operation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested-devices (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to up to 20 years without proper statistical data.

10. Overlapping the Verification of Sections of the Protection System

Table 1 requires that every protection system element be periodically verified. One approach is to test the entire protection scheme as a unit, from voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Unmonitored, Partially Monitored, or Fully Monitored Tables;
- Full monitoring as described in header of Table 1c;
- A performance-based maintenance program as described in Section 9;
- Opportunistic verification using analysis of fault records as described in Section 11

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent Misoperation, as NERC standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity in the record and the associated wiring paths are verified. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.

If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored or partially monitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of full monitoring, the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document full monitoring for some or all sections by:

- Presenting or referencing the product manufacturer’s documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored elements according to the requirements of Table 1.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator’s decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-02 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type devices may not be needed.

15.1 Protective Relays

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, the relays should meet the asset owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.2 Voltage & Current Sensing Devices

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these devices. The important thing about these signals is to know that the expected output from these devices actually reaches the protective relay. Therefore, the proof of the proper operation of these devices also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's protection system maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.

- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Other methods that provide documentation that the expected transformer values as applied to the inputs to the protective relays are acceptable.

15.3 DC Control Circuitry

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be extended to twelve years, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment and not just all equipment.
It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault.

Distribution circuit breakers that participate in the UFLS scheme are excluded from the trip-testing requirements. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distribution breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) in any given trip scheme. These electro-mechanical devices must be trip tested. The PSMT SDT considers these devices to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks.

When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.
New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.4 Batteries and DC Supplies

IEEE guidelines were consulted to arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The present NERC definition of a Protection System is "*protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry*." The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1 of the standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

Batteries cannot be a unique population segment of a Performance-based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems.

15.5 Tele-protection equipment

This is also known as associated telecommunications equipment. The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this standard is applied to equipment used to convey both trip signals and block signals.

It was the intent of this standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping occurs locally when the remote action has been asserted.

Evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates is needed.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.6 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other standards that could, at times fulfill evidence requirements of this standard.

For example: maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

Another example might be:
Some entities maintain records of all interruptions. These records can be concurrently utilized, if the entity desires, as DC Trip Path verifications.

Analysis of Event Recordings can provide details that can eliminate some hands-on maintenance activities; however, merely printing out the event report provides limited benefit of verification of specific maintenance items.
Standardized-forms, hard or soft copy, can be created, filled out and archived. These forms can be of the entities’ design and can be aimed at answering the specific requirements of the Standard as well as additional requirements as needed by the entity.
Fill-in blanks, check-boxes, drop-down lists, auto-date formats, etc. can all be used as the primary action is the maintenance activity; the secondary action is to verify that the maintenance activity was performed.
Other evidence of compliance might be, but is not limited to:

Prints, maintenance plans, training materials, policies, procedures, data print-outs or exhibits, correspondence, reports, data-base records, etc.
There is the legacy method of paper trail for everything, this is acceptable. There are also paperless systems existing and evolving that are also acceptable.
Proof of compliance should simply be the entities' records of maintenance completed.

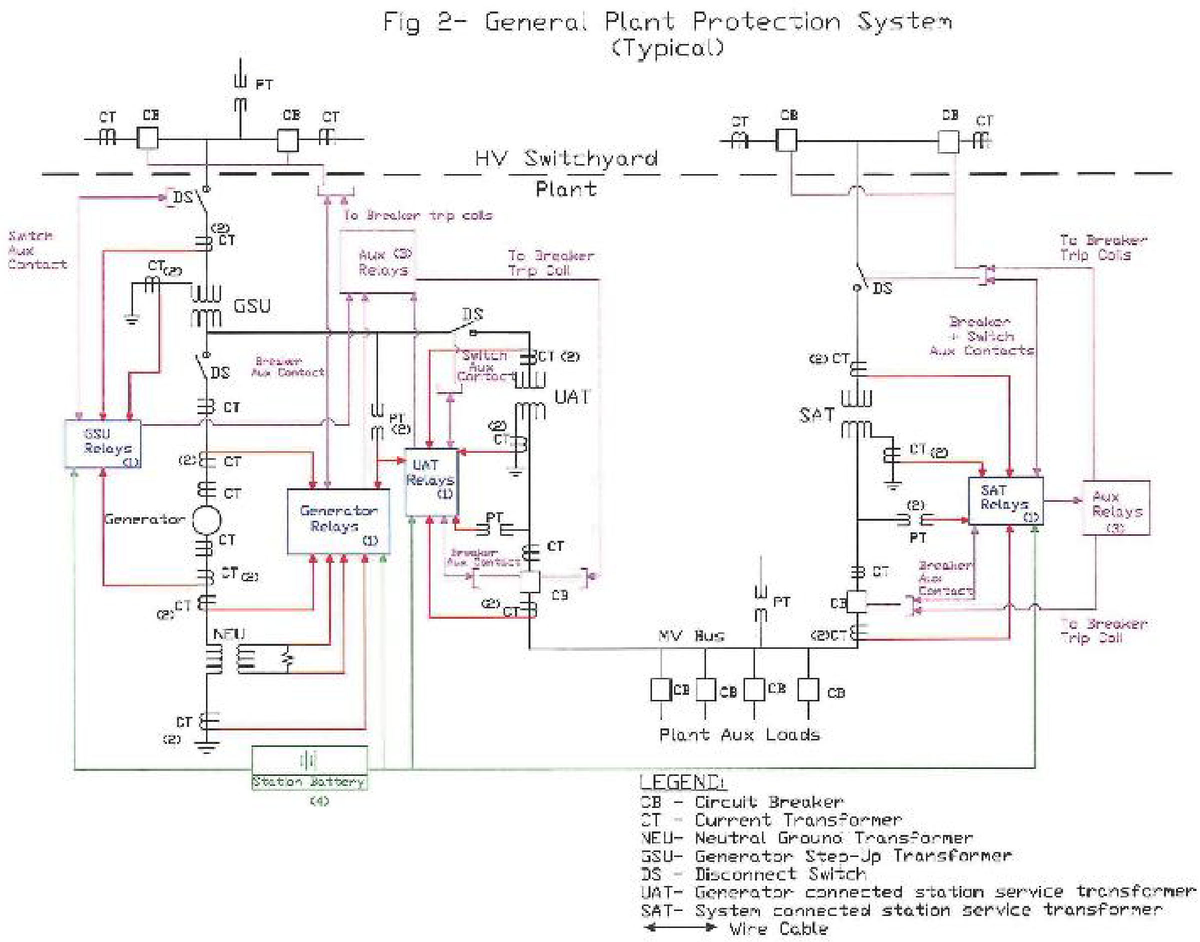
Figure 2: Typical Generation System



For information on numbered components, see ***[Figure 1 & 2 Legend – Components of Protection Systems]***

([Return])

Figure 1 & 2 Legend – Components of Protection Systems

Number In Figure	Component of Protection System	Includes	Excludes
1	Protective relays	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage & Current Sensing Devices and associated circuitry	The signals from the voltage & current sensing devices for protective relays as well as the wiring (or other medium) used to convey signal output from the sensor to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	DC Circuitry	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Associated communications systems	Tele-protection equipment used to convey remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable).	Any communications equipment that is not used for remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable).

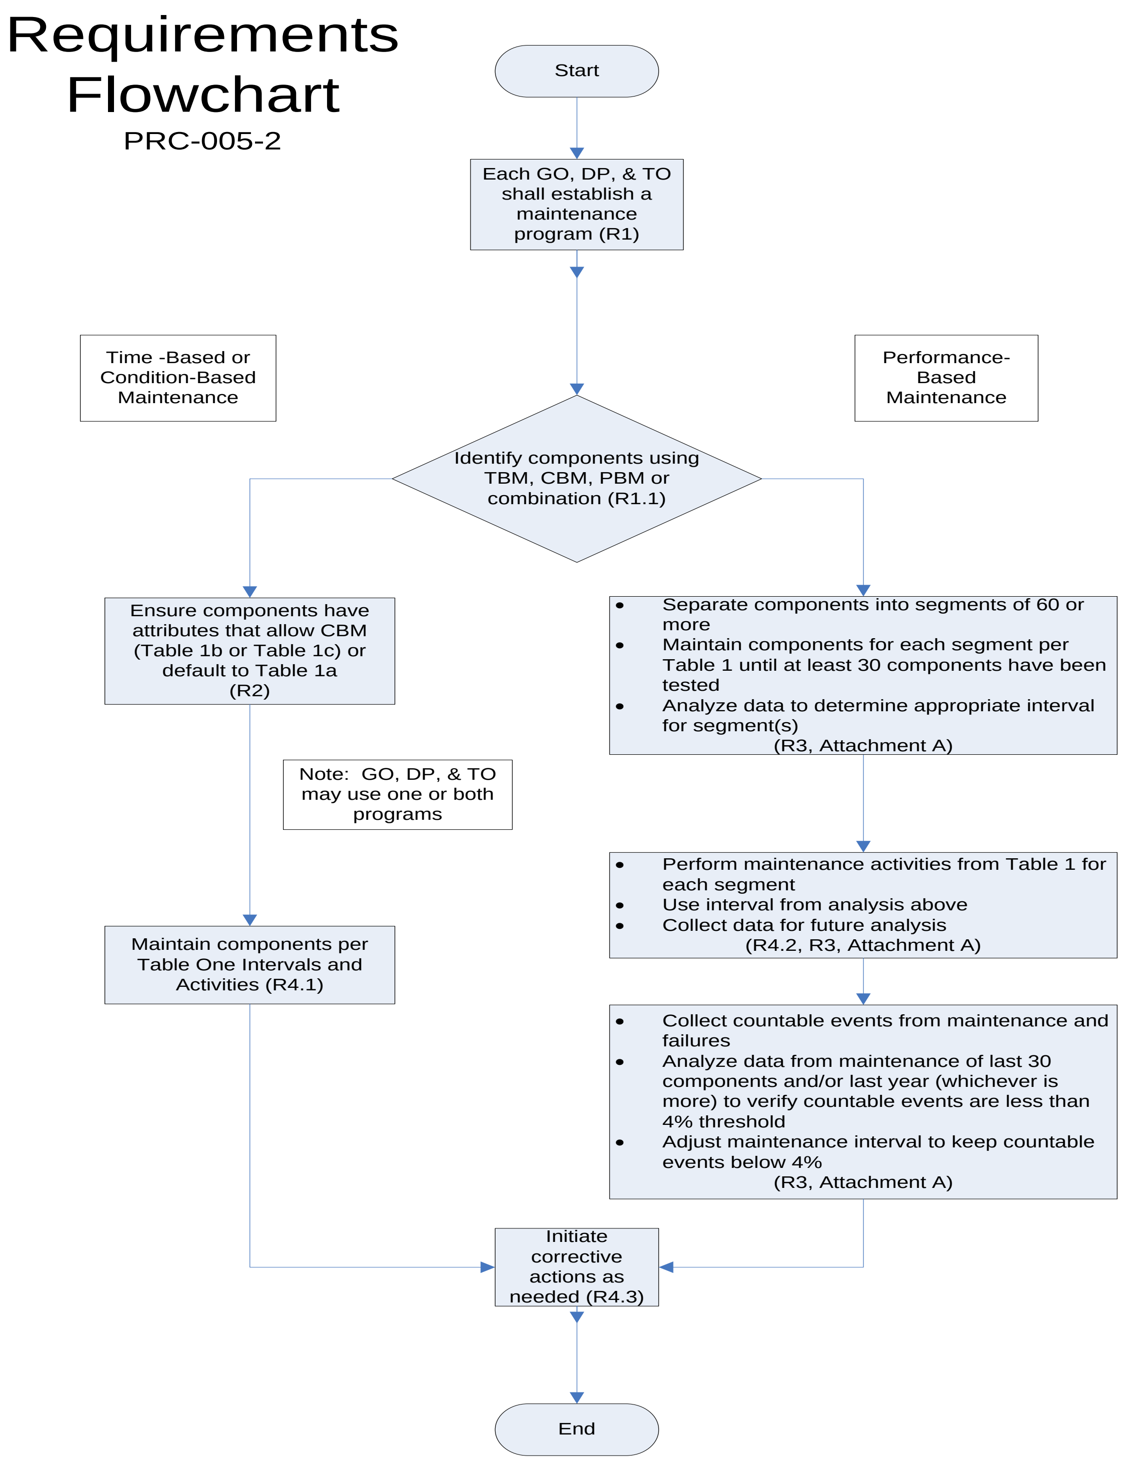
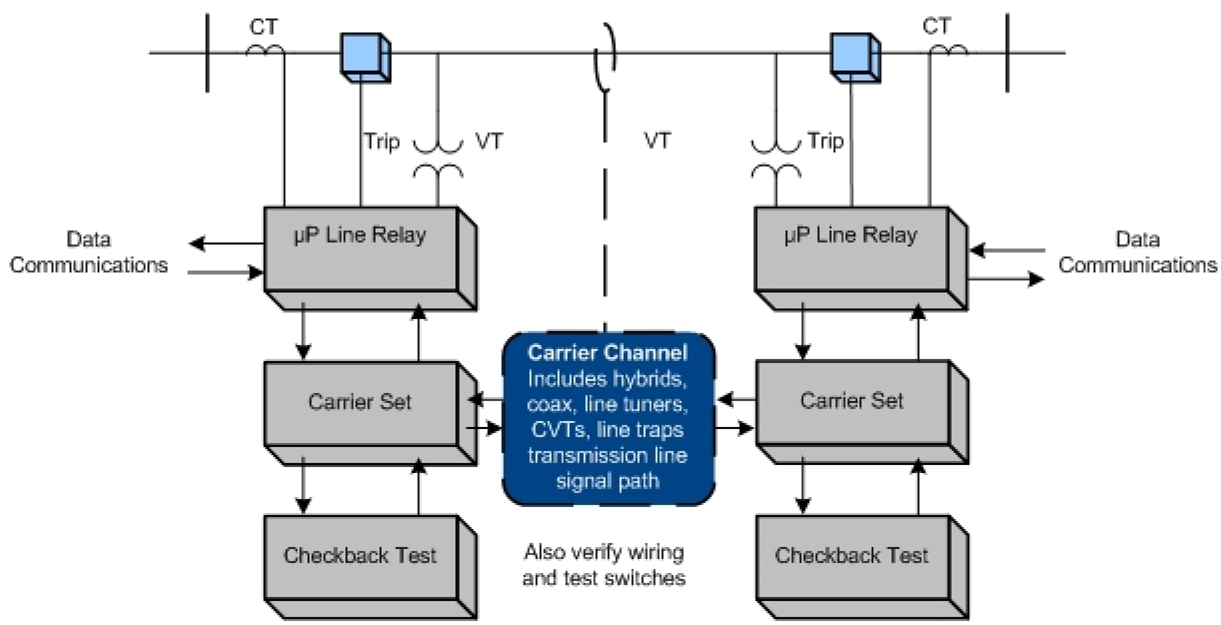
Figure 3: Requirements Flowchart



Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing

Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

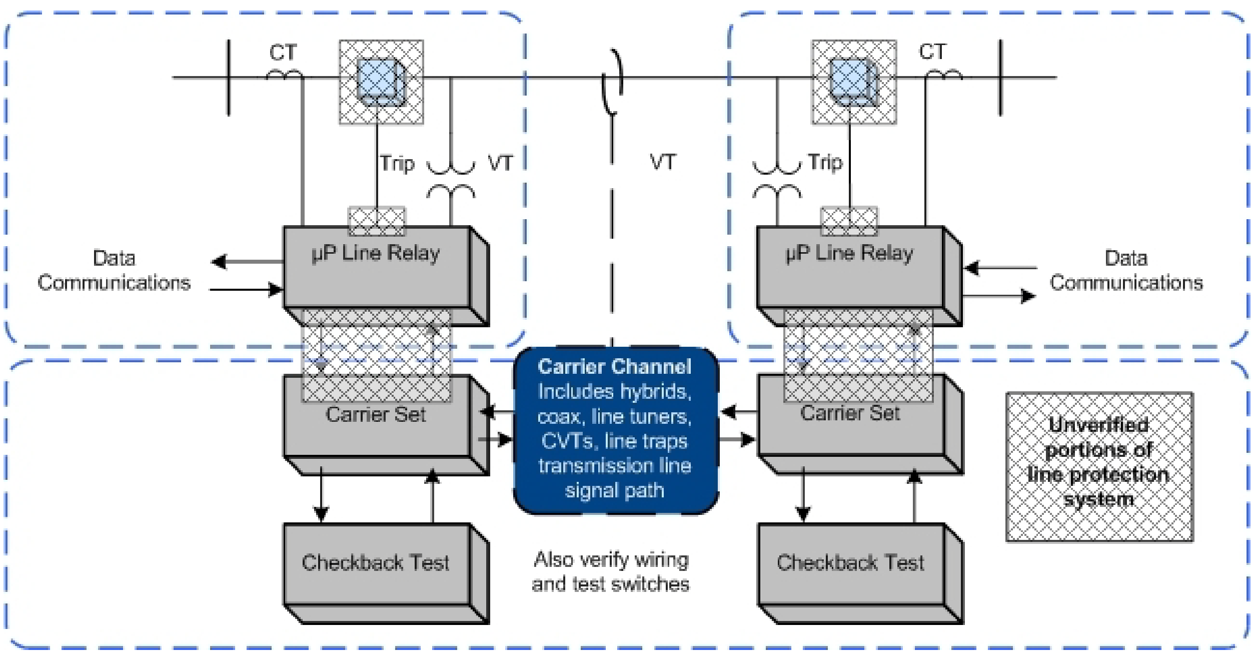
5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.

6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.

7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

PRC-005-2

Project 2007-17

Table of Contents

This supplementary reference to PRC-005-2 borrows heavily from the technical reference by the System Protection and Control Task Force (SPCTF) (Protection System Maintenance Technical Reference paper approved by the Planning Committee in September 2007). Additionally, the Protection System Maintenance and Testing Standard Drafting Team (~~PSMT SDT~~PSMTSDT) for PRC-005-2 (Project 2007-17) utilized ~~data available from IEEE, EPRI and~~ maintenance ~~programs~~program data from various generation and transmission utilities across the NERC boundaries~~.~~; as well as data from IEEE and EPRI.

1. Introduction and Summary

NERC currently has four reliability standards that are mandatory and enforceable in the United States and address various aspects of maintenance and testing of ~~protection~~Protection and ~~control~~Control systems. These standards are:

PRC-005-1 — *Transmission and Generation Protection System Maintenance and Testing*

PRC-008-0 — *Underfrequency Load Shedding Equipment Maintenance Programs*

PRC-011-0 — *UVLS System Maintenance and Testing*

PRC-017-0 — *Special Protection System Maintenance and Testing*

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. This revision of PRC-005-1 combines and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a fault or other power system problem requires that they operate to protect power system elements, or even the entire Bulk Electric System (BES). Lacking faults or system problems, the protection systems may not operate for extended periods. A ~~misoperation~~Misoperation - a false operation of a protection system or a failure of the protection system to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide area disturbances or unnecessary customer outages. A maintenance or testing program is used to determine the performance and availability of protection systems.

Typically, utilities have tested protection systems at fixed time intervals, unless they had some incidental evidence that a particular protection system was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring relays, and correctness of settings. Typically, a protection system must be visited at its installation site and removed from service for this testing.

Fundamentally, a reliability standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of components such that a properly built and commissioned Protection System will continue to function as designed over its service life.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To ensure all transmission and generation Protection Systems affecting the reliability of the Bulk Electric System (BES) are maintained and tested.

PRC-005-~~-~~1 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms ~~Used in Reliability Standards~~ used in Reliability Standards indicates what must be included as a minimum.

Definition of *Protection System* (excerpted from the NERC Standards Glossary of Terms):

Protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation~~, transmission,~~ and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Proposed Modification to NERC Glossary Definition

The Protection Systems Maintenance and Testing Standard Drafting Team (PSM SDT), proposes changes to the NERC glossary definition of *Protection Systems* as follows:

Protection System (modification) - Protective relays, ~~associated~~ communication systems necessary for correct operation of protective ~~devices~~functions, voltage and current sensing devices inputs to protective relays and associated circuitry from the voltage and current sensing devices, station DC supply, and ~~DC~~ control circuitry, associated with protective functions from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:
"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:
"*… and that are applied on, or are designed to provide protection for the BES.*"

The drafting team intends that this Standard will not apply to "merely possible" parallel paths, (sub-transmission and distribution circuits), but rather the standard applies to any Protection System that is designed to detect a fault on the BES and take action in response to that fault. The Standard Drafting Team does not feel that Protection Systems designed to protect distribution substation equipment are included in the scope of this standard; however, this will be impacted by the Regional definitions of the BES.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those relays ~~that~~ that use measurements of voltage, current, frequency and/or phase angle and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE device # 86 (lockout relay) and IEEE device # 94 (tripping or trip-free relay) as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, pressure, seismic, thermal or gas accumulation) are not included.

3. Relay Product Generations

The likelihood of failure and the ability to observe the operational state of a critical protection system, both depends on the technological generation of the relays as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices such as primary measuring relays, monitoring devices, control systems, and telecommunications equipment.

Modern microprocessor based relays have six significant traits that impact a maintenance strategy:

- Self monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs such as trip coil continuity. Most relay users are aware that these relays have self monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the protection system must be monitored, or else verified periodically.
- Ability to capture fault records showing how the protection system responded to a fault in its zone of protection, or to a nearby fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-fault times. The relays can compute values such as MW and MVAR line flows that are sometimes used for operational purposes such as SCADA.
- Data communications via ports that provide remote access to all of the results of protection system monitoring, recording, and measurement.
- Ability to trip or close circuit breakers and switches through the protection system outputs, on command from remote data communications messages or from relay front panel button requests.
- Construction from electronic components some of which have shorter technical life or service life than electromechanical components of prior protection system generations.

4. Definitions

Protection System Maintenance Program (PSMP) – An ongoing program by which Protection System components are kept in working order and proper operation of malfunctioning components is restored. A maintenance program ~~can include~~for a specific component includes one or more of the following activities:

An ongoing program by which Protection System components are kept in working order and where malfunction components are restored to working order

Verification – A means of determining that the component is functioning correctly.

- **Monitoring** – Observation of the routine in-service operation of the component.
- **Testing** – Application of signals to a component to observe functional performance or output behavior, or to diagnose problems.
- **~~Physical~~ Inspection** – To detect visible signs of component failure, reduced performance and degradation.
- **Calibration** – Adjustment of the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

- **Upkeep** – Routine activities necessary to assure that the component remains in good working order and implementation of any manufacturer's hardware and software service advisories which are relevant to the application of the device.
- **Restoration** – The actions to restore proper operation of malfunctioning components.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which protection systems are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on protection system components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire protection system tripping chain is able to operate the breaker.

Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed, and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may ~~prove~~verify that some portion of the protection system has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components.

- PBM – performance-based maintenance ~~– maintenance~~- intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

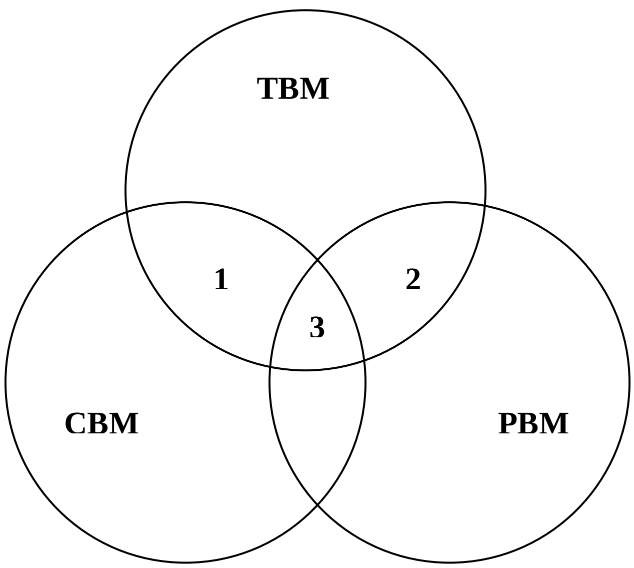
- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self diagnostics.

  Microprocessor based protective relays that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include the ac signal inputs, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals. For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours or even milliseconds between non-disruptive self monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM. This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



Relationship of time-based maintenance types

5.1 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the protection system, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relay self monitoring, for example), the intervals may be extended or manual testing may be eliminated. This is referred to as condition-based maintenance or CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended while still achieving the desired level of performance. This is referred to as performance-based maintenance or PBM. It is also sometimes ~~also~~ referred to as reliability-centered maintenance or RCM, but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot ~~prove~~verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor protection system elements. These relays and IEDs generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in relay logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillograph records for faults and disturbances, metered values, and binary input status reports. Some of these are available on the relay front panel display, but may be available via data communications ports. Large files of fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the protection system.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

1. Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.
2. Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a

hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some relays will show health problems by incorrect relaying before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval.

7. Time-Based versus Condition-Based Maintenance

Time-based and condition-based maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1 that includes a requirement that maintenance and testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-2. The defined time limits allow for longer time intervals if the maintained device is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the protection system owner knows about it, for the monitored segments of the protection system. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification (as specified in the header and the “Monitoring Attributes” column of Tables ~~1a,~~ 1b and 1c of PRC-005-2), meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system elements as contained in Table 1a.

The result is that:

This NERC standards permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern protection systems to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within maximum time intervals specified in Tables 1a, 1b and 1c of PRC-005-2.

8. Maximum Allowable Verification Intervals

The ~~Table of~~ Maximum Allowable Testing Intervals and Maintenance Activities ~~and Maximum Interval~~ requirements ~~shows~~show how CBM with newer relay types can reduce the need for many of the tests and site visits that older protection systems require. As explained below, there are some sections of the protection system that monitoring or data analysis may not verify. Verifying these sections of the Protection Systems requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities ~~via data communications~~can be used to verify function of one tripping path and proper trip coil operation, if there has been no fault or routine operation to demonstrate performance of relay tripping circuits.

Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period ~~of time~~ of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total protection system functions from measurement of power system values, to properly identifying fault characteristics, to the operation of the interrupting devices.

8.1 Table of Maximum Allowable Verification Intervals

Table 1, in the standard, specifies maximum allowable verification intervals for various generations of protection systems and categories of equipment that comprise protection systems. The right column indicates ~~verification or testing~~maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted line protection system comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows a typical Generation station layout. The various subsystems of a Protection System that need to be verified are shown. UFLS, UVLS, and SPS are additional categories of Table 1 that are not illustrated in these Figures.

While it is easy to associate protective relays to the three levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables (Tables 1a, 1b and 1c collectively *Tables*) from PRC-005-2:

- First check the table header description to verify that your equipment meets the monitoring requirements. If your equipment does not meet the monitoring requirements of Table 1c then check Table 1b. If your equipment does not meet the requirements of Table 1b then use Table 1a.
- If you find a piece of equipment that meets the monitoring requirements of Table 1b or 1c then you can take advantage of the extended time intervals allowed by Table 1b and 1c. Your maintenance plan must document that this ~~category of equipment~~component can be maintained by the requirements of Table 1b or 1c because it has the necessary attributes required within that Table.
- Once you determine which table applies to your equipment's monitoring requirements then check the Maintenance Activity that is required for that particular ~~category of equipment.~~component. This Maintenance Activity is the minimum maintenance activity that must be documented.
- If your PSMP (plan) requires more then you must document more.
- After the maintenance activity is known, check the Maximum Maintenance Interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this ~~category of your equipment~~component.
- If your PSMP (plan) requires activities more often than the Tables maximum then you must document those activities more often.
- Any given set of Protection System equipment can be maintained with any combination of Tables 1a, 1b and 1c. An entity does not have to stick to Table 1a just because some of its equipment is un-monitored.

- An entity does not have to utilize the extended time intervals in Tables 1b or 1c. An easy choice to make is to simply utilize Table 1a. While the maintenance activities resulting from choosing to use only Table 1a would require more maintenance man-hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System component, Table 1 shows maximum allowable testing intervals for unmonitored, partially monitored and fully monitored protection systems:

Table 1 Maximum Allowable Testing Intervals and Maintenance Activities ~~and Maximum Intervals~~

Level 1 Monitoring (Unmonitored) Table 1a

This table applies to electromechanical, analog solid state and other un-monitored Protection Systems components. This table represents the starting point for all required maintenance activities. The object of this group of requirements is to have specific activities accomplished at maximum set time intervals. From this group of activities it follows that CBM or PBM can increase the time intervals between the hands-on maintenance actions.

Level 2 Monitoring (Partially Monitored) Table 1b

This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location (at least daily) where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process – the monitoring and alarming functions must be shown to work.

Level 3 Monitoring (Fully Monitored) Table 1c

This table applies to microprocessor relays and other associated Protection System components in which every element or function required for correct operation of the Protection System component is monitored continuously and verified, including verification of the means by which failure alarms or indicators are transmitted to a ~~central location for immediate action.~~location within 1 hour or less of the maintenance-correctable issue occurring. This is the highest level of monitoring and if it is available then this gives an entity the ability to have continuous testing of their (Level 3 Monitored) Protection System Component and thus does not have to manually intervene to accomplish routine testing chores. Level 3 Fully Monitored yields continuous monitoring advantages but has substantial technical hurdles that must be overcome; namely that monitoring also verifies the failure of the monitoring and alarming equipment. Without this important ingredient a device that is thought to be continuously monitored could be in an alarm state without the ~~central location~~asset owner being ~~made~~ aware of this alarm state.

Additional Notes for Table 1a, Table 1b, and Table 1c

1. For electro-mechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor-relays with no remote monitoring of alarm contacts, etc, are un-monitored relays and need to be verified within the Table interval as other un-monitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a protection system or SPS (as opposed to a monitoring task) must be verified as a component in a protection system.

4. In addition to verifying the circuitry that supplies dc to the protection system, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System elements physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for Vented Lead-Acid, Valve-Regulated Lead-Acid, and Nickel-Cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner ~~should attempt to~~might use the applicable IEEE recommended practice which contains information and recommendations concerning the maintenance, testing and replacement of its substation battery. However, the methods prescribed in these IEEE recommendations cannot be specifically required because they do not apply to all battery applications.

5. Aggregated small entities ~~will naturally~~might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program.

6. Voltage & Current Sensing Device circuit input connections to the protection system relays can be verified by comparison of ~~known~~measured values ~~of other sources~~ on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected, (phase value and phase relationships are both equally important to ~~prove~~verify).

7. Verify the protection system tripping function by performing an operational trip test on all components contained in the trip circuit. This includes circuit breaker or circuit switcher trip coils, auxiliary tripping relays (94), lock-out relays (86), and communications-assisted trip scheme elements. Each control circuit path that carries trip signal must be verified, although each path must be checked only once. A maintenance program may include performing an overall test for the entire system at one time, or several split system tests with overlapping trip verification. ~~Trip coil continuity and aux-contact verification may be accomplished by inspection for the proper control panel light indication. Remote alarm monitoring of the trip coil and aux-contact continuity eliminates the need for tri-monthly inspections of trip coil indications.~~ A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test.

8. “End-to-end test” as used in this supplementary reference is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc Control Circuitry. A documented real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to ~~prove~~verify each and every parallel trip path that participated in any given dc Control Circuit trip. Or, another possible solution is that a single trip path from a single monitored relay can be ~~proven~~verified to be the trip path that successfully tripped during a real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

9. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

10. Notes 1-9 attempt to describe the testing activities they do not represent the only methods to achieve these activities but rather some possible methods.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three year retention cycle, the records of verification for a protection system will typically be discarded before the next verification, leaving no record of what was done if a ~~misoperation~~Misoperation or failure is to be analyzed.

PRC-005-2 corrects this by requiring~~ that the ~~:

The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation ~~be retained for~~ of the two most recent performances of each distinct maintenance ~~intervals. Additionally, this~~activity for the Protection System components, or to the previous on-site audit date, whichever is longer.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits.

8.3 Basis for Table 1 Intervals

SPCTF authors collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak load, or 64% of the NERC peak load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of protection systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of 5 years for electromechanical or solid state relays, and 7 years for un-monitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond 7 years, based on favorable experience with the particular products they have installed. To provide a technical basis for such extension, SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1] as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1 only when such relays are monitored as specified in the header of Table 1b. Monitoring is capable of reporting protection system health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, protection system availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve protection system availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades protection system availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for partial monitoring as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a fault occurs, leading to failure to operate for the fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ~~STvalues~~ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a protection system)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a protection system repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for Relay Unavailability and Abnormal Unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years – the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

PSMT SDT further notes that the SPCTF also allowed 25% extensions to the “maximum time intervals”. With a 5 year time interval established between manual maintenance activities and a 25% time extension then this equates to a 6.25 year maximum time interval. It is the belief of the PSMT SDT that the SPCTF understood that 6.25 years was thereby an adequate maximum time interval between manual maintenance activities. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. A 10 year interval with a 25% allowed extension equates to a maximum allowed interval of 12.5 years between manual maintenance activities. The Standard does not allow extensions on any component of the protection system; thus the maximum allowed interval for these devices has been set to12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval". The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electro-mechanical protective relay that is maintained in year #1 need not be revisited until 6 years later (year #7). For example: a relay was maintained ~~December 15~~April 10, 2008; ~~it would be due for~~ maintenance ~~again~~would need to be completed no later than December 31, 2014.

Section 9 describes a performance-based maintenance process which can be used to justify maintenance intervals other than those described in Table 1.

Section 10 describes sections of the protection system, and overlapping considerations for full verification of the protection system by segments. Segments refer to pieces of the protection system, which can range from a single device to a panel to an entire substation.

Section 11 describes how relay operating records can serve as a basis for verification, reducing the frequency of manual testing.

Section 13 describes how a cooperative effort of relay manufacturers and protection system users can improve the coverage of self-monitoring functions, leading to full monitoring of the bulk of the protection system, and eventual elimination of manual verification or testing.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a performance-based maintenance process may be used to establish maintenance intervals~~.~~ (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A performance-based maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a performance-based maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered protection systems in order to provide historical justification for intervals other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Utilities with performance-based maintenance track performance of protection systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a performance-based maintenance program would serve the utility well in explaining to regulators and the public a ~~misoperation~~Misoperation leading to a major system outage event.

A performance-based maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality management systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance~~ Based~~-based Maintenance (PBM) program the asset owner must first sort the various Protection System components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM but does not own 60 units to comprise a population then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of like devices from the same manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment and the remaining 30 from a clean environment.

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:
B = bound on the error of distribution (allowable error)
z = standard error
π = expected failure rate
n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance ~~Based~~-based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason the following assumptions are made:

B = 5%
z = 1.96 (This equates to a 95% confidence level)
π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance ~~Based~~-based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%
z = 1.44 (85% confidence level)
π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended:

Minimum Population Size to use Performance ~~Based~~-based Maintenance Program = 60

Minimum Sample Size to evaluate Performance ~~Based~~-based Program = 30.

Once the population segment is defined then maintenance must begin within the intervals as outlined for Level 1 monitoring, (Table 1a). Time intervals can be lengthened provided the last year's worth of devices tested (or the last 30 units maintained, whichever is more) had fewer than 4% countable events. It is notable that 4% is specifically chosen because an entity with a small population (60 units) would have to adjust its time intervals between maintenance if more than 1 countable event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a mis-operation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of countable events equals or exceeds 4% of the last year's tested-devices (or the last 30 units maintained, whichever is more) then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the countable events is less than 4%; this must be attained within three years.

This additional time period of three years to restore segment performance to <4% countable events is mandated to keep entities from "gaming the PBM system". It is believed that this requirement provides the economic disincentives to discourage asset owners from arbitrarily pushing the PBM time intervals out to ~~20 years as subsequent analysis might show that an excessive number of countable events could then require that the entire population segment be re-tested and re-evaluated within 3 years.~~up to 20 years without proper statistical data.

10. Overlapping the Verification of Sections of the Protection System

Table 1 requires that every protection system element be periodically verified. One approach is to test the entire protection scheme as a unit, from voltage and current sources to breaker tripping. For practical ongoing verification, sections of the protection system may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a protection system may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment as given in the Unmonitored, Partially Monitored, or Fully Monitored Tables;
- Full monitoring as described in header of Table 1c;

- A performance-based maintenance program as described in Section 9;
- Opportunistic verification using analysis of fault records as described in Section 11

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve fault event records and oscillographic records by data communications after a fault. They analyze the data closely if there has been an apparent ~~misoperation~~Misoperation, as NERC standards require. Some advanced users have commissioned automatic fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured digital fault recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on protection systems whose operations are analyzed. Even electromechanical protection systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of faults in the vicinity of the relay that produce relay response records, and the specific data captured.

A typical fault record will verify particular parts of certain protection systems in the vicinity of the fault. For a given protection system installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external fault records that completely verify the protection system.

For example, fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby protection systems may verify that they restrain from tripping for a fault just outside their respective zones of protection. The ensemble of internal fault and nearby external fault event data can verify major portions of the protection system, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity in the record and the associated wiring paths are verified. Be careful about using fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple faults close to either side of a setting boundary, setting or calibration could still be incorrect.

If fault record data is used to show that portions or all of a protection system have been verified to meet Table 1 requirements, the owner must retain the fault records used, and the maintenance related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to protection system performance.

Monitoring does not check measuring element settings. Analysis of fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them. For background and guidance, see [5].

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple. With legacy relays (non-microprocessor protective relays) it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored or partially monitored intervals established in Table 1.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of full monitoring, the manufacturers of the microprocessor-based self-monitoring components in the protection system should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact protection system performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

With this information in hand, the user can document full monitoring for some or all sections by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission facilities through which failures are reported ~~to remote centers for immediate action~~within a given time frame to

allocate where action can be taken to initiate resolution of the alarm attributed to a maintenance correctable issue, so that failures of monitoring or alarming systems also lead to alarms and action.

- Documenting the plans for verification of any unmonitored elements according to the requirements of Table 1.

14. Notification of Protection System Failures

When a failure occurs in a protection system, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable loading conditions.

This formal reporting of the failure and repair status to the system operator by the protection system owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance but if its battery maintenance program is lacking then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-02 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore *manual intervention* to perform certain activities on these type devices may not be needed.

15.1 Protective Relays

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a faulted portion of the BES. Devices that sense thermal, vibration, seismic, pressure, gas or any other non-electrical ~~input~~inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor based equipment in the following ways, ~~but~~ the relays ~~must~~should meet the ~~calibration requirements of the~~ asset ~~owner~~owners' tolerances.

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
  - There is no specific protective relay commissioning test or relay routine test mandated.
  - There is no specific documentation mandated.

15.2 Voltage & Current Sensing Devices

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these devices. The important thing about these signals is to know that the expected output from these devices actually reaches the protective relay. Therefore, the proof of the proper operation of these devices also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device all the way to the protective relay. The following observations apply.

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; by calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to ~~prove~~verify the circuit ~~to the satisfaction of~~meets the asset ~~owner~~owner's protection system maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this therefore tests the CT as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the real-time loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay then the verification activity has been satisfied. Thus event reports (and oscillographs) can be used to ~~prove~~verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and vars around the entire bus; this should add up to zero watts and zero vars thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Other methods that provide documentation that the expected transformer values ~~are~~as applied to the inputs to the protective relays are acceptable.

15.3 DC Control Circuitry

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a monitoring system is installed that verifies every parallel trip path then the manual-intervention testing of those parallel trip paths can be extended to twelve years, however the actual operation of the circuit breaker must still occur at least once every six years. This 6-year tripping requirement can be completed as easily as tracking the real-time fault-clearing operations on the circuit breaker.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment and not just all equipment.
It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device if this ground switch is utilized in a Protection System and forces a ground fault to occur that then results in an expected Protection System operation to clear the forced ground fault.

Distribution circuit breakers that participate in the UFLS scheme are excluded from the trip-testing requirements. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping-action of a single distribution breaker will be far less significant than, for example, any single Transmission Protection System failure such as a failure of a Bus Differential Lock-Out Relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just fault clearing duty and therefore the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) in any given trip scheme. These electro-mechanical devices must be trip tested. The PSMT SDT considers these devices to share some similarities in failure modes as electro-mechanical protective relays; as such there is a six year maximum interval between mandated maintenance tasks.

When verifying the operation of the 94 and 86 relays each normally-open contact that closes to pass a trip signal must be verified as operating correctly. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.
New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment.

15.4 Batteries and DC Supplies

IEEE guidelines were ~~used~~consulted to ~~mandate~~arrive at the maintenance activities for batteries. The following guidelines were used: IEEE 450 (for Vented Lead-Acid batteries), IEEE 1188 (for Valve-Regulated Lead-Acid batteries) and IEEE 1106 (for Nickel-Cadmium batteries).

The present NERC definition of a Protection System is "*protective relays, associated communication systems, voltage and current sensing devices, station batteries and dc control circuitry*." The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

~~To insure that there are no open circuits in a lead acid battery string, IEEE 450-2002 recommends that during the monthly inspection "battery float charging current or pilot cell specific gravity" should be measured and recorded. Similarly IEEE 1188-2005 states that during the monthly general inspection, the "dc float current (per string)" should be checked and recorded "using equipment that is accurate at low (typically less than 1 A) currents." These tests are recommended by the IEEE standards for lead acid batteries to detect an open circuit in a battery set that will make a battery unable to deliver dc power.~~

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to the two methods recommended in the IEEE standards. Continuity as used in Table 1 of the standard refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station.

Batteries cannot be a unique population segment of a Performance ~~-Based~~-based Maintenance Program (PBM) because there are too many variables in the electro-chemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery systems.

15.5 Tele-protection equipment

This is also known as associated telecommunications equipment. The equipment used for tripping in a communications assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested.

Besides the trip output and wiring to the trip coil(s) there is also a communications medium that must be maintained.

Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology.

For example: older technologies may have included *Frequency Shift Key* methods. This technology requires that guard and trip levels be maintained.

The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests.

Emerging technologies transfer digital information over a variety of carrier mediums that are then interpreted locally as trip signals.

The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore this standard is applied to equipment used to convey both trip signals and block signals.

It was the intent of this standard to require that a test be made of any communications-assisted trip scheme regardless of the vintage of the technology. The essential element is that the tripping occurs locally when the remote action has been asserted.

Evidence of operational test or documentation of measurement of signal level, reflected power or data-error rates is needed.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.6 Examples of Evidence of Compliance

To comply with the requirements of this Standard an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other standards that could, at times fulfill evidence requirements of this standard.

For example: maintaining evidence for operation of Special Protection Systems could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus the reporting requirements that one may have to do for the misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-2.

Another example might be:
Some entities maintain records of all interruptions. These records can be concurrently utilized, if the entity desires, as DC Trip Path verifications.

Analysis of Event Recordings can provide details that can eliminate some hands-on maintenance activities; however, merely printing out the event report provides limited benefit of verification of specific maintenance items.
Standardized-forms, hard or soft copy, can be created, filled out and archived. These forms can be of the entities' design and can be aimed at answering the specific requirements of the Standard as well as additional requirements as needed by the entity.
Fill-in blanks, check-boxes, drop-down lists, auto-date formats, etc. can all be used as the primary action is the maintenance activity; the secondary action is to verify that the maintenance activity was performed.
Other evidence of compliance might be, but is not limited to:
Prints, maintenance plans, training materials, policies, procedures, data print-outs or exhibits, correspondence, reports, data-base records, etc.
There is the legacy method of paper trail for everything, this is acceptable. There are also paperless systems existing and evolving that are also acceptable.
Proof of compliance should simply be the entities' records of maintenance completed.

Figure 1 ~~and~~& 2 Legend ~~—~~– Components of Protection Systems

Number In Figure	Component of Protection System	Includes	Excludes
1	Protective relays	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage & Current ~~& voltage sensors~~Sensing Devices and associated circuitry	~~Transformers or other~~The signals from the voltage & current ~~& voltage~~ sensing devices ~~that produce signals~~ for protective relays as well as the wiring (or other medium) used to convey signal output from the sensor to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including sync-check systems, metering systems and data acquisition systems.
3	DC Circuitry	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current. ~~Also, it includes auxiliary contacts providing breaker position data that is necessary for the proper operation of the Protection System.~~	Closing circuits, SCADA circuits
4	~~DC Supply~~Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Associated communications ~~equipment~~systems	Tele-protection equipment used to convey remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable~~)~~).	Any communications equipment that is not used for remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable~~)~~).

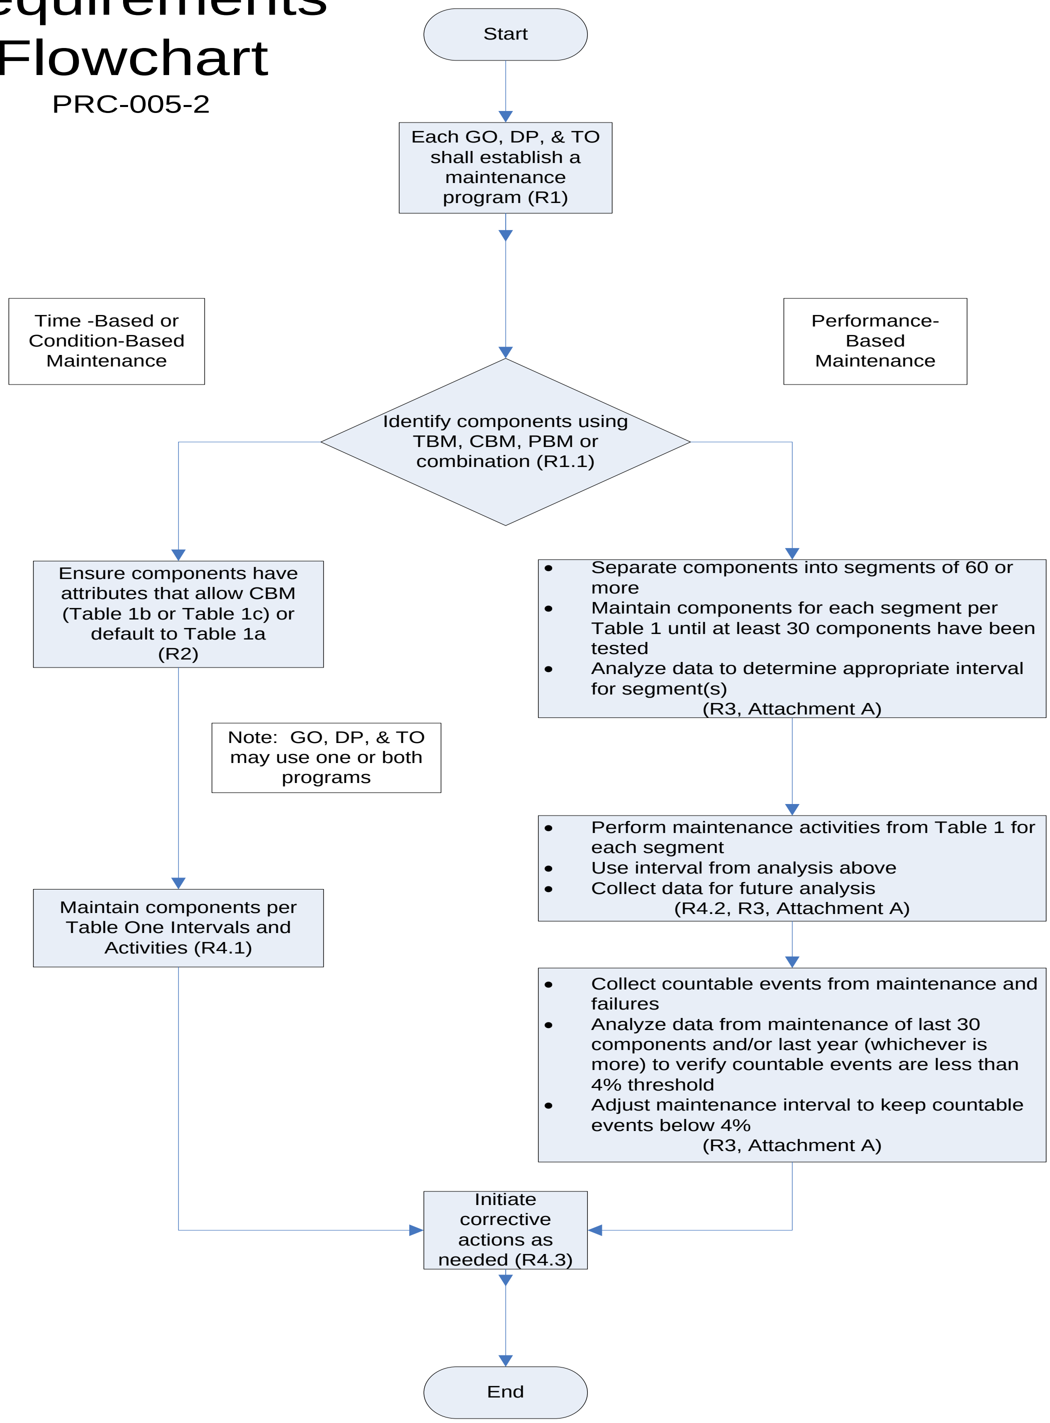
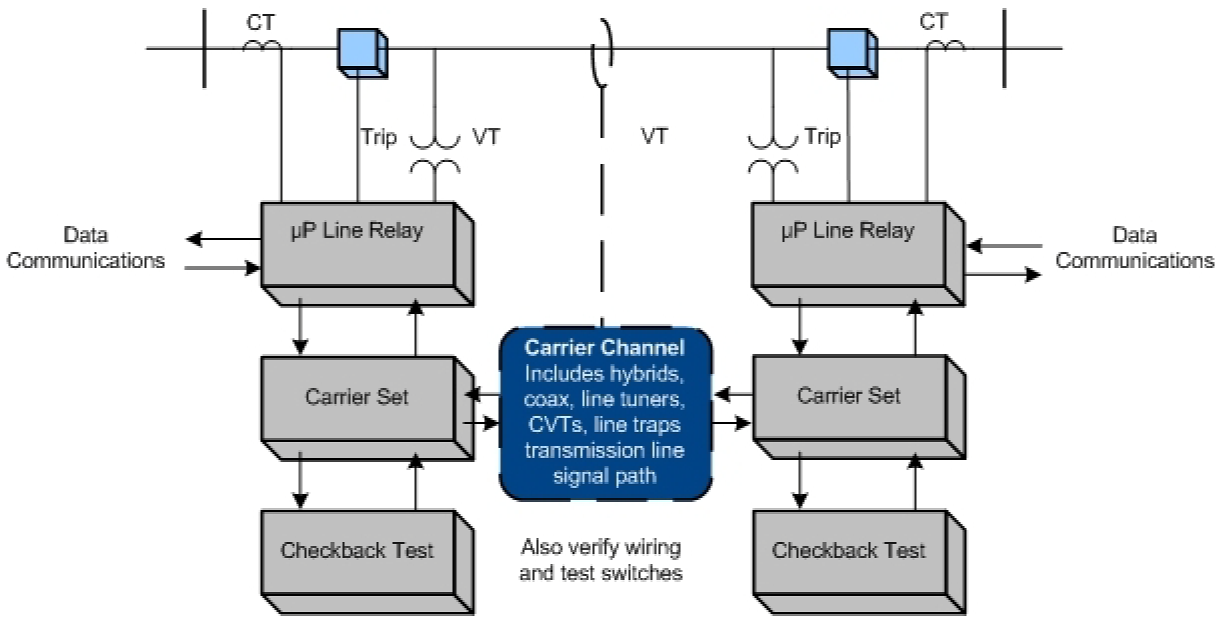
PRC-005-2



Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line faults, and to avoid over-tripping for faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies Voltage & Current Sensing

Devices, wiring, and analog signal input processing of the relays. One effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

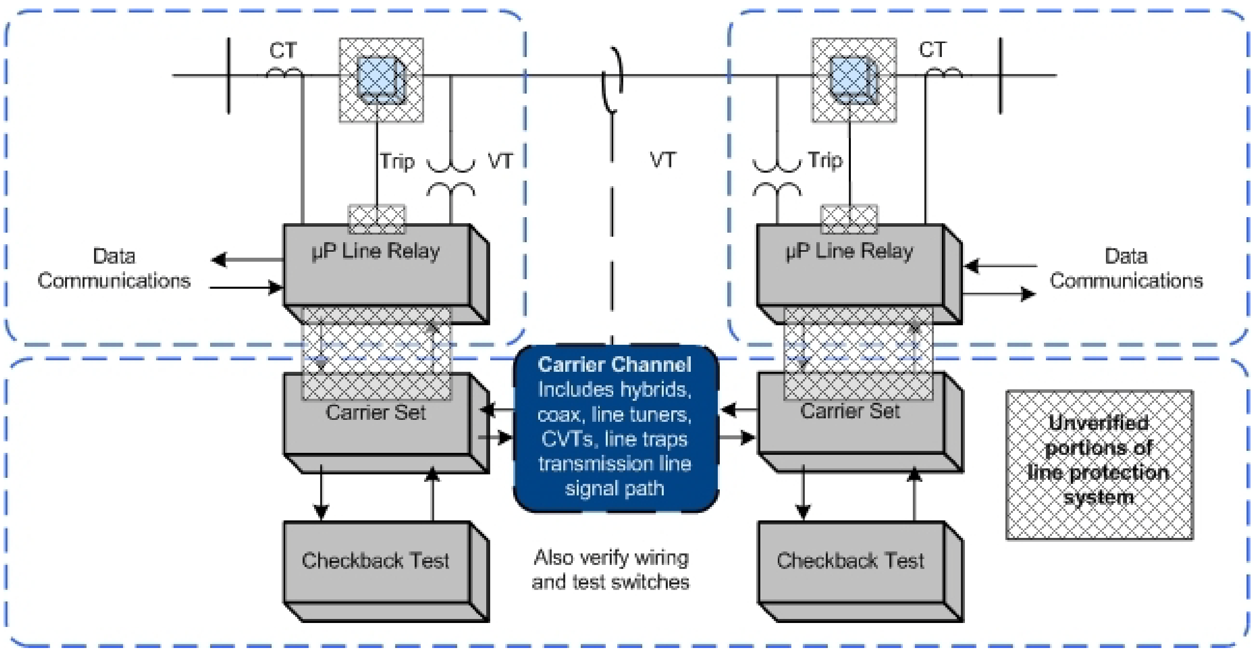
5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.

6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.

7. Correct operation of the on-off carrier channel is also critical to security of the protection system, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the protection system elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005 does not address breaker maintenance, and its protection system test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated fault with a relay test set. However, utilities have found that breakers often show problems during protection system tests. It is recommended that protection system verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Protection System Definition

Current Approved Definition:

Protective relays, associated communication systems, voltage and current sensing devices, station batteries and DC control circuitry.

The drafting team initially proposed changes to the definition as shown below:

Protective relays, associated communication systems necessary for correct operation of protective devices, voltage and current sensing inputs to protective relays ~~devices~~, station DC supply ~~batteries~~, and DC control circuitry from the station DC supply through the trip coil(s) of the circuit breakers or other interrupting devices.

Based on stakeholder comments, the drafting team made minor changes to the proposed definition as shown below.

Protective relays, ~~associated~~ communication systems necessary for correct operation of protective ~~devices~~functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and ~~DC~~ control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

The proposed definition of Protection System reads as follows:

Protective relays, communication systems necessary for correct operation of protective functions, voltage and current sensing inputs to protective relays and associated circuitry from the voltage and current sensing devices, station dc supply, and control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers or other interrupting devices.

McMeekin	2007-17	PRC-005-2	R3 and Attachment A	Yes	12/19/2012

Standards Announcement
Initial Ballot Windows Open
July 8–17, 2010

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-17: Protection System Maintenance and Testing
An initial ballot window for standard PRC-005-2 — Protection System Maintenance and Testing and a separate initial ballot for the definition of "Protection System" are now open **until 8 p.m. Eastern on July 17, 2010**.

In addition, members of the ballot pool associated with the standard will be able to vote in a concurrent non-binding poll on the standard's Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs). Members who joined the ballot pool to vote on the standard were automatically entered in a separate pool to participate in the non-binding poll for the VRFs and VSLs. The non-binding poll will appear in your list of current ballots, and is labeled accordingly. (As a reminder, this new approach for VRFs and VSLs is one of the updates reflected in the recently FERC-approved Reliability Standards Development Procedure — Version 7.)

Instructions
Members of the ballot pools associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Next Steps
Voting results will be posted and announced after the ballot windows close.

Project Background
The draft standard combines the following previous standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The proposed standard addresses FERC directives from FERC Order 693 as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are

116-390 Village Blvd.
Princeton, NJ 08540
609.452.8060 | www.nerc.com

maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices, and for a performance-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Project page:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Special Notes:
On March 18, 2010, FERC issued several orders and notices of proposed rulemakings pertaining to standards development activities and processes, suggesting a lack of progress in responding to directives from Order 693 as well in the timeliness of standards development in general. At the May 2010 NERC Board meeting, Gerry Cauley, NERC's President, also expressed these concerns, indicating that the resolution to these concerns is one of NERC's top priorities in the near term. As a result, the Standards Committee has authorized deviations from the normal standards development process for the Protection System Maintenance and Testing project, as well as other projects that have been through significant stakeholder review through the development process, to demonstrate that the NERC enterprise is responsive to FERC directives, and is making progress in developing new standards.

The Standards Committee approved the following deviations from the standards development process:

- The proposed changes to the standard and definition will be posted for 35-day comment periods (rather than 45-day comment periods). The ballot pools will be formed during the first 21 days of the 35-day comment periods;
- The initial ballots will be conducted during the last 10 days of the 35-day comment periods; and
- The drafting team may make modifications between the initial and recirculation ballots based on stakeholder comments to improve the overall quality of the standard and definition.

Project 2007-17: Protection System Maintenance and Testing

Project 2007-17: Protection System Maintenance and Testing

On March 18, 2010, FERC issued several orders and notices of proposed rulemakings pertaining to standards development activities and processes, suggesting a lack of progress in responding to directives from Order 693 as well in the timeliness of standards development in general. At the May 2010 NERC Board meeting, Gerry Cauley, NERC's President, also expressed these concerns, indicating that the resolution to these concerns is one of NERC's top priorities in the near term. As a result, the Standards Committee has authorized deviations from the normal standards development process for the Protection System Maintenance and Testing project, as well as other projects that have been through significant stakeholder review through the development process, to demonstrate that the NERC enterprise is responsive to FERC directives, and is making progress in developing new standards.

The Standards Committee approved the following deviations from the standards development process:

- The proposed changes to the standard and definition will be posted for 35-day comment periods (rather than 45-day comment periods). The ballot pools will be formed during the first 21 days of the 35-day comment periods;
- The initial ballots will be conducted during the last 10 days of the 35-day comment periods; and
- The drafting team may make modifications between the initial and recirculation ballots based on stakeholder comments to improve the overall quality of the standard and definition.

Ballot Pools (through July 2, 2010)

- There will be two ballot pools: one for the standard (PRC-005-2), which includes the proposed definition of "Protection System Maintenance Program" and a separate ballot pool for the proposed definition of "Protection System."

- Registered Ballot Body members may join the ballot pools **until 8 a.m. Eastern on July 2, 2010** to be eligible to vote in the upcoming ballots at the following page: https://standards.nerc.net/BallotPool.aspx. Members who join the ballot pool to vote on the standard (PRC-005-2) will automatically be entered in a separate pool to participate in the non-binding poll of the associated violation risk factors (VRFs) and violation severity levels (VSLs). (As a reminder, this new approach for VRFs and VSLs is one of the updates reflected in the recently FERC-approved Reliability Standards Development Procedure – Version 7.)

- During the pre-ballot window, members of the ballot pools may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The ballot pool list server for PRC-005-2 and "Protection System Maintenance Program" is: bp-2007-17_PRC-005-2_in@nerc.com. The ballot pool list server for the proposed definition of "Protection System" is: bp-2007-17_definition_in@nerc.com.

Comment Periods (through July 16, 2010)

There will also be two comment periods: one for the standard (PRC-005-2), which includes the proposed definition of "Protection System Maintenance Program" and a separate comment period for the proposed definition of "Protection System."

Please use this electronic form to submit comments on PRC-005-2 and "Protection System Maintenance Program." Please use this electronic form to submit comments on "Protection System." If you experience any difficulties in using the electronic forms, please contact Lauren Koller at 609-524-7047.

Documents for this project — including an off-line, unofficial copy of the questions listed in the comment forms — are posted at the following site:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Project Background

The draft standard combines the following previous standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The proposed standard addresses FERC directives from FERC Order 693 as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices, and for a performance-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

Standards Announcement
Initial Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Project 2007-17: Protection System Maintenance and Testing

The initial ballot for standard PRC-005-2 — Protection System Maintenance and Testing and a separate initial ballot for the definition of "Protection System" ended on July 17, 2010.

Ballot Results for Standard

Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 91.12 %
Approval: 22.91 %

Since at least one negative ballot included a comment, these results are not final. A second (or recirculation) ballot must be conducted. Ballot criteria are listed at the end of the announcement.

Ballot Results for Definition

Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 87.85 %
Approval: 39.35 %

Since at least one negative ballot included a comment, these results are not final. A second (or recirculation) ballot must be conducted. Ballot criteria are listed at the end of the announcement.

Violation Risk Factor (VRF) and Violation Severity Level (VSL) Non-binding Poll Results

For the non-binding poll, 86 % of those registered to participate provided an opinion; 28 % of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Next Steps

As part of the recirculation ballot process, the drafting team must draft and post responses to voter comments. The drafting team will also determine whether or not to make revisions to the balloted item(s). Should the team decide to make revisions, the revised item(s) will return to the initial ballot phase.

Project Background

The draft standard combines the following previous standards:

- PRC-005-1 — Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 — UVLS System Maintenance and Testing
- PRC-017-0 — Special Protection System Maintenance and Testing

The proposed standard addresses FERC directives from FERC Order 693 as well as issues identified by stakeholders. In accordance with the FERC directives, this draft standard establishes requirements for a time-based maintenance program, where all relevant devices are maintained according to prescribed maximum intervals. It further establishes requirements for a condition-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the known and reported condition of the relevant devices, and for a performance-based maintenance program, where the hands-on maintenance intervals are adjusted to reflect the historical performance of the relevant devices.

More information is available on the project page:
http://www.nerc.com/filez/standards/Protection_System_Maintenance_Project_2007-17.html

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Ballot Criteria

Approval requires both a (1) quorum, which is established by at least 75% of the members of the ballot pool for submitting either an affirmative vote, a negative vote, or an abstention, and (2) A two-thirds majority of the weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and nonresponses. If there are no negative votes with reasons from the first ballot, the results of the first ballot shall stand. If, however, one or more members submit negative votes with reasons, a second ballot shall be conducted.

MRO's NERC Standards Review Subcommittee (NSRS)
Joseph DePoorter
Midwest Reliability Organization
No
The NSRS feels additional changes are needed. The functional testing requirement should be altered or removed as it increases the amount of hands-on involvement and the opportunity for human error related outages to occur, thereby introducing a greater risk to decrease system reliability. As noted on p. 8 in the supplementary reference document, "Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability." By removing circuits from service on the proposed timelines for functional testing, the chance for human error is greater than a mis-operation from faulty wiring. Alternatively, entities may choose to schedule more planned outages to conduct their functional testing in order to limit the risk of unplanned outages resulting from human error. Under this scenario, more elements will be scheduled out of service on a regular basis, thereby reducing transmission system availability and weakening the system making it more challenging to withstand each subsequent contingency (N-1). Thus testing an in-tact system is more desirable than taking it out of service for testing. While the SDT has included language in the draft standard to use fault analysis to complete maintenance obligations, in practicality, this option does not offer any relief to taking outages to perform functional tests. Nearly all BES circuit breakers are equipped with dual trip coils. Identifying which trip coil operated for a fault only covers the one trip coil. Functional tests would still be needed on the other. The likelihood of having multiple trips on a given line in the course of several years is very low. Given it can take a year to schedule some outages; planning maintenance with random faults is unpractical and will create unacceptable risk to compliance violations. A better approach is to use the basis in schedule A, but extend this to cover the entire protection schemes. The document should establish target goals for mis-operation rates (dependability and security). This would allow the utilities to develop cost effective programs to increase reliability. The utilities would have incentives to replace poorly performing communications systems; they would be able to quantify the value of upgrading relay systems.
No
The NSRS disagrees with the VRFs as specified in the standard. R1 VRF would more likely be

classified as “medium” and R2 through R4 should be classified as a “High” VRF.
No
The NERC standard assigns a retention period for the two most recent performances of maintenance activity which implies two intervals of documentation being maintained. The NSRS does not agree that requiring all data for two full cycles is warranted. The volume and length of data retention is unreasonable. The NSRS recommends that the entity retain the last test date with the associated data, plus the prior cycle test date only without retaining the test data.
Yes
Yes
No
The FAQs are helpful, however, with the revised standard as written, The NSRS has issues with the answers provided. Please refer to Question #7 for areas of concern.
The NSRS does not support the existing 2nd Draft of PRC-005-2 Standard because it is our opinion that: • There is a high probability that system reliability will be reduced with this revised standard. • The utility industry is in the business of keeping the lights on, but these requirements will force the industry to take customers out of service in order to fulfill these requirements. A possible solution is to increase the test intervals, set performance targets, test set on a basis of past performance, etc. • The number of unplanned outages due to human error will increase considerably. • The requirement of a complete functional trip test will reduce the level of reliability and all levels of the BES to include distribution systems. • Availability of the BES will be reduced due to an increased need to schedule planned outages for test purposes (to avoid unplanned outages due to human error). • To implement this standard, an entity will need to hire additional skilled resources that are not readily available. (May require adjustments to the implementation timeline.) • The cost of implementing the revised standard will approximately double our existing cost to perform this work. Requests that relevant reliability performance data (based on actual data and/or lessons learned from past operating incidents, Criteria for Approving Reliability Standards per FERC Order 672) be provided to justify the additional cost and reliability risks associated with functional testing. Under a Performance-Based Program, what happens if the population of components drops below 60 (as all will eventually)? Is there an implementation period to default to TBM? Please clarify. In R1, the statement “or are designed to provide protection for the BES” re-opens the argument about transformer protection or breaker failure protection for transformer high-side breakers tripping BES breakers being included in the transmission protection systems. Also, for Table 1b “Verify that each breaker trip coil, each auxiliary relay, and each lockout relay is electrically operated within this time interval” should be changed from a 6 year interval to a 12 year interval similar to the relay input and outputs. Experience has shown that these both have very similar reliability. The standard as currently drafted raises concern as it relates to the identification of all Protection System components, particularly those with associated communications equipment. In the case of leased lines, a utility would be expected to maintain equipment they do not own. Recommend revising the standard to consider maintenance activities on a communications channel basis in which intermediate device functioning can be verified by sending a signal from one relay to another. Clarification should be given as to the reason for stating control circuitry separately, such as in “Control and trip circuits”. As currently stated, this implies that close circuit DC paths are now subject to a protection system maintenance program when reclosing and closing of breakers have never before been considered part of a Protection System. Statements 3 (For microprocessor relays, check the relay inputs and outputs that are essential to proper functioning of the Protection System.)and 6(Verify correct operation of output actions that are used for tripping. in Table 1b for Protective Relays essentially address the same issue. Please clarify if these are addressing the same issue or not. If the purpose is to describe the functionality of the protection system, that should be covered under another section in the table, such as DC circuitry. How one identifies a voltage and current sensing input is not well defined. In most cases, this should already be identified with the relay. Also, the scope of detail required is ambiguous. Would individual cables, terminal blocks, etc. need to be identified as would be implied by “associated circuitry”? Please clarify. The NSRS recommends that individual cables, terminal blocks, etc are not included in this program. Recommend removing “proper functioning of” from the maintenance activities for voltage and current sensing inputs in Table 1b. A utility is not verifying the functionality of the signal(s), they are verifying the signals themselves. Any functioning of the signals, which is related to ensuring proper relay interpretation, would be covered under the protective relay section. In general, has thought been put into the possibility of degrading reliability by implementing such a rigorous maintenance program? To implement such a program, the number of scheduled outages would greatly increase resulting in scheduling conflicts that will increase, as well as degrading system conditions by taking lines, transformers, etc. out of service. Because of past design practices many of the requirements for maintenance will only be able to be performed by lifting wires to isolated trip paths. Potential error is introduced anytime a wire is lifted, especially numerous wires, by means of ensuring they are put

back in the correct place. Redundancy is one thing that has been implemented in great detail throughout the history of protection systems to ensure that they work as intended. Diligent commissioning may need to be given its due credit.

No
Clarification is needed for “to a location where action can be taken”. Some examples in the FAQ will help in this clarification. What type of documentation is required to show compliance that maintenance correctable issue has been reported? Clarify the removal of requirement (see redline version, third row of Table 1a) for testing of unmonitored breaker trip coils. Is it the intention of the SDT to remove a requirement that would drive the industry to install TC monitors on breakers to improve reliability? UFLS/UVLS DC control and trip circuits (Rows 5 and 6 of Table 1a) – Due to the distributed nature of this program, random failures to trip are not impactive to the overall operation of the UFLS protection. There should be no requirement to check the DC portion of these protections any more often than the DC circuit checks associated with that LV breaker. Since it is clear the requirement does not include the need to trip the breakers why the need to check the trip paths? Deletion of this requirement leaves the requirement to check only the relays and relay trip outputs from the protections every 6 years (or as often as the protective relay component type). Should the maintenance activities for “UVLS and UFLS relays that comprise a protection scheme distributed over the power system” not be the same as “Protective Relays”? V and I sensing to relays have a 12 year Maximum Maintenance Interval listed. It is good work practice to have this activity done the same time as maintenance activities associated with relay maintenance. What is the basis for the various Maximum Maintenance Intervals listed in Table 1a? From page 12 of the redline version, for "Station dc Supply (used only for UFLS and UVLS)", is the requirement applicable to distribution substations only? For “Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems only)” under Maintenance Activities - the word “complete: may be removed as it requires to actually trip the breakers. The sentence that tripping of the circuit breakers is not required contradicts with the word “complete”. More specifics are required to spell out the adequate testing e.g. up to the lockout with the trip paths isolated etc. See Page 12 of the redline version. For “Station dc Supply” having 18 calendar months as the Maximum Maintenance Interval, a battery has a 20 year life. IEEE standard PM is on a quarterly basis. What is the basis of the 18 calendar month interval? See page 12 of the redline version. For “Associated communications systems” with a Maximum Maintenance Interval of 6 Calendar years, why is this required? The text "Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relay(s)" seems sufficient to ensure reliability. See page 15 of the redline version. For “Relay sensing for Centralized UFLS or UVLS systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system” under maintenance activities, clarify “overlapping segments”. What is the specified interval? Is actual breaker tripping required? See page 15 of the redline version. On the row for Associated communications systems in Table 1c, in the Level 3 Monitoring Attributes for Component column, suggest a change in wording to: Evaluating the performance and quality of the channel as well as the performance of any interface to connected protective relays and alarming if the channel/protective relay connections do not meet performance criteria. In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour. A 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues is recommended.
Yes
No
Clarification is needed for “on-site audit” – does it include audits by any of the following - NPCC/NERC/FERC. Several small entities do not have on-site audits and participate in off-site audits. Hence, suggest deleting “on-site” from the requirement. Further clarification is required to the Data Retention section to coordinate with the statement in FAQ (Section IV.d p. 22 redline). Suggest the following revised Data Retention requirement consistent with the statement and example given in FAQ: “The Transmission Owner, Generator Owner, and Distribution Provider shall each retain at least two maintenance test records or statistical data to demonstrate compliance with test interval required for each distinct maintenance activity for the Protection System components. The Compliance Enforcement Authority shall keep the last periodic audit report and all requested and submitted subsequent compliance records.”
No
R4 under Severe VSL mentions – Entity has failed to initiate resolution of maintenance-

correctable issues. What proof will satisfy the requirement that the entity has initiated the resolution? R1 under Severe VSL – Move the first criteria “The entity’s PSMP failed to address one or more of the type of components included in the definition of ‘Protection System’” under High VSL since this criteria cannot have the same VSL level as “Entity has not established a PSMP”.
No
There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components. However; an example in the reference document will provide clarity. Page 7 of the redline version of Supplemental Reference – bullet 1 under Maintenance Services, paragraph 2 states “ If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components.” Resetting the time clock will make tracking difficult (unless entities have a sophisticated automated tool for tracking). Another option where an entity can take credit for a correct performance within specifications at the time of the maintenance cycle should be included.
Yes
UFLS systems by design can suffer random failures to trip. A requirement should exist that stipulates to perform maintenance on the UFLS relay as their failure to operate may affect numerous distribution level feeders. However maintenance on associated DC schemes connected to the devices should only be done on the same frequency as maintenance on the relevant interrupting devices. Consideration should be given to exempting schemes that have a maintenance program in place on those distribution level devices from PRC-005 Standard-specified maintenance intervals. Such Standard-specified intervals could apply to interrupting devices that have no maintenance program in place. This standard is overly prescriptive. Owners of protection system equipment establish maintenance procedures and timelines based on manufacturers’ recommendations and experiences to ensure reliability. Maintenance intervals change with improved practices and equipment designs, and whenever that occurs PRC-005 will have to go through the revision process, which would be frequent and unnecessary if the standard were more general.

1)Comment on Control Circuitry – Below in Figure 1 is a previous version of Table 1. It clearly shows 3 levels of monitoring for Control Circuitry. For Unmonitored schemes such as EM, SS, unmonitored MP relays, you must do a complete functional trip test every 6 years. For partially monitored schemes such as MP relays with continuous trip coil/circuit monitoring, you must do a complete functional trip test every 12 years. For fully monitored schemes where all trip paths are monitored, you do not have to trip test the scheme but you still have to operate the breaker trip coils, EM aux/lockout relays every 6 years. This is very clear and reasonable. The latest version of Table 1 is not very clear or reasonable. The previous Partially Monitored control circuit monitoring requirements were deleted and the Fully Monitored control circuit monitoring requirements were moved to Partially Monitored requirements. We are not sure why this major change in philosophy was made?? This makes all of our MP relay control schemes that continuously monitor trip coils/circuits fall into the unmonitored category and therefore requires a 6 year full functional trip test. For a scheme that monitors 99+% of the control scheme (and probably 100% of the control scheme that actually has problems) to be considered Unmonitored does not seem logical or reasonable to us. This puts these “highly monitored” schemes in the same category and requires the same maintenance requirements / intervals as EM relays with no alarms whatsoever. This also seems to contradict the intent of the following statement from the Supplementary Reference doc on page 9: Level 2 Monitoring (Partially Monitored) Table 1b This table applies to microprocessor relays and other associated Protection System components whose self-monitoring alarms are transmitted to a location (at least daily) where action can be taken for alarmed failures. The attributes of the monitoring system must meet the requirements specified in the header of the Table 1b. Given these advanced monitoring capabilities, it is known that there are specific and routine testing functions occurring within the device. Because of this ongoing monitoring hands-on action is required less often because routine testing is automated. However, there is now an additional task that must be accomplished during the hands-on process – the monitoring and alarming functions must be shown to work. Recommendation - Please consider going back to the previous table as shown below in Figure 1. It seems much clearer and reasonable. Feel free to convert the old wording to the latest wording. Figure 1 - Previous Table – Control Circuitry See Figure 1 in email documentation sent to Al McMeekin. Current Table – Control Circuitry (see pdf file) See pdf file PRC-005-2_clean_20 10June88131418.pdf in email documentation sent to Al McMeekin. 2) Comments: The comments

below are grouped by component type. The following (5) comments pertain to the maintenance intervals for protective relays: 1.Is the “verify acceptable measurement of power system input values” activity listed in the protective relay 6 year interval in Table 1a the same activity as the 12-year activity for Voltage and Current Sensing Inputs in the same table? 2.Please clarify the meaning of “check the relay inputs and outputs” that are specified to be checked for microprocessor relays at the following table locations: the protective relay 6 year interval in Table 1a, the protective relay 12-year interval in Table 1b. Is this referring to a check of the relay internal input recognition and output control ending at the relay case terminals, or is this referring to a check extending to the source (and target) of all inputs and outputs to the relay? The latter interpretation results in a repeat of the maintenance required for dc control circuitry. 3.Are the second, third, and fourth maintenance activities in the Table 1a Protective Relay, 6-year row those activities that apply to microprocessor relays? If so, we suggest rewording these items as follows: For microprocessor relays, verify that the settings are as specified, check the relay digital inputs and outputs that are essential to proper functioning of the Protection System, and verify acceptable measurement of power system analog input values.” 4.Please clarify the meaning of “Verify proper functioning of the relay trip contacts” found in protective relays with trip contacts 12 year interval in Table 1c. Is this verification a check of the relay internal contact to the relay case terminals or is this meant to be a trip check functional test? This category of component does not appear in table 1a or 1b. Should it? Is this activity the same as the protective relay Table 1b maintenance activity “output actions used for tripping”? If so, please make the wording match exactly to clarify. 5.Table 1c introduces the use of “Continuous” Maximum Maintenance Intervals. This is inconsistent with the Table 1a and Table 1b usage of the interval. In Tables 1a and 1b this interval is used to describe the maximum time frame within which the activities shown in “Maintenance Activities” must be completed. The table column “Maintenance Activities” has been used to identify those activities which must be performed in addition to those accomplished by the monitoring attributes. To maintain consistency in use of the interval and activity columns of Tables 1a, 1b, and 1c, each entry that uses the “Continuous” interval should be changed to N/A and the Maintenance Activities should be changed to either “No additional activities required” or “None, due to continuous automatic verification of the status of the relays and alarming on change of settings” [example given for Table 1c, Protective Relays] The following (8) comments apply to Maintenance Tables 1a, 1b, and 1c for Station DC supplies. 1)In Table 1a, Station dc supply, 18 calendar month, the verify item “Float voltage of battery charger” is not listed in Table 1b. Is this requirement independent of the level of monitoring and always required? If so, should it be added in to Table 1b and 1c, Station dc supply, 18 calendar months above the “Inspect:” section? 2)The 6 year interval maintenance activity for NiCad batteries in Table 1a and Table 1b should read “station battery” rather than “substation battery”. 3)It is recommended to simplify the Station dc supply sections in each of the three maintenance tables by relocating the common items that do not change dependent upon the level of monitoring. Specifically, the following rows of each of the three tables have identical maintenance requirements that are independent of the level of monitoring. The tables would be significantly simplified if these “monitor level independent” requirements are moved outside of the table: a.Station dc supply; 18 calendar months; Inspect: “ b.Station dc supply (that has a s a component Valve Regulated Lead Acid batteries) c.Station dc supply (that has as a component Vented Lead Acid batteries) d.Station dc supply (that has as a component Nickel Cadmium batteries) e.Station dc supply (battery is not used) 4)Table 1a has 18 calendar month requirements for “Station dc supply (battery is not used)”. This category is missing from Table 1b – was this intentional? 5)Table 1a has 6 calendar year and 18 calendar month requirements for “Station dc supply (battery is not used)”. This category is missing from Table 1c – was this intentional? 6)Please clarify the meaning of “Battery terminal connection resistance”. Does this apply only to multi-terminal batteries? Is this referring to the cables external to the battery (to the charger and load panel)? 7)Table 1c contains a Type of Protection System Component not found in any of the other tables: “Station dc supply (any battery technology). Is this the same as “Station dc supply” found in Tables 1a and 1b? 8)The Level 3 Monitoring Attributes for “Station dc supply (any battery technology)” are identical to the Level 2 Monitoring Attributes for “Station dc supply”. This appears to be duplicative in description with two different “maximum maintenance intervals” and “maintenance activities” listed. The following (3) comments pertain to the Voltage and Current Sensing Input component type: 1)Why is “signals” bolded in the Table 1a row for this component type? 2)Are the Table 1a, 12 year maintenance activities for this component type a duplication of the Table 1a, Protective relay, 6 year maintenance activity for microprocessor relays (verify acceptable measurement of power system input values)? 3)Why is this component type highlighted in bold in Table 1c? The following (8) comments pertain to the Control and Trip Circuit component type: 1)Why are microprocessor relay initiated tripping schemes excluded from the 6 year complete functional testing? The auxiliary relay operations resulting from these initiating devices are just as likely to stick (mis-operate) as those initiated from electromechanical devices. 2)We propose simplifying Table 1a for this component type by grouping the two 6 year and the two 12 year interval maintenance lines into two rather than four table rows. The 6 year interval maintenance activities for the UFLS/UVLS systems could be addressed in the table row above using a parenthetical adder to the existing text = (for UFLS/UVLS systems, the verification does not require actual tripping of circuit breakers or

interrupting devices). All of the other text in the UFLS/UVLS table row matches that found two rows above. The same parenthetical adder in the first 12 year interval row for this component type would eliminate the need for the (UFLS/UVLS Systems Only) row for 12 year intervals. 3)If the two rows are combined as suggested previously – this comment is irrelevant: The Table 1a 6 year interval activity for UFLS/UVLS Systems Only is missing the word “contacts” after auxiliary. 4)There appears to be no difference in the 6 year interval maintenance activities for this component type in Table 1a and Table 1b. Table 1b monitoring attributes include “Monitoring and alarming of continuity of trip circuits”, but the interval between electrically operating each breaker trip coil, auxiliary relay, and lockout relay remains at 6 years. What maintenance activity advantage do the Level 1b monitoring attributes provide? 5)The difference between the two DC Control Circuits in Table 1b (on page 14) is unclear. What is the difference between the “Control Circuitry (Trip Circuits)” and the “Control and trip circuitry”? We propose combing the multiple table rows for this component type into a single line item for this component type, as it takes a combination of the protective relay action, any auxiliary relay, and the circuit breaker to comprise a complete tripping system. 6)We have three questions on the monitoring attributes given for this component type on page 14: a) Does the attribute beginning “Monitoring of Protection ...” indicate a requirement to monitor every input, every output, and every connection of every Protection System Component involved in each tripping scheme? b) Does the attribute beginning “Connection paths...” related to monitoring of communication paths? c) Does the attribute beginning “Monitoring of the continuity...” require the presence of coil monitoring of any auxiliary relay whose contact is encountered when tracing a tripping path from a protective relay to a breaker? 7)Are the Table 1c attributes for this component type different from the monitoring described in Table 1b beginning “Connection paths...”? 8)Are there no requirements to operate any relays functionally for “Protection System control and trip circuitry” in Table 1c? The devices need to be exercised some or they will not be reliable. The following (1) comment pertains to the Associated communications system component type: 1)The Table 1b monitoring attribute for this component type (communications channel monitor and alarm) clearly should (and does) eliminate the Table 1a, 3 month interval activity (verifying the communication system is functional). The common maintenance activities found in Table 1a (6 year) and Table 1b (12 year) should be same interval – either 6 or 12.

Yes
Yes
Yes
General FAQ 1)Attached is an elementary drawing showing a typical transmission line relay protection scheme utilizing SEL-351S and SEL-321 microprocessor relays. Does this qualify as partially monitored control circuitry? See pdf file Control Elementary_1-07-13 & Control Elementary_2-07-13in email documentation sent to Al McMeekin. •If not, and this is an unmonitored circuit, what would be the appropriate maintenance interval (6 years or 12 years) for the Control and Trip Circuits from page 9 of PRC-005-2? The description of the two choices is ambiguous See pdf file PRC-005-2_clean_2 010June8.pdf in email documentation sent to Al McMeekin. •If not, what would it take to make this circuit partially monitored (including inputs)? 2) Table 1a, page 9, row 2 (Voltage and Current Sensing Inputs) Question – Does this mean secondary quantities from CT’s and VT’s only? If so, please consider changing the wording from “Voltage and Current Sensing Inputs” to “CT and VT secondary quantities”. 3) Table 1a, page 9, row 3 (Control and trip circuits with EM contacts) Question - Does "electromechanical trip or auxiliary contacts" mean EM protective relay outputs and EM tripping/lockout tripping contacts only? Or does it also include any part of the trip circuitry such as cutout switch contacts and breaker trip coils plus associated aux. breaker contacts. For example, the schematic with a microprocessor relay described in the first bulleted item could be considered an unmonitored EM control circuitry (6 year interval). Is this because of the mechanical breaker aux contacts, breaker maintenance switch, and FT-1 test switch? If so, how could any control circuitry fall in the solid state trip contacts category (12 year interval)? 4) Table 1a, page 9, rows 3, 4, 5, 6 – Please consider rewording these to make it clear where control schemes with MP relays that do have trip coil / circuit monitors but don’t meet the Partially Monitored requirements fit. (Does this type scheme fit in the 6 year trip test category or the 12 year category?) 5) Table 1a, page 12, row 1 – The maintenance requirements are not the latest wording used for all other Protective Relays. Please consider changing for consistency. 6) Table 1b, page 13, row 1 (Protective Relays) - Line three of the maintenance activities requires us to check inputs and outputs. The last maintenance item is to verify correct operation of output actions that are used for tripping. Question - How is this different than the line three maintenance requirements to check inputs and “outputs”? 7) Table 1b, page 14, rows 1 and 2 – Consider combining these into

one row. The maintenance intervals and maintenance activities are these same. Please specify what is required for UFLS and UVLS control schemes). 8) Table 1b, page 14, rows 1 – The first sentence is very general for a monitoring attribute. ("Monitoring of Protection System component inputs, outputs, and connections with reporting of monitoring alarms to a location where action can be taken.") Consider deleting this row or make it more specific. 9) Table 1b, page 14, row 2 [Control Circuitry (Trip Circuits) (except for UFLS/UVLS)] Question: Should there be a 12 year functional trip test requirement for this partially monitored control circuitry? Should this be added to Table 1b? 10) Table 1b, page 14, row 1 [Control Circuitry (Trip Circuits) (except for UFLS/UVLS)] - It states Monitoring of Protection System component inputs, outputs, and connections … Question – what does "inputs" mean? There are Protection System components such as protective relays, control circuitry, station dc supply, associated communications systems, etc. Does this mean we must monitor inputs to any or all of these Protection System components? How would this be accomplished? 11) Table 1c, page 18, row 4 – Should there still be a requirement to trip breakers by all trip coils every 6 years? Supplementary Reference Document 12) Question on Figure 1, page 27 - Box 1 denoting Protection Relays includes Aux devices, Test or Blocking Switches. The Aux devices, Test or Blocking Switches should be part of Box 3 (Control Circuitry). Please correct or note accordingly. FAQ Document 13) On Page 30, please add an Example with Partially Monitored (Level 2) Control Circuit. 14) On the Control Circuit Decision Tree on page 36, the flow chart does not match the current Table 1 requirements. They match the previous version which is described in the first question of this document. We still propose leaving the flow chart on page 36 as is and change Table 1 to match the original requirements. 15) Please consider adding a diagram /elementary drawing of a Partially Monitored Control Circuit showing the trip output contacts, inputs, etc that must be monitored to meet the Monitoring Attributes / Requirements. A diagram showing an Unmonitored control scheme and what it would take to make it Partially Monitored would be helpful too. Additional General FAQ 16)PRC-005-2, R1 requires the Functional Entity to establish a Protection System Maintenance Program (PSMP). It is not clear if this standard establishes a specified frequency for reviewing and updating the PSMP itself or the PSMP criteria outlined in subparts 1.1 through 1.4. By comparison, EOP-005-1 System Restoration Plans, requires the Functional Entity to (a) have a restoration plan and (b) to review and update the restoration plan annually (see EOP-005-1, R1 and R2). This approach to a comprehensive and periodic review considers the PSMP as a whole and is independent of the specific maintenance methods (time-based, condition-based, or performance-based) and maintenance intervals for those respective methods. It is noted however that PRC-005 Attachment A mentions annual updates to the list of Protection System component. According to the Attachment's subtitle, Criteria for a Performance-Based Protection System Maintenance Program, this annual update seems limited to performance-based maintenance and not inclusive of other maintenance methods. The recommendation is to evaluate the need for a periodic review of the PSMP as a whole. 17)R1, Criteria 1.1, and companion VSL. This Criterion requires the identification of all Protection System components. The VSL for R1 uses a percent-based approach to parse out different quantities of components across the four VSL categories. This implies that a Functional Entity must have the ability to put a numerical quantity on its various components and should be able to demonstrate within certain tolerances that its components are included (or counted). If the number of components within scope amount to hundreds or thousands of individual items, the PSMT SDT should consider the Functional Entities' ability to track and quantify the items for a compliance demonstration. If an entity is not able to reasonably quantify which components are in scope, demonstrating compliance on a percent-basis may prove difficult or impossible. Further review may indicate the need to reformat the VSL. Similar concerns are noted in other VSLs (R2, R3, and R4) and in Attachment A where percentage-of-components are mentioned. 18)R4 essentially requires the Functional Entity to implement its PSMP. R4 takes care to highlight the specific task of "identification of the resolution of all maintenance correctable issues." It is noted that other "identification tasks" are included as criterion for the PSMP in R1. If these tasks are all appropriately categorized as identification-type tasks, it may be more efficient to restructure the standard by incorporating this task into R1 with the other criteria. R4 could remain as a basic implementation requirement with more detail provided in subparts 4.1, 4.2, and 4.3. 19)Footnote No. 2 describes maintenance correctable issues and could be interpreted as a potential new term for inclusion in NERC's Glossary of Terms. The PSMT SDT should conduct further review of this terminology as a potential new Glossary term. 20)At R4, subpart 4.3, insert "design" such that it reads as follows: "Ensure that the components are within acceptable design parameters at the…" Also, this subpart duplicates Footnote No. 3 which describes "maintenance correctable issues" and was established in the main requirement R4 at Footnote No. 2.

Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. There appears to be an inconsistency in the use of "check" vs.

“verify” in the tables. Also, Table 1B, in the second to last row, should be referring to UFLS rather than SPS. Also, note that M2 incorrectly excludes distribution provider. In battery maintenance table, we suggest that “cell/unit” be changed to “cell or unit.”
The SERC PCS expresses no opinion on this question.
Yes
The SERC PCS expresses no comments on this question.
No
In R1, a “Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
The SERC PCS expresses no opinion on this question.
The SERC PCS expresses no opinion on this question.
Descriptors in the "type of the protection system component" column need to be consistent between 1A, 1B and 1C. Also, in the tables, please clarify “complete functional trip test” for UVLS and UVLS trip tests since the breaker is not being tripped. Facilities Section 4.2.1 “or designed to provide protection for the BES” needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. We commend the SDT for developing such a clear and well documented second draft. The SDT considered and adopted many industry comments on the first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. The SERC Protection & Control Subcommittee generally agrees that this second draft will be beneficial to BES reliability.

No
We agree with all proposed intervals in Tables 1a, 1b, and 1c except the 3 calender month interval for Associated Communication Systems in Table 1a. We suggest using a 1 year interval because all other elements of the Protection System are being verified a minimum of every 3 years. Therefore, we believe annual verification of Associated Communication Systems is sufficient.
Yes
Yes
Yes
Yes

In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour. LIPA recommends a 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues. The time identified is report time and not response time to correct issue. LIPA seeks clarification on “to a location where action can be taken”. Some examples in the FAQ will help in this clarification. What type of documentation is required to show compliance that maintenance correctable issues have been reported? What is the basis of the various Maximum Maintenance Intervals tabulated in Table 1a-Time based maintenance?
Yes
No
Two most recent performances of each distinct maintenance activity for the Protection System components will require data retention for an extended period of time. For example, in certain cases, battery maintenance is on a 12 year cycle which suggests that records need to be retained for 24 years. LIPA suggests retaining data for the most recent maintenance activity. LIPA seeks clarification on “on-site audit” – does it include audits by any of the following - NPCC/NERC/FERC. Also, several small entities do not have on-site audits and participate in off-site audits. Hence, LIPA suggests deleting “on-site” from the requirement. In addition further clarification is required to the Data Retention section to coordinate with the statement in FAQ (Section IV.d p. 22 redline).
No
R4 under Severe VSL mentions – Entity has failed to initiate resolution of maintenance-correctable issues. What proofs will satisfy the requirement that the entity has initiated the resolution. R1 under Severe VSL – LIPA suggests moving the first criteria “The entity’s PSMP failed to address one or more of the type of components included in the definition of “Protection System” under High VSL since this criteria cannot have the same VSL level as “Entity has not established a PSMP”.
No
There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components however; an example in the reference document will provide clarity. Page 7 of the redline version of Supplemental Reference – bullet 1 under Maintenance Services, paragraph 2, it says “ If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock is reset for those components. LIPA believes that resetting the time clock will make tracking difficult (unless entities have a sophisticated automated tool for tracking). Another option where an entity can take credit for a correct performance within specifications at the time of the maintenance cycle should be included.
Yes
Table 1a under Maintenance Activities for Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only) states: Perform a complete functional trip test that includes all sections of the Protection System control and trip circuit, including all solid-state trip and auxiliary contacts (e.g. paths with no moving parts), devices, and connections essential to proper functioning of the Protection System., except that verification does not require actual tripping of circuit breakers or interrupting devices. The word complete may be removed as it requires actually tripping the breakers. The sentence that tripping of the circuit breakers is not required contradicts with the word complete. More specifics are required to spell out the adequate testing e.g. up to the lockout with the trip paths isolated etc. Table 1a under Maintenance Activities for Station dc Supply (used only for UVLS or UFLS) states: Verify proper voltage of the dc supply. Is this requirement applicable to the distribution substations only? Table 1a under Maintenance Activities for Station dc supply (battery is not used) – states Verify that the dc supply can perform as designed when the ac power from the grid is not present. - Please clarify this requirement. Table 1a for Associated communications systems - specify the group for the applicability of this requirement. BPS,BES,UFLS etc. Table 1a under Maintenance Activities for Associated communications systems states – Verify that the performance of the channel meets performance criteria, such as via measurement of signal level, reflected power, or data error rate. Why is this required? The requirement "Verify proper functioning of communications equipment inputs and outputs that are essential to proper functioning of the Protection System. Verify the signals to/from the associated protective relays seems sufficient to ensure reliability. Table 1a under Maintenance Activities for Relay sensing for Centralized UFLS

OR UVLS systems UVLS and UFLS relays that comprise a protection scheme distributed over the power system states: Perform all of the Maintenance activities listed above as established for components of the UFLS or UVLS systems at the intervals established for those individual components. The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval, but all of the UFLS or UVLS components whose operation leads to that control action must each be verified. Clarify what is meant by overlapping segments? What is the specified interval? Is actual breaker tripping required?

We agree with most of the changes from the last draft. However, the phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting “unit-to-unit” wherever “cell-to-cell” is used in the table now.
Yes
Yes

is possible that a component that failed to be individually identified per R1.1 was included by entity A’s maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
Yes
Yes
The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don’t match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. We believe this will allow REs to claim non-compliance for every three inch long terminal jumper wire not identified in a trip circuit path. We suggest that the FAQ definitions be included within the standard.

In the tables trip circuit has been replaced by “control and trip circuit”. From the context of the standard and the reference and frequently asked question documents it is clear that the requirement is to test the trip circuit only. Adding the word “control’ introduces ambiguity and the potential to imply the closing circuit of the interrupting device also requires testing under the standard. The word “control” should be removed. On this same subject the nomenclature in Table 1b for type of protection system component is not consistent with Table 1a. In Table 1b in the Level 2 Monitoring Attributes for Component column for Relay sensing for centralized UFLS or UVLS systems there is a reference to SPS. This reference should likely be to UFLS/UVLS. In Table 1a functional testing of associated communications systems is included with a maximum maintenance interval of 3 calendar months. Testing of this equipment at that frequency is not believed to be necessary. It is suggested that the interval be changed to 12 calendar months. For control and trip circuit maintenance the requirement includes “a complete functional trip test”. In order to accomplish this type of testing given current design of lock-out relay and interrupting device trip circuitry multiple breakers and line terminal outages would be required simultaneously. In addition complete functional testing has the potential to result in unintentional tripping of equipment that could cause equipment damage and customer outages. Segmentation of trip circuits by lifting wires has the potential for incorrect restoration following testing. This type of testing has the potential to degrade system reliability as multiple entities schedule this work. An alternate to complete functional testing that does not potentially degrade system reliability should be substituted.
Yes
No
Verification of compliance with the maximum time intervals for testing only needs to include retention of the documentation of the two most recent maintenance activities. The phrase “or to the previous on-site audit (whichever is longer)” should be deleted.
No
The lower VSL specification for R4 should allow for a small level of incomplete testing. Suggest changing “5% or less” to “from 1% to 5%”.
Yes
Yes
From the compliance registry criteria for generator owner/operator and the language in 4.2.5.3 it is implied that the intent is that protection systems for individual generators less than 20 MVA would not be covered by PRC-005. To make this clear in the PRC-005-2 standard, the following footnote to section 4.2.5.3 is recommended: Protection systems for individual generating units rated at less than 20 MVA in aggregated generation facilities are not included within the scope of

this standard. The Request for Interpretation of a Reliability Standard submitted March 25, 2009 indicates that a protection system is only subject to the NERC standards if the protection system interrupts the BES and is in place to protect the BES. The following changes are recommended to clarify this in the standard: A.3. Purpose: To ensure all transmission and generation Protection Systems protecting and affecting the reliability of the Bulk Electric System (BES) are maintained. A.4.2.1. Protection Systems applied on, or and designed to provide protection for the BES. B.R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a PSMP for its Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES and that are applied on, or and are designed to provide…….. FERC Order 693 includes the directive that “testing of a protection system must be carried out within a maximum allowable interval that is appropriate to the type of the protection system and its impact on the reliability of the Bulk-Power System”. If unanticipated conditions (e.g. force majeure) of the bulk-power system do not allow outages to complete protection system maintenance as required by the standard without compromising the reliability of the system delay of the particular maintenance activity should be allowed. This provision should be included in the standard in R4.

In general yes. There are concerns with verifying cell-to-cell resistance in Batteries. On some battery sets this is not possible to do.
No
: The VRF for R1 should be Low. It is administrative to create an inventory list. If R1 failed to be executed but the other requirements wee executed fully then the BES would be properly secured. Compare this against the scenario of performing R1 but failing to perform the other tasks; in which case the BES is at risk. UI recognizes that the SDT considers the inventory as the foundation of the PSMP but it is not the element of the PSMP that provides for the level of reliability sought. R1 should be VERF Low and R2 thru R4 VRF is Medium. UI agrees with the Time Horizon.
Yes
Yes
No
Include a detailed example of an Inventory list. Allow for different means of maintaining the lists electorncially, that is, as spreadsheets, or databases.
No
What actions are taken if the owner can not perform a specific activity elaborated on the tables due to the design of the equipment? Is the owner in non-compliance? Must the owner only accept equipment solutions that allow the maintenance activities elaborated in the standard to be performed?

PRC005-02 Comment We offer some comment for your consideration for incorporation into the Standard PRC-005-02 (draft) as presented in the May 27th 2010 PRC 005-02 “Standard Development Roadmap.” RE: Comment on the 2nd Draft of the Standard for Protection System Maintenance and Testing” 1) The term “The Protection System Maintenance Program” (Page 2) appears to be centered on the concept of maintaining specific components as stand alone objects, and therefore infers that the resultant documentation be organized in a similar fashion. Neither is optimal from a practical or a functional perspective. Many rational work practices combine components (example, meggering from the relay input test switch through the cables and the CTs) in the interest of minimizing circuit intrusion and human error. For this reason, such maintenance practices are superior from a reliability standpoint. The t emphasis on “components” in the current draft is, at best, tangential to NERC’s stated goal and purpose of PRC-005 to

improve reliability. How would we fix this? We would insert the phrase “or Element”—as defined in NERC’s Glossary of Terms to include “one or more components / devices with terminals that measures voltage, current, frequency and/or phase angle” to determine anomalies and to trip a portion of the BES” immediately after any occurrence of the word “component” in each of the Requirements or in a Definition paragraph, intending it to be applied globally to R-1 through R4. This would foster the validity of maintenance activities being applied to aggregations of components — “Elements”—such as would occur during Verification of DC control circuitry or through the employment of fault data analysis. 2) Protection System Maintenance Program. The categorization of maintenance into 7 maintenance activities is welcomed as advancing practices which foster BES reliability. Likewise we find the clarifications denoted by superscripts 1 and 2 helpful. However….under C: MEASURES: M1, the last sentence of the paragraph provides: “For each protection system component, the documentation shall include the type of maintenance program applied (time based, etc), maintenance activities (1 or more of the 7 identified) and maintenance intervals…..” This measure goes beyond the requirements of the standard and should be revised consistent with the deletion of the previous R.1.1 as shown in track changes under the version 2 draft which had included the identification of the maintenance activity associated with each component. COMMENT: It should be apparent in reviewing the evidence that one or more of the 7 listed activity categories are represented. The proscription to explicitly call out these categories is thus redundant---the requirement being that at least one has to be identifiable in the program—and will cause unnecessary complications to the Entity and interpretation issues in the Compliance monitoring effort. We recommend that the words “maintenance activities” be removed from the last sentence in the paragraph pertaining to C: MEASURES: M1. We also believe it is unnecessary to restate the definition of “Protection System” in the Measure. 3) A fundamental incompatibility exists between NERC’s proposition of “maximum maintenance (time based) interval” and the typical CMMS PM generation algorithm. SPCTF members and regional compliance engineers have verbally represented that the “maximum maintenance interval” is a precise term “not to exceed—even by one day---“ maximum, otherwise generating a fine-able Violation and that fixed intervals plus or minus a certain additional period of time to account for other operational exigencies are no longer going to be permitted. There is always an interval between the time a CMMS PM is issued and its completion. The time interval between the issue date and the completion date is normally a period of time to allow maintenance staff to schedule their work in an orderly fashion. The maximum time based interval is fixed by the time period specified for issuance of the planned maintenance (PM) work order (e.g. every 3 years) and the defined period of time to complete the work (usually described as a percentage of the PM interval e.g. 25%). So predicating a PM issue date based on the last issue date plus a percentage of the interval time to complete the work is not inconsistent with a fixed time interval. Under the proposed tables, however, there is no accommodation for this predominate maintenance practice. Even if maintenance intervals were shortened to ensure that the required completion date as defined by program intervals does not exceed the NERC maximum interval as described in the tables, this will not be sufficient because auditors may conclude that the tables permit the use of only a single defined interval and not permit an additional defined period of time to schedule and complete the work. Remember, it is immaterial whether the Entity’s interval is more stringent than the NERC maximum, a violation may occur if the maintenance is not performed within the Entity’s maintenance interval, even if it is shorter than the NERC maximum. A precise maximum interval requires constant managerial intervention on the part of the Entity to ensure that operational exigencies do not cause violations on a component-by component (or element) basis. The shortened interval would tend to destroy the sense of rhythm and pattern which should be manifest in a time based program. Further, after one or more iterations, seasonal restrictions on outages begin to impinge requiring adjustments to be made to the Maintenance Program document to adjust the interval or maintenance activity. At best, it results in a clumsy way of doing business and requiring significantly more oversight into keeping the maintenance program document updated for presentation to auditors rather than focusing on prudent maintenance activities as desired by FERC Order 693. Auditing is not any more difficult if the Maintenance Program also specifies that a percentage of a fixed target / time interval is allowed to schedule and complete the work—as meeting the interval requirements of a time based maintenance program. This method allows for a fixed time for issuance of the work order and maintenance personnel some flexibility to schedule and complete their work within a defined period of time. We recommend to vote against adoption until some more workable solution is identified and disseminated, satisfying both the Compliance Authority and the affected Entities. Specifically, we recommend that the drafting team adopt “target” intervals with a +/- range of acceptability, based on percentage or a fixed time per interval, which can be global for the Program or specific to the elements or components in question. The target intervals must be stated in the PSMP, the range of acceptability easily calculable and enforceable, and within the maximum intervals to be identified in the tables 1a, b, and c, satisfying compliance issues. This also allows the Entities to rationally plan their maintenance using existing CMMS technologies. 4) Within the Violation Security levels, we are aware of no activity by NERC to differentiate the relative criticalitiy of components or Elements of the BES system. For example, protection system components or Elements in a regional switchyard may present a larger potential for disruption of the BES in the

event of a mis-operation than does one associated with one generator among fifteen others and which is more electrically remote from and of less consequence to the BES. Unless and until this issue is addressed, both the PRC-005 maintenance and documentation will be less effective and more expensive than it could be. 5) PRC-005-02's proposed effective date is "See Implementation Plan." This is not adequate to provide regulated entities with appropriate notice of the Effective Date of PRC-005-2 standard. " Additionally, NERC has not posted the "Implementation Plan" for comment in the same manner as the proposed standard and thus we are not able to comment on the schedule provided in the Plan. We understand that the retention and documentation cycles go back three years and that a regulated entity, depending on the effective date of this standard and the entity's audit cycle, will be audited to both PRC-005-1 and PRC-005-2 during the same audit period. Some further discussion should be given to allowing comment on the Implementation Plan because of the potential overlapping requirements during a single audit cycle.

It would be very helpful in Table 1a, 1b, and 1c to reference the FAQ or Supplemental Reference by page number and section number for the corresponding Maintenance Actiivity statements. Table 1a, Control and Trip Circuits with electromechanical trip or auxiliary contact – how is the control and trip circuit functional trip test performed without affecting the BES or without tripping more than just the breaker (trip coil)? What is the basis for an actual trip of the breaker that will affect the BES. Functional trip testing will require extensive analysis and could involve an extensive testing evolution to ensure the correct circuit is tested without unexpected trip of other components, particularly for generator protection systems. The complexity of the system and the test would be conducive to an erro that resulted in excessive tripping, thus affecting the reliability of the BES. It would seem that the potential for an adverse affect from this test would be greater than the benefit gained of testing the circuit. In addition, scheduling outages to perform the functional trip testing in conjunction with other outages required to perform maintenance and other construction activities will be difficult due to the large number of outage requiremetns for the fucntional testing. This will challenge the BES more often and thus reduce reliability. Table 1a, Control and Trip circuits with electromechanical trip or auxiliary contacts - What is the differentiation between control and trip circuits? The FAQ appears to use the term interchangeably. • Table 1a, Associated communication systems - What is the basis for checking that the associated communication equipment is functioning every 3 calendar months for unmonitored components?. NPPDs experience indicates that a check every 6 months is sufficient.
Yes
Please provide an example of how the compliane percentage will be calculated for the implementation plan.
Yes
Additional guidance on what is accepatable evidence is always good.
Yes
Yes
Is this document considered part of the standard and may be referenced during audit and self-certification as an authentic source of informaiton?
No
FAQ 2.G, page 24 – NPPD believes system reliablity will be decresed if an entity is considered non-compliant for exceeding a PSMP stated interval that is within the PRC-005-2 Maximum Maintenance Interval. Considering an entity non-compliant for such a situation will encourage establishment of intervals that only meet the minimum standard. There should be one standard interval that all entities must be monitored against. If an entity wants to perform maintenance more frequently, it should not be subject to non-compliance if it misses its target but meets the Maximum Maintenance Interval in the standard. There are definitions at the beginning of the FAQ that should be contained in the NERC definitions and not in an FAQ. Placing these in an approved definition will help avoid interpretation issues that would arise during future audits.
4.2.5.1 (And elsewhere in the standard) Please define auxiliary tripping relays. 4.2.5.5 Do station "system connected" service transformers that do not supply house load for the generating unit, other than during start up or emergency conditions, fall under this clause? If so, can these transformers be eliminated if the house load can be back-fed from "generator connected" service transformer switchgear? What if there are redundant "system connected" feeds? R1 1.4 Clarification requested. This wording would suggest all battery activities fall under Table 1.a. exclusively. R4 4.3 Does initiation of activities require documentation, or is inclusion of "initiation" in the testing procedure sufficient evidence? Tables 1b &1c: Suggestion: If at all possible, combine and simplify. The number of sub clauses and nuances that are being described in these sections (with little change to interval or procedures for that matter) is overwhelming.

These two tables are setting RE's and System Owners up for making errors. Implementation and auditability should be the focus of this standard, SIMPLIFY. • SPS – Does the output signal need to be verified, or does the actual expected action need to be verified. Actual expected action would affect electrical generation production for NPPD's SPS.

The requirement to measure internal ohmic values of the station dc supply batteries every 18 months is excessive. The interval should be 36 months. Our experience from performing our routine maintenance program including cell impedance testing at 3-year intervals has been that the program is fully adequate in monitoring bank condition.
Yes
No
The Violation Severity Level Table listing for Requirement R4 lists the following under "Severe VSL". "Entity has failed to initiate resolution of maintenance-correctable issues" The threshold for a Severe Violation in this case is too broad and too subjective. The threshold needs to be clearly defined with low, medium, and high criteria.
No
There needs to be a defined method of deferral when equipment can't be gotten out of service until a scheduled outage. Give some examples of what "inputs and outputs that are essential to proper functioning of the Protection System" are. Define what a "Control and Trip Circuit" is. Is there one per relay? Do I have to have a list of them in my work management system?
No
If a relay is tested during a generator outage, what date is allowed to be used for compliance - actual test date or date equipment was returned to service? These are usually only a few weeks apart, but may be as much as three months different.

With regard to DPs who own transmission Protection Systems, the standard is still very unclear on when a DP owns a transmission Protection System. Many DPs own equipment that is included within the definition of a Protection System; however, ownership of such equipment does not necessarily translate directly into a transmission Protection System under the compliance obligations of this standard. DPs need to know if this standard applies to them and right now, there is no certain way of determining that from within this language or previous versions of this standard. Additionally, the NPCC Regional Standards Committee withdrew a SAR on this very subject as we informed the question would be addressed in this proposal.

1. R1.1 What is a Protection System component? Could the SDT provide a better understanding of what is meant by component? R4: A “Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. 2. R4: Suggest a stepped VSL for “Entity has failed to initiate resolution of maintenance-correctable issues”. While we understand the importance of addressing a correctable issue, it seems like there should be some allowance for an isolated unintentional failure to address a correctable issue.
No
2. What role with the Supplementary Reference and FAQ play with reference to the proposed standard? We have a concern that the standard will stand-alone and not include the interpretations, examples and expalnations that are needed to properly apply these values in a compliance envoironment. There needs to be a method to include the FAQ and Supplementary Reference. The method will also need to allow for future modifications as the standard is revised, etc.
No
Data retention becomes a complex issue for maintenance intervals of 12 years where the last two test intervals are required to be kept, i.e. 24 years. It would seem much more reasonable to set a limt of two test intervals or the last regional audit, not having to keep some 24 years of documentation with maintenance systems changing and archival records somewhat problematic to keep.
No
We could find no rational provided for the % associated with each VSL, or component rationale used to determine the proposed values listed. Is this included in some documentation that is available but not included as part of this review?
No
The Supplementary Reference document is critical in our current compliance environment to be approved as part of ths standard and any standard modifications need to be kept in synchronization with the FAQ and the Supplementary Reference.
No
Yes the FAQ is also a very immportant document to be approved along with the standard. There must be a way to have the standard and the FAQ go hand-in-hand or the standard must be revised to include much of the FAQ.
The current interpretation by the SDT of paritally monitored is set at a higher bar than most uttilities use in the their current designs today. We all wish to take advantage of the microprocessor relays and their renowned and improved montoring capability. If TC1 is monitored by primary relay A and TC2 is monitored by primary relay B, and these relays in turn monitor their DC supplies, the vast majority of the system is monitored - (partially monitored), including all the control cable out to the remote breakers and their trip coils. To add to this some additional contacts within the scheme, located very near the primary relays, is extending the partially monitored bar to a higher level than most designs incorporate today. If you know that 98% of the DC control system is monitored - isn't that paritally monitored? Please consider changes to the SDT's current view of a paritally monitored protection systems.

The associated maintenance activities are too prescriptive. The activities needed to ensure the reliable service of the relay or device should be left up to the discretion of the utility.
Yes
No
The change to the Protection System definition and establishing a PSMP with prescriptive maintenance activities relative to the voltage and current sensing devices has created a situation where data from original or prior verification not being available or not at the interval to meet the data retention requirement. Although, methods of determining the integrity of the voltage

and current inputs into the relays were used to ensure reliability of the devices meets the utilities requirements, they may not meet the interval requirement and would then be considered a violation due to changes in the standard. Recommend a single exemption of the two recent most recent performances of maintenance activities to the most recent performance of maintenance activity in the first maintenance interval for this component due to the long maintenance interval, the changes in the standard definitions and the prescriptive maintenance activities.
Yes
Yes
Yes
The generator Facilities subsections 4.2.5.1 through 5 are too prescriptive and inconsistent with sections 4.2.1 through 4. Recommend this section be limited to description of the function as in the preceding sections. Clarification is needed on how the “Note 1” in Table 1a, which appears to be used in to define a calibration failure would be used in Time Based Maintenance. In PRC-005-2 Attachment A: Criteria for a Performance-Based Protection System Maintenance Program, a calibration failure would be considered an event to be used in determining the effectiveness of Performance Based Maintenance. It is unclear in how it will be used in time based maintenance.

Scott Berry
Indiana Municipal Power Agency
The proposed effective date working is confusing and maybe incorrect. It looks like the second part of the paragraph refers to the additional maintenance and testing required by requirement 2 of the current version of PRC-005-1. PRC-005-2 will be adding additional maintenance and testing. Since the current wording is confusing, we are not sure when we have to ensure the new testing is done on the protection equipment. When it comes to battery maintenance, the battery cell to cell connection resistance has to be verified. IMPA is not sure how the SDT wants this maintenace performed. Some battery banks are made up of individual battery cases with two posts at each end that contain two to four individual battery cells inside of each case. To actually tear down the individual cells in a case would be extremely hard and maybe impossible on the sealed cases without destroying the cases. It would be nice to describe how the SDT wants the connection resistance of battery cell to cell verified in the FAQ guide. In the same guide, the SDT might give insight on what is meant by verifing the state of charge of the individual battery cell/units (table 1A). It seems like measuring the voltage level of the individual battery would work for this verification, but addditional information of what the SDT wants for this verification would eliminate any doubt and help with being in compliant with this requirement.

1. The descriptoins for the "type of protection system components" do not appear to be consistent between Tables, 1a, 1b and 1c. 2. The maximum maintenance interval for a lead-acid vented battery is listed at 6 calendar years for performing a capacity test.This type of test has been proven to reduce battery life and an interval of 10 to 12 years would be better. 3. The maximum maintenance interval for "Station DC supply" was set at 3 months. This is too short of a period and 6 months would be better. 4. The control and trip circuits associated with UVLS and UFLS do not require tripping of the breakers but all other protection systems require tripping of the breakers, this appears to be inconsistent? 5. Digital relays have electromagnetic output relays. Do they fall into the electromechanical trip or solid state trip? 6. Need for clarification: The standard indicates that only voltage and current signals need to be verified. Does this mean that voltage and current transformers do not need to be tested by applying a primary signal and verifying the secondary output?
Yes
Yes

Yes
It would be good to have the basis of the 5%, 10% and 15% defined. With time and experience these percentages may need to be changed.
No
Further clarification is needed. The information provided on verifying outputs of voltage and current sensing devices is confusing. In one part, it indicates that the intent is to verify that intended voltages and currents are getting to the relay apparently without regards to acccuracy. A pactical method of verifying the output of VTs and CTs is not identified and need to be identified.

Many of the changes to the proposed standard are reasonable and improve the clarity of the standard and its requirements. However, Y-WEA concurs with Central Lincoln and FMPA on their comments regarding the testing of battery cell-to-cell connection resistance. Many types of stationary batteries are actually blocks of two or more cells that are internally connected. This requirement would necessitate either some sort of feasibility exception process (which, as shown by the TFE process with the CIP standards can be very difficult, cumbersome, and time-consuming to develop and administer) or replacement of the batteries in question, which would pose enormous burdens on small entities that must comply with this standard. The language in this requirement should be changed from “cell-to-cell” to “unit-to-unit” in order to avoid these issues.
Yes
Yes
Yes
Yes
Yes
Y-WEA concurs with Central Lincoln regarding the timing of required battery tests. The IEEE standards referenced indicate target maintenance intervals. In order to remain reasonable, then, this compliance standard needs to allow some buffer between a targeted maintenance and inspection interval and a maximum enforceable maintenance and inspection interval. Central Lincoln’s suggestion of a four-month maximum window is reasonable and should be incorporated into the standard. Y-WEA is also concerned with R1.1’s language indicating that all components must be identified with no defined “floor” for the significance of a component to the Protection System. The SDT cannot possibly expect that a parts list containing every terminal block, wire and jumper, screw, and lug is going to be maintained with every single part having all the compliance data assigned to it, but without clearly stating this, that is exactly the degree of record-keeping that some overzealous auditor could attempt to hold the registered entity to. The FAQ is much clearer as to what is and is not a component and should be considered for the standard. Y-WEA also concurs with FMPA’s comments regarding the testing of batteries and DC control circuits associated with UFLS relaying. Many UFLS relays are installed on distribution equipment. Furthermore, many distribution equipment vendors are including UFLS functions in their distribution equipment. For example, many recloser controls incorporate a UFLS function in them. These controls and the reclosers they are attached to, however, are strictly distribution equipment. 16 USC 824o (a)(1) limits the definition of the Bulk-Power System to “not include facilities used in the local distribution of electric energy.” A distribution recloser and its control clearly fall into this exclusion. 16 USC 824o (i)(1) prohibits the ERO from developing standards that cover more than the Bulk-Power System. As such, the DC control circuitry and batteries associated with many UFLS relaying installations are precluded from regulation under NERC’s reliability standards and may not be included in this standard because they are distribution equipment and therefore not part of the Bulk-Power System. The proposed standard needs to be rewritten to allow for this exclusion and to allow for the testing of only the UFLS function of any distribution class controls or relays.

Armin Klusman
CenterPoint Energy

CenterPoint Energy believes the proposed Standard is overly prescriptive and too complex to be practically implemented. An entity making a good faith effort to comply will have to navigate through the complexities and nuances, as illustrated by the extensive set of documents the SDT has provided in an attempt to explain all the requirements and nuances. The need for an extensive “Supplementary Reference Document” and an extensive “Frequently Asked Questions Document”, in addition to 13 pages of tables and an attachment in the standard itself, illustrate that the proposal is too prescriptive and complex for most entities to practically implement. CenterPoint Energy is opposed to approving a standard that imposes unnecessary burden and reliability risk by imposing an overly prescriptive approach that in many cases would “fix” non-existent problems. To clarify this point, CenterPoint Energy is not asserting that maintenance problems do not exist. However, requiring all entities to modify their practices to conform to the inflexible approach embodied in this proposal, regardless of how existing practices are working, is not an appropriate solution. Among other things, requiring entities to modify practices that are working well to conform to the rigid requirements proposed herein carries the downside risk that the revised practices, made solely to comply with the rigid requirements, degrade reliability.

The monitoring attributes required to achieve level 2 monitoring of Station DC supply seem excessive. We are not aware of any other utilities doing automatic monitoring all 6 attributes required. In particular automatic monitoring of electrolyte level & battery terminal resistance does not seem practical. There is inconsistency between Table 1 and the FAQ. In the Group by Monitoring Level section of the FAQ it indicates that a battery with low voltage alarm would be considered to have level 2 monitoring. In Table 1C under the heading "Maximum Maintenance Interval" some of the entries are stated as being "Continuous". In the case of other maintenance activities the descriptor for Maintenance Interval indentifies the maximum period of time that may elapse before action must be taken. "Continuous" implies continuous action, however, in reality continuous monitoring enables no maintenance action to be taken until such time as trends indicate the need to do so. Therefore we recommend that where the maintenance interval be changed to read "Not Applicable".
No
Time horizons to change from present 6 months to 3 months maintenance time intervals within proposed implementation time period is not realistic.
Yes
No issues or concerns at present
Yes
There is no rational provided for the % associated with each VSL, or component rationale used to determine the proposed values listed.
Yes
Yes
Once the new Standard is approved, NERC must allow for a greater implementation stage and no further changes proposed for the foreseeable future. It does take a lot of resources for a Utility to make the required changes in maintenance frequency templates or type of maintenance required as per the proposed "Standard". Regarding the use of the term “Calendar” (i.e. end of calendar year) for maximum maintenance interval. Our utility uses end of fiscal year as our cutoff date for completing maintenance tasks for a given year. It would be considerable work for us to have to switch to end of calendar year with zero improvement in our overall reliability. We suggest it be left up to each utility to define their calendar yearly maintenance cycle when all tasks for that year must be completed.

1. Table 1a has a “Control and trip circuits with electromechanical trip or auxiliary contacts

(except for microprocessor relays, UFLS or UVLS)" component type listed, and there is a "Control and trip circuits with electromechanical trip or auxiliary [editorial comment: add 'contacts'] (UFLS/UVLS systems only)" component type listed. Suggest a "Control and trip circuits with electromechanical trip or auxiliary contacts" for a microprocessor relay application should be addressed since it seems to be missing. 2. The term "check" has replaced "verify" for some of the maintenance activities in this draft version. What is the difference between these two terms, and shouldn't "check" be defined if it is to be included as a PSMP activity term? 3. Assuming the term "check" replaced "verify proper functioning" in order to allow for the completion of a maintenance activity within the required interval and yet account for a maintenance correctable issue being present, suggest the other remaining activities in the tables where the term "verify proper functioning" is used, also be replaced with "check". 4. Consider modifying the definition of "verification" to "A means of determining or checking that the component is functioning properly or maintenance correctable issues are identified", eliminate use of the term "verify proper functioning" (which seems to be redundant by PRC-005-2 standard definition), and simply use the term "verify".
Yes
Yes
No
1. R4: A "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. 2. R4: Suggest a stepped VSL for "Entity has failed to initiate resolution of maintenance-correctable issues". While we understand the importance of addressing a correctable issue, it seems like there should be some allowance for an isolated unintentional failure to address a correctable issue. If possible, consider the potential impact to the system. For example, a failure to address a pilot scheme correctable issue for an entity that only employs pilot schemes for system stability applications should not necessarily have the same VSL consequence as an entity which employs pilot schemes everywhere on their system as a standard practice.
Yes
Yes
We support this project and believe it is a positive step towards BES reliability. However, we believe the draft document needs additional work as per our comments. Also, as indicated by the amount of industry input on the last version draft comments, we believe revisions are still needed to properly address this technically complex standard. If this standard is to deviate from the original project schedule and follow a fast track timeline for approval, then we disagree with the 3 month implementation for Requirement 1 and ask for at least 12 months. The original schedule provided sufficient advance notice to work on an implementation plan and it included the typical time required for NERC Board of Trustees and regulatory approvals. If the project schedule and typical NERC Board of Trustees and regulatory approval times are to be accelerated, the implementation plan should be extended.

Please provide clarity on why Table 1b for "Station dc supply" has a double entry that appears to be contradictory. The table provides monitoring attributes for a maximum maintenance interval of 6 calendar years and the next row says to refer to level 1 maintenance activities.
Yes
Yes
(Note that Section C.M2 leaves off "Distribution Provider" but references Requirement R2 at the end of the Section. "R2 applies to the Distribution Provider.")
Yes
Yes
No
Question/Answer 4-C (Pg. 10 of FAQ) seems to indicate that by documenting breaker operations

for fault conditions the table 1b requirements for control circuitry (Trip Coils and Auxiliary relays) can be satisfied. It is possible that even though a breaker successfully operates for a fault condition one trip coil of a primary/backup design can be inoperable and “masked” by the good trip coil. Although it is likely that a faulty trip coil would be caught by monitoring of continuity it is not a certainty that both trip coils actually operated to clear a fault (example- mechanical binding)
R1.1 states “Identify all Protection System Components”. To avoid confusion this should be clarified. It could be interpreted that discreet components must be individually identified. An example would be as individual aux relays used in the tripping path.
Individual
Jon Kapitz
Xcel Energy
The current language is not aligned with the FAQ concerning the level of maintenance required for Dc Systems, in particular the FAQ states that with only 1 element of the Table 1b attributes in place the DC Supply can be maintained using the Table 1b activities, the table itself is clear that ALL of the elements must be present to classify the DC Supply as applicable to Table 1b. The FAQ needs to be aligned with the tables. The FAQ also contains a duplicate decision tree chart for DC Supply. The FAQ contains a note on the Decision tree that reads, "Note: Physical inspection of the battery is required regardless of level of monitoring used", this statement should be placed on the table itself, and should include the word quarterly to define the inspection period.

As we commented on in the previous draft of the standard that proposed the Supplementary Reference and FAQ, we are concerned as to what role these documents will play in compliance/auditing. It is also unclear how these documents will be controlled (i.e. Revised and Approved, if at all). Inconsistencies have been identified between proposed standard and the documents (e.g. page 29 of FAQ example 1).
No

R1.1 “Identify all Protection System Components” – does this mean that the PSMP must contain a “list”? Please explain what this means. If it is a list, then essentially it will be a dynamic database, not necessarily a “program” as defined in the PSMP R1.3 “include all maintenance activities…” seems to be an indirect way of indicating that the entities PSMP must comply with the tables. Tables – the components related to DC Supply and battery are confusing. It the battery is the specific component then state “battery". If the charger is the specific component, then state “charger”. As currently written, one must sort through all of the different “Station DC Supply” line items to figure out what is required. – In tables 1b and above, it is written “no level 2 monitoring attributes are defined – use level 1 maintenance activities” but then maintenance activities are listed that don’t match with Level 1 maintenance activities. Please clarify what exactly needs to be done if using Table 1 b and above.

No
The VRF's are highly arbitrary because they treat all registered entities and all protective systems alike. They're not. For example, under-frequency relays for generators protect the equipment needed to restore the system after a blackout. The under-frequency load relays prevent a cascading outage. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. That would make under-frequency load relays more important to prevent cascading outages.
No
Measure 1 is complete overkill for a small generating facility. The maintenance program is to inspect and test the equipment within the intervals. A qualified contractor applies industry standard methods to maintain the equipment. Trying to have each entity define the maintenance

program down to the component level does not improve reliability.
No
The VSL's treat all entities, components and problems alike. By combining 4 protection maintenance standards, it elevates the VSL on otherwise minor problems to the highest levels of any of the predecessor standards. The threshold percentages are very arbitrary. Severe VSL doesn't in any way relate to reliability. For a small generator to miss or mis-categorize 1 out of 7 relays is unlikely to have any impact on reliability, much less deserving a severe VSL. The R2 & R4 VSL's don't care about results of the program, only whether all components are covered. Half of the components could fail annually and its not a Severe VSL. The R3 VSL allows 4% countable events, which can be hundreds for a large entity and only allows a few for a small entity.
No
In 2.3, the applicability is stated to have been modified. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. The modified applicablity moves away from the purpose of the standards program to an undefined fuzzy concept. Applicable Relays ignore the fact that some relays, or even some entities, have little to no affect on reliability. The global definition of Protective System encompasses all equipment, and doesn't differentiate the components that meet the purpose of the standards program. The Supplementary Reference doesn't overcome the inherent shortcomings of the standard.
No
The standard should include an assessment of, and criteria for, determining whether a Protective System is important to reliability. It presently treats a fault current relay on a 345 kV or higher voltage transformer the same as one on a small generator on the 115 kV system. The impact of failures on both on a hot summer day like we've had recently in NY, would be very different. As discussed at the FERC Technical Conference on Standards Development, the goal of the standards program is to avoid or prevent cascading outages--specifically not loss of load. This seems to have been lost in the drafting process. Much of the effort expended on complying with the existing PRC maintenance standards, as well as that to be expended on PRC-005-2, has little to no significant in terms of improving reliability. That effort could be better utilized if focussed on activities that could significantly improve reliability. As one of the Commissioners at the FERC Technical Conference on Standards Development characterized the relationship between FERC and NERC as a wheel off the track. The whole standards program, and especially PRC-005-2, is off the track.

SUB appreciates the effort to try to strike a balance between specificity around a specific standard and flexibility to meet the requirement under the standard. The maximum allowable intervals don't seem unreasonable combined with the implementation schedule. However, it seems that the proposed changes stray toward a proscriptive set of maintenance that 1) does not allow for an alternate method of testing and 2)sets unrealistic testing requirements. For example, battery terminal to terminal testing is not feasible with all battery systems. This is a consistent message SUB has heard from others as well. First and foremost - a test or maintenance must be done for each device within the defined interval. With that in mind... SUB's preference would be that the maintenance activities focus on what specifically must be done for a device (may be type specific) vs. what could be done for a device for compliance (as an example of what an auditor could look for when conducting an audit) vs. alternative best-practices for testing and maintenance that the entity demonstrates constitutes as maintenance or test. With regard to the first (maintenance activities focus on what specifically must be done for a device) - it seems that this would apply to a limited number of devices With regard to the second (maintenance activities focus on what specifically can be done for a device) - it seems that this would apply broad number of devices and the list of what can be done should be broad to cover a range of different devices that provide the same function. With regard to the last (alternative best-practices for testing and maintenance that the entity demonstrates constitutes as maintenance or test), it would be helpful to have a mechanism outside the standard itself to either have a NERC technical group craft a series of criteria that must be met for an acceptable alternative maintenance or the entity document the criteria used to determine an adequate test and provide for a test that meets that set of criteria). It would be anticipated that these would fall under a minority of devices.
No
Time horizons for implementation seem adequate and SUB appreciates the attention to putting together a reasonable but assertive implementation plan. The Violation Risk Factors are problematic. With all due respect, it seems that NERC still operates in a "BIG UTILITY" mind set. There are "PROTECTION SYSTEMS" and there are "Protection Systems" - some Protection

Systems are may significantly impact system reliability and others may not. This not promote reliability in that if an entity was thinking about installing a minor system or installing an improvement that enhances reliability (but is not required) that it might back away because of the risk associated with somehow being out of compliance. Reliability runds the risk of being diminished through the standards approach. SUB suggests stepping back and putting more granularity on VRFs and there needs to be more perspective on the purpose of the device when arriving at a risk factor. Perhaps a voltage threshold could be attached to the VRFs. For example language could be added to say "For Elements at 200kV and above, or for Critical Assets, the risk factor is higher" and "For Elements operating at 100kV and above, the risk factor is medium" and "For Elements below 100kV, the risk factor is lower" In SUB's view, a discussion on VRF's needs to coupled with Violation Severity Levels. SUB discusses VRF's later in this comment form. SUB would be supportive of a Medium VRF designation if there were a more balanced VLF structure (please refer to the comments of VLFs)
No
The measures do not seem unreasonable. However the data retention states that documentation must exist for the two most recent performances of each maintenance activity. Stepping back, there is an implementation schedule that is designed to bring all devices into compliance with ONE maintenance or test within (SUB's understanding is) 6 years. There may not be documentation for more than one activity. Further, new or replacement components won't have more than one activity for a number of years. The data retention schedule, left unchanged, will promote non-compliance because it is impossible to have two records when only one may possibly exist. Rather than promote a culture of compliance, the standard promotes a culture of non-compliance by creating an standard that cannot be met. The FAQ addresses this issue, but the Data Retention language seems to be less clear. SUB suggests that the Data Retention language be clear that new components that do not replace existing components may have only one record for maintenance if only one maintenance of the component could possibly exist. SUB suggests that the Data Retention language also be clear that for new components that replace existing components, that the Data Retention requirement reflect that the entity needs to retain the last test for the pre-existing component and the test for the new component (for a total of two tests).
No
The Violation Risk Factors are problematic. With all due respect, it seems that NERC still operates in a "BIG UTILITY" mind set. Big utilities have potentially hundreds or thousands of components under different device types. Looking at the VRFs, the percentages 5% or 15% as an example, are looked at based on a deep pool of multiple devices so a "BIG UTILITY" that misses a component or small number of components may not trigger a high severity level. However a small utility may have only a handful of components under each type. Therefore if the small utility were to miss one component all of a sudden the utility automatically triggers the 5% or 15% threshold. This type of dynamic unreasonable and not equitable. Therefore (in an attempt to work within the framework proposed), SUB proposes that there be a minimum number of components that might not be in compliance which result in a much lower Violation Severity Level. SUB suggests that NERC try to create a level playing field. If 15% of a Big Utility's total number of components averages at around 15 out of 100 total then perhaps a reasonable outcome would be that up to 5 components (regardless of the total number of components an entity has under each type) could be in violation without tripping into a high VSL. (the 5 components threshold may not apply to all types, this is just for illustrative purposes). Also, are the missed components compounding? For example, if an entity missed 5 components on year three and another 5 components in year 10 is the VSL based on 10 components or 5 components. There should be a time horizon attached to the VSL such that the VSL does not count prior components that were brought into compliance through a past action. That intent may be to not have the VSLs be based on compounding numbers of components, however that should be made clear.
Yes
SUB appreciates that Time Based, Performance Based, and Condition Based programs can be combined into one program. However it should be clear that a utility may include one, two or all three of these types of programs for each individual device type. Currently the language reads: "TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System." The "and" requires all three to be combined if they are combined. SUB suggests the and be changed to "or". Language Change: "TBM, PBM, or CBM can be combined for individual components, or within a complete Protection System."
Yes
SUB is supportive of the intent behind the standard and appreciates the ability to provide input into this process. The following is a repeat of the comment in Question #5 with regard to the supplemental reference. SUB appreciates that Time Based, Performance Based, and Condition Based programs can be combined into one program. However it should be clear that a utility may include one, two or all three of these types of programs for each individual device type.

Currently the language reads: "TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System." The "and" requires all three to be combined if they are combined. SUB suggests the and be changed to "or". Language Change: "TBM, PBM, or CBM can be combined for individual components, or within a complete Protection System."

BPA, Transmission Reliability Program
No
The requirements pertaining to dc control circuitry are confusing. To start with, a definition or further explanation is required for the term “auxiliary contact”. Is this strictly a breaker “a” or “b” switch, or does this include lockout relay contacts, etc.? Another confusing point is that the term trip circuit is used in several places throughout the tables, but it is not included in the definition of Protection System, where the term dc control circuitry is used. It is important to use consistent terminology throughout the definition and the standard. The requirements for (dc) control circuits in Table 1a are fairly straightforward, but in Table 1b control circuits are broken down into three parts: trip coils and auxiliary relays; trip circuits; and control and trip circuitry. It is very unclear exactly what each of these three parts includes. In Table 1c, control circuitry is covered as a single element. Please provide clarity to what is included in each part of a control circuit in Table 1b and the monitoring attributes of each. Also, please be consistent in the treatment of control circuits throughout the three tables. Table 1a, SPS, BPA does not understand the following segment of this paragraph “The output action may be breaker tripping, or other control action that must be verified, but may be verified in overlapping segments. A grouped output control action need be verified only once within the specified time interval,..." In one sentence, it says you can test a SPS in segments - and in the next sentence it says you have to verify the grouped output control action at least once within the specified time interval. It seems that the sentences contradict themselves. Table 1b, Control and trip circuitry - "Monitoring of the continuity of breaker trip circuits along with the presence of tripping voltage supply all the way from relay terminals (or from inside the relay) through to the trip coil(s)..." To monitor the trip path as proposed in this Standard would cost some serious time and $$. BPA does not believe there is a way to meet level two monitoring for batteries. In addition, some of the maintenance tasks need to be defined: - monitoring the electrolyte level is not commercially available. - the state of charge of each individual cell may need to be better defined. There are means to verify the state of charge of the entire bank, but not each individual cell. Since a device to provide level 2 monitoring is not commercially available, we would be forced to follow level 1 maintenance guides, which would require maintenance of comm batteries every three months. Many of these batteries are not accessible during 9 months of the year except via sno-cat or helicopter. We currently monitor for some of the level 2 requirements, but not all. Our current practices of monitoring and yearly maintenance supplemented by opportunity inspections have successfully identified problems before we lost DC power to any of our comm facilities. VRLA type batteries: - battery continuity needs to be defined. In regards to the maximum allowable intervals; the frequency with which BPA performs the 18 month maintenance tasks as prescribed in the standard are on a 24 month interval along with visual inspections and voltage measurements weekly to bi-weekly. BPA has seen success with this maintenance program with the ability to identify suspect cells or entire banks with adequate time to perform corrective actions such as repairs or replacements. BPA also does not perform routine capacity testing, this is an as required maintenance task to confirm/validate our other test results if needed. Our suggestion would be to extend the maintenance intervals beyond 18 months, and to provide some clarity on the above items.
Yes
Yes
Yes
The term “maintenance correctable issue” used in Requirement 4 seems to be at odds with the definition given for it. It seems that an issue that cannot be resolved by repair or calibration during the maintenance activity would be a maintenance non-correctable issue. Also, in Requirement 4, the term “identification of the resolution” is ambiguous. Suggested changes for Requirements 4 and 4.1 are: R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, and resolve any performance problems as follows: 4.3 Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate actions to replace the component or restore its performance to within acceptable parameters.

Constellation Power Generation
No
Constellation Power Generation (CPG) does not agree with the maximum maintenance interval for associated communication systems and station dc supply that has as a component any type of battery, which is 3 months. If the intent of the drafting team was to make this test quarterly (as recommended in IEEE-450), than the maximum interval should be 4 months. As written, for a registered entity to ensure they complete this test in an interval less than 3 months, they will most likely complete this test every 2 months. This causes two additional and unwarranted tests every year. CPG recommends an alternate formulation for intervals if the nominal interval is less than one year. Some possible alternatives (assuming a three month nominal interval): Once per calendar quarter no later than the end of the quarter no earlier than one month before it. Four times per year, no more than 120 days apart no less than 60. CPG does not agree with differentiating between the different battery types. A suggestion would be to take the maximum maintenance interval for all the battery types, which is 6 years, and apply them across all types of batteries, eliminating the need to differentiate between them. Furthermore, multiple cell units do not provide the ability to measure cell-cell resistance, and so that requirement should be removed. CPG is not clear why electromechanical tip contacts in microprocessor relays are excluded in Table 1a.
No
Constellation Power Generation questions why the VRF for R1 is High while all other requirements are Medium. This VRF should be changed to Medium to follow suit with the other requirements.
No
Constellation Power Generation does not agree with the proposed data retention section. Retaining and providing evidence of the two most recent performances of each distinct maintenance activity should be sufficient. For entities that have not been audited since June of 2007, having to retain evidence from that date to the date of an audit could contain numerous cycles, which is cumbersome and does not improve the reliability of the BES.
No
Constellation Power Generation does not agree with the proposed data retention section. Retaining and providing evidence of the two most recent performances of each distinct maintenance activity should be sufficient. For entities that have not been audited since June of 2007, having to retain evidence from that date to the date of an audit could contain numerous cycles, which is cumbersome and does not improve the reliability of the BES.
Yes
No
The PT/CT testing section is implying that the testing must be completed while energized, which is counter to industry practice at generation facilities. Leeway should be given to the entities to devise their own methods for testing voltage and current sensing devices and wiring to the protection system.
Constellation Power Generation does not agree with the changes to Voltage and Current Sensing inputs to protective relays in Table 1a. It is inferring that the only way to complete testing on these components to satisfy NERC is to complete online testing, which is dangerous and does not improve the reliability of the BES. In fact, it can be argued that it decreases the reliability of the BES. The verbiage should be changed back to what was originally proposed to allow for offline testing. Furthermore, Constellation Power Generation does not agree with several of the inclusions of generator Facilities in this standard. For example, in 4.2.5.1, the proposed standard looks to include any components that can trip the generator. At a nuclear facility, this could include protection of motors at the 4 kV level that may trip the generator due to NRC regulated safety issues. This should not fall under NERC jurisdiction. The inclusion of station service transformers is another inclusion that should not be in this standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. Additionally, CPG has concerns regarding the vague language of R1.1, which requires the identification of all protection systems components. It provides no elaboration on the level of granularity expected or acceptable means of identification. It is unlikely that the SDT expected the unique identification of every discrete component down to individual test switches or dc fuses. In the case of current transformers, several of which, or even dozens of which may be connected to a single relay there is no apparent reliability benefit that comes from identifying them uniquely so long as it is proven that a protection system is receiving accurate current signals from the aggregate connection. (It may be argued that the revised definition of “protection stems” eliminates the need to include CT’s under R1.1 but that’s just one interpretation.) Some discrete components of communication systems may exist in an environment that is not owned by or known to the protection system owner. Additionally all protection system components may be identified in

documents that are current and maintained but not in the form of a specific search-able list that is limited to components that are within the scope of PRC-005. Examples may be indexed engineering drawings that identify relays and other components for each protection systems or scanned relay setting and calibration documents that are current but not attached to search-able meta data. It is unclear whether or not these would be considered acceptable identification meeting R1.1. If they are not then the implementation plan for R1 is in all probability unachievable. CPG requests that the SDT provide more elaboration on R1.1 in the standard and in the supporting documents. In that vein, to clarify footnote 1 to R1 which excludes devices that sense non-electrical signals, it should explicitly say that the auxiliary relays, lockout relays and other control circuitry components associated with such devices are included. The matter is well-addressed in the FAQ's but could easily be misunderstood if not included here. Lastly, Constellation Power Generation would like to voice concern over the expedited process in which this standard is being developed. Voting within a week of submitting comments does not leave enough time for the drafting team to thoroughly vet through the issues and identify much needed changes, let alone implement them.

Yes
Compliance agrees with the changes as they add clarity though the Tables do not define what is actually required to demonstrate compliance without reading the Supplementary Reference and the FAQs.
Compliance agrees with the measures. Compliance recommends making the Supplementary Reference part of the standard and that it be referenced appropriately in Table 1a, 1b, 1c and Attachment A. Compliance does not agree with the Data Retention as provided in the draft. In order for an entity to demonstrate that they have maintained system protection elements within their defined intervals retention of documentation will be required for many years. This is in order to establish bookends for the maintenance interval. Maintenance intervals commonly span 5 years or more. Entities should be required to retain data for the entire period of the maintenance interval. Data Retention should be changed to: The Transmission Owner and any Distribution Provider that owns a transmission Protection System and each Generation Owner that owns a generation Protection System, shall retain evidence of the implementation of its Protection System maintenance and testing program for a minimum of the duration of one maintenance interval as defined in the maintenance and testing program.
No
Compliance does not agree. The R1 VSL allows too much to interpret. What does no more than 5% of the component actually use to define the percentage; it should be specific if it is referring to the weight of each component and how many components are there. For example, Protective Relay is one component of five. In addition the VSL for Lower, Moderate and High states in the first paragraph that the entity included all of the "Types" of components according to the definition, though failed to "Identify the Component". It needs clarity on how it can be included though not specifically identified like the next two bullets. The same concern applies to R2 and R4. Be specific about what is included (or not) to calculate those percentages.
Yes
Compliance does agree with the clarity and the Supplementary Reference should be specially referenced where appropriate the Tables 1a, 1b, 1c and Attachment A that are included with the Standard. But this reference is not a part of the approved standard and there are no controls which prevent changes in the reference document that could impact the scope or intent of the standard. If the standard is approved with reference to the Supplementary Reference then future changes to the Supplementary Reference should not be allowed without due process. Only the version in existence at the time of approval of the standard could be used to clarify or explain the standard.
Yes
Compliance does agree with the clarity. The FAQ answers should be referenced specifically to the Standard and the Supplementary Reference to further understand those two documents. However, endorsement of the Standard should not imply endorsement of the FAQ and vice versa.
Compliance believes it will be difficult to demonstrate compliance when an entity chooses Condition Based Level 2 or Level 3 maintenance as the details of the requirements are still open to interpretation. The FAQ has answers to specific questions that are multiple choices. Breaking down this standard into this level of granularity requires supplementary documents to understand it and for auditors to understand how to determine compliance. Industry standards are specific to equipment types and should be allowed to set intervals and maintenance tasks rather than a one-size fitting all approach.

1) Standard, Table 1a, “Control and trip circuits with electromechanical trip or aux contacts (except for microprocessor relays, UFLS or UVLS)”: Where would un-monitored control and trip circuits connected to a microprocessor relay fall, and what is the associated interval and maintenance activity? 2) Standard, Table 1a, “Control and trip circuits with electromechanical trip or aux contacts (except for microprocessor relays, UFLS or UVLS)”: Please confirm that the defined Maintenance Activity requires actual tripping of circuit breakers or interrupting devices. 3) Standard, Table 1a, “Control and trip circuits with unmonitored solid state trip or auxiliary contacts (except UFLS or UVLS)”: Please confirm that the defined Maintenance Activity requires actual tripping of circuit breakers or interrupting devices. 4) Standard, Table 1b. On page 13, for Protective Relays, please clarify the intent of “Conversion of samples to numeric values for measurement calculations by microprocessor electronics that are also performing self diagnosis and alarming.” 5) Standard, Table 1b. On page 13, for Protective Relays, please clarify the intent of “Verify correct operation of output actions that used for tripping.” Does this require functional testing of a microprocessor relay, i.e., using a relay test set to simulate a fault condition? 6) Standard, Tables 1a and 1b: Would it be possible to provide an interval credit for full parallel redundancy from relay to trip coil? 7) Table 1a (page 9) Voltage and Current Sensing Inputs to Protective Relays and associated circuitry – This maintenance activity statement implies that signal tests to prove the voltage and current are present is all that is required. Can this be accomplished by adding a step to the Relay Maintenance Job Plan to take a snapshot of the currents and potentials (In-Service Read) with piece of test equipment? 8) Table 1b (Page 14) Control and Trip Circuitry – Level 2 Monitoring Attributes for Component is too wordy and hard to understand the meaning. Does this whole paragraph mean that the dc circuits need to be monitored and alarmed? At what level does the dc control circuits need the alarming? Can this be at the control panel dc breaker output? 9) Table 1b (Page 15) Station Dc Supply – Should this be in Table 1c because the attributes indicate that the station dc supply cells and electrolyte levels are monitored remotely. To do a fully monitored battery system would be cost prohibitive and require a tremendous amount of engineering. 10) Table 1a and 1b (Page 11 and 16) Associated communications system - Western has monitoring capability on all Microwave Radio and Fiber Optics communications systems with the Communications Alarm System that monitors and annunciates trouble with all communications equipment in the communications network. The protective relays that use a communications channel on these systems have alarm capability to the remote terminal units in the substation. Since these are digital channels how does an entity prove channel performance on a digital system?
Yes
Yes
Yes
Yes
Yes
Clarification 1) FAQ, page 36, Control Circuit Monitor Level Decision Tree: It’s not clear if the note on Level 1 device operation is required for Level 3 monitoring.
1) Standard, Page 4, R 4.3: Is the utility free to define its own “acceptable limits”? 2) Standard, Page 4, R 4.3: Must the “acceptable limits” be stated in the PSMP? 3) Standard, Page 4, Footnotes 2 and 3 are the same. 4) Attachment A says we can go to a performance based program; does this apply to every part of the standard? In other words, does this apply to component testing, functional testing, etc., and do we define the intervals of the test. That is, do we determine how long we test the sample of at least 30 units that Attachment A discusses?

No
The SDT is to be commended for the work and details included in the most recent draft revision. The standard – with associated references is easier to interpret. The sections on DC supply are too restrictive. Quartile checks of VLA electrolyte levels for unmonitored systems is reasonable, however the option of checking the electrolyte levels and voltages with less frequency is not an

option with systems that have voltage alarm notification and ground detection monitoring alarm notification unless all level 2 attributes are followed. The level 2 monitoring attributes are too comprehensive to allow for a suggested alternative less restrictive interval of 6 months to a year. Suggest there be an additional option for level 2 monitoring that includes voltage level and ground alarms with a 6 month maintenance activity interval. The perception of table 1a page 12 for station DC supply – “used for UVLS and UFLS” is a maintenance activity to verify proper DC supply voltage when the UVLS and UFLS system is maintained. This is the only DC supply maintenance activity for those applications and the other more rigorous maintenance activities do not apply? If this is a correct interpretation specifically list that as such in the maintenance activity description (State the other DC supply maintenance activities are not applicable for UVLS and UFLS). The maintenance intervals for station DC supply for level 1 and 2 monitoring does not appear to be consistent and is somewhat confusing. A battery system with level 2 monitoring attributes for components has intervals of 6 years, and then in next section states that no level 2 attributes are defined - use level 1 maintenance activities. Suggest that all DC supply / batteries be broken out all be included in one separate -stand alone table with varied maintenance requirements based on monitoring attributes. The maintenance activities shown on table 1b on page 19 for Station DC supply is intended for VLA batteries? If so add that in component definition. For DC systems that use a storage battery, suggest that chargers be eliminated as other required maintenance activities will expose any problems with the charger. The requirements of performing a capacity test every 6 years during the initial service life of a VLA battery in addition to the other maintenance activities are too restrictive and will cause extensive outages of the affected equipment. Suggest that this frequency be extended to 10 years for VLA batteries for the first iteration if all the other maintenance activities are followed. Failure rate of VLA in first 10 years is extremely low. Other maintenance activities will expose significant issues.
Yes
No
Data retention for battery capacity test should be most recent performance, not last 2. The other maintenance activities documentation with one iteration of capacity test is sufficient documentation
Yes
No
Suggest that figure 2 has a line of demarcation added that shows components specifically not part of the standard requirements. (Medium voltage bus). Battery charger should be removed from table of components when a storage battery is used for the DC supply.
No
This is a very useful document and provides a good source of additional information; there are some cases where it could be interpreted as a standard requirement that can lead to confusion if conflicts exist. For example, the group by monitoring level example V.1.A shown on page 29 describes a level 2 partial monitoring as circuits alerting a 24Hr staffed operations center, page 38 shows level 2 monitoring as detected issues are reported daily. The actual standard table 1b level 2 monitor describes alarms are automatically provided daily to a location where action can be taken for alarmed failures within 1 day or less. This is listed as a supplemental reference document in the standard. The FAQ document “supports” the standard but is or is not an official interpretation tool, or if it is state as such.

BGE
No
Comment 1.1: In its decision to use “calendar years” with the maintenance intervals prescribed for most components the SDT has provided a framework that is consistent with a well-run PSMP but with enough flexibility to be practical. However BGE believes the application of this approach to short maintenance intervals, like three months for some battery maintenance will risk numerous violations due to practical scheduling constraints that are not a realistic threat to reliability. As the requirements are presently defined the inherent flexibility for battery maintenance that is nominally done on three month intervals may be as long as 1/3 of the interval or as short as one day (Our interpretation: Maintenance last done on January 1 is next due on April 1 and can be done no later than April 30. Maintenance done on Jan 31 is next due on April 30 and is overdue if done on May 1). The only practical solution is to increase the frequency so that the average intervals are significantly shorter than the nominal requirement. BGE recommends an alternate formulation for intervals if the nominal interval is less than one year. Some possible alternatives (assuming a three month nominal interval): Once per calendar quarter no later than the end of the quarter no earlier than one month before it. Four times per year, no more than 120 days apart no less than 60. Comment 1.2: On page 11, Row-3/Column-

1 of Table-1a includes the following entry for functional trip testing: "Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS)". It is not clear why electromechanical trip contacts in microprocessor relays are excluded. Comment 1.3: On page 12, Row-3/Column-3 of Table-1a includes the following Verification Task for Station DC Supplies: "Verify Battery cell-to-cell connection resistance". Multiple cell units do not provide the ability to measure cell-cell resistance.
No
See comments under 7 regarding the ambiguity of R1.1. A high VRF for some interpretations of R1.1 may not be reasonable. A program may be structured so that sufficient maintenance to ensure reliability is taking place even though a specific component is not identified. Contrasting the high VRF for R1 with the medium VRF for R4 seems backwards.
Yes
No
The VSL's as proposed may be reasonable but it is difficult to endorse them until the ambiguity in R1.1 is reduced.
Yes
No
The FAQ is a very helpful document. A few more changes would be beneficial. See comments regarding manufactures' advisories and R1.1 under section 7 below. It is our recommendation that manufacturers service advisories not be an implied part of the PMSP requirements and that the expectations for R1.1 be more explicitly described in the FAQ.
Comment 7.1 The standard, FAQs, and supplementary reference all make references to upkeep and include in "upkeep" changes associated with manufacturer's service advisories. The FAQs include statements that the entity should assure the relay continues to function after implementation of firmware changes. This statement is uncontestable as general principle but is problematic in its inclusion in an enforceable standard because there is no elaboration on what the standard expects, if anything, as demonstration of an entity's execution of this responsibility. PRC-005-2 appropriately focuses on implementation of time-based, condition based, or performance based PSMPs; but addressing service advisories does not fit well with any of these ongoing preventive maintenance activities. It is instead episodic, more like commissioning after upgrades, or corrective maintenance work generated by condition-based alarms or anomalies discovered by analyzing operations. The standard appropriately steers clear of imposing requirements for these latter responsibilities as long as execution of an ongoing maintenance program is being demonstrated. BGE recommends that implied inclusion of service advisories should be removed from the standard and supporting documents. Comment 7.2 R1.1 Requires the identification of all protection systems components. But it provides no elaboration on the level of granularity expected or acceptable means of identification. It is unlikely that the SDT expected the unique identification of every discrete component down to individual test switches or dc fuses. In the case of current transformers, several of which, or even dozens of which may be connected to a single relay there is no apparent reliability benefit that comes from indentifying them uniquely so long as it is proven that a protection system is receiving accurate current signals from the aggregate connection. (It may be argued that the revised definition of "protection systems" eliminates the need to include CT's under R1.1 but that's just one interpretation.) Some discrete components of communication systems may exist in an environment that is not owned by or known to the protection system owner. Additionally all protection system components may be indentified in documents that are current and maintained but not in the form of a specific searchable list that is limited to components that are within the scope of PRC-005. Examples may be indexed engineering drawings that indentify relays and other components for each protection systems or scanned relay setting and calibration documents that are current but not attached to searchable metadata. It is unclear whether or not these would be considered acceptable identification meeting R1.1. If they are not then the implementation plan for R1 is in all probability unachievable. BGE requests that the SDT provide more elaboration on R1.1 in the standard and in the supporting documents. Comment 7.3 For clarity footnote 1 to R1 which excludes devices that sense non-electrical signals should explicitly say that the auxiliary relays, lockout relays and other control circuitry components associated with such devices are included. The matter is well-addressed in the FAQ's but could easily be misunderstood if not included here.

Northeast Utilities
No
In Table 1c it is required to report the detected maintenance correctable issues within 1 hour or less to a location where action can be taken to initiate resolution of that issue. Even for a fully monitored protection system component it can be difficult to report the action in 1 hour.

Recommend a 24 hour period for both Level 2 and Level 3 reporting of maintenance correctable issues. Additionally, please clarify meaning of “to a location where action can be taken”.
Yes
No
Two most recent performances of each distinct maintenance activity for the Protection System components will require data retention for an extended period of time. From the FAQ, it is understood that “the intent is not to have three test result providing two time intervals, but rather have two test results proving the last interval”. However two intervals still results in an extended period of time. For example, for a twelve year interval, data would need to be retained for ~24 years. During that period of time a number of on-site audits would have been completed - it is not clear why the requirement is the longer of the two most recent performances or to the previous on site audit date.
No
For R1 under Severe VSL – suggest moving the first criteria “The entity’s PSMP failed to address one or more of the type of components included in the definition of “Protection System” under High VSL since this criteria cannot have the same VSL level as “Entity has not established a PSMP”.
No
There is no guidance on how to calculate the total number of components and thus, the percentages under different severity levels. FAQ provides some insight into how an entity can count components however; an example in the reference document will provide clarity.
No
Page 2 under Component definition, term “somewhat arbitrary” is used by the drafting team to address what constitutes a dc control circuit. Though the drafting team has provided entities with flexibility to define as per their methodologies, it is recommended to clearly determine “what constitutes a dc control circuit” since it will be used to determine compliance.
R1.1 It is not clear what would constitute “all Protection System components”. Suggest the addition of a definition for “Protection System components”. R1.4 Suggest revise to read: “all batteries or dc sources” Table 1a vented lead acid -- “Verify that the station battery can perform as designed by evaluating …” -- Please define evaluating, including: • What is the basis for the evaluation? • Is 5% 10% 20% etc acceptable? • Where does baseline come from for older batteries? Request clarification of 2.3 Applicability of New Protection System Maintenance Standards from Supplementary Reference. Specifically, please clarify if a functional trip test is needed to be performed on the distribution circuit breakers to protect the Bulk Electric System (BES) if these low side breakers are not part of the transmission path. (A diagram identifying the applicable breakers would be helpful in the Supplementary Reference)

-For Protective Relays, Table 1a Maintenance Activities has no requirement for verifying output contacts on non-microprocessor based relays. The actual contacts used for tripping should be verified by this activity. -For Protective Relays, Table 1b Maintenance Activities states “Verify correct operation of output actions that are used for tripping”. This requirement is vague and needs to define whether all protection logic or conditions that would initiate a relay trip output are required to be simulated and tested to the relay tripping output contact. -For Voltage and Current Sensing Inputs to Protective Relays and associated circuitry, Table 1a references “current and voltage signals” and Table 1b references “current and voltage circuit signals”. Need consistency or definitions to meet this requirement. -For Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS Systems Only), Table 1a states “..except that verification does not require actual tripping of circuit breakers or interrupting devices.” This exception to the requirement seems to defeat the whole purpose of the standard and leaves a huge gap open to interpretation and conflict. -For Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UFLS/UVLS Systems Only), Table 1a states “..except that verification does not require actual tripping of circuit breakers or interrupting devices.” This exception to the requirement seems to defeat the whole purpose of the standard and leaves a huge gap open to interpretation and conflict. -For Station dc supply, Table 1a requirement includes “Inspect: The condition of non-battery-based dc supply.” This is redundant with the requirements of the section Station dc supply (battery is not used) and should be removed from this section. -For Voltage and Current Sensing Inputs to Protective Relays and associated circuitry, a maximum interval of verification of 12 years seems to contradict the intent of the rest of the Maintenance standard which dictates 6 years on all of the other components. The requirement for these components should fall in line with the rest of the standard.
No

-Why would R1 (PSMP Program Establishment) be a HIGH VRF and R4 (the actual implementation of the plan) be a medium VRF? These two requirements need to have the same implementation and severity.

Yes

No

-VSL's are based on percentages of components, where the definition of a 'component' is in many cases up to the entity to interpret (see PRC-005-2 FAQ sheet, Page 2). Basing VSL's on an entities interpretation (or count) of 'components' is not an equitable measure of severity level.

Yes

Yes

Individual

John Bee

Exelon

No

Exelon does not completely agree with the minimum maintenance activities and maximum allowable intervals as suggested by SDT. Comments on minimum maintenance activities: Reference Table 1a (Page 11) of Standard PRC-005-2: With regard to the maintenance activity: "Verify that the station battery can perform as designed by conducting a performance ……". The standard should clearly define what is meant by "perform as designed" to eliminate ambiguity in future interpretations. Also, Table 1a Station dc supply (that has as a component Vented Regulated Lead-Acid batteries) discusses “modified performance capacity test of the entire battery bank”. This needs additional clarification or should be reworded because modified test includes both the performance test (which is the capacity test) and the service test. Should be reworded to be “modified performance test”. Comments on maximum allowable intervals: Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). If for some reason the schedule window shifts by even a few days, an issue of potential non-compliance could occur for scheduled outage-required tasks. The possibility exists that a nuclear generator may be faced with a potential forced maintenance outage in order to maintain compliance with the proposed standard. For the requirements with a maximum allowable interval that vary from months to years (including 18 Months surveillance activities), the SDT should consider an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or face non-compliance with a PRC-005 required interval. Therefore, Tables 1a, 1b & 1c should include an allowance for any equipment specifically controlled within each licensee’s plant specific Technical Specifications to implement existing Operating License requirements if such a conflict were to occur. Please see additional comments under Q7.

Yes

Yes

Yes

Yes

Yes

Nuclear generators are licensed to operate and regulated by the Nuclear Regulatory Commission (NRC). Each licensee operates in accordance with plant specific Technical Specifications (TS) issued by the NRC which are part of the stations’ Operating License. TS allow for a 25% grace period that may be applied to TS Surveillance Requirements. Referencing NRC issued NUREGs for Standard Issued Technical Specifications (NUREG-143 through NUREG-1434) Section 3.0, "Surveillance Requirement (SR) Applicability," SR 3.02 states the following: "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." The NRC Maintenance Rule (10 CFR 50.65) requires monitoring the effectiveness of maintenance to ensure reliable operation of equipment within the scope of the Rule. Adjustments are made to the PM (preventative maintenance) program based on equipment performance. The Maintenance Rule program should provide an acceptable level of reliability and availability for equipment within its scope. The NRC has

provided grace periods for certain maintenance and surveillance activities. Exelon strongly believes that SDT should consider providing this grace period to be in agreement and be consistent with the NRC methodology. Not providing this grace period will directly affect the existing nuclear station practices (i.e., how stations schedule and perform the maintenance activities) and may lead to confusion as implementing dual requirements is not the normal station process. Nuclear generating stations have refueling outage schedule windows of approximately 18 months or 24 months (based on reactor type). If for some reason the schedule window shifts by even a few days, an issue of potential non-compliance could occur for scheduled outage-required tasks. The possibility exists that a nuclear generator may be faced with a potential forced maintenance outage in order to maintain compliance with the proposed standard. For the requirements with a maximum allowable interval that vary from months to years (including 18 Months surveillance activities), the SDT should consider an allowance for NRC-licensed generating units to default to existing Operating License Technical Specification Surveillance Requirements if there is a maintenance interval that would force shutting down a unit prematurely or face non-compliance with a PRC-005 required interval. Therefore, at a minimum, maintenance intervals should include an allowance for any equipment specifically controlled within each licensee's plant specific Technical Specifications to implement existing Operating License requirements if such a conflict were to occur. PECO would like to have the implementation plan provide at least 1 year for full implementation of the new standard. This will provide adequate time for development of documentation, training for all personnel, and testing then implementation of the new process (es).

ATC feels additional changes are needed. The functional testing requirement should be altered or removed as it increases the amount of hands-on involvement and the opportunity for human error related outages to occur, thereby introducing more opportunities to decrease system reliability. As noted on p. 8 in the supplementary reference document, "Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability." By removing circuits from service on the proposed timelines for functional testing, the chance for human error is greater than a mis-operation from faulty wiring. Alternatively, entities may choose to schedule more planned outages to conduct their functional testing in order to limit the risk of unplanned outages resulting from human error. Under this scenario, more elements will be scheduled out of service on a regular basis, thereby reducing transmission system availability and weakening the system making it more challenging to withstand each subsequent contingency (N-1). Thus testing an in-tact system is more desirable than taking it out of service for testing. While the SDT has included language in the draft standard to use fault analysis to complete maintenance obligations, in practicality, this option does not offer any relief to taking outages to perform functional tests. Nearly all BES circuit breakers are equipped with dual trip coils. Identifying which trip coil operated for a fault only covers the one trip coil. Functional tests would still be needed on the other. The likelihood of having multiple trips on a given line in the course of several years is very low. Given it can take a year to schedule some outages, planning maintenance with random faults is unpractical and will create unacceptable risk to compliance violations. A better approach is to use the basis in schedule A, but extend this to cover the entire protection schemes. The document should establish target goals for mis-operation rates (dependability and security). This would allow the utilities to develop cost effective programs to increase reliability. The utilities would have incentives to replace poorly performing communications systems; they would be able to quantify the value of upgrading relay systems.
No
ATC disagrees with the VRFs as specified in the standard. R1 VRF would more likely be classified as "medium" and R2 through R4 should be classified as a "High" VRF. ATC is O.K. with the Time Horizons specified.
No
The NERC standard assigns a retention period for the two most recent performances of maintenance activity which implies two intervals of documentation be maintained. ATC does not agree that requiring all data for two full cycles is warranted. The volume and length of data retention is unreasonable. ATC recommends that the entity retain the last test date with the associated data, plus the prior cycle test date only without retaining the test data. ATC agrees with assignment of the measures.
Yes
Yes
No

The FAQs are helpful, however, with the revised standard as written, ATC has issues with the answers provided. Please refer to Question #7 for areas of concern.
It is appreciated that the SDT is attempting to provide options for maintenance and testing programs. Practically speaking, it will be difficult to perform any type of program outside of Time-Based Maintenance (TBM). Too many circuits are a mix of technology. For example, a line may have microprocessor relays for detecting and tripping line faults, but the bus differential lockout could also trip the line breaker. One may be partially monitored and the other unmonitored. It will force the utility to perform maintenance at the shorter of the maintenance cycles. Additional time and cost will be required to organize and switch out the applicable equipment for the outage, approximately doubling the cost associated with performing these trip tests. When entities are required to maintain tens of thousands of these devices, the simplest approach will be to revert to TBM. ATC does not support the existing 2nd Draft of PRC-005-2 Standard because it is our opinion that: • There is a high probability that system reliability will be reduced with this revised standard. • The number of unplanned outages due to human error will increase considerably. • Availability of the BES will be reduced due to an increased need to schedule planned outages for test purposes (to avoid unplanned outages due to human error). • To implement this standard, an entity will need to hire additional skilled resources that are not readily available. (May require adjustments to the implementation timeline.) • The cost of implementing the revised standard will approximately double our existing cost to perform this work. ATC requests that relevant reliability performance data (based on actual data and/or lessons learned from past operating incidents, Criteria for Approving Reliability Standards per FERC Order 672) be provided to justify the additional cost and reliability risks associated with functional testing. Under a Performance-Based Program, what happens if the population of components drops below 60 (as all will eventually)? Is there an implementation period to default to TBM? Are the internal relays and timers associated with a circuit breaker included as part of the protection scheme? In the Independent Pole Operation breakers (IPO), there are various internal schemes built to protect for pole discordance (one pole open, two closed, event measured over time frame (milliseconds)), these schemes may re-trip the breaker, initiate breaker failure protection or trip a bus lock out relay. In DC control schemes fuses and panel circuit breakers protect for wiring faults. Do these devices need to be tested? Is there an obligation to test the distribution circuit breakers for correct operation points? Is there an obligation to replace fuses after a defined time period?

In Table 1a for the component “Station dc Supply (used only for UVLS and UFLS)”, the interval prescribed is "(when the associated UVLS or UFLS system is maintained)" and the activity is to "verify the proper voltage of the dc supply". The description of the interval "(when the associated UVLS or UFLS system is maintained)" needs to be changed. Relay personnel do not generally take battery readings. The interval should read “according to the maximum maintenance interval in table 1a for the various types of UFLS or UVLS relays". The testing does not need to be in conjunction with the relay testing, it is only the test interval that is important, although relay operation during relay testing is a good indicator of sufficient voltage of the battery. The monitoring and/or maintenance activities listed for batteries are not appropriate in Tables 1b and 1c. There are no commercial battery monitors that monitor and alarm for electrolyte level of all cells. Why not move the electrolyte level to the 18 month inspection and actually open the possibility of condition monitoring to commercially available devices? Or give an option to do the electrolyte check at other time intervals (perhaps 12 months) by visual electrolyte inspection and still allow the monitoring of other functions on the listed 6 year schedule using condition monitoring. It makes no sense to prescribe an unattainable condition monitoring solution. The way that the tables are written, there is no advantage to use the charger alarms since battery maintenance requirements are not reduced in any way.
Yes
No
The measure includes the entire definition of "Protection System". Remove the definition from the measure and let the definition stand alone in the NERC glossary. 1.3 Data Retention This calls for past 2 distinct maintenance records to be kept. Since UFLS interval can be 12 years, this would mean that we would need to keep records for 24 years. This is not realistic and consideration should be given to choosing a reasonable retention threshold.
Yes
Yes
Yes

The "Supplementary Reference" and the "Frequently-Asked Questions" document should be combined into a single document. This document needs to be issued as a controlled NERC approved document. AEP suggests that the document be appended to the standard so it is clear that following directions provided by NERC via the document are acceptable, and to avoid an entity being penalized during an audit if the auditor disagrees with the document's contents. NiCAD batteries should not be treated differently from Lead-Acid batteries. NiCAD battery condition can be detected by trending cell voltage values. Ohmic testing will also trend battery conditions and locate failed cells (although will usually lag behind cell voltages). A required load test is detrimental to the NiCAD manufacturer's business, and will definitely hurt the NiCAD business for T&D applications. Historically NiCADs may have been put into service because of greater reliability, smaller space constraints, and wider temperature operation range. "Individual cell state of charge" is a bad term because it implies specific gravity testing. Specific gravity cannot be measured automatically (without voiding battery warranty or using an experimental system), and when it is measured, it is unreliable due to stratification of the electrolyte and differing depths of electrolyte taken for samples. "Battery state of charge" can be verified by measuring float current. Once the charging cycle is over the battery current drops dramatically, and the battery is on float, signaling that the battery has returned to full state of charge. This is an appropriate measure for Level 3 monitoring as float current monitoring is a commercially viable option and electrolyte level monitoring is not. In Table 2b, why is Ohmic testing required if the battery terminal resistance is monitored? Cell to cell and battery terminal resistance should not be monitored because they will be taken in 18 month intervals. This further supports the argument that the battery charger alarms would be sufficient for level 2 monitoring, while keeping an 18 month requirement for Ohmic testing, electrolyte level verification, and battery continuity (state of charge). Automatic monitoring of the float current should be sufficient for level 3 monitoring as it gives state of charge of the string, and battery continuity (detect open cells). Shorted cells will still be found during the Ohmic testing and a greater interval is sufficient to locate these problems.

Table 1a, Protective Relays: Change 1st line to: "Test and calibrate if necessary the relays…" Table 1a, Protective Relays: 3rd line: Change "check the relay inputs…" to "verify the relay inputs…". The term "check" is not defined, whereas "verify" is. Tables 1a & 1b We agree that six / twelve years is an acceptable interval for relay maintenance. Table 1a & 1b, Control & Trip Circuits: The proposed addition to require tripping circuit breakers during Protection System maintenance is detrimental to BES reliability and should be removed. Generating unit protection system maintenance is done during scheduled outages. The high voltage breaker on a generating unit often remains energized to backfeed and supply station auxiliaries when the generator is offline. The proposed requirement will increase the amount of equipment requiring an outage for maintenance, and possibly the length of the outage, resulting in significantly more equipment out of service as well as increased costs. This requirement also results in greater maintenance efforts and costs when there are redundant protection system equipment (breaker trip coils, lockout relays, etc), which is contrary to good practice and reliability. Many of the breakers that We Energies, as the Distribution Provider, trips from its BES protection systems are not owned by We Energies and are owned by a separate transmission company. The trip testing and maintenance of the transmission company may not coincide with our relay maintenance testing program. The standard shall have allowances for the entity to ONLY test or maintain equipment that it OWNS! Table 1a, Station dc supply: The activity to verify the state of charge of battery cells is too vague, and requires more specific action. We assume that the drafting committee is recommending specific gravity measurements. Specific gravity measurements have not been shown to an accurate indicator on state of charge. In addition, as shown in the nuclear power industry, there is no established corrective action that is taken based on specific gravity results (eg. Don't require a test where there is no acceptable corrective action). The activities to "verify battery continuity" and "check station dc supply voltage" are also vague and need to be more clearly specified what is intended. The 3 month time interval for battery impedance testing is too frequent. 18 month or annual testing is more appropriate. The 3 calendar year performance or service test is too frequent and will actually remove life from a battery and reduce reliability. Recommend capacity testing no more that every 5 years and more frequent test if the capacity is within 10% of the end of life or design. This is consistent with the nuclear power industry. Table 1b, Station dc supply: Recommend a change or addition to Table 1b - Recommend a level 2 monitoring (not just a default to the level 1 maintenance activities) which allows for the removal of quarterly "check" of electrolyte levels, DC supply voltage, and DC grounds - if station DC supply (charger) voltage is continuously monitored (eg. one should not have detrimental gassing of a battery if the float voltage of the battery is properly set and monitored). Table 1a, Associated communications systems: The requirement to verify

functionality every three months is excessive; verifying this every twelve months is adequate. Tables 1a & 1b – Although the latest standard provided some additional clarification, more clarification is required on what maintenance / testing is ONLY required for UFLS/UVLS protection systems vs. BES protection systems (eg. UFLS / UVLS systems – Is a verification of proper voltage of the DC supply the only battery or DC supply required (eg. no state of charge, float voltage, terminal resistance, electrolyte level, grounds, impedance or performance test, etc.)?
Yes
No
The requirement to retain data for the two most recent maintenance cycles is excessive. The required data should be limited to the complete data for the most recent cycle, and only the test date for the previous cycle.

No
We support most of the maintenance activities detailed in the Tables, but question the verification of battery cell-to-cell resistance. On some types of battery units, this internal connection is inaccessible. We suggest substituting "unit-to-unit" in place of "cell-to-cell".
No
Although we agree that Requirement 1 is important because it establishes a sound PSMP, a HIGH VRF assignment is not appropriate and it should be changed to LOWER. By definition, a requirement with a LOWER VRF is administrative in nature, and documentation of a program is administrative. Assigning a LOWER VRF to R1 is more logical since R4, which is the requirement to implement the PSMP, is assigned a MEDIUM VRF because, if violated, it could directly affect the electrical state or the capability of the bulk electric system. Additionally, revising the VRF to LOWER would provide a consistent assignment to a VRF on a similar requirement in the proposed FAC-003-2 standard.
Yes
We agree with the Measures but suggest some improvements: 1. In Measures M2 and M3, the term "should" must be changed to "shall" 2. In Measure M2, the Distribution Provider entity is missing
Yes
Yes
We support the reference document and appreciate the SDT's hard work developing this document. We offer the following suggestions for possible improvements: 1. The reference document should be linked in Section F of the standard. Otherwise it may be difficult for someone to navigate the NERC website in search of the document. 2. Section 2.2 – It would be helpful if a short discussion of the reasons for the changes to the definition of Protection System was included in this reference document. In addition, it would be beneficial to discuss what is included in "dc supply" components, such as "dc supplies include battery chargers which are required to be maintained per the Tables in PRC-005-2." 3. Section 8.1 – The fourth bullet which reads "If your PSMP (plan) requires more then you must document more." Should be removed. This is already covered in the sixth bullet which states "If your PSMP (plan) requires activities more often than the Tables maximum then you must document those activities more often."
Yes
We support the FAQ document and appreciate the SDT's hard work developing this document. The reference document should be linked in Section F of the standard. Otherwise it may be difficult for someone to navigate the NERC website in search of the document.
Implementation Plan a. We do not support the 3 month implementation timeframe for Requirement 1. For many entities, it will take some time to develop a sound PSMP that meets the new PRC-005-2 standard. We suggest a 12 month implementation which we believe is more logical and in alignment with the implementation timeframe for Protection System Components with maximum allowable intervals of less than 1 year, as established in Table 1a. b. Although we

support the implementation timeframes for Requirements R2, R3, and R4, we do not support the required periodic percentages of protections systems to be completed. There could be numerous reasons where an entity has to adjust its program schedule which could lead to noncompliance with these percentage milestones. We suggest simply requiring 100% completion of the maintenance per the maximum maintenance intervals. Alternatively an entity should have the flexibility to indicate they have fully transitioned to the new standard during the early stages of the implementation plan if their existing maintenance practices meet or exceed the standards minimum expectations. Doing so should negate the need to produce the "% complete" implementation status.

1. If multiple redundant Protection System components, with associated parallel tripping paths, are provided, Table 1a, 1b, and 1c require that each parallel path be maintained, and that the maintenance be documented. Often, these multiple schemes are provided not to meet specific reliability-related requirements, but instead to provide operating flexibility. Testing these likely will require outages, and those outages may result in decreased reliability. Further, the documentation related to maintenance of all paths will be very cumbersome, and will lead to increased compliance exposure simply by its volume. This may perversely lead to entities NOT installing the redundant schemes, resulting in decreased reliability. 2. Many of the activities described in the Tables are not, by themselves, clear. The standard should include sufficient detail such that entities are clear as to what must be done for compliance, rather that relying on supplementary documents for this information. For example, it’s not clear, in Table 1a (Station DC Supply), what is meant by, “Verify that the dc supply can perform as designed when the ac power from the grid is not present.” Similarly, it isn’t clear from the general description within the Tables that components possessing different monitoring attributes within a single scheme, may be distinguished such that differing relevant tables can be used for the separate components. 3. In Table 1a, Station DC Supply, one of two optional activities is to “Verify that the station battery can perform as designed by evaluating the measured cell/unit internal ohmic values to station battery baseline. Battery assemblies supplied by some manufacturers have the connections made internally, making this option unavailable. Experience with ASME standards show that NERC and SDT members may be jointly and separately liable for litigation by specifying methods that either prefer or prohibit use of certain technologies. 4. Two of the four Maintenance Activities that begin with “Perform a complete functional trip …“ conclude with “… does not require actual tripping of circuit breakers or other interrupting devices. Do the other two such activities therefore require tripping of circuit breakers or other interrupting devices? 5. Performance of the minimum activities specified within Table 1a for legacy systems, particularly regarding control circuits, will require considerable disconnection and reconnection of portions of the circuits. Such activities will likely cause far more problems on restoration-to-service than they will locate and correct. We suggest that the SDT reconsider these activities with regard for this concern.

1. FAQ II.3A attempts to clarify the requirements of “Verify the proper functioning of the current and voltage signals necessary for Protection System operation from the voltage and current sensing devices to the protective relays” suggesting that “simplicity can be achieved” by verifying that the protective relays are receiving “expected values.” It concludes with a statement of the need to “ensure that all of the individual components are functioning properly …” implying that just verifying “expected values” at the protective relay end of the circuit may be inadequate. 2. FAQ II.4D describes what is required for testing of aux relays to include, “that their trip output(s) perform as expected”. Does that include timing tests? (Example – high speed ABB AR relays vs. standard AR relays). 3. The SDT responses to the Draft 1 comments regarding “grace periods” essentially says, “Absolutely not”. However, FAQ IV.1.D reflects data retention requirements relative to an entities’ program which includes a grace period!
1. In the Standard, Footnote 2 and Footnote 3 are identical. We presume that some information has been omitted. 2. We do not agree that Footnotes are an appropriate method of providing information that is important to the application of the Standard. Important information should be provided within the standard text.

No comment.
Yes
Yes
We are concerned with the long-term implementation of the data retention requirements for activities with long maximum intervals. For example, if you are performing an activity that is required every 12 years, the implementation plan says that you should be 100% compliant in 12 years following regulatory approval. However, assuming that 100% compliant meant that you got through all of your components once, you still would not be able to show the last two test dates. 12 years from now, would you still have to discuss the program you were using prior to 12 years ago for those components to have a complete audit, because of having to address the last 2 test dates?
No
In R1, a "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
No Comment.
No comment.
There is some discussion in the documents, such as the definition of component in the Frequently-Asked Questions, about the idea that an entity has some latitude in determining the level of "protection system component" that they use to identify protection systems in their program and documentation. The example given is about DC control circuitry. There are requirements in this standard that are specific to a component, such as R1.1 – Identify all protection system components. Historically, if your maintenance and testing program is defined as (say, for relays) testing all the relays in a station at one time, your program, test dates, etc. could be identified by the station. There needs to be some addition, possibly to the Frequently asked questions, to explain what kind of documentation will be required with this new standard. For example, if your program is to test all the relays at a station every 4 years, and all the relays are tested at the same time, can your documentation of your schedule (the "date last tested" and previous date) be listed by station (accepting that you should have the backup data to show the testing was thorough) or must you be able to provide a list by each relay. Without some clarification, it seems like this could get confusing at an audit with many of the requirements pertaining to "each component."

Yes
The SDT has made significant and worthwhile changes to these tables. However, these tables still seem overly complex and should be simplified. One possibility would be to eliminate Table 1c and use Table 1b for those components that meet certain monitoring attributes. There are some errors in Table 1a in rows 5 and 6. In row 5 in the component column the word "contact" is missing. In the same row in the third column, there is an extra period. In row 6 in the third column, "circuit" should be "circuits" as in the other rows. The maintenance intervals seem to give preference to solid-state outputs but there is no evidence given that these are truly more reliable than an electromechanical trip at least not sufficient to double the maintenance interval.
No
R4 is the implementation of a maintenance program which is extremely important. Effective operation of the BES is so dependent on adequate maintenance that requirement R4 warrants a High VRF. It seems that requirement R3 may actually be better categorized as having an Operations Assessment Time Horizon as the entity needs to review events to analyze the adequacy of maintenance periods.
Yes
Yes
Yes
Yes

The SDT should be congratulated on its hard work in making substantial improvements to an existing standard. In revising the draft standard, the SDT should consider the difficulty an entity will have in providing the evidence required to show compliance. R1 unnecessarily limits PSMPs to "Protection Systems that use measurements of voltage, current, frequency and or phase angle to determine anomalies." However, if an entity applies devices that protect equipment based on other non-electrical quantities or principles such as temperature or changes in pressure, the entity is not required to maintain them. These types of devices have long been considered by many organizations as important forms of protection and therefore in some instances are connected to trip. There are also many organizations that consider these types of devices too unreliable to use as protection and therefore only connect them for monitoring (and not to trip). If protection based on non-electrical quantities is not properly maintained, it will Misoperate and will negatively impact reliability. The standard cannot simply ignore a type of protection that can ultimately affect the reliability of the BES.

Yes
Yes
Agree with the exception that the time horizon for implementation needs to recognize that documentation for maintenance tasks performed prior to this standard may not match current requirements and there should be no penalty for this.
No
Data retention requirements need to be modified. The need to maintain records of two previous tasks is excessive, one should be adequate. Per the two previous task requirements an entity may need to maintain records for 35 years.
Yes
Yes
Yes
R1.1: Please clarify what the requirements for "identify" means. Does each component need to be "identified" in our maintenance system, or at least referenced in the maintenance program or labeled in the field??? R4.3: Please provide guidance on what will be required to prove compliance that "maintenance correctable issues" have been identified and corrective actions initiated. What is the implication of finding maintenance correctable issues as it relates to other requirements for no single points of failure? In other words, if during maintenance a relay is found to have failed, is there an acceptable time period under which we may operate the system without redundancy until a repair can be made? Similarly, if part of a redundant relay system is taken out of service for maintenance, may the facility it was protecting be left in service? If not, then is the implication that protection systems must be triple redundant in order to do relay maintenance on in service equipment? Otherwise facilities would always have to be removed from service to do relay maintenance. Section D / 1.3: The data retention requirement for the two most recent performances of each maintenance activity is excessive. The requirement should be limited to the most recent or all activities since the last on-site audit. At the worse case an entity would have to retain records for up to 35 years for maintenance performed on a 12 year cycle. Table 1a "Protective Relay" entry: The last maintenance activity is listed as "for microprocessor relays verify acceptable measurement of power system input values " for which a 6 year interval is provided". How is this different than the next item "Voltage and Current Sensing Inputs to Protective Relays and associated circuitry" which is on a 12 year interval?? Please clarify this. Implementation Plan: This revised standard will drive significant revisions in existing maintenance programs. 3 months is not adequate time after approval to ensure compliance with R1. A minimum of 6 months should be utilized after regulatory approval. The Implementation plan requirements should also recognize that if the requirement to maintain records of the two previous maintenance tasks is implemented, it may not be possible to produce this information upon implementation. The implementation plan should be structured that the requirement to produce previous maintenance records should be phased in as the maintenance is performed. (ie. The requirement to produce two previous records for maintenance performed on a two year cycle should not be enforced until four years after implementation).

Tyge Legier
San Diego Gas & Electric

No
Proofing of CT circuits is not always trivial. Given this function is not presently being performed and documented by the company, a reasonable grace period would be required to achieve compliance. The company believes present practice, such as verification that relay current inputs are not zero and that phases are balanced, is a reasonable indication individual CTs are functioning properly. An entities protection system maintenance program is a Time Based Maintenance program. The protection system maintenance program describes the maintenance intervals and states that the protection system maintenance is triggered every 4 years. The maintenance program describes that the due date for compliance is 6 months past the trigger date to allow for planning and scheduling of the maintenance activity. Therefore the actual due date for the 4 year maintenance interval is 4 years and six months from the last maintenance completion date. The four year six month time based interval is within the six year maximum time based interval as required by PRC-005-2. Given the above, is the four year six month interval as described in the entities maintenance program compliant with PRC-005-2?

Will the Standard Introduce Technical Feasibility Exceptions to PRC Standards? A large proportion of the batteries (as high as 50% as reported by some SMEs) are not able to accommodate all of the tests prescribed in the draft standard. The phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment. And because buying battery units composed of multiple cells allows space saving designs, entities may be forced to buy smaller capacity batteries to fit existing spaces. This may end up having a negative effect on reliability. Suggest substituting “unit-to-unit” wherever “cell-to-cell” is used in the table now. The Standard Reaches Beyond the Statutory Scope of the Reliability Standards As written, the standard requires testing of batteries, DC control circuits, etc., of distribution level protection components associated with UFLS and UVLS. UFLS and UVLS are different than protection systems used to clear a fault from the BES. An uncleared fault on the BES can have an Adverse Reliability Impact and hence; the focus on making sure the fault is cleared is important and appropriate. However, a UFLs or UVLS event happens after the fault is cleared and is an inexact science of trying to automatically restore supply and demand balance (UFLS) or restore voltages (UVLS) to acceptable levels. If a few UFLS or UVLS relays fail to operate out of potentially thousands of relays with the same function, there is no significant impact to the function of UFLS or UVLS. Hence, there is no corresponding need to focus on every little aspect of the UFLS or UVLS systems. Therefore, the only component of UFLS or UVLS that ought to be focused on in the new PRF-005 standard is the UFLS or UVLS relay itself and not distribution class equipment such as batteries, DC control circuitry, etc., and these latter ought to be removed from the standard. In addition, most distribution circuit are radial without substation arrangements that would allow functional testing without putting customers out of service while the testing was underway, or at least without momentary outages while customers were switched from one circuit to another. Therefore, as written, we would be sacrificing customer service for a negligible impact on BES reliability.
No
R1, R2 and R3 are administrative in nature and ought to be a Low VRF, not a High or Medium VRF. R4 is doing the actual maintenance and testing and ought to be the highest VRF in the standard. Medium VRF is appropriate for R4.

Yes
M1 could be shortened to just a program in accordance with R1, rather than repeat the entire requirement
No
For the VSLs of R1 and R2, we do not understand where the 5%, 10% come from. There are only a few types of components, relays, batteries, current transformers and voltage transformers, DC control circuitry, communication, that's 6 component types by our count, so, missing 1 component type in discussing the type of maintenance program is already a 17% error and Low, Medium and High VSLs are meaningless as currently drafted and every violation would be Severe, was the intention to apply this is a different fashion? Perfection is Not A Realistic Goal R4 allows no mistakes. Even the famous six sigma quality management program allows for defects and failures (i.e., six sigma is six standard deviations, which means that statistically, there are events that fall outside of six standard deviations). PRC-005 has been drafted such that any failure is a violation, e.g., 1 day late on a single relay test of tens of thousands of relays is a violation. That is not in alignment with worldwide accepted quality management practices (and also makes audits very painful because statistical, random sampling should be the mode of audit, not 100% review as is currently being done in many instances). FMPA suggests considering statistically based performance metrics as opposed to an unrealistic performance target that does not allow for any failure ever. Due to the shear volume of relays, with 100% performance required, if the standards remain this way, PRC-005 will likely be in the top ten most violated standards for the forever. In other words, 1-2% of components outside of the program should be allowed without a violation and Low VSL should start at a non-zero number, such as "Entity failed to complete scheduled program for 3-6% of components based on a statistically significant random sampling" or something to that affect. There is a fundamental flaw in thinking about reliability of the BES. We are really not trying to eliminate the risk of a widespread blackout, we are trying to reduce the risk of a widespread blackout. We plan and operate the system to single and credible double contingencies and to finite operating and planning reserves. To eliminate the risk, we would need to plan and operate to an infinite number of contingencies, and have an infinite reserve margin, which is infeasible. Therefore, by definition, there is a finite risk of a widespread blackout that we are trying to reduce, not eliminate, and, by definition, by planning and operating to single and credible double contingencies and finite operating and planning reserves, we are actually defining the level of risk from a statistical basis we are willing to take. With that in mind, it does not make sense to require 100% compliance to avoid a smaller risk (relays) when we are planning to a specified level of risk with more major risk factors (single and credible double contingencies and finite planning and operating reserves).

General comment – the draft changes the word "verify" to "check" in several places; should use consistent phrasing throughout the standard. With regards to Table 1a, we have the following comments: • Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays. UVLS or UFLS) – We believe that while there may be value in a 6 calendar year cycle, this will be difficult to accomplish, since you either have to get outages scheduled or block protection, which risks reliability. Since this is essentially a re-commissioning check, the cycle should be 12 calendar years. Also 6 years appears to be in conflict with the system protection standard. • Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (except for UVLS or UFLS) – agree with 12 calendar years as consistent with electromechanical above. • Control and trip circuits with electromechanical trip or auxiliary (UVLS or UFLS Systems Only) – 6 year cycle should be changed to 12 calendar years (see comment above on non-UVLS/UFLS). • Control and trip circuits with unmonitored solid-state trip or auxiliary contacts (UVLS or UFLS Systems Only) – agree with change to 12 calendar years. • Station dc Supply (used only for UVLS or UFLS) – Strike the word "Station". We don't differentiate between dc supply used for UFLS and other protection. • Station dc supply – Change 18 calendar months to 24 months, since this testing requires generator outages. Nuclear plant fuel cycles can be longer than 18 months. • Associated communications systems – More clarity is needed regarding what is to be included in the definition of "Associated".
Yes
No
M4 states that entities shall have evidence such as maintenance records or maintenance summaries (including dates that the components were maintained). We would like to see M4 revised/expanded to explicitly include the FAQ Section IV 1.B information which states that forms

of evidence that are acceptable include, but are not limited to: • Process documents or plans • Data (such as relay settings sheets, photos, SCADA, and test records) • Database screen shots that demonstrate compliance information • Diagrams, engineering prints, schematics, maintenance and testing records, etc. • Logs (operator, substation, and other types of log) • Inspection forms • U.S. or Canadian mail, memos, or email proving the required information was exchanged, coordinated, submitted or received • Database lists and records • Check-off forms (paper or electronic) • Any record that demonstrates that the maintenance activity was known and accounted for.
No
The VSLs for PRC-005-2 requirements R1, R2 and R4 have significantly tighter percentages than the corresponding requirements in PRC-005-1. We believe that the Lower VSL should be up to 10%, the Moderate VSL should be 10%-15%, the High VSL should be 15% to 20%, and the Severe VSL should be greater than 20%, which is still a lower percentage than the 25% Lower VSL currently in PRC-005-1.

Table 1a: o V and I sensing to relays – 12 years? Why not perform this activity with mtce activities associated with relay mtce so that they line up? It would only be an incremental amount of work to perform this with associated relay maintenance work o Removal of requirement for testing of unmonitored breaker trip coils? Is it really the intention of the SDT to remove a requirement that would drive the industry to install TC monitors on breakers to improve reliability? o UFLS/UVLS DC control and trip circuits – Due to the distributed nature of this program, random failures to trip are not impactive to the overall operation of the UFLS protection. There should be no requirement to check the DC portion of these protections any more often than the DC circuit checks associated with that LV breaker. Since it is clear the requirement does not include the need to trip the breakers why the need to check the trip paths? Deletion of this requirement leaves the requirement to check only the relays and relay trip outputs from the protections every 6 years (or as often as the protective relay component type). o Along the same lines as the above comment should the maintenance activities for “UVLS and UFLS relays that comprise a protection scheme distributed over the power system” not be the same as “Protective Relays” Table 1c: o Level 3 attributes for “Associated communications systems” might better read “Evaluating the performance and quality of the channel as well as the performance of any interface to connected protective relays and alarming if the channel/protective relay connections do not meet performance criteria” o We believe that some

of the proposed maintenance intervals for station DC supply are too stringent and that they would not produce significant increase in reliability to justify associated incremental expenditure. For example we suggest that the following changes are considered: - The interval for eelectrolyte level check for all batteries except VRLAs and internal measured cell/unit Ohmic value for VRLAs be extended to 6 months instead of current time period of 3 months. - The performance or service capacity test of the VRLA battery banks to be extended from 3 years to 5 years.
Yes
Yes
Yes
Yes
Yes
o Footnotes 2 and 3 on page 4 are identical. Delete footnote 3. o UFLS systems by design can suffer random failures to trip. It would make sense for a requirement to exist to perform maintenance on the UFLS relay as their failure to operate may affect numerous distribution level feeders. However maintenance on associated DC schemes connected to the devices should only be done on the same frequency as maintenance on the relevant interrupting devices. Consideration should be given to exempting schemes that have a maintenance program in place on those distribution level devices from PRC-005 Standard-specified maintenance intervals. Such Standard-specified intervals could apply to interrupting devices that have no maintenance program in place.

PPL Generation, on behalf of the entities listed above, has the following comments on the dc entries in these tables: 1. Table 1a, Table 1b, Table 1c- Station DC supply - Maintenance Activities – references substation batteries. For generators, shouldn't that reference be station battery? Substation implies an association strictly with transmission, not generation. 2. Station DC supply - verify Battery continuity. What is the technical basis for this requirement? Neither battery installation and operation instructions nor technical reviews explain the basis for how this verification is supposed to work. NERC's Protection System Maintenance: A Technical Reference does not address this requirement. The Frequently-Asked Questions provides some ways that this verification can be completed. However, one example is tied to the microprocessor battery chargers. If there is a technical basis for this requirement, it should be provided. 3. Condition based monitoring on station dc supply - it appears the Table 1b excludes any condition based monitoring of the batteries because of the requirement for monitoring electrolyte level, individual cell state of charge, cell to cell and battery terminal resistance. Most monitoring equipment does not monitor those functions. 4. In general, the Tables are especially confusing in the dc system area. The “lines” overlap and need to be labeled, so they can be referenced in a maintenance document to show how the appropriate program can be followed. Each line should be separate in the function stated, so one can identify what has to be done to comply. 5. Provide examples of “non-battery-based dc equipment” that is covered under this standard. 6. For dc supply, the changes from the Sept. 2007 NERC “Protection System Maintenance”, A Technical Reference seem too restrictive. The Sept. 2007 document contained a solid maintenance program. What is the basis for the change?
No comment.
No
Measurers M1 – requires having a maintenance program that addresses control circuitry associated with protective functions from the station dc supply through the trip coil(s) of the circuit breakers. Some generators do not own this equipment to the circuit breaker or other interrupting devices. The requirement should be to maintain and test the equipment owned by the generator. Data Retention 1.3 references on-site audits. Entities registered as GO and GOP are not audited on-site.
No Comment.

No Comment.
1. For applicability to generators, the responsibility for a maintenance program will usually rest with the plant operator when the operator and plant owner(s) are different entities. Consider

changing the applicability as it applies to the generator in such situations. 2. Time-based frequency should allow for flexibility; i.e. engineering analysis should allow the entity to exceed the intervals noted in the table. An engineering evaluation that defines a test interval differently than those intervals prescribed in the table should allow an entity to build a program with different intervals. 3. A Grace Period should be defined. This allows a tolerance window to allow for unforeseen occurrences. A grace period would allow for some schedule flexibility and reduce the number of reports to the regulator for exceeding an interval by a reasonable about. 4. The implementation plan for this revision should take into account that a generator outage may be required to implement a new maintenance frequency. The implementation plan should account for outage time, especially nuclear plants that have extended operating cycles. 5. Table 1b Protective Relays Level 2 Monitoring Attributes includes input voltage or current waveform sampling three or more times per power cycle. No further guidance is provided in the reference documents. If this sampling rate is not provided in the specification by the manufacturer, what can the entity use to demonstrate that the attribute is satisfied? Please provide additional guidance. 6. Consider numbering the tables to improve cross-referencing the entries in program documentation. This will allow entities to reference in program documents exactly which activities are being implemented in accordance with the standard. 7. Requirement 1.1 states, “Identify all Protection System components.” This is too broad and must be clarified.

- Table 1a. Protective relays oFor microprocessor relays need guidance in how all the inputs/outputs will be checked and how is determined which one are “essential to proper functioning of the Protection System” oFor microprocessor relays need guidance in how the acceptable measurement is physically determined. - Table 1a. Voltage and current sensing inputs to Protective Relays and associated circuitry oHow verify the proper functioning? By ratio test comparison? - Table 1a. Control and trip circuits with electromechanical trip or auxiliary contacts (except for microprocessor relays, UFLS or UVLS) oThis can be dangerous if backup protection or breaker failure protection schemes not disabled at the time of the functional trip test - Table 1a. Control and trip circuits with electromechanical trip or auxiliary (UFLS/UVLS systems only) oMissing the word “contacts” in the naming of the type of PS component oIf distribution circuit has no breaker bypass will require a tremendous amount of switching or customer outages. - Table1a. Station dc supply (that has as a component Vented Lead-Acid batteries) oWhy is this 18 months when Regulated batteries are required to be verified every 3 months? - Table1a. UVLS and UFLS relays that comprise a protection scheme distributed over the power system oNeed to define this type of UVLS and UFLS relays
No
- We do agree with the majority of the assignments that have been made, however the standard needs specific guidance so to be clearly evidentiated the components as included in the definition of Protection System. The applicability of the standard does not address the current issues regarding radial + load serving only situation when Protection System not designed to provide protection for the BES. - Not sure if the percentages corresponding to the events and activities are appropriately assigned. What were the criteria on which all these percentages are based upon? - Requirement R3 Severe VSL note 3 allows smaller segment population than the Lower VSL. How these segment limits were developed?
- Definition of Terms Used in the Standard. Protection System Maintenance Program oMonitoring. Concerned about the interpretation of this activity description oUpkeep. Not sure about how this activity will be enforced - A. Introduction. 4.2. Facilities. oThe applicability does not address the current issues regarding radial + load serving only situation when Protection System not designed to provide protection for the BES. Standard should clearly state this exemption. - B. Requirements. o1.1. The standard does not provide guidance in how to identify the components of a transmission Protection System (tPS). See prior comment referring to the case of a radial load serving transmission topology. o1.3. Requirement should read “For each identified Protection System component from Requirement 1, part 1.1, include all maintenance activities listed in PSMP and specified in Tables 1a, 1b, or 1c associated with the maintenance method used per Requirement 1, part 1.2.” o1.4. This requirement should be eliminated since already included in Table 1a and covered through Requirement 1, part 1.3. o4.3. Footnote 3 shall be eliminated since duplicates footnote 2 - C. Measures oM1. The added wording in the Protection System definition, requirements and measures with respect to the inclusion of the “associated circuitry from the voltage and current sensing devices” and control circuitry “through the trip coil(s) of the circuit breakers or other interrupting devices” seem right but a bit excessive under current

circumstances (form of the standard). The standard should clearly specify how the maintenance program will address the verification, monitoring, etc. of the actual wiring and the trip coils. We suggest that the wording of the standard to reflect that the maintenance activities on the wiring will be conducted in a visual fashion without implying activities that require disconnecting the primary equipment. We recommend to change the Protection System definition to read “up to the trip coils(s)” instead the word “through” (see comment on the definition as well). We consider that the gain in reliability by pursuing a thorough maintenance program that require to take primary equipment out of service (which in many instances will lead to the entire substation being put out of service) cannot counterweight the sole purpose of the standard and the economics emerging from this program.

ameren
No
Ameren does agree that draft 2 is a considerable improvement from draft 1 of PRC-005-2; however the following still need to be addressed. 1) Use “Control circuitry” to be consistent with the proposed definition. If ‘and trip’ was included so that users would know this is a trip circuit, then the definition should use ‘Trip circuitry’ instead of ‘Control circuitry’. It is important to use consistent terminology throughout the definition and the standard. 2) Please add row numbers in each of Tables 1a, 1b, and 1c, and arrange so that row 1 in each table corresponds, etc. (or state which rows correspond to each other.) This would help clarify movement from table to table. The number of sub clauses, nuances, and varied Type of Component descriptors among rows in the same table as well as from table-to-table can be overwhelming. This would help keep Regional Entities and System Owners from making errors. 3) Please clarify that the instrument transformer itself is excluded. The standard indicates that only voltage and current signals need to be verified. The FAQ seems to cover this, but see our comments on your question 6. 4) Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. Digital relays have electromagnetic output relays. Do they fall into the electromechanical trip or solid state trip? 5) There appears to be an inconsistency in the use of “check” vs. “verify” in the tables. Consider modifying the definition of “verification” to “A means of determining or checking that the component is functioning properly or that the maintenance correctable issues are identified”, eliminate use of the term “verify proper functioning” (which seems to be redundant by PRC-005-2 standard definition), and simply use the term “verify”. 6) Alternately if the term “check” replaced “verify proper functioning” in order to allow for the completion of a maintenance activity within the required interval and yet account for an outstanding maintenance correctable issue being present, suggest the other remaining activities in the tables where the term “verify proper functioning” is used, also be replaced with “check”. 7) If there is an intentional difference between “verify” and “check”, shouldn’t “check” be defined if it is to be included as a PSMP activity term? 8) Functional trip testing will require extensive analysis and could involve an extensive testing evolution to ensure the correct circuit is tested without unexpected trip of other components, particularly for generator protection systems and some transmission configurations. The complexity of the system and the test would be conducive to an error that resulted in excessive tripping, thus affecting the reliability of the BES. It would seem that the potential for an adverse affect from this test would be greater than the benefit gained of testing the circuit. In addition, scheduling outages to perform the functional trip testing in conjunction with other outages required to perform maintenance and other construction activities will be difficult due to the large number of outage requirements for the functional testing. This will challenge the BES more often and thus reduce reliability. For these reasons functional trip testing is too frequent, and should be extended to twelve years. 9) In battery maintenance table, we suggest that “cell/unit” be changed to “cell or unit.” Suggest substituting “unit-to-unit” wherever “cell-to-cell” is used in the table now. Many batteries are packaged such that the individual cells are not accessible. 10) IEEE battery maintenance standards call for quarterly inspections. These are targets, though, not maximums. An entity wishing to avoid non-compliance for an interval that might extend past three calendar months due to storms and outages must set a target interval of two months thereby increasing the number of inspections each year by half again. This is unnecessarily frequent. We suggest changing the maximum interval for battery inspections to 4 calendar months. For consistency, we also suggest that all intervals expressed as 3 calendar months be changed to 4 calendar months. 11) Replace “State of charge of the individual battery cells/units” with “Voltage of the individual battery cells or units”. 12) The maximum maintenance interval for a lead-acid vented battery is listed at 6 calendar years for performing a capacity test. This type of test has been proven to reduce battery life and an interval of 10 to 12 years would be better. 13) The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don’t match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. 14) Also, Table 1B, in the second to last row, should be referring to UFLS rather than SPS.
No

The VRF for R1 should be Medium because the failure to do so is commensurate with the risks of the other requirements. For example, failing to establish a PSMP for some portion of the entity's components could lead to their maintenance not meeting this standard; this is the same is establishing the PSMP and then not performing the maintenance per the standard.
No
1) M2 incorrectly excludes Distribution Provider. 2) For those components with numerous cycles between on-site audits, retaining and providing evidence of the two most recent distinct maintenance performances and the date of the others should be sufficient. If an entity misses a required maintenance, that results in a self report. We are subject to spot audits and inquiries at any time between on-site audits as well. 3) For those components with cycles exceeding on-site audit interval, retaining and providing evidence of the most recent distinct maintenance performance and the date of the preceding one should be sufficient. Auditors will have reviewed the preceding maintenance record. Retaining these additional records consumes resources with no reliability gain. 4) FAQ II 2B final sentence states that documentation for replaced equipment must be retained to prove the interval of its maintenance. We oppose this because: the replaced equipment is gone and has no impact on BES reliability; and such retention clutters the data base and could cause confusion. For example, it could result in saving lead acid battery load test data beyond the life of its replacement.
No
1) The Lower VSL for all Requirements should begin above 1% of the components. For example for R4: "Entity has failed to complete scheduled program on 1% to 5% of total Protection System components." PRC-005-2 unrealistically mandates perfection without providing technical justification. A basic premise of engineering is to allow for reasonable tolerances, even Six Sigma allows for defects. Requiring perfection may well harm reliability in that valuable resources will be distracted from other duties. 2) In R1, a "Failure to specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance" by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based. 3) It is possible that a component that failed to be individually identified per R1.1 was included by entity A's maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
No
1) Is this document considered part of the standard? We expect to use it as a reference in developing our PSMP, during audits, and for self-certification as an authentic source of information. It is also unclear how this document will be controlled (i.e. Revised and Approved, if at all). 2) On page 22 please clarify that only applies to high speed ground switches associated with BES elements. 3) We appreciate the SDT providing this valuable reference.
Yes
1) Is this document considered part of the standard? We expect to use it as a reference in developing our PSMP, during audits, and for self-certification as an authentic source of information. It is also unclear how this document will be controlled (i.e. Revised and Approved, if at all). 2) The FAQ needs to be aligned with the tables. The FAQ also contains a duplicate decision tree chart for DC Supply. The FAQ contains a note on the Decision tree that reads, "Note: Physical inspection of the battery is required regardless of level of monitoring used", this statement should be placed on the table itself, and should include the word quarterly to define the inspection period. 3) We appreciate the SDT providing this valuable reference.
1) We commend the SDT for developing a generally clear and well documented second draft. The SDT considered and adopted many industry comments from the first draft. It generally provides a well reasoned and balanced view of Protection System Maintenance, and good justification for its maximum intervals. Ameren generally agrees that this second draft will be beneficial to BES reliability, but several inconsistencies, unclear items, and a couple issues need to be addressed before we will be able to support it. 2) Facilities Section 4.2.1 "or designed to provide protection for the BES" needs to be clarified so that it incorporates the latest Project 2009-17 interpretation. The industry has deliberated and reached a conclusion that provides a meaningful and appropriate border for the transmission Protection System; this needs to be acknowledged in PRC-005-2 and carried forward. 3) We are concerned over R1.1, where all components must be identified, without a definition for the word component or the granularity specified. While the FAQ gives a definition, and allows for entity latitude in determining the granularity, the FAQ is not part of the standard. Certainly this could confuse an entity or an auditor and lead to much wasted work and / or violations for unintended or insignificant issues. We suggest that the FAQ definitions be included within the standard. 4) Implementation of the PSMP must coincide with the beginning of a calendar year. 5) Generating Plant system-connected Station Service transformers should not be included as a Facility because they are serving load. Omit 4.2.5.5 from the standard. There is no difference between a station service transformer and a transformer serving load on the distribution system. This has no impact on the BES, which is defined as the system greater than 100 kV. 6) The term "maintenance correctable

issue" used in Requirement 4 seems to be at odds with the definition given for it. It seems that an issue that cannot be resolved by repair or calibration during the maintenance activity would be a maintenance non-correctable issue. Also, in Requirement 4, the term "identification of the resolution" is ambiguous. Suggested changes for Requirements 4 and 4.1 are: "R4. Each Transmission Owner, Generator Owner, and Distribution Provider shall implement its PSMP, and resolve any performance problems as follows: 4.3 Ensure either that the components are within acceptable parameters at the conclusion of the maintenance activities or initiate actions to replace the component or restore its performance to within acceptable parameters."

In Table 1a section-Station DC Supply – 18 calendar months, under Maintenance Activities column, suggest changing under Verify: Battery terminal connection resistance To: Entire battery bank terminal connection resistance (This could have been interpreted as individual batteries) And change: Battery cell-to-cell connection resistance To: Battery cell-to-cell connection resistance, where an external mechanical connection is available. In Table 1a-Station dc supply (that has a component Valve Regulated Lead-Acid batteries) suggest changing Max Maintenance Interval=3 Calendar Years or 3 Calendar Months to 4 Calendar Years or 12 Calendar Months. Our concern is that the insurance companies may push NERC maintenance intervals on all battery banks not associated with the BES. Table 1a-Station dc supply (that has as a component Lead-Acid batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. Table 1a-Station dc supply (that has as a component Nickel-Cadmium batteries) Max Maintenance Interval=6 Calendar Years suggest changing to 10 Calendar Years. Reason: performance tests may degrade the battery. Table 1b - Level 2 Monitoring Attributes for Component in the row labeled (Control and trip circuitry) we suggest the following change: If a trip circuit comprises multiple paths, at least one of those paths is monitored. Alarming for loss of continuity or dc supply for trip circuits is reported to a location where action can be taken. While all tripping circuits are not completely monitored, the trip coils and the outdoor cable runs are completely monitored. The only portion that would not be monitored is a portion of inter and intra-panel wiring having no moving parts located in a control house. Our company has extremely low failure rate of panel wiring and terminal lugging. I don't think that there is provision for moving control and trip circuitry to performance based maintenance? This control circuitry should be maintained less frequent than un-monitored trip circuits (6 years).

No
• The modified definition of "Protection System" (page 2 of the clean version of PRC-005-2) uses the terminology "control circuitry associated with protective functions" whereas Table 1a rows 3-6, Table 1b Rows 3 and 5, and Table 1c Row 4 uses the terminology "control and trip circuits." This is a conflict. "Control" implies that the standard applies to closing/reclosing circuits as well. We do not believe that is the intent. • Row 7 of Table 1a (page 10 of the clean version of PRC-005-2) indicates that proper voltage of the station dc supply must be verified when the associated UVLS or UFLS maintenance is performed. It is not clear whether this requirement is over and above the quarterly and 18-month battery maintenance listed elsewhere in the table or is it the only battery maintenance required for UVLS and UFLS systems? If the intent is to check the station dc supply only when UVLS and UFLS maintenance is performed, the other rows addressing station dc should be revised to exclude UVLS and UFLS. • Row 4 of Table 1b (page 14 of the clean version of PRC-005-2) indicates that remote alarms must be verified every twelve calendar years for control circuitry (trip circuits) (except UFLS/UVLS) provided "Monitoring of Protection System component inputs, outputs, and connections" exists. Clarification should be made to indicate how to monitor inputs. For example, a breaker auxiliary switch is relied upon to

communicate breaker status to a protective relay. If the switch is out of adjustment so that incorrect breaker status is reported to the relay, the relay may not operate when needed. Could proper operation of the auxiliary contacts be credited through in-service operation or the six-year breaker operation maintenance? • The term “calendar years” is used to define the maximum intervals. Does this mean that a six-year PM could go one-day shy of seven years? For example, if a six-year maintenance PM was last performed on 1/1/2010, it would be due on 1/1/2016. Could this allow until 12/31/2016 to complete the maintenance? • Table 1b, Row 14 (Row 2 on page 17): Under the “Level 2 Monitoring Attributes for Component,” UFLS/UVLS should be referenced instead of SPS. • Clarifications need to be made on testing requirements on trip contacts relative to microprocessor vs. EM relays. • There appears to be an inconsistency in the use of “check” vs. “verify” in the tables. • In battery maintenance table, we suggest that “cell/unit” be changed to “cell or unit.”
Yes
No
M2 incorrectly excludes Distribution Provider.
No
In the VSL for R1, a failure to “specify whether a component is being addressed by time-based, condition-based, or performance-based maintenance” by itself is a documentation issue and not an equipment maintenance issue. Suggest this warrants only a lower VSL, especially when one of the required components can only be time based.
Yes
No
FAQ II.2.A: What degree of testing is required for a relay firmware upgrade? Complete commissioning tests? FAQ V.1.A. There appears to be a typo in Example #1 for “Vented lead-acid battery with low voltage alarm connected to SCADA (level 2)”: Table 1b does not list any level 2 requirements. Rather, the table refers reader back to the Level 1 requirements. Same comment for Example #2 as well. FAQ III.1.A: Project 2009-17 provides a response to a request for interpretation of the term “transmission Protection System” as related to PRC-004-1 and PRC-005-1. The interpretation addresses the boundaries of the transmission system. NERC should investigate whether this same boundary should be defined within the new PRC-005-2. Also, numerous potential boundary issues exist between entities which should be contemplated and addressed. See the examples below: • Utility A may own equipment in Utility B’s substation. Utility A contracts Utility B to perform maintenance on their equipment. However, the two utilities have different maintenance programs and intervals for the same types of equipment. Who is responsible for NERC compliance? Would Utility A be found in violation because their equipment is being maintained under Utility B’s program which deviates from Utility A’s maintenance basis? • EMC protection is fed from a utility’s instrument transformers. Who is responsible for validation of the relay inputs and testing of the instrument transformers? • Utility-owned communication units (used for transfer trip or carrier blocking) are coupled to the utility’s power line using customer-owned CCVTs. Who is responsible for maintenance and testing of these CCVTs? • Utility A owns all equipment at one end of line (line terminal A) and Utility B owns all equipment at other end of line (line terminal B). Who is responsible for demonstrating the carrier blocking scheme or POTT scheme works correctly?
• R1.1.1 states that “all” protection system components be identified. Does the term “all” refer to the major components identified in the Protection System definition (protective relays, communication systems, voltage and current sensing devices, station dc supply, and control circuitry) or does it include all sub-components (jumpers, fuses, and auxiliary relays used in dc control circuits and communication paths/wavetraps/tuners/filters)? We assume the former but request clarification. • Draft Implementation Plan for PRC-005-02: The phased implementation plan for R2, R3, and R4 seems reasonable. However, the three-month implementation plan for R1 seems extremely short. Utilities will have to change procedures, job plans, basis documents, provide training, and change intervals in their work tracking databases. In addition, if the utility wants to take advantage of the longer intervals allowed by partial monitoring, significant print work must be performed up front. • Descriptors in the type of the protection system column needs to be consistent between 1A, 1B and 1C. In the tables, please clarify “complete functional trip test” for UVLS and UVLS trip tests since the breaker is not being tripped.

Pepco Holdings, Inc. - Affiliates
Richard Kafka
Pepco Holdings, Inc.
There were numerous comments submitted for Draft 1 indicating that the 3 month interval for verifying unmonitored communication systems was much too short. The SDT declined to change the interval and in their response stated: The 3 month intervals are for unmonitored equipment and are based on experience of the relaying industry represented by the SDT, the SPCTF and

review of IEEE PSRC work. Relay communications using power line carrier or leased audio tone circuits are prone to channel failures and are proven to be less reliable than protective relays. Statistics on the causes of BES protective system misoperations, however, do not support this assertion. The PJM Relay Subcommittee has been tracking 230kV and above protective system misoperations on the PJM system for many years. For the six year period from 2002 to 2007, the number of protective system misoperations due to communication system problems were lower (and in many cases significantly lower) than those caused by defective relays, in every year but one. Similarly, RFC has conducted an analysis of BES protection system misoperations for 2008 and 2009, and found the number of misoperations caused by communication system problems to be in line with the number attributed to relay related problems. If unmonitored protective relays have a 6 year maximum maintenance/inspection interval, it does not seem reasonable to require the associated communication system to be inspected 24 times more frequently, particularly when relay failures are statistically more likely to cause protective system misoperations. As such, a 12 or 18 calendar month interval for inspection of unmonitored communication systems would seem to be more appropriate. FAQ II 6 B states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks. The phrase “Verify Battery cell-to-cell connection resistance” has entered the table where it did not exist before. On some types of stationary battery units, this internal connection is inaccessible. On other types the connections are accessible, but there is no way to repair them based on a bad reading. And bad cell-to-cell connections within units will be detected by the other required tests. This requirement will cause entities to scrap perfectly good batteries just so this test can be performed, with no corresponding increase in bulk electric system reliability while taking an unnecessary risk to personnel and the environment.
No
An explanation is needed to justify why the VRF for R1 of the PSMP is High whereas the implementing and following of the PSMP is Medium, R2, R3 & R4.
No
The present wording regarding data retention states - The Transmission Owner, Generator Owner, and Distribution Provider shall each retain documentation of the two most recent performances of each distinct maintenance activity for the Protection System components, or to the previous on-site audit date, whichever is longer. This wording was changed by the SDT following comments received from Draft 1. However, the present wording is somewhat confusing. It is assumed that the intent of the SDT was to require documentation be retained for the two most recent performances of each distinct maintenance activity, regardless of when they occurred (i.e., whether prior to, or since the last audit), since the phrase whichever is longer was used. In addition, for those activities requiring short maintenance intervals (such as battery inspections), records must be kept for all performances (not just the last two) that have taken place since the last on-site audit. For example: Assume a PSMP with a 6 year interval for relay maintenance and 3 month interval for battery inspections. At a particular station assume the batteries have been inspected every 3 months; the relays were last inspected 5 years ago, and before that 11 years ago. The last audit was 2 years ago. Records from each 3 month battery inspection going back to the last audit needs to be retained. Also, both relay maintenance records from 5 and 11 years ago needs to be retained, despite the fact that this interval should have been reviewed during the last audit. Documentation from the 11 year ago activity can be discarded when the relays are next maintained. Is this what the SDT intended? If so, the requirement should be re-worded to better explain the intent. Also, examples should be included in either the FAQ or Supplemental Reference to demonstrate what is expected.
No
It is possible that a component that failed to be individually identified per R1.1 was included by entity A’s maintenance plan. This documentation issue gets a higher VSL than entity B that identified a component without maintaining it. We suggest the R1 VSL be change to Low, since we believe lack of maintenance to be more severe than documentation issues.
No
Figure 1 & 2 Legend (page 29), Row 5, Associated Communications Systems, includes Tele-protection equipment used to convey remote tripping action to a local trip coil or blocking signal to the trip logic (if applicable). This description does not include all the various types of signals communicated for proper operation of various protective schemes (i.e., DUTT, POTT, DCB, Current Differential, Phase Comparison, synchro-phasors, etc.) A more inclusive and generic description might be – Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions. This is also consistent with the revised definition of Protection System. Conversely, excluded equipment would be - Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

No
The three month inspection interval for communication equipment mentioned in FAQ II 6 B should be extended to 12 – 18 months (see response to Question #1). In addition, the example used in this section should address what is expected for ON-OFF carrier systems. Checking that the equipment is free from alarms and still powered up does not seem sufficient to verify functionality. The FAQ states that the concept should be that the entity verify that the communication equipment...is operable through a cursory inspection and site visit. However, unlike FSK schemes where channel integrity can easily be verified by the presence of a guard signal, ON-OFF carrier schemes would require a check-back or loop-back test be initiated to verify channel integrity. If the carrier set was not equipped with this feature, verification would require personnel to be dispatched to each terminal to perform these manual checks.
Dates of the Supplemental Reference Documents in Section F of the standard need to be updated. The word “calendar” is used widely to define month and year intervals. Sometimes causes confusion, need definition/examples. The level 2 table regarding Protection Station dc supply states that level 1 maintenance activities are to be used, but then goes on to give a list of Maintenance Activities that don’t match those in level 1. Which activities shall we use? Same situation for Station DC Supply (battery is not used) where the 18 month interval is missing. Req 1.1: “All Components” wording should say something like all components covered in our plan

No
There is no reliability based justification to alter the standards to include allowable intervals. The intervals prescription for performance based PSMP virtually eliminates the capability of smaller utilities who do not have a large equipment database to justify a performance based system that may be sound based on their experience. This overly prescriptive approach should be eliminated and return to allowing utilities to justify their programs. The standard should return to addressing real reliability impacts as required by law. This would be to develop a maintenance required which identifies that if it is shown that an event in which reliability is impacted by the utilities PSMP, as evidenced by disturbance reports, the utility would be required to submit to the RRO a corrective action plan which addresses how the PSMP will be revised and when compliance with that PSMP is to be achieved. Finally, the standard presumes that components within a BES Element will cause a reliability impact to the BES. In numerous meeting with NERC and WECC it was emphasized that a reliability impact has been described as causing cascading outages or causing loss of service to load above a certain magnitude. The BES has an ability to absorb element outages resulting from a variety of causes without impact load or resulting in cascading outages.
No
The Time Horizons are too narrow for the implementation of the standard as written. The SDT appears to have not accounted for the data analysis associated with performance based systems. The data collection, analysis, and subsequent decisions associated development of a maintenance program and its justification do not occur overnight especially with larger utilities. In addition, this new standard will require complete rewrite of maintenance programs. The internal processes associated with these vary based on the size of the utility. Since this standard is so invasive into the internal decisions concerning maintenance, the standard should allow at least 18 months for entities to rewrite their internal maintenance programs to meet the requirements and 18 months to train the staff and implement the new program.
No
The measures M2, M3, and M4 are redundant to measure M1. Either eliminate M1 or M2 through M4. The entity must provide documentation of its maintenance program in M1 irrespective of the type used. As previsouly mentioned there is not reliability based justification for the documentation required. The Entity should be afforded the freedom to make intelligent maintenance choices based on inumberable factors. These choices will be reviewed if a reliability impact is determined to be related to the choices.
No
The VSL's use terms that are not tied back to a requirement and appear to be based on the concept that every component will cause an impact on the BES. The VSL's use the term "coutable event" to score the VSL; hoever, there is no requirement associated with the number of "countable events". The VSL's should allow for minor gaps in maintennace documentation where there is no impact to the BES if the component failed.
No
It is not reasonable to assert that a statistical analysis of survey data is a reliability based justification for requiring specific maintenance intervals. The reference document admits that intervals varied widely. To assert a postage stamp interval does not account for other variables which optimize a specific maintenance program. That is not say that the reference documents is worthless. Indeed it has many good suggestions. However, to impugn the maintenance programs

in practice because they do not follow the "weighted average" is hardly scientific or credible. The reference document should analyze the maintenance programs from the stand point of the outages associated with those facilities. If a specific maintenance practice was shown to have compromised the performance of the facility and the reliability of the BES, then it would added to the statistical database of practices which would not be acceptable. Now the statistical analysis of the database would show that certain practices have consequences which impact reliability and a requirement can be constructed to disallow them.
The sub-requirements for R1, are not criteria, rather implementation requirements more suitable to be included in R4. Examples of what the PSMP shall address which would be more consistent with the language in R1 would be: How are changes to the PSMP administered? Who approves the determination of the use of time-based, condition based or performance based maintenance. Who reviews activities under the PSMP References used within the standard are not consistent. In R1.2 Attachment as is referred to as Attachment A. In R3 Attachment A is referred to as PRC-005 Attachment A. This implies a difference. Under a voluntary world, we could draft criteria and procedures with this problems and interpret them correctly. Today in the compliance world, the language must be precise and unambiguous. The reference must be the same it means something different. The requirement in R1, which is consistent with the purpose, does not support the applicability in R4.2.5.4. Protection systems associated with stations service are not designed to provide protection for the BES. In particular we have been told that intent was not to look at every device that tripped the generator but devises that sensed problems on the BES and trip the generator. Hence we include such things as frequency relays, Differential relays, zone relays, over current, and under voltage relays. Even a loss of field looks at the system as included. Speed sensing devices were explicitly excluded. As such, if the stations service transformer protection looks toward the BES (e.g. differential relays and zone relays) they would be included. Over current would not as it would be on the station side. If a Station Service transformer saw excess current, the system would in most cases fail over to other side. If not, it would cause the generator to trip much like a generator thermal device which is also excluded. Maintenance programs offer a unique problem to the FERC and regulatory world. The knee jerk reaction is to define them. What happens if the solution is bad, who will accept the consequences that narrow prescription was wrong and the interval caused a reliability impact. It would no longer be the Entity. History is replete with examples of this type of micro managing. Rather than fall into the same trap, and suffer the consequences of the unknown, allow Entities to optimize their programs to ensure reliability of the BES and create a standard of disallowed practices which have a demonstrated impact on reliability.

Make sure that the use of verbs like “shall,” “should,” and “will” is consistent across Requirements and Measures. In these four measures, all three verbs are used, and they should be made uniform to avoid misinterpretation.
Yes
Yes
NERC staff is pleased with the current iteration of this standard. The staff understands that while PRC-005-2 has historically been the most frequently violated standard, it has mostly been due to documentation issues. The standard has not been much of a heavy hitter in causal or contributive aspects, and with respect to relay operations, there have been very few times that lack of maintenance has been the problem. NERC staff does propose a slight change to 4.2.5.1. The concern is that 4.2.5.1 could be interpreted to apply to devices that protect the generator as opposed to those that protect the Bulk Electric System. The suggested language is as follows: “Protection System components that act to trip generators that are part of the BES, either directly or via generator lockout or auxiliary tripping relays.” Additionally, staff suggests some changes to R1. In that requirement, the PSMP covers “Protection Systems that use measurements of voltage, current, frequency and/or phase angle to determine anomalies and to trip a portion of the BES...” It probably would be better if the list was limited to voltage and current or if the list was replaced with electrical quantities. The former would be okay since voltage and current are the only two electrical quantities that relays measure directly. To remove
